Before briefly describing these pictures, we may mention some circumstances which led to their production. In 1776 the Society of Arts, in possession of its new house in John-street, Adelphi, offered the loan of its premises for the exhibition of paintings to the members of the then young and growing Royal Academy, upon the consideration that the members should decorate the walls of the Great Hall. These terms of lease, however, the Royal Academy, under the presidency of Sir Joshua Reynolds, rejected. In the following year, "James Barry, who had signed the refusal, volunteered to decorate the room without any remuneration." The "Handbook of London" says that when he made his offer he had but sixteen shillings in his pocket. The Society of Arts accepted it, and supplied him with the necessary materials during the six or seven years which he appears to have taken to paint his pictures. He was allowed to make what money he could out of the admission fees paid by the public who came in to see his work, and the Society also made him a present of 200*l*. When he died, his remains lay in state in the great room of the Society.

His series of paintings consists of six large panels, entirely filling the upper half of the walls of the room. At each end of the room are a pair of large square paintings, the two long sides being devoted each to a single composition. The subjects of the four square paintings at the ends are,—"Orpheus," "A Grecian Harvest Home," "The Thames," and "The Society of Arts." The "Victors at Olympia" are portrayed upon the length of wall opposite the entrance to the hall, and facing this is a composition of equal size, entitled "Elysium, or the State of Final Retribution." The text upon which this great pictorial sermon is preached is "That the attainment of happiness, individual as well as public, depends upon the development, proper cultivation, and perfection of the human faculties, physical and moral, which are so well calculated to lead human nature to its true rank, and the glorious designation assigned for it by Providence."

In the "Orpheus" picture, which is the first of the series to be examined by those who desire to follow Barry's development of his subject, is depicted the god, singing divine poems; his right hand stretched towards the sky, and his left hand holding the traditional lyre. Beyond him is a wild and mountainous district, and upon the slopes may be detected a woman milking a goat. Her two children sit near the entrance of their rustic habitation, above which is lurking a lion ready to pounce upon them. Further in the distance are two horses, one of which is being attacked by a tiger. In the foreground are groups of figures of a barbaric type, in various attitudes of attention, as they listen to Orpheus's music. The motive of this picture is said to be one which may show the benefits accruing to mankind from religion and poetry, and the necessity of a pure civilisation in lieu of barbarism. Between the "Orpheus" and the "Grecian Harvest Home" is an upright panel of H.M. the Queen and several of the royal children, painted by J. C. Horsley, R.A. It completely disassociates itself from Barry's paintings, though it conduces to the decorative unity of the room. The "Grecian Harvest Home" is, of the whole series, perhaps the merriest and brightest. Young men and women are dancing to the tune of pipes and tabor round two terminal figures of Sylvanus and Pan. The landscape is that of a rich agricultural country. The harvest is being carried; a marriage procession is wending its way from a temple. With the view of emphasising the season of the year, and to add to the brilliancy of the picture, Ceres, Bacchus, Pan, and others are benignantly smiling upon the scene from the clouds, whilst a peacock,—"Juno's bird with eye-spotted train,"—is perched upon the shed on the right of the composition. We now come to the long triumphal train of the "Victors at Olympia." Suitable to the shape of his long stretch of canvas, Barry has adopted for this subject a sort of frieze treatment. The Olympian games are terminated; and the prize-winners are defiling before the judges, from whom, and in the presence of a concourse of spectators, they receive their olive wreaths. At the head of the procession almost, is a group of two athletic figures, bearing on their shoulders their aged father,—"Diagoras of Rhodes," "who having in his youth been celebrated for his victories in the games, has in his advanced age the felicity of enjoying the fruits of the virtuous education he had given to his sons amidst the acclamations of the people of Greece," some of whom are strewing flowers around the old man's head, while one of his friends is grasping his right hand, and supposed to be making the celebrated speech recorded on the occasion,—"Now, Diagoras, die, for thou canst not be made a god." The Earl of Chatham's portrait, robed as Pericles, in conversation with Cymon and others, is near the athletic group. Behind comes a spirited horse-racer, who is preceding a chariot, drawn by four horses. In the distance rises the temple of Jupiter Olympus. To the left foreground is a sitting figure of Barry himself in the character of Tymanthes, holding a picture of the Cyclops and Satyrs. Figure-drawing and rendering of spirited action are artistic features of this painting. Turning, now, to the adjacent end of the room, and above the rostrum of the president of the Society of Arts, we have Mr. Cope's full-length panel of H.R.H. the late Prince Consort in his robes of the Garter, a painting corresponding in size to that of Her Majesty the Queen. On the left of Mr. Cope's upright panel is another four of the Barry series, "The Thames." The most striking object in this is probably the huge and unwieldy construction, supported by Tritons, which is said to be a "Naval pillar, mausoleum, observatory, and lighthouse." In front of it, to the left, is Father Thames in a marine car, surrounded by sea-gods, typical

of Europe, Asia, Africa, and America. In the immediate vicinity of the car appear the heads of Sir Francis Drake, Sir Walter Raleigh, Sebastian Cabot, and Captain Cook, placed on the shoulders of Tritons. Sailing-ships and some slight coast scenery are indicated in the background. Among the sea-nymphs, introduced as a tribute, apparently, to music, whose claims as an art or a science are neglected in the great Elysium painting, the portrait of Dr. Burney, Henry Purcell, and Dr. Arne, not to name other famous English musicians, have no place with the various eminent men whose portraits Barry has included in his series. Considering the stir which Handel was making in the musical world, especially with his performances at the Foundling Hospital and Vauxhall Gardens, about Barry's time, it is a matter of surprise that music should have been so scantily treated by Barry, unless, indeed, he was deprived of sympathy with this sister art. The painting on the right of the Prince Consort's portrait represents the Society of Arts. Here is an assemblage of distinguished persons whose names are connected with the early history of the Society, from the founder (sitting in the left corner), Mr. Wm. Shipley, to Lord Romney, the then president of the Society. A farmer is displaying specimens of grain to the president, Mr. Montagne; a philanthropic lady of distinction is showing off the work of a young woman; and the Duke of Northumberland, and the Earl of Radnor,—the son of the Society's first president,—are examining some drawings by young students who figure in this group. Many portraits of eminent members and vice-presidents of the Society are to be found here. Amongst them is that of Dr. Johnson, who appears between the Duchess of Rutland and the Duchess of Devonshire. The accessories of the picture consist chiefly of portions of well-known public buildings in London,—like Somerset House and St. Paul's Cathedral. A picture and a statue are introduced to show the Society's connexion with the fine arts. We now come to the sixth and last painting of the series. It is that of the "Elysium," which, as we have said before, is the companion in size to the "Victors at Olympia." The Elysium here depicted requires, for the enhancement of its glories, that a gloomy, garish Hades, inhabited by vices who are being whirled towards a fiery gulf, shall occupy an important position on the right of the canvas. A striking figure, forming a sort of link between the Elysium and Hades, is a great female archangel, with immense arm and hand outstretched over a corner of the Hades. A little above her is a figure of a seated guard in contemplation. The main portion of the great canvas is filled with a crowded series of distinguished men,—poets, philosophers, potentates, legislators, artists, architects, &c.,—those in the foreground forming picturesque groups in varied attitudes. Much of the composition partakes of that convenient conventionality of arranging rows of heads which has been adopted almost as much by early Christian mosaicists and formal fresco-painters as by the great Tintoretto himself in his gigantic work of the "Day of Judgment," in the great Council Chamber at Venice. At the same time, there are many less uninteresting and formal portions in the "Elysium," and some good figure studies. Without a key-sketch, visitors will be somewhat puzzled to find out all the celebrities who, represented by Barry as having "attained the glorious designation assigned for them by Providence," are here congregated together in more than social amity. A former critic of this picture, some thirty years ago, said of this "Elysium" scene that the artist had "with wonderful sagacity, and without any of those anachronisms which tarnish the lustre of other very celebrated performances, brought together those great and good men of all ages and nations who have acted as cultivators and benefactors of mankind." In a composition like this, based upon purely imaginative conceptions, anachronisms, so far as human nature understands the word, are evidently unavoidable, and it can only be in the hands of a great master to so control the impulses of imagination that by dignity of treatment, or some such means, ridiculous effects which, as a rule, are the result of anachronisms, may be avoided. Thus, with much deference to the genius of Barry, it is within comprehension that an observance of simplicity and even uniformity of costume might conduce to the realisation of a more solemn ideal than that which is expressed in broad-brimmed Quaker hats, snuff-coloured suits, togas, and chlamys, Imperial Roman armour, and Saxon fur-trimmed cloaks, a quaint *mélange* of all known costumes. At the same time, one cannot shut one's eyes to the difficulty of making popularly intelligible who is Homer, who Shakspeare, who is Phidias, who Inigo Jones, or Sir Christopher Wren, without using the distinguishing marks which the costumes of their different periods offer.

It is interesting to note that the condition of the paintings is fairly good. The pigments used by Barry do not seem to have been mixed with deleterious vehicles, and excepting for high lights, are not massed up into thick impasto. There are consequently few, if any, cracks. This condition has, no doubt, favoured the cleaning operations, which have been of a very simple character, skilfully carried out under the superintendence of Mr. F. W. Andrew, of the Art Department of the South Kensington Museum.

AN ÆSTHETIC INSURRECTION IN INDIA.

From the more observant of Anglo-Indian residents and students there has been not infrequently a lamentation over the injury done to the indigenous art of the great peninsula by the importation of British arts and manufactures, and the consequent perversion of the native Hindoo taste in the effort to produce or imitate European art. In the matter of architecture, earliest of all and the most persistently, we have in our own columns expressed regret in regard to the prevalence of bad Renaissance in modern Hindu palaces and other buildings, displacing the native style of the country. Others have brought home to us similar reflections in reference to the decorative art of the Hindus, and, if we remember rightly, in reviewing a little while since Dr. Birdwood's guide to the Indian collection at South Kensington, we called attention to his remarks on this topic. It is to this gentleman that we owe the intelligence that the Hindu mind is itself awaking to a perception of this false æsthetic situation, and that something like "revival-hymns" in praise of indigenous art are being systematically sung in the market-places in the towns of western India. In a communication which appeared in the *Times* of the 14th, Dr. Birdwood gave some remarks as to the general nature of the movement, and a translation of one of these revival odes is subjoined. He affirms that the district in which this movement has arisen is one which has advanced immensely in material prosperity of late under our rule, but in spite of this there are people there who are "not happy." Their unhappiness has found vent in ballads (*kirtans* is the original word) which are sung by itinerant minstrels who profess to be indifferent to gain, even to refuse money for their songs, and to be anxious only to disseminate principles. As you strolled into the market of such a town as Indapur, for instance, on a Sunday afternoon, the chief attraction would be not so much the shops as the hustling crowd of sightseers and purchasers, which "is sure to be thickest round those shops in which are piled up from floor to roof the rolls of many-coloured Manchester goods. It is in the midst of such an eager huckstering concourse, gathered from all the country-side around, that these industrial ballad-singers are wont to appear. A space is cleared around them, and after a little tuning up of their banjos and hurdy-gurdies, they at once begin their song." The translation of the song (one of them) was then given entire in the *Times*, and a very curious and significant composition it is.

It commences, like all Hindoo compositions, with invocations to various gods of the immense Hindoo hierarchy, to "the auspicious Saraswati, who is fair and fragrant as the sweet white flowers of the jasmine," "to the elephant-headed god whose vehicle is a mouse," &c.; and then follows an enumeration of the fourteen sciences, viz.:—Divine knowledge, chemistry, music, the Vedas, astronomy, grammar, archery, swimming and navigation, logic, the art of love, knowledge of the horse, riding, courage, and palmistry. But, after another invocation to the "one-toothed god," comes the sad declaration that "the fourteen sciences have disappeared." The real gist of this sweeping and rather alarming statement seems to be that the native artists are deteriorating in the practice of their art, and that machine-made work is taking the place of handwork. Once an Indian shawl was unequalled in other countries, once a pair of waist-cloths were sent packed in a mango-stone; but there is no one who can make such work now. "Remember who our ancestors were, and be vigilant." "Necklaces, bracelets, rings for the fingers, and earrings set with gems, beautiful earrings for the women, of diamonds and double drops of pearls, all have been lost. Women now adorn themselves with gilt ornaments. Imitation jewelry has been introduced; real things have disappeared, and false ones are used for show." European learning is condemned, and the study of it by natives. "Some have become B.A.s, and some have become M.A.s, but have no money" (a state of things not quite unknown in some Western countries), the significance of the remark lying in the idea that evidently pervades the whole composition, that loss of the real wealth of India has resulted from this decline in her native manufactures; though at the same time the most prominent and foremost complaint is that art has been deteriorated. There is no denial made of the excellence of our manufactures from some points of view. The people who came from England "filled the country with beautiful-looking and charming articles, and had songs sung in their praise. This is attributable to the skill of these people. Glass came first. It was a great shock to caste. Now there are not five persons left who do not buy it. The high-standing metal candelabra have disappeared, and 'wál-shets'" [wall-shades,—this seems to be the English name Indianised] "have taken their place. Their hanging globes have brought about a general pollution of the four castes. Brass hanging lamps have disappeared, and glass chandeliers have increased. Oil has passed into the background, and kerosene oil has come forward. The wicks have been blown out, and candles which make people sick are lighted."

This and some other remarks belong rather to the prejudices of a *laudator temporis acti* pure and simple than an artistic reformer. But some of the succeeding remarks have more direct point:—"Articles which only seem bright, but which are in reality as deceptive as fire-flies, are freely purchased. Their nails and sickles, and bright scales, their knives, scissors, and spoons are good only in appearance, but they are not durable, and are made for sale only, like the *palgunika*" (ladies of a certain description, we believe). Is this a true bill? English cutlery may be presumed to be still worth something when it is good; is all the rubbish sent out to India, or are our minstrels only speaking out of the lips of general discontent? Wearing apparel has been subjected to the same unhappy innovations. "Broadcloth has displaced the thick cashmeros, as also the thin *alwans* [a sort of cotton cloth]. Their sheetings appear cheap, but they are not so beautiful as flannel, so warm, so soft. Their imitation waist-cloths have borders, which are dyed with imported powders [aniline dyes]. The borders appear, but their colour is false and transient. You have a great liking for these things, and use them, and reject the indigenous cloth. You at this moment seek after Horrocks's long-cloth." The solemn tone of this last accusation is very impressive, and no doubt "Horrocks" will have felt it. "You have been enticed by the show of their skill. Even if their goods are delivered packed up, you blindly receive them." It is, however, satisfactory to find this statement followed by a testimony in favour at least of our moral character, that "although they know this, they do not abandon honesty," and that some of our stuffs are very good in their way. But in other respects, our innovations in the matters of utensils and dress are to be protested against. "Porcelain dishes have entered our houses and filled our brazen dishes with fear." This seems to reverse the proverb about the clay pot and the brass pots. "You ought to purchase country shoes, but you think it a pleasure to buy their boots and pumps, with their appurtenances, blacking and brushes. You have a great desire to have their umbrellas, walking-sticks, Guernsey frocks, neck comforters, waistcoats with green and red buttons" [where on earth do these last come from?], "caps, gloves, and stockings, double coats, watches, and chains. These you purchase with great delight, and you pour out the crucible of wealth to fill up the holes in the houses of foreigners."

After some further description of the variety of Western-made utensils of different kinds which have supplemented the Indian brass-work, there is an exhortation to the hearers to love their country, to cherish pride, and to promote the arts, with the addition that this latter course is the way to acquire wealth; and the song coincides with the expressed conviction that,

although there was much to complain of in the doings of the resident Government officials, if their sufferings become known to the Queen, "who is our mother," all will be speedily set right.

There is a good deal in the matter and manner of this curious production which, we confess, would lead us to the conclusion that it is not a spontaneous outbreak of popular feeling so much as a deliberately-conceived protest on the part of a section of people who are discontented under our rule. At the same time the feeling that an inferior art has taken the place of the art of the country is obvious and in some passages apparently sincere and strongly felt. If asked what is to be done in such a case, by those who regret the corruption of the purity and richness of Indian art for the sake of a sham Europeanism, all we can say is that we do not believe anything can be done. It is a natural result of the invasion of a land by a foreign race, that the native race are influenced by the arts and manufactures of their invaders. It always has been so more or less; one nation cannot mingle with another without a great deal of mutual imitation and interchange of fashion in arts and manufactures taking place. However superior we may know the native art to be, ours is new to them; and to a large proportion of them, no doubt, new styles of design and new accomplishments in manufacture are more interesting than the style which has been handed down to them from their own ancestors. It is impossible, we imagine, to take any definite steps to counteract this: we may regret it, and we do regret it, but it is almost a law of Nature, and we can really do nothing definite in opposition to it.

The neglect of indigenous art in favour of that introduced by Europeans is, of course, not peculiar to India; we have just the same thing in Japan, where the most curious interchange of tastes has been going on, our people having imbibed a love for Japanese art, while the Japanese themselves are becoming Anglicised in their tastes. All this is only part of a general movement which must go on increasingly as the constantly increasing facilities for travel bring together into close intercourse peoples who were formerly precluded from any real knowledge of each other. The world is becoming, in fact, Europeanised, and will become more and more so, and one necessary consequence of this is that native arts, which formerly were marked by a distinct style and taste, will lose their special character, and blend with the art of the European world, though not without influencing it very decidedly in the process. The unconscious and spontaneous character of national arts will give place to the self-conscious art of cultured societies. At present the loss is very obvious, but we need not think that therefore no good result even to art can ultimately arrive. As long as we, in mere caprices of fashion, adopt the style and productions of the art-work of the Eastern countries with which we come in contact, and as long as they take up with our art merely as a novelty that attracts them, the result must be unpropitious to a true artistic temper of mind on either side. But we have gained much, and may gain more, from a closer acquaintance with Eastern art; and in the end Eastern peoples whom we come in contact with may gain from the European mind a power of analysis and criticism which will bear new fruit in its turn. We may regret the loss of the marked varieties of national arts, but we cannot prevent their assimilation; and a "revival movement" such as that we have had described to us, even if absolutely sincere, can do nothing permanently to avert the process. What we must hope for is that the West will catch the influence of the rich fancy and the harmony of colour of Eastern work, and that the people of the East may learn from Western thought and culture how to carry their artistic impulse into new forms, based on choice and not merely on traditional usage.

Epworth.—The Church Needlework Society of Epworth has presented, as one of the results of its labours, a small stained-glass window for the east end of the south aisle, to fill the place of the old window which has been taken away to make way for the new one. The window, which is of one light, was put in the day before the harvest thanksgiving. The subject is "The Good Shepherd." The window has been executed by Mr. W. H. Constable, of Cambridge, and the fixing of it was done by Mr. F. Grant, stonemason, of Epworth.

FROM THE BANKS OF THE SEINE.

Rarely has public opinion, which may, by the way, be said scarcely to exist in France, such as we understand it, raised its voice so unanimously as it has within the last few weeks against what has variously been named, among other titles, the "Infections of Paris," the "Odours of Paris," or, more simply, the "Drains." For some time past it is undeniable that in certain parts of the capital the drains have been giving forth odours such as are calculated to alarm not only the timid, but the properly cautious. On this point all are agreed. As to what cause to attribute the dangerous odours and what remedy is necessary there is much discussion, which has extended not alone through the columns of the daily journals, but, after passing through the municipal council, has been continued in the august precincts of the Institute. The complaints as to the existence of the odours and the inconvenience caused received only too terrible support when, a few days since, a fatal accident in the drains, and in which several workmen lost their lives, asphixiated by the foul air, excited a wide-felt attention. The inquiry as to the exact reasons for the existence of the bad gas that caused the death of the men is at present pending; but the public have almost made up their minds regarding the cause. The drains in Paris are intended for the street dirt and comparatively clean water. It would appear, however, that they are too often used as receptacles for the household refuse and fœcal matters, for the removal of which there exist several systems, all in daily use, in Paris. As happens in every great city, the drainage question is far from being in a satisfactory condition, and much as the municipality expend on the provision and maintenance of the drains throughout Paris, at this moment whole streets are pulled up, and neighbourhoods until now unsupplied, are having a system of drainage laid down. By the nature of the construction of the drain and its numerous mouths in the street, should the slightest action of fermentation commence, the gases escape directly into the air,—and this is the cause of the recent complaints. A sufficiency of water, some urge, is necessary to well sluice the drains. Plentiful as seems the supply, so far, it would appear to be inefficacious; more water is wanted,—and in what large town is not more water wanted? With the proper quantity of water, argue many, the foulest deposits may be prevented from infecting the air. There remains only the question of the eventual outlet of all the refuse, which here in Paris, as in every great city, is no small matter. Already a large quantity is profitably utilised on the great plain of Gennevilliers, but the site is insufficient; and the recent proposal to utilise for this purpose a portion of the forest of St. Germain roused thunders of opposition. The objectors to the flushing system very warmly condemn, on hygienic grounds, the apparently cleanly method of sluicing the drains, into which everything shall have been allowed to flow. Others urge the efficacy of a comparatively recent innovation on the primitive "fosse,"—which often remained, and still remains, unemptied for a year or more,—the so-called *système diviseur*, by which the fœcal matters are roughly separated from the liquid, being retained on a sort of strainer, contained in a zinc cylinder (*tinette*), removed from time to time. But this system,—though a decided improvement on the older and pestilential mode,—is not perfect. There remains, therefore, to be applied some method by which no solids can enter the drains, as it is proved by the chemists that the mere liquids are harmless. The solid matters thus collected, and properly treated, may be made to serve excellently for agricultural purposes. Till this system is satisfactorily and universally applied, the drainage will continue to trouble and punish alike the worthy and unworthy residents of Paris. These are questions of sanitation that cannot be carelessly put aside,—they demand, not alone in Paris, but in every great city, immediate and searching attention, which can scarcely be more profitably applied than to such points as these.

An important branch of Parisian commerce has been for some time past suffering from a serious strike. The cabinet-makers of the busy and crowded Faubourg St. Antoine have demanded higher wages. The origin of the movement may be traced back much further than is apparent to the ontside observer. Indeed, as long ago as July last, symptoms of disaffection were noticeable. The *ébénisterie* trade being a very large, important, and exceedingly respectable one,—Paris is its head-quarters,—the serious nature of the lock-out may be understood. In other parts of the country the Paris lock-out has incited discontent. The three principal points of the men's demands bear on the reduction of the day's work to ten hours, though on this head no great stress is laid, as the arrangements regarding time are matters to be settled between the employer and his men; the second point bears on the increase of the hour's pay to 80 centimes,—nearly 8d. In this case the masters have seriously urged on the men to remember that the chief source of profit to the trade lies more in the manufacture of ordinary everyday furniture than in that of artistic productions; such is always the case in businesses of this sort. Wedgwood, it will be remembered, recouped himself for his costly outlays only by the sale of his purely serviceable wares, which are to be found to this day in common use in many parts of the Continent. The third point of the programme of the workmen's delegates claims for piecework a rearrangement of the tariffs, based on the price adopted for the hour; this of course depends on the second point. After due deliberation, the masters' delegates made known their replies to the men. The question of the hour's work was agreed to; 75 centimes was the pay accorded, subject to proper revision; the delegates further promised to those men who would agree to these terms that the workshops would open on the morrow. To this, the men's delegates replied that they had no power to accept the diminution of the price of the hour's work, and so the settlement was put off. If the crisis is prolonged, many millions of francs will be lost to the country, for in strikes of this nature masters and men suffer alike. New relations are opened, new inlets to foreign enterprise, which will with difficulty be closed again. In one of their many resolutions, the masters admitted that "it was notorious that business with foreign parts and with the provinces was following a downward slope"; the competitors most dreaded, it would appear, are Belgium, Germany, and the United States.

In a chronicle from the banks of the Seine it would be, indeed, unjust to pass over without mention the death of Jules Jacquemart, an artist whose name and works have long been familiar in England. Carried off at the early age of forty-two, Jacquemart has by his industry made for himself an enviable reputation as an etcher, who may be said to have been the first in modern days to throw an artistic charm into his technical representations of articles of domestic decoration. His numerous illustrations to the work of his father on the "History of Porcelain" are familiar to the artistic world. His works, which have appeared from time to time in the pages of the *Gazette des Beaux Arts*, reprodnctions of famous pictures, &c., have long been remarked as specimens of etching, but which are, however, not invariably as good as his representations of armour, china, and furniture.

Since we have mentioned the death of poor Jacquemart, it would be unjust not to devote a few lines to a notice of the death of Jules Labarte, whose name is familiar to many in his profession. Jules Labarte, unlike Jacquemart, died at an advanced age, for he was in his eighty-fourth year. His name will always be connected with the superb illustrated work on the "History of the Industrial Arts in the Middle Ages and the Renaissance," and which long since received the honour of an English translation. Another of his works, the "History of Enamel Painting in Antiquity and in the Middle Ages," is still an esteemed handbook with collectors, while to the professional reader and archæologist, the "Imperial Palace of Constantinople and its Approaches, such as they existed in the Tenth Century," is a work of more than usual interest. M. Labarte succeeded, now some nine years since, as perhaps will be remembered, M. Texier, as travelling archæologist. He had long been a free member of the French Academy.

Mural Painting.—Mr. Philip H. Newman has just completed, on the south wall of the chancel of St. Peter's Church, Belsize Park, a painting representing Our Lord healing the Sick, size 15 ft. by 8 ft. It is a spirit fresco after the method recommended by Mr. Gambier Parry, and adopted by Sir Frederick Leighton in his lunette recently finished at South Kensington.

ON THE RELATION OF ART TO SOCIAL SCIENCE.*

I have said that the reproductions in photography should include other examples than pictorial art, for though examples from that ancient and modern form of art are necessary to the beginning of cultivation, not only on account of their innate beauty of design and form, but also on account of the beautiful ideas by which they have been stimulated, with which they are connected, others of a more directly practical nature should be added. And for this reason: among those,—in fact, most of those who are being educated by our Board Schools,—there are children who may become members of trades in which taste and a faculty acquired for design will be of great service. So photographs of beautiful ironwork, such as that beaten by the Flemings and Dutch, will be invaluable as training the taste of the child who may become a blacksmith. Again, the future cabinet-maker may have his imagination stimulated and his admiration kindled by examples of Italian or Dutch marqueterie. He who by-and-by is to carve the capitals of future churches, and,—who knows?—perhaps to design them as well, will not be the worse off for having had in childhood his attention drawn to casts from some carvings of the front of Wells Cathedral or other examples in the art of which he is to become so important an exponent. Nor is it impossible, but highly probable, that artistic natures dormant from want of calling out, or from want of opportunities of seeing beautiful art, may be awakened into a desire to design by a stimulus exciting a desire to emulate the beauty of the art they are permitted to see, and concerning which they may receive valuable instruction. Although I have ventured to lay some stress on the practical advantages of learning to draw, it is not so much upon this that it appears necessary to appeal, for I believe that at present, in the Board Schools, children can learn to draw, although upon a routine as yet not satisfactory. Yet the question arising for our consideration is really whether the scholars would not be wholly benefited, improved, and for their lifetime refined, by being accustomed in early childhood, and, during its impressionable educational period, to have before their eyes art, in some of its foremost, poetic, and practical phases constantly. And whether, being thus trained and accustomed to see beautiful works, the taste and workmanship of the coming generation would not be elevated, its labourers more refined, and the need for better art become a part of its natural existence. Farther, whether such refinement begotten of art would not act upon morals, reduce drunkenness and crime, having sown the seed of perceptions in a beautiful direction, in a class sadly needing them, and if directed in practice, benefit the career afterwards chosen or forced by circumstances upon the individual scholar. It seems to me here at this Social Science Congress that we meet rather to suggest and discuss possibilities, than to draw up any definite and possible Governmental schemes by which our ideas might be carried out, and that we must leave it for others versed in political or other economy to tell us how far the rates would stand the pressure upon their funds of an outlay needful to carry out our suggestions. But this much may be stated, that if it were proved that by an increased interest given to artistic cultivation, if more insistance were made by the Government upon it, and it became generally recognised that our lower classes are capable of æsthetic culture, and that such culture would tend to the progress rather than to the decline and fall of our nation, our country would not be slow to expend a portion of such money (as is now spent upon a 100-ton gun, to be shortly superseded by a further improvement) upon the taste and moral advancement of its people. The real point of difficulty is to convince the general mass of men, Governmental or other bodies, that the æsthetic soul is worth saving at all, or that art and taste are of any value whatever, excepting as a pastime for the rich, or a *dilettante* diversion for the lazy. On the other hand, there is a set of, as some think, madmen, who imagine that the influence of art has drawn nations from barbarity; that the Christian religion has found it a fair handmaid in her teachings; that the lower classes of all countries have emotions worth educating; and that these lower classes are more than beasts of burden,—beings whose welfare, happiness, and taste we who have experienced the advantages of culture are bound to assist and foster.

It will very justly be asked, Who are there, if such a scheme as is here suggested he thought practical, whose power in teaching would be sufficient to carry it out with success? The answer to this question is not simple. The Government Schools of Design are constantly educating men as art-teachers; these are sent from the South Kensington Museum to take in charge local Art Schools. Where those have been educated others can be educated; the supply will come when there is a demand generally. But great care would have to be taken that those who are to teach and guide the tastes of the Board scholar should not only he qualified to do so in the practice of drawing, designing, or carving, but that they should be men enthusiastic about their educational work; capable, too, of giving clear lectures on art, in precept and practice, to children, and, while they instruct, to amuse and excite their young minds. Beyond these, teachers being now in an age of much voluntary work, much self-sacrifice on the part of the upper and educated classes, no doubt many willing persons could and would be found willing to give up a small portion of their time, now and then, to lecture to their poorer little brethren, and to give to them some of the result of that art-education which circumstances have allowed them to be possessors of. Time will not allow me to go farther into this side of our question; slightly, indeed, only, and rapidly, have I been able to touch upon it, but the suggestions I have made may be modified or augmented by others, if any are found to take interest in them. There are other questions which I am anxious to touch upon now. It was asked in the earlier part of my address what agencies are at work in our great cities which are acting against the artistic development and good taste of the poorer class?

Now there is one which will at once appeal to us all. The great competition existing in our age, the anxiety for prominence, the desire to out-Blondin Blondin, to fall farther than Zazel, to expose the last result of African conquests to view, makes advertisement into a possible art. What a means this system of large advertising pictures might be made, if rightly used, for the education of taste among the lower classes! What a blot and abuse it is in our streets as at present used! It is difficult to find words strong enough to declaim against the miles of walls which are covered with vulgar and revolting placards. And now the Brobdingnagian dimensions they assume are positively alarming in their gigantic hideousness. We have an inspector of plays, an inspector who is bound to see that no public morals are injured by what is produced upon the public stage. Why should we not have an inspector of moral tastes for our still more public streets? It will, perhaps, be said that this would be interfering with the liberty of the subject; that you could not exercise such a right without injury to it. But you have an inspector of architecture, you are obliged to build to a certain symmetry with other houses, the frontage of your house must be in accordance with frontages of your neighbour's house; and furthermore, alas! for the beauty of our streets, the houses must look as much as possible as though they were turned out of the same mould. Well, we will admit that this supervision is a failure, and that the laws under which it acts are detrimental to beauty, invention, and variety. But it need scarcely be thought that such transient works as advertisements would be injured in the subject of their taste by an artistic overseer who would have the public good taste at his heart. I say transient advertisements: this in a sense they are, but in another sense they are the very reverse, for their bad and vile art is lowering to the taste of the very class we are most anxious to elevate, and must leave behind it an indelible injury the reverse of transient. If those who advertise would get the advice of good artists,—and there are among our best designers those who would gladly assist in such a worthy cause,—not only would they profit by the attraction well-designed advertisements would have, but also they would, instead of doing a public harm, as they are now doing by using a powerful weapon in an ostentatious and vulgar way, be public benefactors by disseminating good art in the most public manner possible. We all know the admirable work done by Mr. Walter Crane, in his "Baby's Opera," and by Mr. Caldecott in his illustrations to John Gilpin, and other excellent designs. Taking these two artists, whose facility and taste especially fit them both for designing where rapidity of invention and execution, humour and pathos, are such necessities, let us imagine what a difference there would be on the hoarding boards, omnibus interiors, and railway stations, if the works here were executed under the supervision of such excellent designers. Where at present our eyes are disgusted, our sense of all refinement insulted, we should,—and what is still more important, the workmen and labourers would,—find something worth looking at, something which, instead of lowering, would elevate taste. All the freedom so boasted,—freedom of the press, British rights, cant about liberty,—has had such a swing, and still has such sway, that it may be said to be licence, not liberty; the world has been so busy making itself rich, running headlong after every facility for doing so, has got us into such a state of anarchy, carelessness, and total disregard for matters of taste, that we must look round now and see whether the reaction now setting in against mere utilitarianism cannot be pushed further, and whether the ordinary human being has not, after all, something in his nature well worth cultivating besides his greed for success in money-making.

It must appear strange that any one should dare to mention "the freedom of the press" in a derogatory tone, for its advantages are enormous; but while they must be admitted to be so, certain evils touching upon such freedom cannot be denied. By these evils I mean the low taste of such papers, to give an instance, as the *Police News*, bearing a sheet of odious woodcuts, representing, with the worst possible taste, the last ghastly murder, arson, or wife-beating. It is no exaggeration to say that this art, if art it can be called at all, is doing incalculable mischief both to morals and taste; nor will any one fail to observe, if he take the pains to do so, how knots of children of tenderest years collect round, and with tragic and pathetic curiosity, are rapt in contemplation of these horrid pictures of the basest crimes. When we think what a seed of taste and demoralisation is sown by the fact of children taking into their minds, almost with their mother's milk, impressions so utterly at variance with every noble instinct or healthy desire, so contrary to the pure nature of childhood, we can hardly help feeling ashamed and aghast at a Legislature which, while it is indeed rich in Poor Laws, while it is in earnest, too, concerning the bodily wants of its lowest class, permits such a social scandal to taste and morals to exercise itself upon the childhood of the rising generation of its poor but most sensitive class.

Yet another influence is at work, and this not only upon the morals and tastes, but on the health of our citizens. Of course, to those who do not believe in beauty and morals acting one upon the other, who consider that man's mind is not influenced through his body, who imagine that it is idle and lost time to consider the cultivation of a love of beauty, all that I have said, and what I still have to say, will appear fanciful, Utopian, unnecessary,—in fact, harmful. But those who agree with us, who love beauty and art, and believe in their distinctly moral influences, must see that the absence of light and clear atmosphere, the almost total obscuring of the sun during eight months out of the twelve, cannot but have the most depressing effect upon a class whose conditions of poverty and overcrowding are sufficiently accentuated already.

Were it absolutely necessary, were it indispensable to the comfort of all, that our cities should be covered with a thick pall of smoke, we might be willing to bear with it; but when we know that this is not the case, that such a state of things need not exist, it is exasperating to find that there is such a want of desire among men for the blessings of a clear, clean, bright, healthy atmosphere; that there are very few who regard with any regret that the sun and sky are denied them, being so used to the denial of them; that these shrug their shoulders with some scorn, and even pity, that there should be those who are so weak as to love beauty while they can have money, or that the outward appearance of nature should affect them while their pockets are full. A few days since there was an article in the *Daily Telegraph*, sensible in what it said, namely,—that it was to be lamented that while scientific men were so busy occupying themselves over inventions such as telephones, telephotes, photophones, and other

* By Professor W. B. Richmond, M.A. (see p. 467, *ante*).

fantastical inventions, clever and wonderful, useful too, perhaps, they should not turn their attention to something easy and practical,—having proved their abilities to overcome apparent impossibilities,—which would restore us a clear atmosphere.

As our cities become larger,—and they do and must become larger,—this evil of smoke destroying the surface of stonework must increase, rendering sculpture out of doors almost an absurdity; causing such risk to all kinds of mural decoration that it scarcely seems worth while to attempt it. Embroideries, tapestries, all delicate workmanship suffer,—in fact, are ruined unless protected by glass. The beautiful objects collected by art-lovers during the spare hours from business cannot be made use of as they should be; embroidered curtains from India, or Japan, or Persia, of delicate colour and exquisite work which would perish under the hand of a cleaner, cannot adorn the windows or walls of our rooms; they must be hermetically sealed, put away, or they are ruined. It is really very little use talking about art until this condition is changed, and very little good expecting that we as English, or you as Scotch, people, care about the subject of art, or believe with any sincerity in its usefulness, until we are all determined, each one of us, to believe that beauty is better than ugliness, that it is more important than fashion or wealth, that a clear sky is better than a black pall, and that that noble self-respect belonging to man is far more likely to increase and flourish, under cleanliness and brightness than under dirtiness and dulness. Art has never flourished, and never will flourish, under depressing or degrading circumstances. She is not the sister of dulness, dirt, and darkness; she is the sister of cheerfulness, brightness, and light. She belongs to happy conditions of life, to a contented and thrifty people; she will not go where she is not wanted; squalor and degradation she shrinks from, but she should be the property of the poor as well as of the rich.

The question immediately connected with this Art Section I have not touched upon; the question immediately touching upon my own art I have already lectured upon. Those relating to music and the dramatic art, although I consider them of the greatest importance, I preferred to leave in the hands of such masters in these arts who are here more qualified to deal with them than I should be. Still, though it is not my intention to dwell upon either subject under the pretence of doing it justice, I may permit myself, if you will permit me, to say a few words concerning these arts as refining agents, upon a popular and generally social scale. The growing love for music in the United Kingdom is enormous. Even in the memory still fresh of those younger than myself, London contained but few concert-rooms, and in these but a limited range of music was given; the seats, too, were of such expense that but few, excepting well-to-do people, could afford to avail themselves of them. Now there are many concert-rooms, and continual concerts going on, where the very best music can be heard at a reasonable rate. For one shilling now, instead of three shillings formerly, the works of the greatest composers can be heard. The result of this has been that a far larger circle of people now is interested in the greatest music, and there has arisen a chaster and stronger taste for severe and classical music than heretofore. Good music is no longer called heavy and dull, as the custom of constantly hearing it has caused people to appreciate its sound and lasting merits above the mere passing pleasure,—purely sensuous,—of music having nothing to touch the human heart or intellect in it. By grand music we are lifted out of the every-day burdens of life; we are transported by it to another land, as it were; we are elevated, refreshed, strengthened by it as by a tonic, and encouraged by its recreative powers to go about our labours with renewed cheerfulness and energy. Cheaper and cheaper may our concerts become, so that the whole of our brethren may be able to profit by them.

The efforts made in the direction of dramatic art have been successful in many directions. Would, however, that the public taste had declined in its love for horrors. Would that the theatres were found to draw better for "Romeo and Juliet" than for the "Ticket-of-Leave Man." Let us wish Mr. Irving well, whose sense of the importance of his art as a public benefactor and factor for the product of intellectual enjoyment and taste, has made him, with manly consistency, adhere to his Shakspeare.

If, gentlemen, aught has fallen from my lips of too strong language; if anything said here has wounded the sensibilities of any one, I hope it may be forgiven. It has been my endeavour to place before you, in as strong a light as lay in my power within the limits of my time, that art, to exist, must be national; that the poor should possess it with the rich; that there should be a chance for all to drink of its refreshing streams; and that unless a nation is in pursuit of the beautiful, it can scarcely be said to have arrived at the extreme power of civilisation.

IN THE ART DEPARTMENT: SOCIAL SCIENCE ASSOCIATION.

THE NUDE IN ART.

On the 12th inst. Dr. Phené read a paper "On the Humanising and Refining Effects of Art." He remarked that though popular impression generally gave supremacy to pure Greek art, and considered its effect on Rome and its inhabitants as unique, yet that schools as important, in both painting and sculpture, existed in Asia Minor prior to the great advance in Greek art, and that, indeed, they were the source whence Greek art was taught, and whence it drew its knowledge and refinement. The Ionians, themselves Greek in descent, were, from their geographical position, thrown into contact with the most highly cultivated countries in the world, —Assyrians, Egyptians, and Persians,—and with their natural Greek refinement of feeling, and subtle and delicate perception of the beautiful, not only designed the most exquisitely pure order of architecture, but, as proved by the great wealth attained by their painters, and the enormous sums paid for paintings, must have been masters of that art also, which could not have been otherwise than of the highest order, as the painters had to compete with the most perfect sculptors, to whom anatomy and symmetry were elementary studies. When the wealth and art of Asia were poured into Rome, her inartistic people, untutored, and unable to discern the delicacy of an art which, through the human form and features, endeavoured to represent the mind, saw only the outlines of nude but beautiful beings, which inflamed their imaginations and aroused their passions. And when, added to this, Asia's subtle mysteries were introduced among them,—equally ignorant of higher conceptions concealed under symbolic forms and ceremonies,—they received them in their externals only, which they exaggerated, and at once converted into a source of evil, beneath which ancient Rome fell hopelessly, and from which moral degradation she never recovered. From facts of history the writer deduced, first, the powerful effect of art as a refiner and educator of the mind, if judiciously used; secondly, that the misuse was as dangerous as the proper use was beneficial, and the consequent injury to any nation or community from the introduction of open exhibitions to the eyes of the ignorant, and even of those wanting simply in art education, where those exhibitions permitted the general appearance of undraped statuary or paintings. Art, as a mentor, he said, might and should refine and elevate, and for this, multitudinous examples of the more graceful and endearing acts of life were at command,—life as it was to-day amongst ourselves, known to and fully capable of being appreciated even by the inartistic of every civilised people. The leaders of public taste should use their influence, not only to exclude subjects likely to excite prurient feelings from the higher art-galleries, as was for the most part carefully done, but to prevent general exhibitions of the human form at places of amusement and resort for those who, as a rule, knew nothing of art, and who saw in them only the human figure. Without in any way depreciating the beauty and value of classic sculpture, he submitted that, as we had no sympathy with the divinities of Greece, and the intention of these sculptors being now of no importance, except to the scholar and the connoisseur, they should be restricted to art schools as much as anatomical studies were to schools of surgery. There had, he thought, been a marked decrease in modesty since the extensive exhibition of such objects at the great places of public amusement within the last twenty years.

Mr. M. C. Rendall, Leith, thought that there was a certain amount of confusion in the paper. Dr. Phené spoke of the luxury and immorality of Rome; but they should consider their own immorality if they were to speak of immorality at all. It might be a question whether modern Christianity had done for art what ancient Christianity did for it. The Church of Rome had done more for art than the Protestant Church had done, and although he did not wish to commend the Church of Rome, he must say he thought Christianity generally might do an immense deal more for art than it had done.

Mr. Herdman, R.S.A., as a practical artist, was greatly interested with the paper, and the discussion which had followed. Such a discussion was good for professional artists, because it made them think of the importance of the work in which they were engaged, and the responsibility attaching to them in carrying on that work. It was also good for society to be reminded that the great subject of art was something more than a mere pastime,—something to give a few moments' delight.

Mr. Rathbone, Liverpool, believed there was nothing in art so beautiful as the human form; and if the human form were more generally treated, he believed morality would not suffer, but be very much improved. Even our health and methods of dress might be improved, for we did not want to see the abomination of women making themselves into wasps, or by means of high-heeled boots throwing the whole body out of gear; nor did we want to see ladies, who were so very charming by nature, make themselves hideous by art. The superstition about the undraped in art was completely divorced from any pruriency until these abominable Asiatics came in. It was of the greatest importance, both for morality and health, that we got rid of this idea about the undraped human form. Two or three years ago there was exhibited in Liverpool a picture, by Alma Tadema, which had been hung in the Academy without attracting any notice. The whole town was in arms; but, this year, instead of having one young lady in a nude form, they had three, and not the slightest notice was taken of them, because the people had been told that it was the right thing. In his opinion, there ought to be specimens of the nude human form in every museum throughout the country.

The President (Professor Richmond) said the subject was an extremely delicate one; but one, he thought, that must receive attention. Dr. Phené said he thought the ancient subjects were unfitted for modern art. He disagreed with that statement. He thought they were eminently fitted, especially subjects taken from the Greek poets, not only inasmuch as, by choosing these subjects, the painter might show his exquisite taste in form, but also because most of these subjects were of a highly moral and extremely beautiful character. If they took the whole of the Iliad of Homer, as Mr. Gladstone once observed to him, they could not find a line of impurity in it from beginning to end; and if they took the Odyssey, what perfection of taste and elevation of sentiment pervaded the work. Surely, that being the case, such ideas as were there suggested could find a place upon the canvas of modern painters. If the world was of such a prurient nature that it could not stand at the side of the nude, he was sorry for it. To treat the nude, he was free to admit, entirely depended upon the purity of the individual treating it. Where the mind of the painter was defiled, his art would be defiled. Where his mind was pure, no one would see in his art impurity, excepting those narrow-minded people who went about the world like roaring lions, seeking whom they might devour. Much damage had, it appeared to him, been done in modern times by French art, and the treatment which the nude had received in that country. In Greek art, as Dr. Phené had said, you never saw a trace of anything that the most morally-trained person could take exception to; but he was bound to say that, although he had been familiar with the nude form from his childhood, he could not go into the Paris *Salon* and look at their interpretation of the nude form without blushing. That, he must say, he had never seen in an English exhibition. The nude was always treated by us with dignity. He was quite of Mr. Rathbone's opinion, that our ladies would do well if they did not lace so tightly and wear such high-heeled boots.

WHAT SHOULD BE DONE FOR SCULPTURE.

Mr. Boyes read a paper by Mr. Hamilton P. M'Carthy, offering suggestions for the promotion of sculptural art. The writer endeavoured to show that, art having become influenced by the caprices of passing fashion, painting failed to fulfil its higher functions in historic and figure

subjects; and the older, grander, and more important art of sculpture was utterly neglected. He therefore suggested that copies of the best examples of ancient and modern statuary should be placed in our public parks and gardens, which would not only raise our cities in dignity and attractiveness, but would familiarise the masses with the highest standard of taste and the truest type of beauty and proportion. He further suggested the desirability of the appointment of a Minister of Fine Arts, or other responsible Government authority, empowered to prevent the incongruities in architecture which frequently disfigured our cities. Also, that Government should be petitioned to allocate an annual subsidy for the special encouragement of the sculptor's art, which would doubtless lead to its receiving more general patronage from public corporations, rich mercantile bodies, and the general public. Mr. MacCarthy extolled the citizens of Edinburgh for their public spirit and appreciation of their beautiful city shown in the erection of so many fine public buildings and monuments, putting to shame the metropolis and other richer cities, and hoped that, by the addition of fine ideal statuary, it would become a veritable modern Athens. He also took occasion to announce an important discovery made by a gentleman of a new material for use in sculpture and architecture, which, while possessing the whiteness, beauty, and hardness of marble, was impervious to all climatic influence, smoke, or dirt, perpetually retained its colour, and cost considerably less than any existing material.

Dr. Farquharson, M.P., did not see what the object of the paper was at all. It began by saying that sculpture was in a decaying state. That was quite true. It was so expensive that no one could buy it, and in the Royal Academy it was treated with scant ceremony, so that between these drawbacks and the deficiency of material, there was no doubt it was decaying. Another point they must agree to was that sculpture had been made very unpopular by the very depressing examples of the art to be seen in many large towns,—those unfortunate people sitting in arm-chairs, and dressed up in costume they were never intended to wear. He should like to point out to the author of the paper that Edinburgh had carried out what he recommended. The visitors, he thought, must have observed that in Edinburgh there was a very good statue gallery. Many friends would bear him out in saying that the Edinburgh gallery would compare favourably with that of any other town. There was a valuable collection of casts, showing a little of the beauty of ancient sculpture, and Edinburgh might favourably compare its monumental sculpture with that of almost any other city. They could not fail to admire the very spirited sculpture by Sir John Steel as compared with what was to be seen in his (Dr. Farquharson's) native city of Aberdeen. If any one visited Aberdeen he would see a statue of the Prince Consort which, he thought, for sheer degradation and contemptible treatment could not be exceed d in the world.

Mr. Rathbone remarked that there was nothing sadder than to see Greek buildings entirely unfinished in consequence of the want of that sculpture which was a necessary part of them. In his opinion, it would be much better to go in for smaller buildings and finish them properly, than have enormous unfinished edifices.

Mr. Boyes did not like the tone in which the author of the paper spoke about the relationship between architecture and sculpture. He spoke about architecture as if it should be kept in the background for sculpture. That was a tone which had often been adopted by sculptors and painters. Painters often spoke as though the walls of a building should be arranged so as to afford them spaces for decoration. He maintained they should never have any true art without a proper combination of the three, and that sculpture and painting must be subordinate to architecture, and that they would each gain by that subordination.

The President disagreed with the way the paper had been received. He did not think there was anything new in it; but some people were very slow of apprehension, and even truisms constantly required to be stuffed down people's throats. The whole tone of the paper seemed to be that we wanted more sculpture in our towns. That he entirely agreed with; but he disagreed entirely with calling out the old artists of Greece and Rome and the Middle Ages to help us in that. It would, he thought, be a great mistake to put up casts of ancient art in our public parks and buildings. It would be rather an insult to contemporary art. If we wanted to encourarge art, we must employ artists; and if we wanted to give sculptors a chance to show what they could do, we must give them commissions. He should recommend the city of Edinburgh to employ sculptors. There were plenty of them, no doubt. He did not think that architecture should be supreme, but that the painter, the sculptor, and the architect should work together. It would, he thought, be of great advantage to the architect, when a great building was to be erected, if he would call in the painter and the sculptor. Certainly that was done in Athens.

IN THE HEALTH DEPARTMENT: SANITARY CONGRESS.

On the 12th inst. Dr. Stevenson MacAdam read a paper on the

VENTILATION OF SEWERS AND DRAINS.

The efficiency of the sewerage system of any town, he said, depended upon two main factors—(1) The facility of run or fall for the transmission of the sewerage; and (2) the ready means for admitting of the escape of foul or sewage gases. In the older systems of drainage the latter factor was scarcely thought of, because the common built drains were not tight, and allowed of the escape of gases between the stones. In the more modern systems, however, with brick conduits and glazed pipes, the sewers were practically impervious to gas. The more thorough sealing of the sewers and drains had led to the sewage gases being driven back into our dwelling-houses, causing disease and death. The quantity of sewage gas thus sent into houses fluctuated from hour to hour during the day, as the sewerage increased and decreased in volume, rendering the air-space less, and especially during the influx of warm water, which expanded the gases, and still more so during rainy weather, when the whole of the sewage gas was liable to be forced from the sewers. A mile of medium-sized ordinary town sewer contained about 12,000 cubic feet of air space, and more or less of this large volume of air, contaminated with sewage gas, was liable to be discharged through the house-service drains. This arrangement had led to the saying that town sewers were retorts generating sewage gas, which was laid on to our houses in a manner similar to ordinary coal-gas mains with their branch house-service pipes. The first precaution to be taken was to cut off the house-service drains from the main sewer by thorough trapping, and to ventilate the house-drain by level ground ventilators where practicable, or by pipes; and further, to carry the separate closet-pipes to the open air. The main sewers themselves should then be thoroughly ventilated. For the letting off of compressed gases, the so-called ventilation might be accomplished by shafts or by open street gratings; but the shafts will not insure the through aëration of the sewers, which ought to form the main feature in the efficient ventilation of the sewers. The open street gratings thoroughly served three conditions which were essential:—(1) They admitted of the ready escape of gas; (2) they admitted of abundance of air passing through the sewer to dilute the gas before escaping; and (3) they admitted of so thorough an aëration of the main sewers that any foul matter there would tend to be oxidised or burnt up rather than to enter into ordinary putrefaction.

The Rev. Mr. Graham, Newhaven, read a second paper by Mr. John Coley Bromfield, sanitary engineer, bearing upon the same subject. The paper was entitled, "Wholesome houses under the Banner system of ventilation of sewers," and was written to prove the successful working of that system in several large houses in London. The object of the system was to ensure a constant current of air, which should carry the foul air and gases from the ingress pipe of the sewer to the outside of the top of the house.

In the discussion which took place on the two papers, general approval was expressed of the importance of the subject with which they dealt. The systems of sewer ventilation which they advocated did not meet with the same general acceptance. Whilst several speakers, including Dr. Aubrey Husband, Dr. Elliot, Carlisle, and Bailie Fergus, Portobello, warmly approved of ventilating gratings level with the street, others, including Mr. Brodie, Mr. Tait, the Rev. Mr. Graham, and Dr. Littlejohn, expressed an opposing opinion. The idea of shaft ventilation received a more general, but not an altogether unanimous, support. Ultimately,

Dr. Littlejohn moved,—

"That it be a recommendation to the Council of the Association that the Local Government Boards of England and Scotland be requested to cause an impartial inquiry to be made into the system of open-air ventilation as practised in England and Scotland."

Mr. Stevenson Macadam seconded the motion.

Mr. H. H. Collins pointed out that in England they were fairly well satisfied with the open-air system, and that, if it was wished that a practical result should follow the resolution, the inquiry should be confined to the Board of Supervision in Scotland, who might get proof of English experience if that were desired. He moved, as an amendment, that the words in the motion, "Local Government Boards of England and Scotland," should be replaced by "the Board of Supervision of Scotland."

After some discussion, it was agreed to accept Mr. Collins's alteration of the original resolution, which was, with this amendment, unanimously adopted.

TREE-PLANTING IN TOWNS, AND TOWN FOGS.

Dr. Phené, F.S.A., read a paper on "The Sanitary Results of Planting Trees in Towns." Among the beneficial results which he claimed for tree-planting in towns was that it attained, or at any rate much aided, just that which was effected by the use of green or blue glasses in strengthening and sustaining the power of sight. Again, the chemical properties of trees gave them important standing on sanitary ground, irrespective of ornament or the pleasure they produced. He pointed out that all the nations of Western Europe used trees, for both their pleasure and health-giving properties.

Dr. Littlejohn read a paper by Dr. Alfred Carpenter, Croydon, on "The Causes of the Fogs which now belong to large Towns: a Proposal for their Prevention." Referring to a recent London fog, he said he had traced its cause to kitchen-fires alone; and he had found that the air contained unconsumed carbon in great quantity, and sulphurous acid, which acted injuriously on the respiratory organs. For the removal of the evil, he urged upon local authorities the duty of insisting upon the provision of self-cleansing sewers, and that the air should be purified from unconsumed carbon and sulphurous acid by the use of gas-stoves and fires for cooking purposes. Pea-soup fogs would, he said, become a thing of the past if,—(1) a tax should be put upon grates not so constructed as so consume their own smoke; (2) a tax should be put upon landlords for chimney-stalks; (3) local authorities should acquire the gas-works, and make every ratepayer a part shareholder, paying the cost-price only of the gas consumed; and (4) the law as to smoky chimneys, &c., should be enforced against all offenders.

In the discussion which took place on the two foregoing papers, approval was expressed of the objects of both; but doubt was indicated as to the suitability to all localities and circumstances in our towns of tree-planting; and also as to the feasibility, with coal-gas at its present price, of at all largely replacing coal-fires with gas-stoves and fires for cooking.

DECORATIVE SUGGESTIONS FROM NATURAL FORMS.—No. 3.

We give some further suggestions derived from the same two species of aloe figured in our last. *Aloe plicatilis* is more highly conventionalised and applied to a capital of Classic type. *Aloe variegata* is taken as the suggestion for a chased and jewelled silver cup,—the variegated patches of colour, and their arrangement in the original plant, being conventionally imitated by the setting of the stones in the artificial leaflets, and the triangular plan of the original plant furnishes the plan of the cup. The two plants are combined in a wall-paper, or a wall-diaper, which forms the background.

Trinity College, London.—The winter course of special lectures for the session 1880-81 will be delivered on the third Thursday evening of each month from October to March, commencing with,—October 21, Mr. William Spottiswoode, "Polarised Light." November 18, Dr. Francis Hueffer, "Musical Criticism." December 16, Professor Leone Levi, "Change for a Sovereign." January 20, 1881, Dr. B. W. Richardson, "Breath and Breathing."

BRADFORD NEW TECHNICAL SCHOOL.

For some few years the trade upon which Bradford, in Yorkshire, relies for its prosperity has been greatly depressed, and amongst the causes was the change of fashion which set in in the manufacture of dress fabrics, and that change came about without the manufacturers taking sufficient cognisance of it, until it was seen that many of the orders which were formerly executed in England were being bestowed upon foreign houses. The advantage which had been gained was freely admitted, and it was at the same time seen that the technical schools in France and Germany, in which the student was not only taught the principle of aiming at perfection in everything he undertook, but also the spirit of beauty and taste in every article he executed, had played no small part in the revolution that had taken place. English manufacturers, and especially Bradford manufacturers and merchants, recognised the imperative necessity that if the position of England as a manufacturing nation was to be maintained, it could only be done by imparting to the workpeople the technical knowledge which the French and German artisan employed and utilised with such deterrent effect upon English manufactures. Improved machinery was of very little benefit unless there was a corresponding improvement in the theoretical and practical knowledge of the workman, and it was seen that the latter could only be thoroughly and properly brought about by the erection of a technical institution, where the art of designing and weaving could be properly studied. Hence the determination to erect the Bradford Technical School.

As early as 1877 a "School of Weaving" was established in the Bradford Mechanics' Institute. Money was raised by an appeal to the town, Mr. J. Ashenhurst was appointed Instructor, and some good work was done in the right direction. In order to ensure the success of the undertaking, the Clothworkers' Company promised an annual subscription of 100*l*., and to establish at the same time two scholarships of the annual value of 25*l*. each, tenable at the Yorkshire College. In order, too, that the benefits and privileges of the new institution might be more usefully extended and enjoyed, Mr. Jacob Behrens presented two free scholarships, open respectively to boys attending the Board Schools and the classes of the Mechanics' Institute, the praiseworthy object of the donor being to enable deserving lads to devote themselves to the study of science and art as applied to industry, and thus not only adding to their own material welfare, but benefiting the community at large. Opening under such favourable auspices it was not perhaps surprising that the school should become popular, and the committee very soon experienced a difficulty in dealing with the large number of students who presented themselves for admission. The total number who joined the school during the opening session was 340. It was now felt that some earnest endeavours must be made to erect a permanent school, which should not only be sufficiently spacious, but should be at the same time an important addition to the building of a town justly honoured for its handsome public buildings. An appeal to the Clothworkers' Company resulted in a promise of a conditional building grant of 2,000*l*. in lieu of the annual subscription of 100*l*., and at a public meeting held in the Mayor's parlour at the Town Hall in October, 1878, the proposal to erect a permanent home for the Technical School was taken up with such warmth that subscriptions amounting to 11,000*l*. for the furtherance of the object were announced at the meeting. Some considerable information was obtained respecting the working of the technical institutions of the Continent, and this having been considered, and some additional subscriptions having been obtained, raising the total sums promised to 17,000*l*., a scheme was propounded for the erection of a school which should be thoroughly organised, well equipped, and replete with all the appliances necessary for the study of science and art as applied to manufacture. An excellent site, both pleasant and central, was obtained at the junction of Great Horton-road and Carlton-terrace. The site covers nearly an acre of ground, but some portions of the ground having been quarried in an irregular manner some fifty or sixty years ago, some considerable difficulty was at first experienced in obtaining a good and sure foundation. Excavations in some places had to be made to a depth of six or seven yards, whilst in others only to a depth of a single yard, but ultimately a good foundation upon rock was secured. In response to the invitation of the council of the Technical School, some sixteen architects sent in competitive designs for the erection of a building at an estimated cost of 12,000*l*. Most of the designs were of good character, and the result of the competition was that Messrs. Hope & Jardine, of Bradford, obtained the first premium, Messrs. F. & T. Healey taking the second, and Messrs. Hargreaves & Bailey the third. Since the adoption of the premier design several additions and alterations have been made, and the total cost of the building will now rather exceed 13,000*l*. The plans show that the principal features of the building, as seen from Horton-road, will be a tower rising in the principal front to a height of 120 ft., and an imposing general elevation, the front being relieved by fourteen Corinthian columns. The principal entrance will be in the centre of the Great Horton-road front, and it will divide the building into two parts. The Great Horton-road frontage will be 152 ft. with a height of 50 ft., whilst the Carlton-place frontage will extend to 217 ft. The left side of the entrance will be devoted to what may be termed the management department, and here will be located the subscribers' reading-room and library (38 ft. by 19 ft.), council chamber (19 ft. by 19 ft.), secretary's rooms, curator's room, and the necessary cloak-rooms. On the right-hand side will be the large lecture-hall, 68 ft. long, 46 ft. wide, and 32 ft. high, having a gallery round three sides, and capable of accommodating 800 persons. The hall will be divided into nave and aisles by two rows of pillars connected longitudinally by semicircular arches which, owing to the hall having a span of 46 ft., will be necessary for the support of the rooms above for the art-classes. The ceiling of the hall will be panelled, and surrounded with a bold cornice. The ground-floor of that part of the building which will front Carlton-place will be devoted more especially to the practical work of the school. It will contain a room 45 ft. by 32 ft. 6 in., to be devoted to the teaching of handloom weaving; another, 45 ft. by 44 ft. 6 in., to be devoted to powerloom weaving; a third, for teaching spinning; four class-rooms, each 23 ft. 6 in. by 30 ft. together with a storeroom and a large workshop 46 ft. by 40 ft. In the same part of the building will be a large lavatory, and a separate entrance will be provided for the use of the students, so that the work of the school may be carried on without interfering in any way with those using the public hall or the rooms in the management department. On the first floor, over the class-rooms and workshop, will be a smaller lecture-hall, seated in raised stages, to be used for science-lectures, &c., together with a chemical laboratory, with demonstrator's room adjoining, and a large room, 46 ft. 6 in. by 40 ft., in which dyeing will be practically taught. This part of the building may be reached either by means of the principal staircase, or by one which is provided near the students' entrance. The first floor of that part of the building which fronts Great Horton-road will be reached by means of a handsome stone staircase, which will lead up from the principal entrance-hall. One-half of the first floor will be taken up by the gallery of the large public hall, and the other half, over the management department, by a large room 50 ft. by 46 ft., which is intended to be used as an industrial museum, and which will have galleries around all sides. To this room there will be separate entrances on its area and gallery floor, and a separate staircase will connect the galleries with the floor below. On the second-floor level over the large lecture-hall will be rooms in which classes for the study of mechanical drawing, &c., will be taught. The Horton-road front of the building, the tower, and the end of the lecture-hall fronting Carlton-place, will be built of oleansed ashlar, and the remainder of cut wallstone. The building, when finished, will probably be the largest and most complete building devoted entirely to technical education in this country, and the desire of the council is that it shall be as handsome as it is hoped it will be useful. The building is being erected under the superintendence of Messrs. Hope & Jardine, Mr. Ashner Rhodes being clerk of the works. The contractors for the various works are as follow:—Mason, Mr. E. Atkinson; joiners, Messrs. Deacon & Whittaker, Shipley; plumber, Mr. S. Ryder; plasterers, Messrs. C. Howroyd & Sons; slater, Mr. J. Smithies, Great Horton; and iron-founders, Messrs. Taylor & Parsons.

We must congratulate Bradford on the course that has been pursued, and we anticipate excellent results. We have but one suggestion to make. We observe that rooms are provided for the teaching of "mechanical drawing": it is to be hoped that free-hand drawing will not be neglected, and that in other respects the great importance of the art side of the question will be fully recognised and acted on.

RESIDENCE, CECILY HILL, CIRENCESTER.

The building at the foot of Cecily Hill, Cirencester, formerly used as a brewhouse for the mansion, having fallen into disuse and decay, has been lately pulled down and rebuilt after the style of the Domestic architecture of the fifteenth and sixteenth century, to harmonise with the buildings in this quaint old-fashioned town, noted for Roman relics. The building forms a pleasing finish to a range of stable offices recently erected, and to the buildings at the foot of Cecily Hill, which is the chief approach to one of the finest parks in England. The residence, like the new stables, is built of rubble stone, with Box-ground stone dressings to doors, windows, chimney-heads, &c., and the roofs are covered with slate and lead. The works have been carried out by Messrs. J. B. & E. D. Bridges, of Cirencester, who also executed the works at the mansion-house, stables, &c., under the direction of Mr. John Birch, of John-street, Adelphi.

OBITUARY.

Colonel Ponsonby Cox, R.E., was for some years one of the engineer inspectors of the Local Government Board, and was well known in Lancashire, Yorkshire, and other parts of England. It is about twelve months since he resigned his appointment, and left England for Bombay, with the result as stated in an Indian newspaper. There is something peculiarly melancholy about the death of Colonel Cox, while acting as chairman of the Bombay Port Trust. The appointment he filled was created when the Port Trust was reconstituted, and a considerable amount of criticism was evoked by the way in which a very important and highly-paid office was called into existence by Sir Richard Temple without any reference to the trustees, while the appointment to the office of a military man who had only recently come to India as Military Secretary to the Commander-in-Chief, and who was almost necessarily ignorant of everything appertaining to the trade of this port, gave the new chairman a very unpopular start. The critics, ourselves among the number, were all most agreeably disappointed. On assuming office Colonel Cox exhibited the highest administrative talents. His experience as an engineer officer, his subsequent training as an inspector of the Local Government Board at home, and the energetic manner in which he set to work from the very first, enabled him to master the intricacies of a very important business concern at a very important period of its existence. In a few weeks those who had opposed his appointment most honestly were convinced of its fitness; in a few weeks more they were among his friends and admirers; and in a few weeks more they had to regret his loss. We never remember a case in which prejudices, which had appeared quite legitimate at the time, have been so rapidly lived down, and we doubt if any man who has lived so short a time in Bombay has ever left so many friends behind him. To great natural gifts Colonel Cox added those charms of manner and address which make an official's life as pleasant to others as to himself. His close attention to the wishes of shipowners and merchants has done much to do away with the unpopularity of the Prince's Dock, and his invariable courtesy endeared him to all who had business relations with him; and not least of all to his colleagues on the Port Trust, who had felt themselves slighted by Government when he was first appointed. The Port Trust offices were closed on receipt of the intelligence of Colonel Cox's death, and several members of the Port Trust proved the esteem in which he was held by starting for Poona immediately to attend his funeral. The Local Government Board had no abler inspector;

firm, conciliatory, quick, but gentlemanly. He shortened his inquiries without giving offence, and reported briefly, but to the point. A good man has been sacrificed to climate.

The Marchese Giovanni Pietro Campana, whose excavations among the remains of the cities and cemeteries of Etruria some twenty-five years ago attracted a great deal of attention, and whose museums in his house in the Babuino and his villa near St. John Lateran were among the most interesting sights of Rome, died on the 10th inst., at the age of 72 years.

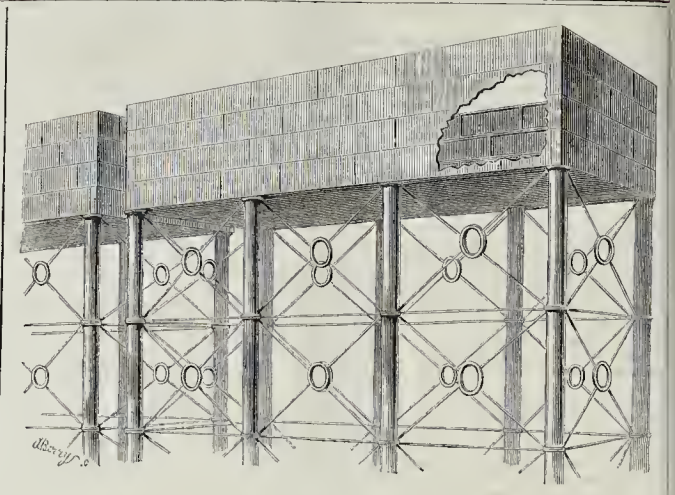
A VISIT TO OLD LONDON.

In accordance with a suggestion made during the late Congress at Devizes, a meeting of country and town members has been organised to visit some of the ancient portions of London, commencing on Monday next, when members and friends are to assemble, by 11.30 a.m., in the cloisters of Westminster Abbey and its precincts. Westminster Hall, the Crypt of St. Stephen's Chapel, and St. Margaret's Church will also be visited. After taking lunch they will go along the Albert Embankment and inspect Lambeth Palace and the Church of St. Mary, Lambeth, afterwards dining together at the Freemasons' Tavern. On Tuesday, the 26th, St. Saviour's, Southwark, will be visited, after which the party will cross London Bridge to the Coal Exchange, and inspect the remains of the Roman villa beneath that building; and then to Guildhall, the City Museum, the Charterhouse, the Church of St. Bartholomew, in Smithfield, and the old Gateway of St. John's Hospital. After luncheon the party will go to Gray's Inn Chapel, the Temple Church, and the Hall of the Middle Temple. On Wednesday the Tower will be inspected, including the Church of St. Peter-ad-Vincula. The remains of Roman London and the Roman Wall, Cripplegate Churchyard, and a fine portion of the old wall in Wood-street, Cheapside; the Churches of St. Helen, Bishopsgate, St. Andrew Undershaft, and St. Catherine Cree, Crosby Hall, and the Church of All Hallows, Barking, will all be visited; also Paul Pindar's House, in Bishopsgate-street, and the Church of the Austin Friars. A visit to the British Museum will be arranged for the next day (Thursday) for those who like to attend. At each place visited, some particulars will be given by some well-known antiquaries, who have promised to attend for the purpose. Tickets may be obtained of Mr. John Reynolds, Redland, Bristol, or of Mr. George Patrick, Drummond Chambers, John-street, Adelphi.

ST. PANCRAS INDUSTRIAL EXHIBITION.

The second St. Pancras Industrial Exhibition was opened on Saturday by Sir Thomas Chambers, Q.C., M.P., at the Tolmers-square Institute, Drummond-street, Hampstead-road. The exhibition contains 544 entries from 350 artisans and others. Sir T. Chambers delivered an address, in which he dwelt upon the awakening in recent years of all classes of the people to the possession of talents and tastes which might be developed into perfection by well-directed industry. Mr. Daniel Grant, M.P., said that those whose whole life was spent in giving polish to the top of a nail or sharpness to its point might compensate themselves for the repression of individualism in their ordinary life by taking up an artistic occupation in their leisure hours. Prizes are to be given for painting (oil, water, and on glass), cabinet-work, wood-carving, fret-cutting, working models, imitation of wood and marbles, turnery, wrought-iron work, art metal-work, &c.

The collection is superior to that of last year. Several specimens of *repoussé* work by A. W. Austin, A. de Caesemaeker, B. Humphreys, and others, are very creditable. One of the first objects that meets the eye of the visitor is an ornamental stand for flowers in wrought-iron (14) by E. A. Mills, made in his overtime; it ought to find a purchaser. W. Aumonier, G. H. Bull, and others, send some good wood-carvings. An ebonised cabinet by J. Flattely is very good of its kind. No. 72, an inlaid cabinet, sent by W. Langdale, carpenter, is a specimen of good work wasted on a bad design. Such absence of knowledge is shown that we have as an inlaid inscription "Britons scorn to *yeald*." Amongst the specimens of painted glass, one panel (94) by Nathaniel Seare, glass-painter's apprentice, gives excellent promise. Another youngster, O. R. Plummer, cabinetmaker's apprentice, sends a carved oak chest of drawers (436), indicative of industry and aptitude, and makes us desire he should get right teaching. The paintings and drawings are mostly very indifferent.



The Crystal Palace Tank.

THE BURSTING OF THE CRYSTAL PALACE TANK.

Sir,—If you can find space to insert a small woodcut from the rough sketch (made after a visit to the spot), which I enclose, I think it is likely to be of interest to many persons who have large water-tanks under their charge, in conjunction with the observations from "Civil Engineer" which appeared in your last number. Fortunately the failure of the tank, which occurred on Thursday, the 30th of September, at half-past one p.m., was unattended by personal injury, although there were some narrow escapes; but the damage to property was considerable, and there are in many places tanks so situated that their failure would be a very serious matter.

The cause of this accident is stated to be the corrosion of one of the tie-rods or stays connecting the flat sides of the tank, but it does not appear quite certain that the couplings or means of attachment were satisfactory either in design or in condition at the time of the failure; and although the outsides of the tanks were always kept in good condition, and well protected by paint, no attention appears to have been paid to the condition of the interior, and to me it appears more than probable that some one or more of the stays having been removed to effect some slight repairs or alterations, or even to clean the tank, had never been properly readjusted. Any information on the exact circumstances of the failure would be, I feel sure, of great value, as the popular accounts which are to be found in the daily papers on such matters are frequently not reliable in their figures, notably as to the height of the tanks from the ground, which, instead of 200 ft., is about 80 ft. Perhaps some one connected with the Palace, or the engineers who designed the work, will confer a benefit on your readers by giving such information as they may feel inclined to furnish through the medium of your columns.

C. E.

Sir,—The rules as to cast-iron water-tanks given in your issue of the 16th by "Civil Engineer," are instructive, but I firmly believe that it is not always owing to the constructors of such tanks that the plates may be ruptured through faulty workmanship. Cast iron is brittle, and when tanks of this material are carried on columns or on walls, with probably sinking foundations, to such may most likely the breakage be due, "stay" the tanks as you like.

I prefer wrought-iron tanks, not too large. If a great mass of water is to be stored, let there be a series of tanks, connected by "double-flanged pieces." I find such tanks less costly to erect; they have a better bearing, and I must say I have never, in my twenty years' experience, heard of one giving way.

Mechanical Engineer.

EDINBURGH.

The Scott Monument.—The Treasurers' Committee of the Edinburgh Town Council have had under consideration a motion by Bailie Hall to have the remaining niches of the Scott Monument filled with statuettes. A committee, of which Sir James Falsbaw was the chairman, some time ago handed over the balance of a fund, it is said, in their hands, amounting to about 160*l.*, to the Town Council, for the purpose of being expended on the monument. There is also a balance of about 1,000*l.* in connexion with the monument fund of the Town Council, and as there are about thirty niches which have not yet been filled, it is proposed to apply these sums in completing the structure as far as they will go. The statuettes proposed are those of characters in the works of "The Wizard of the North" which are not yet represented on the monument. It was agreed by the committee to recommend that the proposal be approved of by the Council.

Ventilation of Water-closets on Common Stairs.—At a meeting of the Edinburgh Town Council on the 28th ult., on a report by the burgh engineer, the Public Health Committee recommended that that official be authorised to call upon the owners on the common stair at No. 6, Gladstone-terrace, to have their water-closets ventilated to the open air. Mr. M'Laoblan asked upon what principle they proceeded in this matter, seeing that the Dean of Guild Court sanctioned plans of houses with water-closets in them, constructed upon the very principle which was condemned by the burgh engineer. (The Dean of Guild.—That is not true.) Mr. M'Lachlan went on to state that he had quite recently seen plans, which had been approved of, which did not provide for the ventilation of the water-closets into the open air. Were they to have this conflict going on between the Dean of Guild Court and the Public Health Committee? It was a serious question, and one deeply affecting the health of the community. The Dean of Guild said he had most distinctly to contradict Mr. M'Lachlan. Since the new Act came into force the Dean of Guild Court had passed no plans where the water-closets were not ventilated into the open air. They had insisted that each water-closet should be ventilated by a 4-in. pipe into the open air. Mr. Gowans said he did not know that the pipe mentioned by the Dean was a proper method of ventilation. If he put a candle to the mouth of one of those pipes he would find that the draught was often downwards and not upwards. That was only what might be anticipated if the interior of the house was hotter than the outer atmosphere. After

further discussion, the recommendation was adopted.

The North Bridge.—The east footpath of the North Bridge is now being relaid with Limmer Rock asphalt. The work is being done by Mr. William Briggs, the agent for the asphalte in Scotland, under the direction of his Edinburgh manager, Mr. Adam Loch.

WESTMINSTER NEW VESTRY HALL.

A committee of the Vestry of the united parishes of St. Margaret and St. John held a meeting on Tuesday, to confer with the authors of the first premiated design, Messrs. Lee & Smith, of Queen Victoria-street. The sum which the Vestry had decided not to exceed was 15,000*l.*, but Mr. Barry (the referee) had reported that the buildings would cost 22,092*l.*, carried out according to Messrs. Lee & Smith's design. In answer to various questions put by the members of the committee, Messrs. Lee & Smith admitted that, in order to give the whole of the accommodation required for 15,000*l.* the interior must be finished in the plainest and barest manner; but they had no doubt tenders would be obtained for the works finished in every way in a satisfactory manner, at such a price as would approximate the total cost of the buildings to 20,000*l.* After further discussion, it was resolved to report the result of the interview to the Vestry, and to recommend that Messrs. Lee & Smith be employed as the architects of the new buildings. It was also resolved to send on the approved design and plans to the Local Government Board for consideration.

YORK MINSTER.

The restoration of the south transept of York Minster, now just completed, was commenced nine years ago. The *York Herald* says that the work embraced the repairs necessary to the interior of the transept, and whilst this was going on the transept was separated from other portions of the minster by the erection of two partitions of timber and stoothing covered with a coating of plaster. The clearstory walls were found to be in a very unsafe condition, which was attributed to imperfect construction originally. In their rebuilding a different mode has been adopted. They are formed of solid masonry, laid in with Portland cement, and thus united the two constitute a firm and compact mass. The walls are also tied by wrought-iron rods running through each of them from the south front to the lantern tower, the effect of which is to keep the walls properly fixed and immovable. Additional strength, too, is imparted by the use of several transverse iron cramps. When the west clearstory wall was removed one of the triforium arches was found to have sustained some injury at an anterior period, the joints having given way several inches. The defect was remedied as far as possible, and greater strength and stability were imparted. The arches composing the different bays of the transept were rebuilt in a more vertical form. Most of the shafts were renewed, as were also the various Purbeck marble shafts, and the quantity of this marble which was thus brought into requisition may be judged of from the fact that upwards of 1,180 lineal feet of shafting, varying in diameter from 4½ in. to 7½ in., were used in the transept. The interior of the central roof was strengthened by the addition of extra braces and trusses, and the west aisle roof was raised to its original pitch. The groined ceilings of the two aisles of the transept were denuded of the plaster, which opened out to view the original stonework, and thus those unique examples of the quadripartite, quinquepartite, and sexpartite vaulting were exhibited with pleasing effect. The date of the main roof of the transept is the thirteenth century, and the style of decoration adopted was an exact reproduction of the original mode of embellishment. The foliage of the bosses was gilded, and the background was picked out in vermilion. The vaulted ceiling in its renovated beauty presents a striking appearance. During the progress of the restoration, it will be remembered the celebrated dial-clock above the south doorway was taken down, and the mechanism of it was placed in the clock-chamber of the western tower. The space thus vacated was occupied internally by a string of small arcades, with Purbeck marble shafts of the same description as those which existed before the clock was obtained in 1750. On the completion of the interior restoration of the south transept, in the latter part of 1874, a series of inaugural services were held in the minster, which drew together immense congregations, and a large amount was thus realised to enable the work of exterior restoration to proceed. The south front throughout presented externally a shattered appearance, the effects of weather and time having told very perceptibly on the walls and on the prominent features of the architecture. The figure of the old fiddler on the pinnacle surmounting the southern gable was removed some time ago, and recently a cross was erected in place of it. When the fiddler was taken down traces of a cross that had previously terminated the apex of the transept were discovered, which showed that the erection of the present one was in keeping with the original style. The carving of the south front is generally admired, and the clever execution here, as in the artistic work of a similar kind throughout the south transept, redounds to the credit and ability of the artist, Mr. Milburn. The great work of restoration having now been completed, the southern front of the cathedral, which has been hoarded in for the past nine years, will again be opened out to public view.

OLD STONE PULPITS IN ENGLAND.

A large number of the examples in the following list were kindly forwarded to me by Mr. A. W. Morant, F.S.A. I have noted others, and the whole may be acceptable, as I am not aware of a similar list. Those marked with (D) are engraved in Dollman's "Examples of Ancient Pulpits existing in England," 4to., 1849, 30 plates :—

Bedfordshire.—St. Paul's Church, Bedford.
Cheshire.—Nantwich, at junction of north transept and chancel.
„ *c.* 1270.—Chester. St. Werburga Abbey, refectory (D).
Cornwall.—Egloshayle.
Cambridgeshire.—Newton Nottage.
Devonshire. — Harberton; Chittlehampton; Paignton.
„ *c.* 1530.—North Molton (D).
„ *c.* 1500.—Totnes (D).
„ Sonth Wooton; Dartmouth, St. Saviour's.
Dorsetshire.—*c.* 1450.—Frampton (D).
Gloucestershire.—*c.* 1460.—North Cerney (D). Cold Ashton; Pitcombe; Staunton All Saints.
„ *c.* 1520.—Winchcombe (D). Lechlade; Ellestow; Northleach, SS. Peter and Paul Church; Gloucester Cathedral.
„ *c.* 1450.—Cirencester, St. John (D).
Hampshire.—1260.—Beaulieu Abbey, refectory.
Isle of Wight.—Shorwell.
Hereford.—Cannon Peon.
Oxfordshire.—1400. — Oxford, St. Peter's Church.
„ 1480.—Oxford, Magdalen College, external.
„ *c.* 1370.—Coombe.
Shropshire.—*c.* 1320.—Shrewsbury Abbey (D).
Somersetshire. — Bristol Cathedral, near a pillar on north side of nave.
„ *c.* 1500.—Glastonbury, St. Benedict (D)
„ *c.* 1500.—Cheddar (D).
„ *c.* 1480.—Banwell (D).
„ *c.* 1500.—Nailsea (D). Kew Stoke; Stogumber; Wrington.
„ 1547.—Wells Cathedral, nave.
Staffordshire.—*c.* 1480.—Wolverhampton Collegiate Church, near one of the south pillars of the nave (D).
Sussex.—Arundel; Clymping.
Yorkshire. — Ripon Cathedral; Beverley Minster.
Warwickshire.—*c.* 1470.—Coventry, Trinity Church.
Worcestershire.—Worcester Cathedral. Pl. 42 and 43, vol. ii. of Pugin's "Specimens of Gothic Architecture."

I am not aware that there is any old stone pulpit in Scotland; and only one apparently in Ireland,—namely, in the cloisters at Sligo Cathedral. Wales affords one,—namely, in the refectory at Tintern Abbey, Monmouthshire.

Wyatt Papworth.

DRINKING-WATER AND ENTERIC FEVER AT LLANDUDNO.

A family staying at Llandudno for a few days during the month of September, three of whom were water-drinkers, found some of their party very unwell shortly after returning home. A medical man was at once called in, and pronounced it to be a severe attack of enteric fever. After suffering for many days, two of the family are out of danger, but the third still remains in a precarious condition. It is worthy of note that only the water-drinkers of the family were attacked, the others escaping entirely.

It is not known if the source of supply was a well or the waterworks, or whether the mischief may have arisen from the overflow of the cistern being connected with the soil-pipe; but that the fever was due to the drinking of water (polluted water) whilst at Llandudno there is no doubt. And it would be well for the Llandudno Sanitary Authority to investigate the matter without delay, lest a more general and dangerous outbreak drive visitors from their town.

SALE OF ILFORD GAOL.

Under the Prisons Act of the late Home Secretary, several of the disused prisons in different parts of the country are from time to time being publicly sold and converted to other uses, and last week the Ilford Prison was offered for sale at the Auction Mart by Messrs. Beadel & Co. It was described as situated on the borders of the town of Ilford, comprising a substantial pile of buildings, with a large area of garden-ground, presenting an eligible frontage to the main Essex road, the site altogether containing three acres, and forming a good site for the erection of villa residences. It was stated that the existing erections, which comprised the governor's house, chapel, court-house, cells, offices, and outbuildings, were all in a very substantial condition. The biddings started at 1,000*l.*, and quickly went up, by advances of 1,000*l.*, to 3,000*l.*, on which the auctioneer stated that he was then at liberty to say that it was an entirely open sale, and in the hands of the company for what it would fetch. The property was then bid up to 3,800*l.*, at which sum it was sold to Mr. George Blizzard, of Ladbroke-road, Notting-hill.

WORKMEN'S EDUCATION.

Sir,—"A fair field and no favour," as Mr. W. Cave Thomas has justly said, is what we workmen require, and depend upon it when we obtain that there will be but little reason to complain of an absence of "the spirit of emulation" among us. But while employers maintain a demand for ignorant and inferior workmen, and it is to men's interest to be such, we may be sure the supply will not fail. When, however, our ablest and most intelligent men, instead of our biggest fools (as is now too often the case), are selected to occupy positions of responsibility, as foremen or managers; when we have foremen who can do something more than drive,—men who can, when necessary, instruct and direct those under them,—then shall we have a better class of workmen than at present, and the best men will then by preference be retained, as the jealous fear for their own position, now so prominent a feature in some of our present foremen, will then be a thing of the past; neither will it then be found necessary to resort to abuse and invectives as a cloak for ignorance and incapacity, an expedient now in great favour with many foremen.

When the existing premium is taken off ignorance, and we have a "fair field without favour" granted us, then will merit, asserting its rights, meet with the recognition it deserves, and we shall have both good foremen and good workmen. But at present, to our shame, men are not allowed to know, or even to think; their hands only are hired upon the understanding that they leave their brains at home.

The special training that "E. G." advocates is already within the reach of all workmen, for the various technical and science and art classes now established in all parts of the country ably supplement the practical lessons of the day by the theoretical instruction they impart of an evening. The value of these classes, however, seldom meets with the appreciation, or even recognition, of employers, although they are the parties principally benefited by them.

The students, who usually pursue their studies under great difficulties, meet with scant encouragement, and often with serious opposition; their aspirations are nipped in the bud, their hopes disappointed. Is it then to be wondered at that apathetic indifference is the ultimate result? E. W.

THE SCULPTURE FOR BLACKFRIARS BRIDGE.

Sir,—I see the "Bridge House Committee" have issued an advertisement, which appears in the *Builder*. As far as I can judge and can learn, for of course I have inquired where I could among sculptors, the matter put forward in this crude way will meet with no response at all,—at least, from any of those whom it is desirable to interest.

It is not for a looker-on to move further if sculptors remain quiescent.

The Committee have simply shirked the whole question, and a magnificent opportunity runs the risk of being wrecked. Z.

MARGINS OF SAFETY.

Sir,—Some time back (June 12th) I called the attention of your readers to the unsatisfactory nature of our knowledge of dealing with ironwork; but, important as the subject is, no further information was elicited.

The draughtsman has a similar difficulty in regard to margins of safety. The greater the number of "authorities" he consults, the greater is his difficulty in arriving at a conclusion. For example, the weight of a crowd of men closely packed is given as 120 lb. per foot super. by Hurst, as 84 lb. per foot by Young, as 102·6 lb. by Campin. The weight of a man being a variable quantity, each of the foregoing may be correct, but is the same "margin" to be always allowed?

The factor of safety is given as one-sixth to one-tenth of their strength for cast-iron columns by Hurst, as one-fourth by Molesworth, and by Humber as one-third to one-fifth for metal structures generally; Fenwick gives one-fourth to one-eighth. I believe the custom of giving a margin up to nine-tenths of the breaking-weight is most general in this case.

The factor of safety for wrought-iron structures is given by several authorities as one-third load and two-thirds margin, but one-fourth to one-fifth load is more like the general custom.

According to Young, brickwork in cement can safely bear three tons per foot super., and Hurst gives it as one-fifth of thirty tons. In buildings, such piers often have to stand (and do so) eight to ten tons; but I am not advocating the advisability of loading to such an extent.

The quality of the materials supplied must always affect the question of "margins of safety," especially as this is to the draughtsman an uncertain element. Let him also guard against the usual and pernicious custom of "roughly guessing" and "lumping" loads on structures.

I believe the most satisfactory results are to be arrived at only by considering every element of load in detail, omitting nothing, and only giving a sufficient margin of safety to counteract "those powers of nature that are subject to no calculation." A. Harland.

ROAD FORMATION.

Sir,—In an article on "Road Formation and Street Pavements" in your issue of October 9th, by a "Civil Engineer," your correspondent gives what in his opinion is the best method of laying wood pavement. In this case, as in many other articles on practical subjects, there is considerable room for divergence of opinion. I am not a civil engineer, and do not intend to refute the assertions made in the article by any theoretical problems, but by the actual experience of the systems of wood pavement laid in London during the present year.

The table accompanying the article I will not discuss in detail, but simply refer to one item, which is the statement under the heading "Estimated Life" of wood pavement, which is stated by the author to be for the Asphaltic Wood Pavement Company's paving, from twelve to fifteen years. Now, Sir, I think this statement will astonish the strongest advocates of wood pavement, for no engineer or contractor will (considering the traffic on the principal London thoroughfares) expect to do less than entirely renew the wooden surface at least once in the course of fifteen years, and in some cases this amount of renewal will not be sufficient.

My object in writing at the present time is to dissent from the assertion by your correspondent that, "the best system is when the wooden blocks are laid on a bed of tarred felt, jointed with a bed of close felt (close jointed). A thin layer of asphalte over the concrete may take the place of the bed of felt, but both will be better." I maintain that wood pavement has received a fair trial in London, and no doubt the various bodies interested have made themselves thoroughly conversant with the various systems, and the result of their careful inquiries and experiments must prove what the great majority of them think the best pavement. Now, the work of the present year is what I submit should show this opinion. Note the result: there has been laid in London of the system or systems recommended by your correspondent about 10,000 square yards; this quantity includes both systems, although none of it was laid with the combination; whereas, of the pavement generally adopted there has been laid over 20,000 square yards, the whole being laid with the wood directly on the concrete foundation, proving that in the minds of most people there is no necessity for the costly and fanciful bedding of felt or asphalte recommended by a "Civil Engineer." Fact.

MATERIALS FOR ROADS.

Sir,—In reply to the inquiry of "One Interested," I venture to supply some information upon this important and interesting subject.

Having had tested by Mr. Kirkaldy some 1½-in. cubes of Guernsey granite and Quenast porphyry from Belgium,—the latter largely used in the street paving of Paris and other Continental cities,—I am in a position to give you the result. Thus:—

Guernsey crushed at 14,015 lb. per sq. inch.
Quenast " 24,460 " "

Now, without committing myself to the statement that therefore Quenast stone is superior to Guernsey in the ratio of 12 to 7, I may safely venture to assert, upon this evidence alone, that Quenast must be a very superior material for macadam roads.

I can, however, speak from a somewhat extended experience of its value as a road metal, having, during the last four years, used it largely in some of the principal thoroughfares of the metropolis, and am satisfied that it is, if not the best, certainly one of the best yet introduced.

I venture to say this much in its behalf as it is a newly-introduced material, and therefore is not as widely known as it ought to be.

Surveyor.

GIVE, AS WELL AS TAKE.

Sir,—We are most of us, more or less,—more, I may say, than less, if we look at things fairly and philosophically,—fortunate, and those are happy, too, as well as fortunate, who give a helping hand, when opportunity serves, to a failing or a fallen brother. Hence I am tempted, without a word of apology, to quote the following extract from a letter I have just received from my good friend, Mr. Edward Ashworth, of Exeter. Here it is:—

". . . . If ever there was a case needing charity it is that of poor Strachan. When I worked as his assistant at Hong Kong, in 1844-45, he had a large house of his own, had servants, and an excellent professional practice amongst the merchants there, although I used scarcely say specifications were not carried out in China to the letter as they are here. Afterwards he carried out some large gasworks at Shanghae, then went home, as men will do, to get married. Coming out again, he found his absence had injured his connexion, and that his practice was, to a great extent, gone. Then his wife's health failed, and he returned to England. Gradually his resources ebbed away, and a family coming on in the meanwhile, he went hopelessly down in the world.

In 1875 I recognised an advertisement of his soliciting architects' and surveyors' work; but the lack of any response to this and other such applications, as well as continued ill-luck in every way, preyed upon his spirits terribly. I heard no more of him until the beginning of this year, when he wrote asking me to give him a testimonial, and fill up the necessary papers preparatory to applying for some allowance from Sir John Soane's legacy fund for distressed architects or their widows. I did this, making, as I thought, a good case out; but, alas! he got nothing, the applicants were so numerous. He has six children, and is now much too ill and infirm to take any employment, even if he could get it. Mr. Strachan is an Edinburgh man by birth, and I can warmly testify to the constant opportunities I had of witnessing his untiring industry and good moral conduct when we were both residing at Hong Kong."

Thousands of eyes, in every part of the world, will read these lines; and, I hope, many hearts will respond thereto, and send a trifle to you, Mr. Editor, for the poor fellow's benefit. Harry Hems.

HOUSE-DRAINAGE AND SEWAGE WORKS AS A SPECIALTY.

"In exposition of the ignorance which is prevalent there [*i.e.*, in the United States] as well as here, he [Mr. G. E. Waring] states, for example, that the particular idea of the size of a drain required to receive the drainage of a house, or of a number of houses, is strangely in error."

Sir,—The above extract from the *Builder* of September 25th, is, in part, the utterance of, and the rest is sanctioned by, an eminent sanitarian. The report from Boston on the common defects of drainage, and the introductory remarks by Mr. Chadwick, show up so well the scamping way of doing work (or not doing it), and covering it up, that I feel a bit sorry to break a lance with such good intentions.

But the assertion and recommendation of small-bore drains in preference to larger ones needs limitation. Readers must not fondly imagine that that is the panacea for all evils. The theory that a pipe-drain, being full of liquid, cannot contain gases at the same time, is very well in type or in a drawing, but in practice there are difficulties.

This theory of small drains is by no means a new one. Some six years ago, I saw in the *Scientific American* that a 4-in. pipe would do so much, under such and such conditions, and having some drainage in hand at the time for a client who wished to be economical, we resolved to make the experiment. The length of drain was 161 ft., the fall in its whole length 14 in., and it had to carry the sewage from two pan closets, discharging itself into a 9-in. pipe drain. It worked beautifully for about a month, and then, in consequence of frequent stoppages, we finally lifted the 4-inch pipes, and laid 6-in. ones, which gave no trouble whatever. Now the question comes, how is it that a 6-in. pipe worked so well? Because there was space for the sewage and space for the fur.

When furring takes place in a pipe, we know it must diminish the bore, and then what happens? Why a little silting up here, or some half-floating substance there, adheres to the fur, and lo! the embryo stoppage.

Any plumber knows what furring means, from lavatories and especially from dish-washing places; unfortunately householders get too often acquainted with it too. It is a pity the practical men, the men who do the work, do not join in such discussions as these, as it would undoubtedly contribute to the elucidation of much which is at present very little understood in the office of the so-called professional. When we come to practically look upon a sewer or a drain as an elongated cesspool, then we shall be face to face with our foe. But when we succeed in, as Mr. Chadwick says, the grand desideratum—getting the sewage out of the sewers and drains before it is twenty-four hours old, then yes! then we may rejoice and say the sanitary millennium has come, so far as drainage goes, any way.

Practical Sanitarian.

CHURCH-BUILDING NEWS.

Walsall.—Walsall parish church was reopened on the 21st ult., after extensive alterations and re-decoration. Formerly the nave was filled with high-backed pews of antique make, fronted by a huge structure in three stages, combining pulpit, reading-desk, and clerk's desk. These have been removed; the chancel arch has been cleared of the organ and gallery; the arch has been widened and rebuilt, and the gable above raised and pierced with two lights. The eastern wall is filled with a memorial window to Sister Dora; in the side walls (of the chancel) instead of the old windows are new ones in the style of the fourteenth century, with stone mullions and cathedral glass, being exact copies of an original window which was found blocked up by the organ. A roof of oak occupies the place of the whitewashed ceiling, and the floor is laid with encaustic tiles; whilst two ancient doorways, leading into the crypt, and a canopied sedilia, which were discovered during the progress of the works, have been restored with scrupulous fidelity to the original work. The old oak stalls are retained in the chancel, new ones being added, and the organ is located within an archway to the north, the old vestry having been enlarged and transformed into vestries for the clergy and choristers. The organ has undergone complete restoration, modernisation, and enlargement, at the hands of Messrs. Bishop & Son, London. The "Sister Dora" window has the spaces between the tracery of the upper portion filled with representations of the four Archangels, the twelve Apostles bearing a scroll inscribed with the Apostles' Creed, the Agnus Dei, and other sacred symbols. The five lights in the lower part are filled with ten designs, the centre one in the upper row being a figure of Christ, and those to the right and left figures of the Virgin and St. John; whilst the other seven contain representations of the seven corporal works of mercy,—giving water to the thirsty, feeding the hungry, clothing the naked, receiving the stranger, visiting the sick and the prisoner, and comforting the mourner. This window is from the works of Messrs. Bullison & Grylls, Newman-street, London, and cost upwards of 300*l*. The alterations and restorations have cost 5,000*l*. The architect is Mr. Ewan Christian, of London, and the builder was Mr. Thomas Williams, of Harrington-square, London.

Ashley.—On the 29th ult. the Bishop of Chester consecrated the new church of St. Elizabeth, at Ashley. The new church, which is in the Gothic style, has (according to the *Manchester Courier*) been erected from the designs of the Hon. Wilbraham Egerton, M.P., and together with the site, is the gift of Lord Egerton, of Tatton Park. With the exception of the helfry, which is of Runcorn stone, the building is of brick and terra cotta. The font is of Dumfries stone, with Connemara marble columns, and the symbols of the Evangelists are carved in the alabaster panels. The reredos is in five panels of Dumfries stone with green marble columns. It is intended to fill the recesses with a cross and floral patterns in mosaics, manufactured by Salviati, of Venice. The contractor for the fabric is Mr. H. Ormson, of Bowdon, and the internal fittings are by Messrs. Jones & Willis. The peal of five bells, with chiming apparatus, has been put up by Mr.

Taylor, of Loughborough. The edifice has been erected at the cost of over 3,000*l.*, and is constructed to accommodate about 250 persons, all the seats being free.

Poplar.—On the 29th ult. the new Church of All Hallows, East India Docks, was consecrated by the Bishop of Bedford. Towards the outlay necessary for the erection of the church, &c., estimated at 14,700*l.*, 2,000*l.* were received from the Bishop of London's Fund, and the sum of 9,000*l.*, derived from the proceeds of the sale of site of All Hallows, Bread-street, City, was placed at the disposal of the committee. From the latter church, in which Milton was baptised, several pieces of furniture were transferred; also the communion vessels, which were in silver gilt; the organ, which has been repaired and improved; the pulpit, some old panels, and two bells. The accommodation consists of 900 20 in. seats. The edifice is in the Early English style, 111 ft. long by 63 ft. broad, and 51 ft. from the floor to the centre of the roof (inside measurement). It has two entrances, one from the East India-road and another from Atholstreet. The architect is Mr. Ewan Christian, and Mr. George Shaw was the contractor.

Waenfawr, Carnarvon.—The new church here, dedicated to St. John, was consecrated by the Bishop of Bangor on the 28th ult. The building, which is in the Early English style, has been erected from a design by Mr. Henry Kennedy, architect, Bangor. The site is the gift of the late Mr. Christopher Holman, of Glyn Afon. It is estimated that the cost will be about 2,250*l.*

Wigton.—At a meeting of the parishioners on the 23rd ult., it was resolved to apply for a faculty to re-seat Wigton Church, and to carry out other works, under the direction of Mr. Ferguson, architect, Carlisle, at an estimated cost of 700*l.* The faculty was decreed on the 13th inst. by the Carlisle Consistory Court.

Hallonghton.—Hallonghton Church was re-opened, after restoration, on the 29th ult. The new roof, which has been raised, is of the same design as the one it has replaced, and is of carved oak. The screen, dating from the early part of the fifteenth century, has been restored, and two stained-glass windows have been added at the east end of the chancel, the gift of the Rev. J. Barrow (Southwell), whose father was for sixty years the incumbent of the parish. A carved oak pulpit occupies the site of the old one, and the old seats have been replaced by low-backed pews of pitch-pine. Accommodation is now provided for about eighty persons. The work has been carried out by Messrs. Clipsham & Son, of Norwell, under the supervision of Mr. Ewan Christian, architect to the Ecclesiastical Commissioners.

Books.

The Index to our Railway System, and on Leading Lines: a Comprehensive Analysis of Railway Property. Fourth Number. By W. Fleming. London: E. Wilson. 1880.

Mr. Fleming has reached the fourth number of his painstaking and useful Index. He does not congratulate railway shareholders on the result of the movement of the year. We must make due allowance for the spirit of disappointment, not to say of irritation, which it is but natural that those railway economists who, during the past four or five years, have endeavoured to ascertain the real profits and losses of the English railways, should feel at the hindrances thrown in their way. The Parliamentary returns, whether purposely or not, are so framed that the clue to the whole question,—the statement of the work separately done in each of the three main departments of railway transport,—is sedulously concealed. The managers of the companies are deaf to every appeal for information on this cardinal point. The Board of Trade, which a year or two ago admitted the extreme importance of obtaining such detailed information as to the working of the railways of the United Kingdom as is given in France, in Austria, in Germany, in India, in America, and, most carefully of all, in New South Wales, seems now to have abandoned the hope of giving real value to the Parliamentary returns. It is due to this persistent concealment, which must be more injurious to the shareholders than to any one else, joined to the complexion of some of those statements which it is impossible to conceal, that analysts like Mr. Fleming are driven to form inferences which it is possible that a fuller statement of accounts would overthrow.

Meantime, public gratitude is due to those who perseveringly endeavour to throw the light of scientific investigation on the subject. In regarding the palpable fact of the constant increase in capital cost of our railways, Mr. Fleming takes views of the increase of dividend at the cost of capital which we should be glad to see disproved. One thing is certain, and that is, that if untrue, they are capable of disproof. And so long as those who have the proofs in their hands remain silent, they cannot blame those who draw an adverse inference from this silence.

Without attempting to discuss any details that may prove dry to the general reader, we will give one example of the mode in which figures may be so dealt with as to afford contradictory results, in the absence of a proper debtor and creditor account. Mr. Fleming states (p. 45) that since 1874 the increase in the number of locomotives and vehicles owned by the railway companies has been double the increase in the length of line and earnings. He infers that a sum of 3,780,000*l.* has been improperly expended on plant; and that by means of the saving thus effected in repairs, a proportionate sum has been paid out of capital by way of dividend.

When we observe that every locomotive on an average earned 4,934*l.* in 1874, and only 4,508*l.* in 1879, this looks like a confirmation of Mr. Fleming's charge. Going back a little, we find that in 1877 every locomotive earned on the average 4,750*l.*, and in 1878 4,661*l.*, or 89*l.* less. But if we inquire what work was done to obtain these earnings, we find that the mileage of trains drawn by an engine was actually identical in 1877 and in 1878, and within seventy-nine miles, or less than two days' work, of the same, in 1879, the respective mileages being 17,223 17,223, and 17,144 miles run. In 1874 the mileage ran per engine was 17,418 miles.

If we look at the locomotive as the bread-winner of the companies, and endeavour to form an idea of their respective economy of management by their employment of their engines, we are struck with extraordinary differences. On the Metropolitan Railway, in 1879, every locomotive on the average ran 24,000 miles, while on the adjoining Metropolitan District line each engine ran more than 33,000 miles. Yet every Metropolitan engine earned a gross sum of above 12,500*l.*, while each Metropolitan District engine earned a little under 11,000*l.* The former line paid 37 per cent. of gross revenue for working expenses; the latter 42 per cent. These differences are probably mainly due to the fact that the density of the population, or of the course of traffic, on the former line is such as to fill the carriages fuller than on the latter, although the two lines are really integral parts of the same system. These lines are exceptional. But we may compare the London and South-Western, as relates to engine earnings, with the London and North-Western. On the former line each engine ran above 23,000 miles, and earned 6,114*l.* in the year. On the latter each engine ran 14,600 miles, and earned 4,138*l.* during the same period. And yet the working cost of the London and South-Western line was 57 per cent. of revenue against only 52 per cent. on the London and North-Western. But again, on the other hand, the gross traffic of the London and North-Western was 5,298*l.* per mile of line, while that of the London and South-Western was only 3,324*l.* It is evident that there are in these two cases so many elements of comparison, that it is quite impossible to tell how far any one may affect any of the others, without the possession of the cardinal information of the cost of conveying, on each line, a definite weight for a definite distance. The capital of the London and South-Western Railway had a gross earning power of 12·05 per cent. in 1874, which had fallen to 11·76 per cent. in 1878. The capital of the London and North-Western had a gross earning power of 12·18 per cent. in 1874, which fell to 11·55 per cent. in 1878. The net earnings in the latter year were respectively 4·90 and 4·80. But this covered a nominal increase of capital in the latter case. There can be little doubt that the detailed accounts of these two lines would afford valuable information as to the most economical form of locomotive power. But the partial facts which are afforded form only a hopeless puzzle, in the absence of the one controlling fact of the mechanical work actually done in each case.

Thus it is evident that the London and North-Western line is worked, on the whole, ten per cent. cheaper than the London and South-Western. It is, however, probable that the difference is mainly due to the great volume of traffic over which the fixed expenses are distributed. The London and North-Western is the sixth, the London and South-Western the twelfth, in the order of traffic of the English lines. Taking the cost of locomotive power alone, the proportion borne to receipts does not very materially differ in the two lines. But the question remains whether a much greater economy might not have been effected on the Northern line had the locomotive power been conducted on the principles adopted on the Southern. On the other hand has to be urged the economy of giving to engines, as to horses, a certain interval of rest. The results of a difference of more than a third in the average annual mileage performed by two sets of engines are enough to clear up this, among other, vexed questions. But with the accounts before the public it is not possible even for the expert to give the information which it is so important to secure.

We give the above as an instance of the way in which it is possible to attach much value to such work as that of Mr. Fleming, without implicitly accepting all his conclusions. But the very fact that conclusions of such magnitude should be in doubt is a fresh proof of the desirability of that clear statement of work done, and cost incurred, which is demanded by the railway economist. Of the value of the statistical analysis and tabulations contained in the Index, no two opinions can be formed. This is not the first time that we have expressed our own.

VARIORUM.

The current number of *St. James's Magazine* includes a paper by Mr. H. Reid, C.E., entitled, "Hand-made Homes." This is the ending of it:—"People will prefer to live in good houses when they have guarantees that they are so, and therefore bad houses will be empty, and if unoccupied, and no tenant to be found, they must become all but worthless. They cannot be taken down by the man who built them, for the freeholder has them fastened and rooted to his title, and therefore they must eventually revert to him; but he will, again, be puzzled how to dispose of them. Landlords in the agricultural direction have farms thrown on their hands which they have not the sense or means of cultivating, and so it has been for years with house-owners. The time will, and must, come speedily, when it will be impossible for the most expert speculating builder to throw into the human dwellings any of the rubbish now so frequently used, for our authorities will have awakened to a sense of their duty and position, and make it compulsory on all concerned to test the materials to be used in all buildings, of whatever kind. It is unnecessary for us to say that our remarks apply only to the worst class of houses, which the present generation have seen reared in their midst, for we are happy to be able to admit that there are many good and true houses, where any one may live in comfort. The builders of these houses reap their due reward, for not only are such a class of dwellings readily occupied, but when offered for sale the character of their builders, and their well-earned reputation for good and substantial work, insures a fair and remunerative price, even under the disadvantage of a forced sale."——The *Leisure Hour* says, justly, of Edinburgh,—"Probably there is no spot on the face of the earth of which so much has been well said and well sung. The novelists, like Scott and Galt and the Wilsons, not to mention a number of other and many inferior names, have set the social manners of the people, the scenery, and the historical incidents in such a pleasing light; the poets, like Scott again, Burns, Fergusson, and Ramsay, have made every variety of beauty familiar to all readers by their verse. No other spot has been honoured by such a crowd of artists and engravers, illustrating and realising the charm of scenery, the romantic structure of old buildings, or the curiosities of old manners. And then the archæologists and historians of Edinburgh and Scotland, like Burton, Rogers, Pitcairn, Chambers, have explored every cranny where a fact or a forgotten incident might be supposed to lie. Edinburgh is a place of which not only its citizens, but all England and all English colonies, may well be proud."——A new feature has been introduced in *Engineering*, in the shape of an "Illustrated Patent Record." This will be of much service in many ways to inventors, patentees, and others.——A European

edition of *Harper's Magazine* is projected, to be published by Messrs. Sampson Low & Co., London. This periodical, whose name is a household word in America, where it circulates 140,000 copies, has been the means, in its sixty volumes, of introducing to the American public many of the leading novels of Bulwer, Dickens, Thackeray, and George Eliot, and other English writers. It is understood that Mr. Thomas Hardy is engaged upon a new novel, to be illustrated by Mr. Du Maurier, of *Punch*, which will accordingly appear exclusively in *Harper's*. The illustrations are, in fact, a chief feature of this monthly, which, in its 160 pages, gives commonly from 70 to 100 wood-engravings.—— A selection from the miscellaneous scientific papers of the late Professor W. J. Macquorn Rankine is about to be published by Messrs. Charles Griffin & Company. It will include an introductory memoir of the author by Mr. P. G. Tait, M.A., and be edited by Mr. W. J. Millar, C.E.

Miscellanea.

The late Mr. T. H. Wyatt, Architect.—The *Citizen* states that probate of the will of Mr. Thomas Henry Wyatt, late of 77, Great Russell-street, Bloomsbury, architect, who died on the 5th of August last, was granted on the 6th ult. to Messrs. Matthew Wyatt and Thomas Henry Wyatt, the only sons, the executors, the personal estate being sworn under 30,000*l*. The testator bequeaths the goodwill of his business, the lease of his offices, and all his architectural drawings and books, to his son Matthew; to his daughter, Constance, in addition to other provision, 6,000*l*. for life; at her death such sum is to go among his son Thomas Henry's children; and there are many other bequests to his children and others. He also bequeaths to the Architects' Benevolent Institution, the Incorporated Society, the Middlesex Hospital, and the Royal Institute of British Architects, 100*l*. each; and upon the death of the daughter of his old friend, George Moore, a certain trust fund of 500*l*. is to be paid either to the treasurer of the R.I.B.A. or to the Artists' Benevolent Institution. One-third of the income of the residue of his property is to be paid to his daughter-in-law, Mrs. Charlotte Wyatt, and the other two-thirds to his son Thomas Henry (and on the latter's death to his wife, Mrs. Julia Wyatt); ultimately the said residue is to be divided between his grandchildren, the children of his said sons.

Examination of Candidates for District Surveyorships.—At the meeting of the Metropolitan Board of Works on the 15th inst., on the recommendation of the Building Act Committee, it was resolved that the Royal Institute of British Architects, in reply to their letter as to the examination of candidates for certificates of competency to perform the duties of a district surveyor in London, be informed that the Board concur in the views of the Institute as to the desirability of making the examination of an improved character, and see no objection to the proposed imposing of a moderate fee upon each candidate.

Roman Villa at Brading, Isle of Wight. With reference to certain complaints Mr. Cornelius Nicholson says,—"A contract was signed a week ago for the complete roofing of all the mosaic floors, and the framework of the roof is now in course of erection. As to the dyke between Lady Oglander's land and Mr. Munn's farm, negotiations are now on foot for having this removed; and, for the future, it is our intention to make only one charge of 6*d*. to visitors. On the question of expenses, I feel certain that this great undertaking cannot be effectually completed unless the public assist us with the ways and means. We are already heavily and personally pledged."

Stained Glass seems steadily to be taking higher ground in Scotland. Two national historical windows have recently been undertaken by Ballantine,—the one illustrative of the Regent Murray's life, for the Murray aisle in St. Giles's; the other of single figures from the "Fair Maid of Perth" for the Town-hall in that city, of which we recently gave a plan and view.

Gipsy Hill.—Extensive additions to the schools and public hall, Gipsy Hill, have just been completed by Messrs. Bowyer & Son, of Upper Norwood, builders. The cost of the new buildings was defrayed by Mr. James Sidebottom. The architect was Mr. Ernest Turner, of Regent-street.

Homes for Aged Mariners, Liverpool.—On the 16th inst. the foundation-stone of the central block of the Homes of Aged Mariners, near Egremont, was laid by Mrs. William Cliff. The site for the erection of the principal block stands upon a promontory, so to speak, on the coast line from Egremont to New Brighton. The area of the park, which is being laid out by Mr. W. H. Tyerman, is about 5 acres in extent, and is to bear the name of the Roger Lyon Jones Park. Mr. William Cliff, of Liverpool, has undertaken to defray, to the extent of 5,000*l*., the cost of an erection to accommodate fifty aged mariners of the Mercantile Marine; but, finding that it was desirable to make the central block of sufficient capacity to accommodate for social purposes those living in detached residences, and to provide enlarged reading, smoking, and other entertaining rooms, the original scheme was gradually expanded, and included the addition of a large central tower, 120 ft. high, which will accommodate a clock and bells, visible from a long range by sea and land, and Mr. Cliff has undertaken to pay the necessary additional cost. The contractor for the works is Mr. Richard Beckett, of Hertford, the amount of the contract being about 10,000*l*. Mr. Edward Roberts is the clerk of the works, and the architect is Mr. D. Walker, of Liverpool. The scheme proposed is (1) a home, with entire maintenance, for friendless single aged mariners; (2) cottage homes in the same park (with or without pension) for aged mariners who have wives or other relatives to care for them; and (3) out-pensions and relief for aged mariners and widows who cannot leave their friends.

Society of Medical Officers of Health.—The inaugural address in connexion with this society was delivered by the president, Dr. Bristowe, F.R.C.P. Lond., at 1, Adam-street, Adelphi. After some introductory remarks, the president observed that the public, especially its poorer portion, habitually disregarded precautions which were not, and some of which could not be, compelled by law, but without which the efforts of sanitary authorities became practically useless, and it was most desirable to leaven the public mind with the practical truths of sanitary science. He was certain that damp rooms tended to cause inflammation and affections of that character, and that the removal of dampness from houses was likely to improve the health of inmates in that respect. After discussing the relation of medical officers of health to the vestries and district boards which employed them, or, rather, he might say, of sanitary officers to the bodies with whom they co-operated, and to the population for whom they acted, he affirmed, in conclusion, that the position which a medical officer of health might hold in his district depended mainly upon himself. It was not the law which he administered which gave him the chief power for good, but the moral influence which he might acquire, and he need not look for conspicuous examples of the truth of his assertion.

Board Schools, West Bromwich.—The new Board schools at the Lyng, West Bromwich, have been opened by Mr. Daniel Howard, vice-chairman of the School Board. The schools are planned in three departments,—for boys, girls, and infants,—and to accommodate 826 children. They are erected in a Domestic Gothic style, the walls being constructed of red brick, the elevations relieved by stone dressings and bands of blue brick. The schools were erected by Messrs. Jones & Son, of Sedgley, the amount of the contract being 3,960*l*., and that, with the cost of site and other contingencies, brings the cost to less than 6*l*. 12*s*. per head. The schools were erected under the supervision of the architect, Mr. E. J. Etwell, of West Bromwich, whose designs were selected by the Board in competition.

Tramways for South Shields.—On the 13th inst., at a special meeting of the South Shields Town Council, it was resolved to apply for a Provisional Order from the Board of Trade sanctioning the construction of certain lines of tramway within the Borough. The Borough Surveyor (Mr. M. Hall) presented a report on the subject, stating that the total length of tramways proposed to be constructed is (including double lines and passing points) upwards of seven miles. He estimated the cost of the lines at not less than 4,500*l*. per mile, or about 33,000*l*. for the whole. In connexion with the execution of the works it is proposed to widen and extend some of the thoroughfares and to improve their gradients.

New Battersea Bridge.—At the last meeting of the Chelsea Vestry, it was resolved, on the motion of Mr. Davidge, "That this Vestry, having been informed that the Metropolitan Board of Works intend applying in the next Session of Parliament to rebuild Battersea Bridge, are of opinion that any suggestions to destroy an ancient thoroughfare by removing it to another site are strongly to be deprecated, especially as a large sum of money has already been expended by the Metropolitan Board of Works and this Vestry in opening up direct communication to it from South Kensington and the Fulham-road, and they respectfully urge on the Metropolitan Board of Works that in the preparation of plans the present position may be maintained."

Wiltshire Archæological Association.—The annual meeting of this Association was held on the 13th inst., at Devizes. In consequence of the recent visit of the British Archæological Association, no excursion was made to any place or object of interest. The Rev. C. W. Hony presided. The committee in their report stated that the success of the society had in no degree diminished, the membership having reached the number of 392, being a slight increase on last year. The event of the visit of the British Archæological Association was dwelt upon at length. The museum continued to hold its reputation as one of the best collections of antiquities in the provinces. Lord E. Fitzmaurice, M.P., was re-elected president of the Association for the ensuing year, with Mr. W. H. Butcher as hon. secretary, and Mr. H. Cunnington and the Rev. H. A. Olivier has hon. curators of the museum. All the other officers were re-elected without exception.

Technology.—A prospectus from University College, London, just now issued, with special reference to applied science and technology, shows that very complete arrangements are made for giving to students wishing to devote themselves to engineering, architecture, applied chemistry in any of its branches, or any other manufacturing or commercial pursuit, a systematic training in the application of scientific principles to industrial purposes. As in all other departments of the college, there is in it an unrestricted admission of students, without previous examination, to any class or classes they may select. The prospectus may be obtained from the Secretary, at the college.

Desecration.—At the Bucks Quarter Sessions, Aylesbury, on the 18th inst., before Mr. Cripps, Q.C., a man named Warren, and four other men, were charged with stealing lead from coffins in a vault in Cold Brayfield Church. Warren was contractor for restoring the church. The evidence showed that early on the morning of the 10th of July, with the other prisoners, he opened a vault in the chancel, sawed the ends of six coffins, wrenched the leaden shells from other portions, and strewed the human remains among quicklime. Warren was sentenced to twelve months' imprisonment; the others were acquitted.

A new Clock has just been erected in the central tower of the General Hospital at Swansea. It shows time on three large illuminated dials, strikes the hours, and chimes the quarters. It is fitted with all the latest improvements, and has automatic apparatus for turning the gas up and down. It is the first chiming clock in the town. Mr. John Smith, Midland Clock Works, Derby, has carried out the work.

Wakefield Town-hall.—On Monday last the new Town-hall at Wakefield was opened. It has been built in the Renaissance style from designs by Mr. Collcutt, of London, and, including police premises adjoining, has cost about 80,000*l*. The foundation-stone was laid in October, 1877, by Alderman Gill, the mayor. The building comprises a council-chamber, borough court, mayor's room, and banqueting-room, with offices for all the corporate officials.

A Lucrative Appointment.—According to the *Cornishman* for last week, a clerk of the works being wanted for Kelynack School, St. Just, Mr. Francis Gibson has been appointed to that post, and his salary for the work there and *in the town* is to be 25*s*. a week.

The Severn Tunnel.—Operations at the Severn Tunnel works, suspended in consequence of the inflow of water filling the horings and shafts twelve months ago, have been resumed. The new pumps reduced the water 18 ft. in twenty-five minutes.

Ipswich New Corn Exchange.—The corner-stone of this new building was to be laid this Friday (the 22nd), with Masonic ceremonies.

Extinguishing Fire.—Some experiments have been tried in Oil-street, Liverpool, with the "Rapid" fire-extinguisher, Mr. Gibbs representing Messrs. Jarvie & Miller, the inventors. A pile of old tar-barrel staves, and other inflammable materials, was raised and set fire to. When the flames had got sufficient hold, Mr. Gibbs directed the hose of his machine upon the burning mass, and in less than half a minute there was nothing but smoke to be seen. The whole fire was completely extinguished. The engine is charged with water, bicarbonate of soda, and sulphuric acid. The acid is put in last, in a bottle with a glass ball working like that of a soda-water bottle. When the engine is on its end the ingredients do not mix, but once on its side the gases amalgamate, and the pressure is directed to the fire.

The Late Edward Blore.—A handsome monument, executed in marble and granite, by Mr. Forsyth, has just been placed over the remains of this well-known member of the profession, in Highgate Cemetery. It bears the following inscription:—"In memory of Edward Blore, Esq., Architect, D.C.L., F.R.S., F.S.A., born in the parish of All Saints, Derby, September 16th, 1787. Died at 4, Manchester-square, London, September 4th, 1879." "Also of Sarah Ann his wife, who died August 4th, 1867, aged 69."

The Gladatone Bridge, Rhyl.—This bridge, constructed over the London and North-Western Railway Company's land near the railway station, and connecting the hitherto severed portions of the town with each other, has been completed. It has been constructed from designs prepared by Mr. B. Nelson, architect, Llandudno. The stonework was let to Messrs. Braddock & Mathews, of Southport, and the wrought-iron girders to Capt. S. Woodall, of Dudley. The total cost was about 10,000*l.*

Messrs. Bunnett & Co. (Limited) have received instructions from the Master of the Household to replace the existing lift at the Royal Laundry, Richmond, with one of their patent lifts. Messrs. Bunnett & Co. have also just completed fitting their steel shutters to the strong-room at the offices of the Crown Agents of the Colonies, Whitehall, for H.M. Board of Works.

St. Michael's Church, Cornhill.—The income of this church is estimated at 3,000*l.* a year. The prodigality of the expenditure may be estimated from the statement that, in order to give the organist complete control over the choir, electric communication has been made from his seat on one side of the church to the organ on the other.—*The Electrician.*

Alexandra Palace Exhibition.—Francis J. Bancroft, a junior in the highway surveyor's office, St. Mary's, Islington, has been awarded a silver medal by the Alexandra Palace Exhibition Committee for his drawings of timber and iron roof construction, suspension-bridge, road-construction, and ornamental ironwork.

The Works of the late William Daniels. Mr. William Tirebuck, of Leeds, in a letter to a Liverpool paper, says that there are in Liverpool sufficient of the works of the late William Daniels to form a fairly representative collection, and he suggests an exhibition of them.

Wood Paving.—We understand that Mr. H. Allnutt, of the *Estates Gazette*, Fetter-lane, will shortly publish a pamphlet descriptive of laying wood pavement on Kensington high road, a distance of three-quarters of a mile, costing about 11,000*l.*

Architectural Association.—The President and Council have issued cards for their usual *conversazione*, to be held on Friday, the 29th of October.

TENDERS

For roads and sewers on the Oak Lodge Estate, Edgware-road, the property of the United Land Company, Limited, including Aberdeen granite kerb:—

Watts	£5,910 5 0
Pizzey	4,545 0 0

A Sanitary Aspect of Construction.

ODERN investigation and experience in regard to the best conditions for healthiness in hospitals have proved that in regard to such buildings at least it is not only important to consider how completely satisfactory ventilation and drainage are to be provided for, but how precaution is to be taken against the retention of impure matter in the very materials themselves of the building. It is not only a question of how the building is constructed, but of what it is constructed;

d one conclusion at least has been unaniusly arrived at,—that smooth, impervious, d washable materials are the most likely answer the desired end. And along with e conclusion is one which almost necesrily accompanies it,—that all receptacles d corners where matter may be collected and difficult to dislodge are almost certainly of injurious tendency. The medical part of the timony is unanimous on this point.

All dwellings are not hospitals; but it may worth consideration whether some of the nciples which are regarded as *de rigueur* in e case of hospitals ought not to be to a certain ent acted upon in regard to all buildings for man habitation, as far, at least, as is conkent with convenience, comfort, and a sonable economy in regard to the general s of a habitation.

Every house which is fairly well built and ished in the ordinary methods looks sound l healthy when new. It is when such houses ne to be examined after a certain lapse of ie, for a new tenant, or for purposes of valuaı or dilapidation, that the inherent defects of inary building are so prominently brought . Every one who has had to survey old ise property, especially in the smaller streets large towns, knows how many things there in such houses which are certain to be found state of dilapidation. Wainscots and skirtings broken and started from the floor, and con l behind them long passages and crevices ore all kinds of minute *débris* have accumed unknown and unremovable. Casings have er been properly fitted or backed, and ough the decay of wood blocks are loose in ir seat, and leave gaping crevices between woodwork and the plaster; chinks for which only good word that can be said is that they uetimes afford compulsory inlet ventilation when otherwise there would be no such thing. Chimneypieces are in like manner whited sepulchres, which mostly do not even appear "beautiful outward"; they are all in slabs one of which is sure to have got loose, having been badly set originally, and is either gone, leaving an unsightly gap into the regions behind this arrangement of slabs, or is knocking about half in its place and half out. The papers are thick upon the walls one over another, forming so many layers of semi-decayed and sometimes even putrid paste and paper. And what goes on between the ceiling joists and the flooring-boards, who can tell? The house is full of spaces which no one can get at to clean them, and of constructions which have been essentially rickety at first, though looking well enough when quite new and covered with fresh paint, but which are now ragged, and shaking in their places.

All this, of course, may be a providential arrangement for securing work to repairing joiners and to "dilapidating" surveyors, but in an economical point of view no other class of person, except the original speculating builder who produced the structures, is likely to find a good account in it. There is, however, another view of the matter which is even more important than the economical one. The difficulty of keeping houses healthy (apart from drainage questions) is undoubtedly very much greater in a crowded town than in the country. The population is much denser, the air is laden with impurities of smoke, of dirt and dust, of human and animal emanations, all of which find a lodgment somewhere until cleaned off or otherwise dispersed; and if not cleaned away attach themselves to and become almost a part of the softer and more porous materials, which thus become radically unwholesome portions of the structure.

To avoid this the great desideratum would be that there should be as few porous substances and as few concealed and un-cleanable places as possible in which impurities can lodge. It may be added that a great part of the depressing effect in the lower parts of crowded towns arises from an aspect of squalor and dilapidation, which is owing in great degree to the employment of methods of building or of finishing buildings which almost inevitably succumb to rapid decay, and become rickety and unsightly. Now, all these drawbacks to the healthiness and cheerfulness of a crowded town district we encourage and foster by certain methods of building which have become traditional, and are carried on without thought and as a matter of course, and as if they were inevitable conditions of building. This applies almost as much to the houses of the better class in the superior districts of towns, as in the inferior; only the evil is more felt in the latter. It is difficult enough under the most favourable conditions to keep crowded districts of a lower class healthy and cheerful; but it becomes more so when the buildings themselves are so constructed as to have a natural tendency to harbour what is unhealthy, and to appear (and to be too often in reality) rickety and falling to pieces.

To exemplify more particularly what we mean, we will draw attention in the first instance to the manner of finishing shop-fronts which prevails both in the better and inferior districts of our towns. By common consent, and merely because it is the fashion, almost every shop has constructed before and around the front of its ground-story a joiner's erection of perishable shallow cornices and pilasters of wood, which, when made gaudy with paint may pass off very well before the uncritical eye of the general spectator, but which is really a mass of utterly useless gimcrack hung on to the building, an excrescence at the very best. In the inferior districts of a town, the frequent re-painting and garnishing of these pieces of cradling cannot be carried on to the same extent as in the superior districts, so that even their value in making a gaudy show is lost. Their effect from an architectural point of view is mean and confused; but this mass of gimcrack shop-fronts must surely have a bad effect in a sanitary sense also. Instead of solid walls, which even if not artificially cleaned, are washed by the rain without any harm to their structure, we have a mass of woodwork with hollow spaces behind, wherein dirt and vermin may lodge unseen and undisturbed, where decay may go on unperceived, and which are not susceptible of outward cleansing except by the application of fresh coats of paint. Surely it would be an advance in the favourable conditions for sanitation of a crowded town neighbourhood, if we did away with all this gimcrack, and insisted on the building of honest brick walls and arches, or stone or iron lintels, showing a plain sound construction, with "no deception," and getting rid of a mass of unmeaning stuff which must come to pieces sooner or later, and which renders the cleaning of the front of the building twice as difficult and ineffectual as it might otherwise be.

When we come to the interior of the house where sanitary considerations more directly, concern the inmates, we find various forms of unpermanent and uncleansable material and construction have established themselves as a matter of prescriptive right. We have a quantity of really unnecessary joiners' work put together, with hollow spaces for the accumulation of dirt and rottenness, in the pulley casings, which are matters of course in English window-hanging. Far more solid and sound construction is the casement-window, with its solid frame, leaving nothing behind and out of sight, no hollows to fill up, no hidden wooden boxes that no one can get at. People imagine that casement windows are not as weather-tight as the sash-windows, a mere prejudice resulting from bad making of the former more than anything else; and it is quite certain that in buildings where work has to be done cheap a casement-window is more likely to be accurately fitted in the walls, and less likely to admit damp and draughts between the wall and the frame, than a sash-window, with all its band-

box appsratns of cssing, which can only he really well and solidly made and kept np at much grsster expense than can nsually he bestowed upon it in houses of an inferior class.

A great part of the interior finish of an ordinary room is composed of perishable, frail, and dirt-holding materials. The ordinary wainscot, which pretends to he a plinth, is a kind of woodsn shell fastened in front of the wsll, the spscs behind which forms a psrade-ground for mice when they get into a house, which they constantly do when tbey find such commodious arrangements msde for their privacy and aecurity. A wsll-sxecnted wsinscot, carried full sbove "chair-back heigbt" ronnd the wall, or a completely wsinscoted room, each has a good effect, tbough it may he doubted whether the latter forms the healthiest lining to a room. When the expense of so costly an adjunct can he gone to, there is a possibility that the work will he solidly put np; but the ordinary house wainscot is a mers piecs of joiner's sham, worst of all when, as is often done, thers is the silly pretence of a sub-plinth to it, of course, in another separate piece set on. A solid piecs of thick wood, with the moulding worked out of it, and fixed olose against tbe wall, would he a very different affair, tbough one can hardly, sven in that cass, see the ahsolute necessity of the addition; but whers this cannot he afforded, it would he far better to he content with merely a solid rail of wood, with a concavs quarter-circle moulding run in it, so as to connect the lines of the floor and wall hy a small curve, which csn he easily swept, instesd of allowing them to for m an angls whers dust and dirt will lis in a way difficnlt to remove. Tbis is assuming the existence of a plastered coating on tbo wall. It seems a qnixotic undertaking to tilt st plaster, whicb has enjoyed so long a lifs as the accepted internal coating of walls; and ws may hs asked what ws would propose as a general snbstitute for it, and may admit that consistently with necessary economy, it is, perhaps, not so easy to say. But it is quite certain that a model wall-finish ought to havs ons of two qualities: it should he capahle of heing easily and tboronghly clesnsed, or it should be capable of easy renewal. Plaster has neither characteristic. It holds a great dcal of dirt, and can hardly he cleaned at all, and it cannot he renewed without much tronhle, dirt, and expense, and emptying the honse or tbe apartment for the purpose. For hospitals there is not so great an objection, hecanse in every well-regnlated hospital every ward should be empty for a time by rotation, and the plaster could be chipped off and renewed dnring that period, if medical sanitarians think (and some of tbem do) that this entire removal of the lining of the ward is the only way to disinfect it thoroughly. But snch a proceeding cannot he conveniently undertaken in a private dwelling-house. In a majority of houses tbe resonrce is papering, and, artistically speaking, a great deal may be said for papering as a means of producing an agreea'le effect in an inexpensive manner, and a great deal of very good decorative art has of late years heen applied to the design of wall-papers. But papers, like plaster, come under tbe denomination of materials which can neitber be well cleaned nor easily changed, and which absorb and hold a great deal of unhealthy matter. They are, of course, much more easily renewed than plaster, hut the temptation in cbeap house property which is not very well looked after to lay one paper over another is very great, and is often indnlged; and nothing can well he more deleterious to tbe healthiness of the room than this; and stripping off and repapering, though much simpler than replastering, cannot be done often enongh to ensure a really clean and healthy state of the walls. Tbere appear to he three courses open to us. One is tbe employment of Parian cement, or some other hard and washahle cement, as the interior lining for walls, when nothing is to be placed over tbe surface. In the poorer class of houses which are not papered, the plaster surface is one of tbe worst in sanitary condition and even in nnsightly appearance, after a certain term of occnpation, which could he fonnd. Mere lime-wbitening, if the wall is a sound one, is a mucb better and healtbier finish, tbongh certainly not agreeable in aspect, and is easily renewed. Where Parian or otber cement is deemed too expensive (although nothing ongbt to he considered too expensive which concerns the actual healtbiness of a babitation), and wbere lime-wash is considered too rough, coating the plaster with such a preparation as silicate paint, which will hesr washing, is a great improvement on papering or on the ordinary paints. In houses of the best class there remains the alternative of building the inner faces of the walls with solid materials of a high class, such as glszed brick or some of the numerous terra-cotta materials which are now offered to tbe choice of those who build. Tbers is then something perfectly capahle of heing cleaned, provided always that it must not have surface decoration which is too deeply cut and which would leave hollow places whers dirt would collect and which would be difficult to clesn satisfactorily. If such an intsrnal finish hs thonght too cold for this climate, then there is the resource (ws are now speaking of habitations whers expense is not a primary consideration) of hangings which can bs sasily tsksn down and pnt np again, changed, cleaned, or renewed, which can he removed from the room when not in use and thoroughly airsd. Thers is the question of picture-banging to bs considered, of course, in a majority of honses. Where some matsrial can be strsined closs to the walls when hnng, pictures can bs hung over it (ss at the Grosvenor Gallery), or a very good effect, combined with warmth and comfort, may hs produced hy tapestry or otber hangings on the lower part of the wall, with tbs solid intsrior surface left above a certain level as a background for the pictnres. Ths object which runs throngh all these suggestions is the same,—to havs tbs walls of our rooms sither of such material, if permanent, ss csn he efficiently cleansed without injuring it, or hung or fitted with such decorative matsrial as csn he easily removed and clesnsed or replaced as often as the greatsst attention to sanitary conditions demands. Now the fsct is that nesrly all inhahited rooms srs at present finished internally in a way which precludes the observances of either of these conditions. With impervions walls, however, let it always bs remembered that ventilation must bs mors especially attended to.

Plastsr is an insidious tempter also in the sxcnse it gives for those foolisb and unmesning ornaments which are called plaster cornices, and which are made worse hy being "enriched" with ornaments nsually qnestionahle in design, always perishable in material, and almost always contrived so as to hold a qnantity of dust, dirt, and soot wbich is never dislodged. It is not easy to say whetber this superstition of the plaster cornice arose in the first instance from the idea that every internal wall mnst have a plinth at the hottom and a cornice at tbe top, because tbe external wall has; or whether the plaster cornice is a kind of reminiscence or anggestion of a corbel to carry the floor ahove. Wbichever he its origin, it is eqnally unmsaning. There is perhaps no part of the internal economy of onr hnildings whicb is more marked hy the spirit of the jerry-builder than the jnnction of walls and floors. A large and pretentious plaster cornice, with its wooden hacking or hraoketing, is really a process of hanging a quantity of stoff on to the walls at that point, in a form which simnlates that of a hracket bearing on the walls and supporting the over-floor. The reasonable and solid way of doing tbe thing would he to project a corhel, say of terra-cotta, built into the walls, and projecting snfficiently into the room to give a hearing for the floor-joists over; and this would form the finish of the wall-surface and fill up the angle hetween it and the ceiling.

The ceiling is a question hy itself, heing as it is under different statical conditions from the wall-surface, and depending even more than that on the principle of construction and the material that may he employed in hridging the space from wall to wall. When wood flooring is employed, the simplest way, no donht, is to leave the joists open, and varnish tbem and the under-side of the flooring-boards, which, in such case, should be thicker than usually employed, and, of course, grooved and tongued. But this is bad in the way of light, and, moreover, does not sufficiently damp sonnd hetween tbe room above and the room helow. What is quite certain is, that to underdraw the joists with lathing and plaster is one of the worst metbods that can be employed. The plaster reflects light, it is true, hut it also collects and renders peculiarly visible all dust from occupation of the room and soot from combustion; it cannot he cleaned except hy the process of rewhitening it, which means shutting up the room for some days, and the plaster is a material peculiarly liahle to crack under the shaking of tbe joists from traffic in the room above. We have before now drawn attention to and explained the small phenomenon which most people bave noticed, especially in small rooms where much gas and coal is hurned in proportion to the area of the room, of the lines of the joists showing on the plaster ceiling in lines rather whiter than the rest of the plaster. The appearances results from the fact that in interspaces between the joists, the porons plastar receives and retains a great amount of soot and dust, which seems to work its way right into tbe plaster, hut which does so less readily where the plsster has the solid hsoking of the joist immediately over it. The shaking of the plaster may no doubt be obviated hy placing it on seps-rate ceiling joists, hut what an amount of perishable material and what holiday spaces for vermin this involves. A wood ceiling is, of course, much snperior, but rather dark, and decidedly costly if well done. A well-known firm of decorators have patented a form of enamelled iron-ceiling material whicb offers some advantages, and can he affixed to wooden joists. The specimens we have observed have been tawdry in design, but this need not be so, and tbe material appears capahle of such treatment as to reflect as much light as a plaster ceiling, and to bs capable of ready cleansing. But it is a matter for serions consideration whether some of the various methods of solid floors of iron and concrete, or other materials, should not he far more used than they are, sven in ordinary dwelling-houses. They possess the immense advantages of solid construction,—no internal hollows and dark recesses; they are mors sound-proof and more safe against firs than timher floors, snd they are capable of being finished as ceilings in a way perfectly capahle of cleansing as often as is thought desirahle. In tbe case of rooms of the better class, a very good effect might he got hy dividing a concrete and cemented ceiling into low domical sections. In houses of the poorer class, and with smaller rooms, concrete floors csn he so easily and chsaply applied, even without any iron in tbe case of small rooms, and are so much mors conducive to good sanitary conditions and constant clsansing, that they seem to hs the most natural method for use in this class of property. There is an objection to concrete floors on account of want of warmth and of the elasticity of a wooden floor. In the case of poor houses in crowded districts, however, the sanitary advantages of a wasbable floor (if utilised) greatly overhalance these drawbacks: in the case of houses of a superior class wood flooring-hoards can be laid down on hearers over the concrete floor, and in tbat case could he laid so as to be easily removable for tborough cleansing of the structure, so as not to leave any long accumulation of decaying matter hetween the boards and the cement floor.

The "hox" marble chimney-piece is not so directly connected with unsanitary results, though it is apt to leave pernicions spaces and hollows in its rear; and it may certainly he said that there is an unhealtby effect produced on the mind by the mero sight of things constructed in a rickety manner, and so as to he bound to come to pieces sooner or later. In a similar way the wooden cornices for carrying gutters, or pieces of joiner's cradling hung on to the wall, contribute to give a disagreeable impression of rickety building, and are indirectly injurious in putting in an exposed sitnation a piece of questionable constrnction in a perishable material. Gutters should he carried on or made of a solid material.

The unsanitary results of insecure foundations, and walls without sufficisnt hond in construction or solidity and mass of material, are too well known and too generally admitted (in tbeory) to need fresh demonstration here. We have wished rather to point out that some methods of hnilding in the detail and finishing of houses, which are almost nniversally nsed, are not only somewhat mean in effect and perishable in quality, but that they have, directly or indirectly, a prejndicial effect on the sanitary character of habitations, especially in a crowded district. In the country this part of the question may be less important. In towns it seems certain that the more solidly and durably houses are built and finished, the more capable they are of continual cleansing without damage to the materials or serious inconvenience to the inmates, the more nearly do they approach to the best sanitary conditions of town hnilding (other sanitary provisions being equally attended to); and that very few ordinary town dwellings are at present built without incorporating in their structure, in a most promiuent and often

wholesale manner, a great amount of perishable, nnwashable, and dirt-holding material. We say therefore emphatically, give ns ths most solid hnilding and the most solid durahle form of internal finish that can be had, even at the expense of heing very plain and losing some cheap form of pretty decoration. Ths real ends of huilding will he hest answered so.

One important *caveat* mnst not, however, be passed over. It mnst be remembered that in proportion as houses are solidly and imperviously hnilt, in that proportion must all provisions for ventilation, hoth for inlet and ontlet, he the more complete and systematic. Pervious walls and floors let in and retain things which they ought not, no douht; hnt they also serve to let in air, for the ingress of which there is often no other provision, and which mnst be had. It is one virtne of solid constrnction that it also almost inevitahly leads to and demands scientific construction.

A GLANCE AT OLD DUMBARTON.

No tourist who has sailed down the river Clyde on hoard the swift *Iona* or *Lord of the Isles* has failed to make special note of the rock of Dnmharton, rising 240 ft. high, with its donhle peak and the scanty remains of its hattlements that from times far remote kept grim watch over the mountains and the valleys of the Lennox. Of this Castle of Dnmharton, the guide-hooks have little to tell heyond the information supplied hy that venerable tourist, Pennant. It is described hy Buchanan as an *arx inexpugnabilis*, and must have heen impregnahle to the ancient manner of besieging. Its name was Dun Briton, and it was also called Arcluith or Alcluith. Wallace was confined here. In A.D. 756 its garrison capitulated throngh famine; in 1571 it was taken hy escalade; and in 1639 it was "surprised" hy the Covenanting party. The castle at this time was held hy Sir William Stewart on hehalf of the king. On the last Snnday in March, Governor Stewart, with his family, attended the parish church, unaware that the enemy had fixed npon that day for the carrying out of a scheme to take possession of the fortress. After service Provost Sempill, a zealous Covenanter, invited Stewart to dine at his honse. On Stewart declining the invitation he was snrrounded hy a troop of forty men, conveyed to the provost's house, and forced to give up the keys of the castle. "Stewart," says Spalding, in his "History of the Troubles in Scotland and England," was compelled to cast off his clothes, "which were shortly put upon another gentleman of his shape and qnantitie, and he putt on his cloathes upon him sgaine. Thus, apparel interchanged, they commanded the captain, under paine of death, to tell the watchword, which, for fear of his life, he truly told. Then they go in the night quietly, unseen hy the castellans, and had their counterfeit captain with them, who cryed and called hy the watchword, which, being heard, yeitts (the gates) are cast open, in goes the Covenanters with greater power than was within to defend it, and mans and fortifies the castle to their mind." A two-handed sword, said to have helonged to Sir William Wallace, is exhihited in the old armoury. Here does not end the romance of the castle; hut we cannot pursue it.

"Dumharton is a small hnt good old town seated on a plain near the confinx of the Leven with the Firth of Clyde. It consists principally of one large street in the form of a crescent. On one side is the Tolhooth, and at the sonth end the ohurch, with a small spire steeple: it had heen collegiate, and was fonnded (1450) hy Isahel, Duchess of Lennox and Countess of Albany." This is all that Pennant had to say ahont the town in 1771, and Robert Chambers, in 1827, has still less to say: "It is a small town undistinguished hy commerce, and possessing no manufactures except glass-making and ship-huilding." The phhlication of the "Dumharton Burgh Records," lately given to the puhlic, is especially valuable for the light these Records throw on the daily life of the townspeople in the seventeenth and early part of the eighteenth centuries. Here are a few extracts. The words are slightly modernised:—"June 22, 1627. The which day they ordained the hailies to cause the glasswright make np a new glass to the Tolbooth in the lowest window, seeing that the old window is all hroken. Also, that the roof of the Tolhooth and the cross be painted and dressed. Also, in regard the painter is in this town, painting Sir William Alexander's ship, they think it meet to cause him to renew the painting and colouring of the orlage (the town clock), *if the bailies can agree with him cheaply on the town's charges.*" We hear of this travelling artist on the 27th of June, 1628: "They ordaine the magistrates to agree with the paynter and cause couler the stake of the cross after it has been oiled." In 1660 the magistrates employ another painter: "James McArthur, the Treasurer, is ordained to pay Gay Littlejohne, painter, the sum of 20 merks, and that in full payment to him for colouring of the council seat and of the horologe; and because the said Gay Littlejohn is owing certain sums to Elizabeth Stirling, ordains the Treasurer to pay the said Elizabeth." This "horologe" was a frequent annoyance to the magistrates. The last heard of it is in 1700, when "Andrew How, of Kilharchan, undertakes to provide a new pendulum-knock (clock) for the Tolbooth, and paint the dial of the same, for 12*l*." Shortly before 1607, Dumharton had snffered from an inundation of the Clyde and Leven, and in that year the Scottish Parliament made a grant to the town of 3,700 merks for the raising of hulwarks. In the "Records" these are referred to as "The Water Work." Scarcely a week passes without a visit paid hy the magistrates at low or high tide, hy night or day, to the "Wattir Wark." Those of the inhahitants who failed to contribute to the expenses of the undertaking were summarily dealt with. "July 20, 1629. The which day it is concluded that the whole persons owing money helonging to the wattir wark he chargit in ward [imprisoned] within the Tolhooth, therein till they pay the same." The Tolhooth, or townhall and prison combined, is in a chronic state of disrepair. The roof of the council-chamher lets in snow and rain, and prisoners are constantly escaping. To remedy the latter evil two hlacksmiths are employed by the magistrates to "make a pair of hogies of a great gad of iron and six iron schikills [shackles] to run therenpon for keeping malefactors in regard of the weakness of the Tolhooth."* Among the motley prisoners were many accused of witchcraft: "March 5, 1632. Forasmuch as David Glen has heen exectionsr of the witches that has heen execnte in this burgh, he is to have a salary of sixteen merks yearly for his thankfnll services."

The townsfolk enter with spirit into the building of an hospital. The stones are to be carried to the place of hnilding hy hoat, and in consequence of the height of the sands, the council "ordains the town to make a trench through the sand, wherehy the hoat may the hetter float, and the stones to he carried away in harrows." The townsmen are divided into "three-thirds," each third, in its turn, coming to the work with spades, shovels, and harrows. The Laird of Buchanan presents his "carrying" hoat to the town to convey stones for the hospital, on condition that hereafter they maintain a hoat, and pay a certain duty out of it to the hospital. The Collegiate Church, already referred to, was in ruins, and its hroken walls formed a convenient quarry for municipal hnilding pnrposes. "April 22, 1628. That the holes in the church vennel [passage or way] he helped and filled up with earth and stones from the colledge [Collegiate Chnrch]," and the magistrates and council appoint a master of the work.

Another of the town improvements is a pier, the construction of which is resolved on in 1632. Nothing more is heard of the pier or "keye" till the last day of June, 1655, when "Rohert Glen, who was appointed overseer of the work and huilding of the common key of this burgh, produced his accompt." The acconnt is interesting, as it shows some of the prices of lahour in those days. The wrights or carpenters are rated at 14s. Scots a day, the layers and hnilders of the stones at 13s. 4d., and the harrowmen at 8s. As all the houses and even the church were thatch-roofed, many precantions had to be taken against fire; the hlacksmith,—there was hut one,—was honnd to use stone and lime in the construction of the wall against which his fnrnace was placed; and Myrie McFarlane, a servant-maid, who, throngh her carelessness with lighted candles had set fire to the honses of two of her masters, was hanished the town, and the inhahitants were cantioned, under heavy penalties, not to admit her into any of their dwellings.

Just one peep into the "Kirk Session Records," appended to those of the hnrgh. "1620. For a sand-glass, 13s.; for an iron to set the glass into, 20s." A shilling Scots equalled in value the present bronze penny.

Before leaving Dumharton mention mnst be made of Tobias Smollett, who received the rndiments of classical learning at the grammar-school of the town. An interesting letter written hy the novelist and historian from Chelsea, March 9th, 1756 (not published in any collection of his works), concludes,—"I have had occasion, lately, to inqnire into the antiquities of onr country. I find the Scots came from Ireland hnt yesterday in comparison with the central city of the Caledonians and Britons of Arcluyd (Dumharton). I would fain derive myself from these last; hnt whether ancient Scot, Briton, or Norman, I am with equal affection and esteem, yonrs, &c., Ts. SMOLLETT."

* See in Scott's "Guy Mannering," the incarceration of Dirk Hatterick.

LONDON WATER SUPPLY.

THE ancient proverh, "That wisdom may cry ahroad in the streets, hnt men will not regard it," seems to he illnstrated very forcihly in the history of the dehate as to the water supply of London. The propriety of beginning at the beginning, in any endeavonr to interfere with a question of such extraordinary magnitnde, is for the most part stesdily ignored. It was ignored hy Sir W. Harcourt's Committee. It was ignored hy the meeting of the delegates from various vestries and district hoards whioh was held on the 20th inst. in St. Martin's Vestry-hall. We are very glad to see snch a meeting convened to discnes snch a snhject; hnt we should have heen more content if any of the speakers had pnt before the assembly the really salient and controlling points of the question.

In the state of jumhle in which the matter is now left, it is almost safe to predict that no real reform can he effected. The qnestions of the rights of the pnhlic, the rights of the companies, the qnality of the existing supply, and the machinery of a new authority, are all hopelessly tangled together; any remark that any speaker makes on one head usnally calling forth some irrelevant remark from some one else npon another.

Coming to husiness: at the meeting we have named, Mr. Beal moved that the Home Secretary should he asked if the Government intended to give notice of a Bill for the constitution of a water anthority,—a Bill limited to snoh object. Of course there can he no objection to the pntting of such a qnestion, though it is a somewhat feehle issue of a pnblic meeting. Mr. Berry, in seconding the motion, referred to the views of Dr. Frankland as to Thames water, and said that it was a question for them to consider whether they should not petition in favonr of an independent source of supply altogether. Mr. Morton supported the motion, and was in favour of a competing supply. Mr. Reed was in favour of the principle of the motion, hut thought the question should not he encnmhered by entering into details. Mr. Potts thought that the different vestries shonld he consulted, and was of opinion that the people of London wonld stand appalled at the idea of having the streets torn np and household affairs completely disarranged in order to estahlish a fresh water-supply. Mr. Redall appealed to the experience of those who had heen drinking London water for many years, and were there still, in proof of the opinion that the water was not so had as was stated. The motion having heen carried, Mr. Beal was for proceeding at a hound to ask the Home Secretary "to arrange, hetween this and the meeting of Parliament, for a valnation of the works and plant of the companies; for a completion of the audit to the 31st of December of the accounts of all the companies; and for a report on the present condition of their works, and on the outlay requisite for their transfer in perfect order." It did not seem to occur to the speaker that his plan could not he carried ont without the full consent of the companies, except hy virtne of some futnre legislation. Mr. Berry very justly protested against the motion as premature, and as invading the functions of the wished-for water anthority. Mr. Potts hoped that the time was not distant when there would be a municipality for all London; and the delegates adjourned to the 3rd of Novemher.

As advocates of the need of water reform, long before the subject hecame a fashionable topic, we wish to say one or two earnest words to those who really, and with single aim, desire satisfactory amendment to he effected. First of all, London is the master of the sitnation, if

London only makes up its own mind. London has not to come as a suppliant to Parliament. The existing companies, sooner or later, all must do this. They must come to Parliament for increased power, and most of them must do so shortly. If London, then, has made up its mind, it can dictate its own terms, or it can raise such an opposition as no company can hope to overcome. The position of the metropolis as a petitioner for a Bill is one thing; its position as the opponent to petitions for Bills to which the great body of the inhabitants are opposed is another. The first position is questionable, the latter is almost unassailable.

Secondly, no new legislation can be anything but tentative, and probably both costly and mischievous, that is effected before the physical problem of the sources of supply is satisfactorily solved. We find that the most opposite views are enunciated on this subject, but the pages are few and far between in which will be found any reference to the real difficulties of the matter. It is not a subject to be dealt with on the hand-to-mouth principle. The water-supply of London in the year 1892 seems to be the utmost range as to which any one has permitted himself even to think. What is to be the source of the supply in 1980? What even in 1930 A.D.? It would be worse than childish to spend millions upon millions without looking forward to the wants of at least another half-century. Yet we have one set of critics gaily cantering on one hobby, and another set on another, just as if the source of the water supply were a matter as to which we had any great choice. One person would not use Thames water on any account; another would only seek supplies from the chalk; a third would avoid the chalk-water as laden with mineral matter, and the hardest of all supplies; another would tap the lakes of Wales, of Westmoreland, or of Cumberland.

But the ugly fact remains that the whole water supply of the Thames valley, or water-shed area, as measured by the outflow of the river, will not very long serve the need of London, unless we invent some method of utilising what now runs to waste. And as to bringing a supply, at the cost of tens of millions of money, for hundreds of miles, the objections are so grave that they may well be regarded as conclusive.

What is needed, then, for the real improvement of the water service of London, is, in the first instance, a thorough settlement of the question of the available sources of the future supply. Until this is made plain, nothing but squabbles can result from attempts at premature legislation. With that question once solved, the details of the settlement with the existing companies will be matter of comparative ease, if we always bear in mind,—although Sir W. Harcourt's Committee omitted to find it out,—that it is the companies that will have to come forward as petitioners, and not the metropolis. London, we repeat, is the master of the situation, when London knows its own mind. And the first facts which London requires to have made plain, in order to come to a wise decision, are the physical facts of the hydrometric supply of water. A businesslike technical inquiry into this controlling part of the subject is the first object at which every honest and intelligent champion of water reform must persistently aim.

OPEN COMPETITION FOR A MONUMENT IN ROME.

In pursuance of a law passed in July last, Signor Cairoli, the president of the Royal Commission appointed for the erection of a monument in Rome to the memory of King Victor Emmanuel, has issued a programme inviting the competition of artists, whether native or foreign, without any distinction. This document declares:—

1. That a competition is opened for designs for an honorary monument to the memory of Victor Emanuel II., liberator of the country, founder of its unity.

2. All artists may compete.

3. No limit is fixed to the invention of the competitors, either with reference to the conception, the style, or the choice of site.

4. The cost of the monument must not exceed 360,000*l.*

5. The "*disegni modelli*" must be so executed as to show clearly the idea of the author. (We leave the words untranslated, in the conviction that it will be important for any artist in the United Kingdom or United States who intends to compete to ascertain directly from the Secretary of the Commission whether that condition will be held to be fulfilled by the preparation of drawings alone, or whether what we usually understand by the word "modelli" will be requisite.)

6. The competing designs may either be signed by the artist, or marked with a motto, which is also to be written on the outside of a sealed letter, containing the artist's name. Only the letters of the authors of the prize designs will be opened.

7. According to the terms of the law of the 23rd of July, 1880, the close of the competition will be the 23rd of September, 1881.

8. The designs must be sent to the Secretary of the Royal Commission, at the Ministry of the Interior, not before the 25th of August, 1881. All the designs, except those obtaining prizes, are to be withdrawn within two months from the publication of the decision.

9. Before the decision, the works are to be exposed to public view. The decision will be published in a report in the official *Gazette* of the kingdom.

10. Three premiums, one of 2,000*l.*, one of 1,200*l.*, and one of 800*l.*, will be adjudged to the three first designs in order of merit. Not less than ten favourable votes will be necessary for each adjudication. The drawings will become the property of the State.

11. The adjudgment of the premium will not bind the State to employ the artist to execute the work.

12. The members of the Commission were named by Royal decree on the 13th of September. They comprise four engineers, two sculptors, one painter, five senators, and four deputies, under the official presidence of the President of the Council of Ministers. The secretary is Signor de Renzis.

As eye-witness to the great peril produced by the Revolutionary movement in South Italy, from which the reluctant intervention of King Victor Emanuel delivered the country, we hail with pleasure this attempt to raise a noble monument to his memory in Rome. For an international competition the terms are well judged. The only question is as to the justice of Article 11, but it must be remembered that a foreign artist might have great difficulty in personally superintending the erection of a great architectural work in Italy. The provision that the designs shall be exhibited before the prizes are adjudged is to be praised, as the public voice will then be heard before it is too late. We beg to offer the committee a motto for the monument:—

"Olim dirept'â Tarquini fronte coronâ
Patria facta a te cingit tua tempora, Victor."

PUBLIC HONOURS TO DAVID D'ANGERS.

The appreciation of artistic genius has overcome the prejudices of party feeling in the land where the Vendéans held out for so long against the Republican forces. The town of Angers has been the scene of a grand demonstration, of public rejoicings, illuminations, and torch-light processions, to celebrate the unveiling of a statue in honour of the sculptor David. The Minister of Foreign Affairs, M. Barthélemy de Sainte Hilaire, and the Under Secretary of State for the Fine Arts Department, were the principal speakers on this occasion, and they both rendered full homage, not merely to the memory of David, but to the success of M. Louis Noël, the artist who conceived and executed the statue which has just been unveiled. The memories this ceremony have recalled are interesting and pregnant with encouragement and a good moral. David d'Angers, like most great artists, had to struggle against adversity during his earlier days, and his efforts were much impeded by the wars that distracted the country at the time. Following his father on the battle-fields, he fought for the Republican cause, and the memory of these experiences furnished him with the subject matter of some of his best works. His father was one of the 5,000 prisoners who were kept in the Church of St. Florent, and would have been executed, but for the dying request of the Vendéan leader, Bouchamp. The politic and humane action which Bouchamp enforced with his dying breath saved the life of David's father, and the son, throwing political animosity aside, carved with his own hands a splendid monument in memory of the Vendéan chief. It was in 1825 that this monument was inaugurated, and the sketches which David took on that occasion are among the most interesting objects exhibited in the Musée David. The old Vendéans came in great numbers to pay homage to the statue of their great chief, and brought with them the guns they had so often levelled against the Republicans. The groups formed by these armed veterans standing round the statue were not only sketched by David, but under each portrait he wrote a few biographical notes. The following is one of David's notes, and it will give some idea of the times and the subject:—

"Louis Châtigner, of Bouchamp's army. After the rout at Le Mans, he was captured with his brother, and both were shot. His brother died instantly, and he fell struck by a bullet that passed through his cheeks. Feigning death, he remained motionless on the ground for several hours, and at night took flight, escaping through the woods."

David d'Angers knew how to respect all great men of whatever party they might be, while remaining himself a fervent Republican. Among his most celebrated works are his statues of Condé, Corneille, Cuvier, Biohat, La Fayette, Goethe, Guttenburg, and Barra. His life was one long devotion to the perpetuation of the features, history, and memory of great men,—of men who rendered notable services to their fellows. Animated with this great idea, he made the cold marble look as if it breathed, and left behind him heart-stirring examples of his genius in immortalising the genius of others. It is satisfactory to find that at present his artistic capacity and work, and not his political views, are uppermost in the public thought, and that all parties are ready to do honour to his memory.

THE LATEST AMERICAN WONDER.

The operation which is necessary for cutting a round or octagon bar of steel into short lengths, such as those that are required for masons' chisels, has never been very elaborate; but a new invention is said to have made its appearance in America which will simplify the process still further. The method that has hitherto prevailed has been to place the bar on an anvil, and after having given it a nick by the blow of a sledge-hammer falling on a sharp chisel in contact with the steel, little difficulty is found in knocking off a length by another stroke. The molecular change that takes place in the neighbourhood of the incision produced by the hammer and chisel is the immediate cause of the bar being so weakened as to admit of its being readily broken, and this alteration in the physical constitution of the steel can be readily recognised by the microscope. Instead of the molecules of the metal lying in the direction of the length of the bar, they are turned about under the sudden pressure of the chisel, and present the same appearance as the section of a bar that has been violently snapped asunder. But interesting as this phenomenon is to the initiated, it is far surpassed by the new invention that is said to be in use in America.

Now-a-days, unless statements are made that are in evident antagonism to known facts, it is often the wisest course to reserve one's judgment. Radiometers and vortex rings, telephones, microphones, and phonographs, were all capable of being romanced about in the earlier stages of their development in such a way that the greatest expert in applied science who happened to have heard of them for the first time, might well have been pardoned if he had regarded them with blank incredulity. Since, however, they have all asserted themselves as facts and not fictions, and have, at the same time, opened up an aspect of natural law that had hardly been suspected and is still little understood, one must listen to the story of further discoveries with reserve. The new American machine includes the apparently inconceivable anomaly of a highly elastic fluid cutting through a solid by reducing it to molten drops that do not burn. Nothing could be more simple than the arrangement of the parts of the apparatus which is said to work such wonders, and indeed it is so simple that any one on this side of the Atlantic who is anxious to test the veracity of the narrative can do so with very little outlay. It consists of a thin disc of soft iron revolving at a high velocity, placed very near to a bar of steel turning in the same direction, at a lower speed, but not touching the disc. When the bar and the disc are revolving, the side of each is, of course, moving in an opposite direction to the other, and it is alleged that when a properly-proportioned

speed is maintained, the steel hegins to melt and drop away, so as to allow of the soft iron disc being moved forward till nothing is left but a narrow neck of steel at the very centre of the bar. This phenomenon of itself must he sufficiently extraordinary and altogether ont of the rango of our previous experience, but what follows in the heatlessness of the molten steel, if the absence of any sensation of heat is to be taken as a test, is still more startling. Along with an account of the apparatus itself, an attempt at explanation has already reached this country, hnt whether it is the real one or not it is impossible for us to say. Certainly, if it be once demonstrated that the har of steel is melted, then it follows that even in the face of this phenomenon there can he little or no exhibition of what we have hitherto known as sensible heat, or else how could the soft iron disc remain unaffected by it? Meantime we can hardly expect ginger any longer "to he hot in the mouth" if molten steel has ceased to convey the impression of beat. If the story is true, it must necessarily lead to some new and very important departure in the study of molecular phenomena. If the machine is only available for cutting small steel hars, then it is qnite in the way of many of our readers who are large users of chisels. If they think the extent of their business would justify them in using machinery for cntting steel bars into longths, they could hardly have a simpler appliance than a thin revolving disc of soft iron. The revolution of the steel bar, which is said to be a necessary condition of success, adds slightly to the complication of the machine, but not so much as to tax very severely the ingenuity of a skilled mechanic. Perhaps, however, it would he wiser, without alleging that the story is a hoax, to wait until we hear something more of its performances, or until a specimen that has done what has been ascribed to it has been actually imported and proved in England.

WOOD-PAVING: ROAD-CLEANSING.

There are several examples of wood paving in London. Some of these may be seen in Pall-mall, at the top of St. James's-street, along parts of Piccadilly, at Knightsbridge, and on to the South Kensington Museum; Sloane-street and King's-road, Chelsea; along the Strand, Oxford-street, and other streets. Most of the wooden blocks are creosoted; some, however, are not. The *Builder* (I assnme) has no desire to puff one form of paving over another, hut it may be allowable to indicate the samples which appear to wear best and look best in wear. The wooden blocks laid on sand and boards, with wide joints filled in with gravel-conorete, have not lasted, and were never smooth to travel over, whilst the wooden blocks laid on concrete, and bedded and jointed with felt (the blocks laid close) present an even, smooth surface; apparently water-tight, and very easy to those who drive over this pavement. London can well afford to pay any moderate extra cost for a sound, safe, smooth, and noiseless road, which shall have n minimum of mud in wet weather, and of dnst in dry weather. If the oheapest road is not also the soundest and safest, it is not even cheap in the end. The traffio of London is so enormons, and clean, noiseless streets have so much to recommend their nse, that any moderate difference in cost is not of much consequonce; that is, from 15s. to 20s. per sqnare yard, and tbe "fad" of having a covering of nsphalte over the concrete, and felt over the thin coating of asphalte, and also close-jointing witb felt, might bring the cost up to one pound per square yard. It may seem to he an absurdity to say that soft wood forming an elastic pavement will wear longer under a quick traffio than a road similar in all other respects, only that the wood shall be harder, and shall he laid hard down upon a rigid foundation; hut experience will give proof in favour of the softer wood, bedded on an elastio cnshion, as the strokes of tbe wbeels in quick motion will be expended in the elastic wood and elastio cnshion; and the springing or jumping of the wheels will be less on the one than on the other. The best granite sets, bedded on concrete, and jointed with Portland cement grout, will no doubt make a sound, long-wearing, and clean street-surface, but will be jarring to vehicles, and noisy to the residents and public. It is, therefore, evident that length of endnrance will not give granite paving the first preference. Asphalte heing semi-vitreous, answers admirably on level streets, hut is slippery, and therefore dangerous, with tbe least greasy mnd. Horses may fall on wood, bnt if they do, comparatively little injury is a consequence.

Asphalte, granite, limestone, and wood may be made dangerously slippory by mnd on level ground, and any one of these forms of pavement will be slippery on steep gradients; bnt horses falling on wood will do themselves least injnry. There will be no broken knees, as on macadam; so that in this respect wood will be the best pavement.

The Corporation of Norwich, some five years ago, allowed one of the companies to lay down wood paving, at a cost of 12s. per square yard, inclnding a concrete foundation. The local surveyor is now going to accept the old street bottoms, and lay down upon them, as a foundation, wood at a oost of 7s. the square yard, saving 5s. per yard; 62,687 square yards of wood are to be so laid, at a cost of 21,940*l*. The life is estimated to he twelve years.

Wood pavements are said to have heen tried in America, and to have heen abandoned, as they absorbed moisture, and became rotten, foul, and pestiferous. These are the assertions; hut we do not know all the facts. Will not some American reader of the *Builder* snpply these, and so enlighten and oblige the residents in the old country?

For good or for evil, London and many other places in England are in for wood pavements in streets of great traffic. We sincerely trnst the evils reported of American wood pavements will not develop here.

Road Cleansing.

It needs no elahorate argument to prove that clean foot-walks and clean streets would he a great comfort, especially if they could be secured all the year round. For foot-walk and street washing, labour, implements, and water will be reqnired. The labour and implements should, however, be parts of the regular scavenging staff. The water must be obtained from one or another of the existing water companies who have water to sell, so as to secnre a dividend-paying profit. This contingent cost is, no doubt, the main canse why the footways and streets of London never are washed so as to be clean, excepting by a thunder-shower; and it is thunder-shower washing which onght to teach the lesson this article is intended to inculcate. The volume of water falling in rain may easily be imitated by hose and jet, which will wash as clean as the thunder-shower does, and do no more injury by splashing. The cost of the water is, however, at present, the bar in London, as will easily be seen when the price is taken into account. The companies do not all charge at the same rate per 1,000 gallons for sanitary and trade purposes, as this ranges from 4d. to 1s. per 1,000 gallons, the lowest price being prohibitive for street-washing. The actual oost of pnmping 1,000 gallons of water does not cost ½d., and if the works were in the hands of a municipality or Government Water Trust, the actual working oost of pumping would be all that need he looked to. Where water gravitates, as at Dnblin, Glasgow, Manchester, and other places, and occasionally flows to waste over the bye-washes, such water might just as well be used in foot-walk and street washing as not, the only cost being that of the labour. The misery of dirty, greasy foot-walks and streets in difficulty of walking is great, whilst the cleanliness of a well-washed and clean foot-walk is a comfort.

Many of the leading streets of London will soon have wooden paved surfaces, and here slipperiness may be easily removed by washing. Foot-walks are now formed of asphalte, York paving, or concrete, and any one of tbese snrfaces may he easily washed, and ought to he washed hy hose and jet, the washing being done from six to eight o'clock in the morning. Hydrants, npon which to fix the bose, should not be more than sixty yards apart. Reels for the hose, on wheels, are nsed for fire-service, and for street watering and washing in Paris, Vienna, and other Continental cities. There is, therefore, no reason why hose ou wbeels should not be used in London.

To wash an area equal to one square acre of surface as effectively as a heavy thnnder-shower does might require about 300,000 gallons of water, which, at ½d. per 1,000 gallons, would give a cost of ahont 12s. 6d. This will be eqnivalent to nearly one mile of foot-walk, 9 ft. in width. The wages of three men, say, equal to one day for one man at 5s. per day, will bring tbe cost np to 17s. 6d.: let 2s. 6d. represent wear and tear and incidentals, and we have 1*l*. as the cost of washing one mile in length of foot-walk. If, however, no charge is made for the water the cost wonld be 7s. 6d.

The foot-walks might not require washing more than once a week, or, say, fifty times in the year; so that the cost per annum for lahonr only to perfectly wash clean one mile of foot-walk would be less than 20*l*., or fifty miles of foot-walk might be perfectly washed ahout fifty times in each year at a cost in round figures of abont 1,000*l*. Think of tbat, „yon shopkeepers in the City, the Strand, Regent-street, and other leading thoronghfares.

Wooden surfaces in streets need not be washed in this perfect manner, and their cost wonld merge in that of scavenging.

These suggestions are made, but with no hope of their being adopted by vestrydom; to bring ahout such work there must be municipal government and the water must he public property. Then hydrants may be multiplied to serve watering-carts and to enable sewer flushing hy properly-arranged flush-tanks heing done each day. Foot-walks washed clean once each week, and water be used on the street surfaces to aid the scavengers. Mnd wonld then he cleansed from tbe surface, and bad smells from the sewers be done away with.

Civil Engineer.

P.S.—At present the notion is that eaoh householder must cleanse the footway in front of his own premises. Consequently, in very bad weather, with muddy streets, the foot-walks are not oleansed. And when heavy falls of snow take place the householder is subjected to heavy hlack mail, in the shape of hired labour; and wbere there are blanks and dead-walls, foot-walks go uncleansed. The entire scavenging shonld, therefore, be by a public department, vestry, or municipality.

THE "LIVADIA" AT SEA: DANGER OF THE ELECTRIC LIGHT.

The first voyage of the *Livadia* has been marked by one of those incidents whioh show how new inventions often develop new and unexpected dangers. One of the great points urged in favonr of the electric light has been its safety. For great libraries, for ships, for coal mines, we are told, absolute security might be obtained by this method, nt the same time with hrilliant illumination. One element of danger, however, was overlooked. On the 16th current a stoker on board the *Livadia*, who was helping to swing an electric lamp in the stoke-hole, while holding the apparatus in one hand, unawares completed the electric circnit with the other. He was instantly struck dead by the force of the electric onrrent. And, as occurs in cases of men struck hy lightning, decomposition of all within the skin almost immediately became evident. The ornate ritual of the Greek Church marked the committal to the deep of the remains of the first victim of marine lighting by electricity.

The vessel is said to have behaved splendidly. But the weather was exceptionally fine. Forty-eight honrs were occupied in running 500 miles. If we allow that five or six were lost in the Irish Channel, hy slackening or lying to in fog, we still have a speed of but little over eleven knots an honr. To obtain this, we are told that *only* 5,000 horse-power was employed, only six of the boilers working. Referring to what we said in July last (*ante*, p. 70) as to the cost of the propulsion of the *Livadia*, it will be seen that this speed should have been attained by under 3,880 horse-power, instead of 5,000, by a vessel of the displacement of the *Livadia*, bnt of better lines. As the difference of resistance increases with the cube of the velocity, the advantage of good lines becomes more and more evident the greater tbe speed. It cannot be donbted that the *Livadia* is a very costly toy, to work as well as to build. We very heartily congratulate the builders, not only on the noble bonns of 40,000*l*. which they are said to have received, hut also on having got the vessel safe off their hands, in spite of the diabolical plot with which it is said that it was menaced; although it is not quite certain that the existence of the plot was anything but a pure invention, framed for the purpose of obtaining money for its denunciation.

On Thursday morning, the 21st inst., in the gale, the bow of the *Livadia* struck some floating wreck, and the vessel has bad to put into Ferrol for repairs.

OLD LONDON.

During the present week a party of from fifty to sixty members and friends of the British Archæological Association has been engaged in visiting some of the principal architectural antiquities of London, and a very pleasant and profitable time has been spent by the visitors, notwithstanding the unpropitious state of the weather. These visits, as we stated last week, were arranged chiefly for the behoof of a few of the country members of the Association, as suggested at Devizes, but were participated in by some of the town members.

Assembling on Monday, at 11.30 a.m., in the Chapter-house of Westminster Abbey, the visitors were met by Mr. J. T. Micklethwaite, F.S.A., who, acting as *cicerone*, first gave a brief historical sketch of the abbey, and then proceeded to conduct the party over the church and its precincts. He commended, as very accurate, the restoration of the Chapter-house by Sir Gilbert Scott, for although a great deal of the work was new, there was was authority for it all, with the exception, perhaps, of the figures in the circle over the door inside. As the company passed out of the Chapter-house, Mr. Micklethwaite called attention to the collection of old capitals on the left-hand side, some of which formed part of Rufus's work in Westminster Hall. The others were contemporary, and belonged to the Early Norman cloister which was built after the Confessor's sanctuary was finished. Many years ago, in pulling down an old house north of the Abbey, another of the last-named series of capitals was found. It was engraved in Brayley's "History of the Houses of Parliament," but Mr. Micklethwaite would be glad to know of its present whereabouts. Conducting the visitors round the cloisters, he pointed out to them the positions of the monks' book-cases, the benches on which the Maunday men sat while having their feet washed by the monks, and, in the portion set apart for the novices, a series of indentations in the benches which must have been made, he said, by the novices themselves in idle moments for the purpose of indulging in a game similar to, if not identical with, that now known as "Go-hang." In the south walk of the cloister two or three early effigies were pointed out. Taking the visitors into the substructure of the dormitory, Mr. Micklethwaite observed that this was about the oldest part of the monastic buildings that now remained. The voussoirs of the arches were, to a great extent, of tufa. This work was not of the Confessor's time, but immediately subsequent to it. Proceeding to the cloister of the infirmary, the visitors were allowed, by the kindness of Canon Duckworth, to pass through his residence, and to descend to a cellar which originally formed part of the prison, and in which is to be seen a fine Early Norman arch in good condition, backed by a wall which Mr. Micklethwaite thought might possibly be of the Confessor's time. Mr. Loftus Brock, F.S.A., however, thought that the wall had been erected subsequently to the arch. Through this cellar passes the Northern Low Level sewer of the Metropolitan main drainage system, the crown of its arch rising through the floor. The remains of the Infirmary Chapel, dating from the twelfth century, were next inspected. This chapel took the form almost of a parish church, having an aisle on each side and a small chancel. The columns of the arcade had the peculiarity of presenting the angle of the octagon to the front instead of the flat face. In this chapel took place a severe pugilistic encounter between the Archbishops of Canterbury and York. It was on record that at a synod held here, the Archbishop of York arrived first and assumed the seat of honour. On the arrival of his Grace of Canterbury, Roger of York was requested by the primate to vacate the seat. His Grace of Ebor refusing to do so, he was literally sat upon by his Grace of Canterbury, and this led to a severe fight, in the course of which the combatants severely "punished" each other. Entering the abbey, the visitors next inspected the choir, the shrine of the Confessor, and Henry VII.'s Chapel, where Mr. Brock took occasion to remark that what was supposed to be a representation of the abbey in Saxon times was shown on the Bayeux tapestry. The church there represented had a central tower arranged not at all in accordance with generally-received notions of Anglo-Norman work, and it had long been suspected that this was a "make-up" on the part of the artist. There had been found of late years, however, so much that was in accordance with what was shown on the tapestry that there could be no doubt that the latter did in a rough way indicate the character of the building, and concurrent testimony in favour of the probability that the tapestry did really represent the building was found in the curious fact that a portion of the figure-head of the Viking ship recently found was precisely the same as a feature which occurred over the ends of the Confessor's church as shown in the tapestry. Having thanked Mr. Micklethwaite for his pleasantly-rendered services,

The visitors next paid a flying visit to the recently-restored Church of St. Margaret, Westminster, where Mr. Lambert said a few words about the curious history of the east window. The general opinion seemed to be that the fine interior of this Perpendicular church had gained very much by restoration.

Westminster Hall and the Crypt of St. Stephen's Chapel were next visited and inspected. Mr. Brock expressed his regret that the superstructure of the latter had not been restored after the fire, as, in the opinion of many archæologists, it could have been. However, it was a great satisfaction to have preserved the beautiful crypt, so well restored by the late Edward Barry, but it was to be regretted that it was now disused.

After luncheon, the visitors crossed Westminster Bridge and proceeded *viâ* the Albert Embankment to Lambeth Palace, where they were received by Mr. S. W. Kershaw, M.A., the librarian, who said he was commissioned by the Archbishop of Canterbury to express his Grace's regrets at not being able to be present to receive the company. Mr. Kershaw first gave a brief outline of the history and character of the library, now, as most of our readers will know, occupying Archbishop Juxon's hall, called after him from the fact that he restored it, the present roof being a copy of the earlier one. The library largely consists of works on divinity, the canon and civil law, histories, and rare pamphlets, but its strength and importance lie in the records and MSS. of the see of Canterbury. There is also a very fine collection of illuminated MSS., the gem of the collection being, perhaps, a ninth-century Celtic one known as the Gospels of Mac Durnan, somewhat of the same character, but smaller than, the famous Book of Kells, preserved at Trinity College, Dublin. In the guard-room the visitors inspected the portraits of a long line of Archbishops of Canterbury, including those of Laud (by Vandyck), Sheldon (founder of the Sheldonian Theatre at Oxford), Tillotson (by Sir Godfrey Kneller), Cardinal Pole (a copy of the portrait in the Barberini Palace at Rome), Warren (by Holbein), Herring (by Hogarth), Secker (by Sir Joshua Reynolds), Moore (by Romney), Manners-Sutton (by Sir Martin Archer Shee), and Sumner (by Richmond). With regard to the portrait of Archbishop Warren, Mr. Kershaw said it was lent to the Royal Academy for their last winter exhibition, and in a note in the catalogue it was stated that it was a copy. He did not know what foundation there was for that statement. Having visited the chapel (recently restored by Mr. Seddon), the "post-room," Cardinal Morton's gateway, and other features of interest, thanks were accorded to Mr. Kershaw (on the motion of Mr. Lambert, seconded by Mr. Morgan), and

An adjournment was made to the adjoining parish church of St. Mary, Lambeth, where Mr. Brock expressed his great regret that the restoration of the church twenty-five or thirty years ago was not carried out on the old lines, as it might easily have been. As it was, a great deal of modern work had been interpolated. One departure made in this restoration could not be justified at all, in his opinion, in any case of church restoration. He referred to the alteration by the restorer of the style or character of the architecture, which was, so to speak, put back from very late Perpendicular (*circa* 1530) to the flowing Decorated of the middle of the fourteenth century now seen. This unwarrantable change of course necessitated the demolition of a great deal of the old work. True it was that when the building came into the hands of the restorer a great deal of the work was structurally unsound, and needed re-building in parts, but that could have been done by taking down the work where necessary, and rebuilding it stone for stone. Fortunately, the tower was unrestored, but with the exception of two beautiful tombs in the chancel, the whole of the body of the church, as it existed prior to its restoration, had been swept away. A word of commendation might, however, be given to the manner in which two brasses had been preserved from destruction by fixing them against the wall. Where a brass had to be removed, from whatever cause, or where it was likely to be worn away by every hob-nailed boot that came in contact with it, no better course could be adopted than that of fixing it to a wall, where it could be seen without being injured. In conclusion, Mr. Brock referred to a few historical incidents connected with the church, reminding his audience that it was in its porch that Mary of Modena, wife of James II., waited with her child for a boat to take her down the river to a ship to enable her to escape from the kingdom at the time of the Great Revolution. Allusion was also made to the pedlar and his dog,—a local tradition, commemorated in one of the windows of the church.

In the evening, several of the members dined together at the Freemasons' Tavern, under the presidency of Lord Nelson.

On Tuesday (a very wet day) the visitors assembled in the Church of St. Saviour, Southwark, where Mr. Brock gave an interesting though brief historical sketch of the church. He referred to the undoubted fact that Southwark, or the "south work," was a fortified place in the time of the Romans, and mentioned in this connexion that in the churchyard, some fifteen or sixteen years ago, a small pavement of Roman tesseræ was dug up by Dr. Druitt, who had evinced great interest in the care of the monuments of the church. After alluding to the legend that the church was founded by a ferryman's daughter in Saxon times, he said that mythical as the story no doubt was, we knew that a Saxon church did exist on the spot, and that church was attached to a nunnery. In about the year 1106 it was re-founded for an order of secular canons, with the assistance of William Gifford, bishop of Winchester, who was said in the old chronicles to have rebuilt the body of the church, by "body" the nave being doubtless meant. A few fragments of enriched Norman work, no doubt part of the rebuilding, were found during the demolition of the nave some fifty years ago,—a demolition that was quite gratuitous and greatly to be lamented. Nothing was mentioned in the old chronicles as to the building of the choir and transepts, but they were of later date than the period referred to as the time of the rebuilding of the nave, but yet earlier than 1209, the date mentioned as that of the rebuilding of the church in an old chronicle now in the British Museum. It might, therefore, safely be assumed that the building of the Norman church commenced at the west end. The architecture of the choir clearly showed that it was earlier than 1209 in date, the piers being built more in the Norman manner, having a casing of Caen stone filled in with rubble masonry. A great fire which occurred in 1212, destroying the houses on London Bridge and many buildings in the immediate vicinity of the church, also burnt down the church, the greater part of which seems to have lain in ruins for many years. Next in chronological order came the founding of the chapel of St. Mary Magdalene, which served as the parochial church in monastic times. This part of the fabric was entirely demolished during the restoration of the church about the year 1822. The architecture of the west end, all swept away at the date last named, was somewhat later still. During the time that the rest of the church is said to have been in ruins, the beautiful lady-chapel was erected. This chapel might also, in Mr. Brock's opinion, have served as a retro-choir. Speaking of the tower over the crossing, Mr. Brock said it was to be regretted that the ringing-floor for the ringers of the celebrated peal of bells had been placed so low as to block out the triforium arches above the four great arches of the crossing, for they formed a sort of lantern. Reverting to the lady-chapel, Mr. Brock said it would be impossible to find a more beautiful example of Pointed architecture anywhere. London was remarkable for three beautiful specimens of Early English architecture, and England might be searched from one end to the other without finding more elegant specimens of Early English work. He referred to the Temple Church, the Chapel of Lambeth Palace, and the lady-chapel of St. Saviour's, Southwark (or, as it was anciently called, St. Mary

Overy's). It was a matter of much congratulation that after the vicissitudes of so many centuries this lady-chapel remained in such good and comparatively perfect preservation. It was built about the middle of the first half of the thirteenth century, that is, 1225; its general resemblance to the work at Lambeth Chapel and the Temple Church hinted the probability that they were all three by the same architect. The lady-chapel had been very carefully restored by Gwilt, to whose memory a tablet and a stained-glass window were erected by the inhabitants in acknowledgment of his labours. Having alluded to what was known as the Bishop's Chapel (from the fact that it formerly contained Bishop Andrewes's tomb, now removed into the lady-chapel), which was a projection eastward of the lady-chapel, demolished at the time of making the southern approach to new London Bridge, Mr. Brock recounted some of the many historical associations of the church. The lady-chapel was used as the Bishop's or Consistory Court, and it was here that Bishop Gardner sat in judgment on Bishop Hooper and many other ecclesiastics who subsequently suffered martyrdom. The church contains a number of very interesting tombs; but the gem of them all is that of John Gower, the poet, now removed to the south-west corner of the south transept. Gower contributed largely to the repairs of the church in 1400. Philip Massinger and many other celebrities were buried in the church or churchyard.

A projected visit to the Coal Exchange, for the purpose of inspecting the remains of the Roman villa found beneath that building (in the preservation of which the Association actively interested itself) was abandoned, owing to stress of weather and want of time, and the party, crossing London Bridge, made direct for the Guildhall, and inspected the interesting and finely-preserved crypt, which now, owing to the preparations for Lord Mayor's day and other festive occasions, presents somewhat the appearance of a temple sacred to Gastronomy.

The Church of St. Bartholomew the Great, West Smithfield, was next visited, and the party was very kindly received by the rector, the Rev. Mr. Ahhiss, to whom was accorded by Mr. Brock a well-merited meed of praise for the measures taken by him to preserve and open out to view some of the most important features of the church, notably the very fine circular arcade at the east end, which had been cut off from view by a wall erected in Perpendicular times. Mr. Brock pleasantly recounted the history of the church, which was built by Rahere, and is the oldest remaining church in London. The oldest work is that at the east end, a marked variation in style showing itself westward of the choir, as was pointed out by Mr. Picton and other visitors. Of the nave, which some said extended westward as far as the present entrance-gateway from Smithfield, only a small portion westward of the crossing now remains. A curious feature in the church is Prior Bolton's oriel window on the south side of the choir, containing on a panel his well-known punning rebus, a tun pierced by an arrow,—"the bolt-in-tun." Leaving the church, after thanking the rector,

The visitors next threaded their way north of St. Bartholomew's Church under the curious overhanging wooden houses known as the Long Alley, and crossing Long-lane and passing through Charter-house-square, arrived at the Charterhouse, where they were received by the Rev. H. V. Le Bas, and conducted over the principal portions of the buildings. In the hall Mr. Lambert read an interesting paper on the historical associations of the place, prefaced by a vigorous argument principally deduced from the Scriptures against the system which he called "monkism," and by a brief history of the rise of the Carthusian order, of which the Charterhouse was one of the principal establishments.

St. John's Gate, Clerkenwell, was the next point made for, and here luncheon was partaken of in the great room over the gateway, Mr. Patrick describing the structure, which has now, by the completion of the new street known as Clerkenwell-road, been more fully opened out to public view. The party afterwards visited the well-known crypt beneath what now remains of the Priory Church of St. John. A visit had been arranged to Gray's-inn Chapel and Hall, and hither some few of the visitors found their way, although the visit had to be abandoned by most members of the party. Those who did not miss Gray's-inn spent some time very pleasantly there under the guidance of the Rev. Alexander Taylor, M.A., the chaplain of the Inn, and Mr. Douthwaite, the librarian. There are some good portraits of legal luminaries in the hall, including, of course, Lord Bacon, whose name is so indelibly associated with the history of this Inn, once the leading legal seminary in London.

It was nearly six o'clock, and therefore quite dark, before the members reached the Temple Church, and the dim light of the few candles which were in requisition was quite inadequate to enable those visitors who had not previously seen the building to fully appreciate its beautiful architecture. This disadvantage was in a great measure compensated for by the address given by Mr. Brock, who said that the body of the church was one of the most beautiful specimens of Early English architecture which the country contained. It bore great resemblance to the Lady Chapel of St. Mary Overy, although far superior in loftiness and size, and there was at any rate, he hoped, an absence of rashness in the statement he had made that the designs of both structures probably emanated from the same hand. He referred in terms of commendation to the public spirit which had restored the church from the deplorable state which it presented at the beginning of this century, although the facing of the walls of the round portion of the church with smooth stone in lieu of the pre-existing rubble work was an instance of zeal untempered by knowledge. However, a great deal that was good had been done, and the custodians of the church were especially to be commended for the care they now took of the building and of the recumbent effigies now preserved in the round portion of the church. In conclusion, Mr. Brock expressed the thanks of the Association to Mr. Hall Dare, Sub-treasurer of the Inner Temple, and the Dean of Llandaff, Master of the Temple, for the facilities they had given for the visit to the church.

A projected inspection of the Hall of the Middle Temple was given up for want of time, and the company separated until the next day, hoping for finer weather.

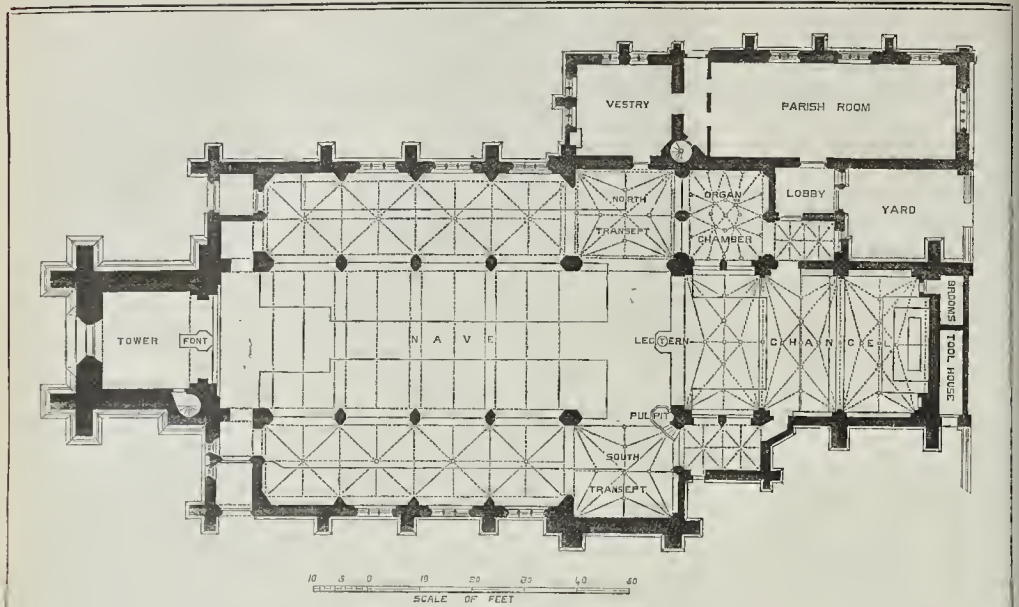
On Wednesday morning the rain was, if anything, more persistent in the spoiling of an archæological outing than on the previous day, and it need hardly be said that the party did not obey the behest of the programme by assembling "in the garden of Trinity-square, Tower-hill." A large party, however, their ardour nothing damped by the weather, did assemble in the waiting-room at the entrance to the Tower precincts and wherever else they could get under cover, and shortly after half-past ten o'clock were very kindly met by General Milman, C.B., Major of the Tower, by whom, and by Mr. Thomas Morgan and Mr. Compton, assisted by other gentlemen hereafter mentioned, the visitors were conducted in and around the fortress, many members of the party penetrating every accessible nook, and most of them ascending every tower which is not modern. The jewel-house, the armouries, and other of the usual "sights" of the place were not forgotten, neither were the recently-restored church of St. Peter-ad-Vincula, on Tower-green, and the exceedingly interesting chapel of St. John in the White Tower, omitted. Beneath the floor of the former lie the mortal remains of many royal and illustrious personages who fell by the executioner's axe; and the latter is, as Mr. Brock took occasion to point out, the earliest example of Norman work we have to which a date can be positively assigned. It was built between 1080 and 1090, and exhibits all the characteristics of Early Norman architecture, the masonry being axed on its surface and laid with wide joints. Of the different places visited, the lower part of the Well Tower (one of the towers of the outer ward, at the south-east end of the river frontage) was one of the most interesting. It consists of a vaulted chamber about 15 ft. long by 10 ft. wide, lately cleared out and conservatively restored, all old work being left untouched. It is utilised as a living-room for one of the warders, and a winding-stair of stone gives access to an upper chamber, used as a bedroom. In this apartment, and elsewhere, the inscriptions and some masons' marks have been carefully protected by movable hinged covers of oak. One of the most interesting sights of the day, however, was that presented by what was declared by Mr. Brock and other authorities to be a veritable piece of the old Roman wall, just uncovered during some excavations near the White Tower. The wall at this point is 7 ft. in thickness, and contains layers of the usual flat tiles, alternating with thick layers of fine rubble-mortar or concrete. It is expected that further explorations will reveal more of this part of the wall. Before leaving the Tower Mr. Morgan proposed, and Mr. Compton seconded, a cordial vote of thanks to General Milman for his courtesy in receiving the company and conducting them over the fortress; to Mr. Taylor, Government surveyor in charge of works now in progress; to Mr. McLishe, clerk of the works; and to Sergeant Andrews, R.E., for the assistance rendered by them. This was of course carried by acclamation, and General Milman replied, expressing the pleasure it would afford him at any time to facilitate the inspection of the fortress by members of the Association.

From the Tower the party proceeded to Barber's Bonded Warehouses in Cooper's-row, Tower-hill, where they dived down into the extensive wine-vaults to inspect another fragment of old Roman wall, touching which Mr. Brock said the wall here had been traced to its foundations, and it was found that its lower portion was of Roman work, containing two courses of Roman tiles, each laid regularly, and each being traced for a long distance. These were, he said, evidently *in situ*, and the contrast between the Roman work and the Norman work above it was most striking.

The visitors next proceeded to the Trinity House, where Mr. Morgan, F.S.A., read an interesting paper descriptive of the topography of Old London and of the characteristics of the Tower as a fortress. This paper would have been read within the Tower precincts but for the badness of the weather, and in the straits to which the company was reduced the authorities of the Trinity House very kindly granted hospitable shelter for a time. Here Mr. Brock again referred to the fragments of Roman wall which had been seen by the visitors, remarking that he was at a loss to understand those who sought to maintain that the Romans did not build a wall round London, although they took care to circumvallate the provincial cities. On the motion of Mr. Williams, one of the Bristol contingent, a vote of thanks was given to Mr. Morgan for his paper, and at the instance of Mr. Compton thanks were tendered to the Corporation of the Trinity House (coupled with the names of Mr. Allan, the secretary, and Mr. Inglis, the sub-secretary) for the use of their premises. A projected visit to the Church of All Hallows, Barking, Tower Hill, having been abandoned, the party proceeded to luncheon at the London Tavern, Fenchurch-street. After luncheon, other items on the programme underwent excision, these including the Church of St. Andrew Undershaft, the Church of the Austin Friars, and Cripplegate Church.

The only churches visited after luncheon were St. Katherine Cree, Leadenhall-street, and St. Helen's, Bishopsgate. At the former the Rev. Dr. Whittemore, the rector, and Mr. Brock, explained the principal features of the church, which, as was also pointed out by Mr. Godwin, is very notable as having been built at the very time when the Gothic and the revived Classic or Renaissance architecture were battling for supremacy. It was extraordinary to find a church with the Classic columns and imposts of the arcade and the cinque-foil headed windows and groining all co-eval. In Godwin's "Churches of London," as Mr. Brock stated, the date assigned to the older work (the remains of the tower of the preceding church, and through which the present church is entered) is 1509. The building of the existing church was commenced in 1628 and finished in 1631. It has been attributed to Inigo Jones, but whoever was the architect, the Catherine-wheel window at the east end was evidently, in Mr. Brock's opinion, designed by some one who was familiar with the large circular window at the east end of Old St. Paul's. Among the tombs in the church is that of Sir Nicholas Throgmorton.

The company next proceeded to the Church of St. Helen, Bishopsgate, where, however, the gas could not be turned on. The few candles hastily procured only sufficed to give those who had not previously seen the church a faint glimmer of its beauty, and many present resolved to make themselves better acquainted with it hereafter. The church was described by Mr. Godwin, who, after referring to the many evidences of Roman occupation of the locality, said that one writer had asserted that there was a church here in 1010, but the evidence he adduced was not convincing. It was known



ST. MARK'S, MILVERTON.—*Plan.*

however, that a church here was made over to the Canons of St. Paul's in 1180. In 1210, the Priory of the Holy Cross and St. Helen was founded here, in honour of Helena, the mother of Constantine, and the discoverer of what was believed to be the true cross, the desire to gain possession of which led to the Crusades. The present church was part of the original priory buildings. It is divided into two aisles by an arcade down the middle, and the northern side or aisle was formerly the nuns' choir, and was screened off from the southern half of the building. The priory buildings extended northward, and there was in existence until 1799 the nuns' hall, with a fine crypt beneath it. The hall above the crypt was for a long period occupied by the Leathersellers' Company as their hall. Having dilated further on the architectural features of the church, Mr. Godwin mentioned several incidents of interest connected with the many eminent men who lay buried here, Sir John Crosby and Sir Thomas Gresham chief among the number. The church was remarkable for the number and richness of its monuments, and on that account it had been called by more than one writer, "the Westminster Abbey of the City." That such an appellation was not undeserved would be seen from the statement that the church contained twenty-five handsome monuments of important personages, besides smaller ones and a large number of brasses. The most important of the monuments from the Church of St. Martin Outwich have lately been brought here, owing to the demolition of that structure and the union of the parish with that of St. Helen.

On the motion of Mr. Morgan, seconded by Mr. Lambert, thanks were given to Mr. Godwin for his discourse, and most of the company ended their three days' outing by a visit to Croehy Hall.

A visit to the British Museum was arranged for Thursday.*

ST. MARK'S, MILVERTON.

The new church recently erected at Milverton by private munificence takes the place of an ugly old chapel known locally as the Pepperbox. The new building is in the Decorated style, in some parts treated freely. We give a view and plan of it. The materials used are red brick with Box stone dressings. The buttresses are all of Bath stone, and the roof covering is of plain tiles. The internal arrangement comprises a chancel at the east end, a lofty nave, north and south aisles, and at the west end a substantially-built tower, in which it is proposed to place a peal of eight heavy bells. The chancel is 49 ft. by 27 ft., and about 51 ft. high. It is lighted by seven mullioned windows, three on the south side, three on the north, and the large east window over the communion-table. The roof of the chancel is composed of wood-groining, with carved oak bosses. The precedent for this part of the work is to be found in the lady-chapel of St. Alban's Abbey, and other old ecclesiastical buildings. The floor of the chancel is laid with black and white marble, and Minton tiles. The altar is a plain oak table, with dossal hanginge and altar-cloth, which have been furnished from designs by the architect by Watts & Co., of Baker-street, London, who have also carried out the decorations of the vicarage-house under the directions of the architect. On each side of the table is a tapestry curtain, fixed against the wall; and the sides of the chancel, above the stone sedilia, are in like manner hung with tapestry. The kneeling-desks are copied from those in the Beauchamp Chapel, Warwick. The lectern is founded on an ancient model, and has been excellently worked out by Watts & Co. The pulpit and choir-stalls have been executed by Messrs. Farmer & Brindley, of Westminster Bridge-road, who have efficiently carried out the carving throughout the church. The nave is separated from the chancel by an arch with carved angels at the springing-points, bearing in their hands musical instruments. The nave is about 87 ft. long by 32 ft. 6 in., and the north and south aisles 40 ft. by 15 ft. 8 in. The seats are open oak, and altogether there will be accommodation for nearly 1,000 persons. The roof of the nave is noticeable for its height, nearly 53 ft. It is an open roof, and is left for coloured decorations. The front of the first row of seats and the back of the last row are carved with sunken tracery. The floor of the church is laid with blue and brown York paving. At the end of the nave there is a tower, 18 ft. square, in which is placed a font, the base of which is Manefield stone, the pedestal marble, while the bowl, which is of alabaster, is supported by eight columns, and is carved with angels. The cover is a carved wooden canopy, nearly 12 ft. in height, and balanced by a gilt cross suspended from an enriched beam. A wooden panelling about 5 ft. in height is carried all round the church against the walls. The adoption of this arrangement gives a warm effect to the church, and is a source of much comfort to those whose seats are near the walls, or who have to stand against them occasionally, or against the pillars. The bottom of the tower at the west end is lighted by a large mullioned window. A spiral staircase in the south side of the tower leads up to the belfry. The side aisles are lighted by three large traceried windows, and the nave by four small clearstory windows on each side. Haden's hot-air apparatus has been introduced for warming purposes, and the lighting arrangements include gas jets along the nave beneath the clearstory windows, and gas standards in the aisles. The pulpit, which is of carved oak, stands on the south-west side of the chancel arch, and is surmounted by a carved canopy. It is the production of Messrs. Farmer & Brindley. On the north side is a chapel (above that an organ-loft), a vestry, and a parish-room for the transaction of parish business. There are also two small chapels on the south side. The groined roof in the chapel beneath the organ-loft is noticeable.

The architect is Mr. George Gilbert Scott, M.A. This church is one of a series of architectural works which have been entrusted to Mr. Scott, amongst which we may mention the new halls at St. Peter's and Christ's Colleges, Cambridge, the extensive works now in progress at Pembroke College, Cambridge, and St. John's College, Oxford, Garboldisham House, Norfolk, and several new churches in different parts of the country, including one at Kennington, and one at Southwark, both of which are of large size.

The work has been carried out by Mr. G. F. Smith, builder, Milverton; Mr. T. Godfrey, of London, being the architect's clerk of the works. The site of the church has been given by Lady Charlee Bertie Percy, and the font is also the gift of the same lady. The entire cost of the buildings, including the vicarage adjoining, comes from the estate of the late Lady Wheler. Her ladyship devised a sum of 9,000*l.* for the purpose of providing a new church for the district of New Milverton, and the remainder of her property went to her two brothers, Mr. Edward Shepheard Carus-Wilson, of Truro, and the late Rev. Carus-Wilson, who was formerly Vicar of New Milverton, and who died suddenly while travelling on the Continent. These two gentlemen have erected St. Mark's, at a cost of 35,000*l.*, and have also provided an endowment fund of 6,500*l.* as a memento of their sister, the late Lady Wheler.

* The visitors are indebted to Mr. G. Wright, Mr. Patrick, and Mr. Reynolds for the arrangements which enabled them to see so much in so short a time.

DECORATIVE SUGGESTIONS FROM NATURAL FORMS.—No. 4.

Haworthia is a tribe of dwarf aloes, of which there are many species; the two figured here (*viscosa* and *tesselata*), which are drawn the natural size, while they mimic in the body of the plant the usual characteristic of design of the aloe tribe, thick infolded spiky leaves, send out long slender shoots, adorned with blossoms of the most exquisite and delicate design, such as seem to have no relation to the general character of the plant from which they spring. In the specimen of the *tesselata* from which this sketch was drawn the shoot bearing the flowers was about 18 in. long; only a part of it is shown here. The blossoms are drawn larger size, in order to show something more of their design, the delicacy of which, however, can be but inadequately expressed with a lithographic pen.

The specialty of these specimens of Nature's design consists in the combination of the short spiky aloe leaves, with the long, fine stalk and delicate blossoms: this is the idea aimed at in the designs based on it. In the tile the body of *Haworthia tesselata*, seen in plan, forms the centre, and the stalks are twisted round and round it, while they carry the blossoms to fill up the angles. The special marking of the main leaf, from which the plant derives its specific name *tesselata* (as if laid with *tesseræ*), makes it very suggestive as a feature for tile design. In the sketch for a brooch above, the tesselated idea of the leaf is carried out by the arrangement of the stones which are set in it, and the buds and flowers droop from it, as a pendant, instead of rising from it. In the glass cup the main leaves of the *viscosa*, which bears nearly the same flower, are on the same principle made the base of the bowl, while the long stems arise from it, and twine round the upper portion. The slight sketch of a panel for terra-cotta shows the two elements in the plant superimposed, instead of following the natural order of growth one from the other.

It will be obvious that we do not attempt to keep to any special scale in drawing the artificial objects: their intended scale must be indicated by their character. Thus in the present case the brooch and the cup would be taken as full size, and the tile would work well at about twice the size shown.

PATRICK STEAD HOSPITAL.

This design was accepted in open competition, the committee adopting the selection of Mr. J. K. Colling, architect, who was appointed referee. The committee's instructions required the arrangement of dispensary, waiting and consulting room, with a separate entrance for out-patients, accident ward, kitchen, and offices, male and female ward for six beds each, day or convalescent room, operating-room, and the necessary bedrooms for matron, nurses, &c. The plans will sufficiently show the disposition of the requirements, special care being taken to obtain compactness and economy in working. Mr. Henry Hall, of Doughty-street, is the author of the design, and the work is being carried out under his direction, the builders being Messrs. Howard & Son, of Halesworth and London.

NIXON'S SCHOOL, OXFORD.

This picturesque old building is situated in the Town-hall yard, at the back of the Post-office. It is built of timber and plasterwork, the entrance doorway being made a little more important by some stone dressings and an ornamented shield over, carved with the city arms. The school is held on the first floor, the ground-floor being appropriated for post-office purposes. It was founded in 1658, by John Nixon, a worthy alderman, to provide free education for forty boys of the city. A master's residence used in old times to adjoin the school (in the left-hand corner of the sketch), but this has long since been demolished. The old school may probably soon share its fate, as preparations are, it is said, in train for building fresh premises elsewhere. H. W. M.

Association of Municipal and Sanitary Engineers and Surveyors.—The Lancashire and Cheshire District meeting is to be held at Salford, on Friday, the 5th of November.

SMOKELESS LONDON.

Sir,—It so chanced that, remembering an article which appeared in your columns on the 21st of February last on the subject of fog, I was just about to address you on the return of the London fog season, when the number of the *Builder* containing your more recent remarks on the very subject reached me.

With the greater part of that article I fully concur. The difficulty that I feel as to altogether agreeing with its outcome is this:—Coal, as we buy it, is a natural product. It is one that is remarkably free from adulteration. Slate, or bricks, or other materials, may be sold by the roguish dealer as coal, but the fraud is easy of detection. There is good coal and bad coal, but the consumer can learn, at little trouble, the earmarks of the different qualities of the mineral, and can purchase (if he goes to a respectable coal-merchant) that kind which suits him best.

Now, it is very possible that an artificial fuel may be produced which shall be better than coal,—at all events, in the matter of smokelessness. But this has yet to be done; that is to say, to be done in so simple a manner that the purchaser will be able to obtain a ton of smokeless fuel at a fair price, and with as much certitude as to what he buys as if he ordered a ton of Hartley's Walls-end. The first thing, then, it strikes me, that would be necessary, in order to introduce such a general improvement in fuel, would be the production of so distinct a manufacture that there would be no room for adulteration or for cheating, so that the purchaser would know what he was doing as well as if he ordered a ton of any given quality of coal.

Practically speaking, this can only be done by the gas companies. The first step, then, it seems to me, towards giving any practical sequence to your suggestion, is to ascertain how far any gas company would be prepared to submit coal to a much less destructive distillation than at present, with the view of offering the public a fuel that would be intermediate between coal and coke. I do not feel prepared to offer an opinion as to the feasibility of the plan. But it seems to me that the way to put it to a practical test will be to make such an application to a gas company. It would probably be found that a considerable alteration, not only in their mode of procedure, but in their retorts, would be necessary to carry out the plans. But it is only by manufacturers of gas on a large scale that it would be economically possible for the scheme to be effected.

My own views point in another direction,—indeed, in that indicated by your former article to which I referred as to the use of gas as fuel. Dr. Carpenter, I observe, suggests that a poorer gas than that ordinarily used might be made for the purpose of combustion for calorific purposes. It must be remembered, however, that a great demand for gas as fuel must be established before it would be worth the while of any one to lay down a new set of pipes to convey this less carboniferous gas wherever it was required. Meantime we have to see what is to be effected with ordinary coal gas, of which the calorific value is so much higher than the luminous value, that more light can be produced by a dynamo-machine, driven by gas, than by burning the same quantity of gas directly for light.

This leads me to another part of the subject; and it is one in which the key to the question will, I think, be found to be hidden. It may be described as carrying out the reflections you suggest as to heat of combustion; but looking at the matter upside down, or in the reverse direction to your view. You say combustion, to be perfect, requires a high temperature. I fully agree. But do we take the proper steps to attain a high temperature? I think we go in quite the contrary direction. Your illustration of the hot-blast is precisely one of the facts on which I have based my opinion. I may add the example of the air-furnace, a contrivance that I have often watched at large works in Staffordshire, in which a nearly perfect combustion is effected by a very simple arrangement. The great requisite for perfect combustion is TO SUPPLY TO THE FUEL THE EXACT AMOUNT OF ATMOSPHERIC AIR NEEDED, AND NO MORE. It is here that our stove-makers err. "Plenty of air, plenty of draught, blow the fire!" is the cry, and the result is to blow so much unconsumed fuel away. For it must be remembered that every cubic foot of air that passes by, through, or over, a mass of burning matter unconsumed, carries off so many units of heat. It chills the fire; it makes smoke. With too little air the combustion flags. Smoke is thus produced from readily vaporizable fuel such as oil or paraffine. Give the exact quantity of air, and you have perfect combustion, and no smoke. Give too much air, and fuel that would not burn, and therefore would not emit smoke, with too little air, now sends out dense volumes of smoke, just in proportion to the chill caused by the excess of air.

I have made many experiments on this score, though they have been principally confined to the combustion of gas. So certain is the scientific basis of the theory, and so great an economy can be produced in the luminous effect of gas by the application of the rule, that I for some little time entertained sanguine hopes of being able to effect a very great reduction in the consumption of gas. My experiments, however, were brought to a close, not by any want of success, for the result went beyond my expectation, but because I did not see my way to an indisputable protection of my process, and thus to any remuneration for months or years of toil. I shall be glad, however, to communicate on the subject with any one who takes an interest in it, and who, by taking the matter in hand as a manufacturer, would not be obliged to rely exclusively on the validity of a patent. And I may add that the first practical application of the method might be to the great desideratum of a better and brighter safety-lamp for the miner.

By regulating the pressure at which ordinary coal-gas issues from the burner, and by proportioning the quantity of air admitted to the flame, the illuminating power of a given quantity of gas may be increased more than ninefold. I refer,—as a proof that I am not speaking without book,—to the report made in 1871 to the Board of Trade by the gas referees, in which it is shown that 1·65 foot of gas per hour can be so burnt as to produce by one method light measured as 7·36, and by another method light measured as 63·5. And in this experiment only a portion of the regulation that I propose was effected. Now if this can be done in the consumption of gas, I do not see why something of the same kind should not be done in the consumption of coal. The question really comes to this. Are we so fondly attached to the barbarous custom of burning coal in an open grate, under a hole in the wall, that goes to the outer air, through which 80 per cent. or more of the heat is abstracted, that we refuse to attempt any improvement in the method of combustion? A great many people, no doubt, are. To those people it is of but little use to preach. Whether you offer them a smokeless fuel, or I offer them a perfectly consuming arrangement, we shall lose our labour. It seems to me that it is only by the argument to the pocket that this prejudice can be combated. Let us convince the public,—or the younger and convincible part of the public,—that they spend five or ten times as much in fuel as they need to spend, and then there will be a *που στω* for the smoke-reformers. As long as we only attempt to modify the open grate,—being careful to supply abundant air to our little furnaces,—so long shall we only increase our annual smokiness. But when we seriously put the question—"How can we warm our houses and cook our dinners most economically?" another state of things will become possible. When the question, "How shall we burn the thousands of tons of coal which we now daily send unburnt up the chimneys of London?" is once put in earnest, it will not be put without a reply. The answer is, "Economise, not only fuel, but heat. Secure perfect combustion by the exact regulation of the supply of air to fuel, and retain all the heat produced by that combustion for use, instead of sending it up the chimney." The margin is so wide, the economy to be effected is so immense, that there is an ample field for the inventor. In fact, it is as to details alone that invention is necessary. The first step to take for the prevention of smoke is the providing for perfect combustion. That step is at the same time a great economical gain. I do not say that London would be rendered smokeless in six weeks, or in the course of the ensuing winter. But I do hold that it may be rendered smokeless by the application of the principles I have ventured to suggest as cardinal, and that this can be done to the great pecuniary gain of every householder. F. R. C.

The Mansion House.—The Right Hon. the Lord Mayor Truscott has sent out invitations to meet members of the Royal Academy at dinner on Wednesday, November 3rd.

PRIVATE BILL LEGISLATION OF THE LATE SESSION.

The list of private Bills passed during the Parliamentary session of 1880 has just been issued, from which it appears that the total number of Bills of all kinds which received the sanction of the Legislature is 172. Of this number, 65 are Bills connected with railways, being about two-thirds of the entire number of Bills of this character which were promoted during the session, amounting to 100. Of the Bills passed, however, 41 only are for the construction of actual works, 24 of them being either for the abandonment of works, or for an extension of time for the construction of works already sanctioned. As regards 18 of the Bills which have become law, they are for the construction of distinct additional railways by entirely new companies, who are empowered to make new lines having an aggregate length of 224 miles, at an estimated outlay of 5,790,299*l.* Nine of these intended new railways are in England, their total length being 131 miles, and their estimated cost 5,306,966*l.* The most important of the new English lines is the Hull, Barnsley, and West Riding Junction Railway, which is 67 miles long, and will involve an outlay of 4,000,000*l.* Four of the new railways are in Scotland, their length being 37 miles, and their estimated cost 845,333*l.*; four in Ireland, length 43 miles, cost 505,000*l.*; and one in the Isle of Wight, length 13 miles, cost 133,000*l.* The number of Bills promoted by existing companies for new works which have received Parliamentary sanction is 23. These several companies propose to construct an aggregate of 152 miles of additional railways and other works, at a cost of 5,298,900*l.*, the intended additional outlay of the Midland Company alone being 1,800,000*l.*

The number of tramway Bills passed during the session is 14, authorising the construction of 114 miles of tramway in different parts of the country, at an estimated cost of 975,550*l.* The longest of these intended tramways are those at Huddersfield, which are 18 miles in length; Gateshead and South Shields, 17 miles; and Coventry and Nuneaton, 15 miles. The powers obtained by these three last-named companies authorise them to use steam power on their lines. It should be added that, besides the several tramway Bills sanctioned by Parliament, the construction of a large number of tramways has likewise been authorised by Board of Trade orders.

In connexion with the construction of new and extended gasworks in the different towns and districts of the country, nineteen Bills were passed during the session, the estimated cost of the various works authorised amounting to 1,204,000*l.* The largest intended expenditure on these works is 187,500*l.* at Eastbourne; 150,000*l.* at Reading; 150,000*l.* at Wandsworth and Putney; and 100,000*l.* at Maidstone. Twelve Bills have also been passed authorising the construction of new waterworks, at a total estimated cost of 4,056,400*l.*, of which sum 3,250,000*l.* are for the works about to be carried out by the Liverpool Corporation for a supply of water from the rivers Vyrnwy, Marchnant, and Afon Cowny, in Wales, leaving 806,400*l.*, as the estimated expenditure for the whole of the other works sanctioned. Of this amount 300,000*l.* are intended to be expended at Wakefield; 120,000*l.* at Edinburgh; 100,000*l.* at Great Yarmouth; and 75,000*l.* at Wrexham. The same remark applies to gas and water projects as to tramways, the Board of Trade having authorised the construction of such works in several towns at an estimated aggregate cost of 392,250*l.*

The town improvement Bills sanctioned are fifteen in number, authorising works of this character in Nottingham, Huddersfield, Preston, Oldham, Liverpool, Bristol, Aberdare, Barton, Glasgow, Kensington, Lancaster, Sandwich, Rochester, Wigan, and King's Lynn.

Case of Mr. Strachan, Architect.—In response to the statement made at p. 514, *ante*, we have received 1*l.* 1*s.* from Mr. Daniel R. Dale, of Union-court-chambers. We shall add 1*l.* 1*s.* ourselves, the case being well recommended, and will wait a week before transmitting the amount, in case any other of our readers should think fit to send a little aid. They have heard of the old epitaph,—

> "What I spent, that I lost;
> What I gave, that I have."

AN ELECTRIC LAMP.

A lecture on Electric Lighting was delivered by Mr. J. W. Swan, before the Literary and Philosophical Society, Newcastle-on-Tyne, on the 20th inst., in which the lecturer seemed to substantiate a claim to a further advance in the subject than has before been made, and to being before Mr. Edison in effecting the economic divisibility of the electric current. Having described the different generators of electric currents in use, and shown that all the means of producing light by electricity are divisible into two classes, namely:—

1. Lighting by the electric arc.
2. Lighting by incandescence,—

he went on to say:—Whilst Mr. Edison was endeavouring to produce a useful incandescent lamp by means of platinum, I was endeavouring to obtain the same end by means of carbon. It had appeared to me for many years that if ever electric light was to become generally useful, it would, most probably, be by means of the incandescence of carbon. I had, long before the time to which I am referring, attempted to render this idea practicable. As a matter of history I will briefly describe an experiment which I tried about twenty years ago. I had a number of pieces of paper and card of various forms and sizes buried in charcoal in a crucible. This crucible I sent to be heated white-hot in one of the pottery kilns belonging to Mr. Wallace, of Fortb Banks. From the pieces of carbonised card which I thus obtained, I selected a long spiral, the ends of this I clipped between small blocks of carbon carried by uprights, and connected with conducting wires. A small glass shade was cemented over this mounted carbon spiral, and the air was exhausted by means of a very good air-pump, lent to me for the purpose of this experiment by the Rev. Robert Green, of Longhorsley. A good vacuum (according to the ideas that then prevailed) having been produced, I applied the wires of my battery (consisting of ten cells of Callan's modification of Grove's battery) with great expectation of a brilliant result; instead of this, there was the most absolute negative presented to me, not a vestige of heat or light appeared in my long ringlet of carbonised paper. It was evident, and I immediately recognised the fact, that the electric current of the strength I was using would not go in sufficient quantity through so long a piece of carbon as I had taken. I, therefore, repeated the experiment with shorter carbon and a greater number of cells, and I obtained, under these altered circumstances, an extremely interesting result. . . . .

After describing the way in which various difficulties were overcome, Mr. Swan exhibited his perfected lamp, and continued:—Is it not a pleasant light? It is not so white as the arc light, but yet a whiter light than gas. Colours are correctly seen by it, as this picture shows. But the great merit of this light consists in its not being in contact with air, and therefore there cannot possibly be the slightest air-pollution caused by it. The rooms in which this light is used will be as pure by night as by day. It is essential to economy in lighting by incandescence that the incandescent carbon should be very thin. The carbon I use is not one-twentieth the thickness of the thinnest of the carbons formerly employed, and therefore one-twentieth of the current costing one-twentieth the price, will produce in my thin carbon the same degree of luminosity as twenty times more current will produce in such carbons as were used in those ancient lamps. You will notice that in my lamp leakage is very thoroughly guarded against, the wire which passes through the glass not only having the glass fused around it where the wire and globe meet,—but in addition to this, the wire is coated with glass almost up to the carbon. In this way the vacuum is preserved very effectually. . . . .

With regard to distribution, I believe it will prove to be practicable to light any large town,—all Newcastle, for instance,—by means of wires laid in the ground as gas pipes are laid, and all branching from one centre, and conveying the electric current to lamps like this. . . . . The economy of lighting by incandescence has not been exemplified by so many instances of actual practical use. One thing is quite clear, and that is, that electric lighting by incandescence is an economical process,—it will be less costly than gas lighting. That is conclusively demonstrated by the fact that 1,000 feet of gas employed in working a gas-engine to develop an electric current, and used in my lamps, will yield more light than 1,000 feet of gas consumed in the ordinary way in gas-burners. This room is now lighted by twenty of my electric lamps, and to produce the current which feeds them 160 cubic feet of gas per hour are being burned in a gas-engine; before my lamps were kindled the room was lighted by seventy gas jets, consuming, I am told on good authority, 210 feet per hour. It is very evident that we have got more light out of the gas through the medium of electricity than was got from the larger quantity of gas which those burners consumed. Our conditions here are somewhat unfavourable to my light for a fair comparison, but from measurements carefully made, both of light produced and current required to produce it, I am warranted in saying that at least twice as much light will be produced by a certain quantity of gas used to generate an electric current employed in my lamps, than would be obtained from this quantity of gas burnt in gas-burners in the usual manner. If that be so, then it is evident that when, instead of the motive power of gas, that of steam produced in the most economical manner is employed, this method of electric-lighting will be very much less costly than gas-lighting. I reckon that 40 lb. of coal employed in raising steam to generate electricity is capable of producing in my lamps the effect of 1,000 ft. of gas burnt in gas-burners in the ordinary manner. The economical view of the question is therefore, in my opinion, very favourable to electric-lighting, and I think fully warrants me in anticipating an extensive substitution of electric light for gas-light. The great difficulty which, till now, has completely blocked the way to any general use of electric light was *the difficulty of division: that difficulty is now completely overcome* by the method of producing electric light by the incandescence of carbon in vacuo.

DISADVANTAGES OF BACK STREETS.

NORTHERN ARCHITECTURAL ASSOCIATION.

At the annual meeting of the Northern Architectural Association, held in the Old Castle, Newcastle, on the 19th inst., Mr. Thomas Oliver, president, read a paper "On some of the Disadvantages of Back Streets in Towns." In his opinion, he said, the retention or abolition of back streets was merely a sanitary question, although there was an economic, as well as an æsthetic aspect of the subject well worthy of consideration. These streets arose out of a necessity, fifty years ago, viz., the removal of refuse, ashes, &c., but this necessity no longer existed, owing to the introduction of sewers, water-closets, and dust-bins. The back street had served its day, and they were now called upon to substitute, under the altered circumstances, a cheaper and a healthier arrangement for the laying out of the environs of dwellings. Before doing so he would draw attention to some of the disadvantages at present felt. The streets themselves, even when paved, were not unfrequently dirty and badly swept, and in remote places they were rarely attended to. They gathered the scattered refuse from neighbouring places, and in windy weather this refuse came whirling in eccentric eddies to the entrances of the back streets, and after passing up and down, left a deposit of straw, paper, old rags, and other filth. The look-out upon the ends of these lanes, from houses on the opposite side of the street, was far from being picturesque or pleasant; for, according to the hour of the day, they might have presented to them the beggar, the thief, the burglar, the burglar's female pioneer, the sweetheart, the tradesman's boy, or the obscene drunkard and vagabond. The view from the back rooms of the houses themselves was not by any means interesting. People thought they could not, and therefore they would not, keep such places clean and respectable. The whole of the ground, both of the yard, outbuildings, and back street, was wasted; for there might be grass, flowers, shrubs, and other healthful or useful things. Just think of the air, after passing over the insalubrious places referred to, entering the bedroom windows, just being closed for the night,—what a mixture of the pure and impure for the sleeping inmates to breathe for the next eight or nine hours! New estates were being laid out, and new streets built up, with a waste of 20 ft. at the back of each double block of houses, while dirty yards and unsavoury outbuildings, for which there was no need, occupied the place that ought to be devoted to grass and trees. During his visit to various cities on the

Continent, to the metropolis, and some of our own more ancient towns during the last 25 years, he had been struck with the absence of the back street nuisance. This led him to suggest in 1875, to a gentleman in Newcastle, the desirability of laying out his estate at Jesmond on the principle he (the speaker) advocated. The Corporation were not yet prepared to carry out the principle, but he had no doubt that they would do so. The plan represented a rectangular plot of land with houses on all sides. There was a small area in front of each house, which was appropriated to dust-bin, coal-place, &c. There were no back streets and no back yards. The back portions were laid out as gardens with low division-walls between the respective portions. The flow of air would be greater than that provided by the back-street system, and it would be quite pure. In the place of unsightly out-buildings there would be gardens capable of growing trees, and large enough for grass lawns, valuable both for pleasure and utility. By adding the quantity of land saved by the back street, it was proposed to make the houses wider in frontage than usual (20 ft. to 24 ft.), and thus obtain three or four rooms on each floor, each room having what might be termed a front view. If the plan were adopted, not only would there be a larger proportion of land to sell, but the tenants or purchasers would be freed of the cost of paving and flagging. It would be a saving of rates, and would certainly redound to the credit of the Corporation officials, as they would be relieved of one of the most unwelcome duties they had to perform.

SOME RECENT METHODS OF TESTING PORTLAND CEMENT.

At the usual meeting of the Manchester Association of Engineers (employers, foremen, and draughtsmen), on the 9th inst., Councillor W. H. Bailey, of the Albion Works, Salford, read a paper on "Some Recent Methods of Testing Portland Cement."

Mr. Bailey said Portland cement, as a material of construction, had increased in popularity during the last twenty years, but especially so during the past five or six years, owing entirely to the scientific methods used both in its manufacture and in the methods of testing the material by those engaged on government, municipal, and other large works. At a recent meeting of the Institution of Civil Engineers a communication was read from Mr. Higgin, who has charge of the extensive operations at Buenos Ayres, under the direction of Mr. Bateman, as engineer-in-chief. The sum of 2,000,000*l.* sterling has been spent in city improvements there, and the spending of this money has afforded a good opportunity of showing what can be done with cement concrete in almost every form that could be devised. No stone was to be obtained in Buenos Ayres; in a radius of 200 miles not a pebble could be found. When the works were begun the province produced no bricks fit for use, and recourse to concrete became imperative. About eleven miles of large subterranean conduits had been built almost entirely of concrete, as well as twelve miles of intercepting-sewers, and twenty to thirty miles of collecting-sewers. Concrete has been used for the workmen's houses,—for the roofs of engine-houses, in the copings of walls, tops of columns, retaining-walls, filters, settling-beds,—indeed, for every conceivable purpose. Mr. Higgin states that for all the fine work the mixture used was one part of Portland cement to six parts of coarse sand. Portland cement is composed of silica, alumina, and carbonate of lime. This is produced by mixing clays and limestone or chalk in combination with water, which mixture, after being baked and calcined in a kiln, is ground to fine powder. Mr. Henry Reid, who has written many books on the subject, insists that it is absurd to send this useful material many miles any where, as the ingredients for its manufacture can nearly always be found at one's elbow if we only look. In many rivers and creeks the raw material exists. Common flint, pit-clay, marine-clay, the shales and sand of Warwickshire, Derbyshire, Northamptonshire, and Somersetshire, should be used for cement-making. For the like purpose Mr. Reed names the basaltic columns of the Giant's Causeway, the limestone formation at Kendal, and the various lavas and slate deposits in different parts of this country. The strength of Portland cement increases with its fineness. The most popular method of testing the cement is by subjecting it to a severe tensile strain; but much can be said in favour of testing by compression, and the latter would be more in use but for the costliness of the apparatus. Mr. Bailey described a simple hydraulic compressor for the testing of Portland cement, which he had designed. It was possible, however, that cement should be tested both for tensile strength and resistance to crushing. Professor Thurston (America) has introduced a method of testing by torsion or twisting. The Thurston tester not only gives the torsional resistance, but also the limit of elasticity and the exact angle of torsion. The limit of elasticity is the amount of twist a material will bear without becoming permanently distorted. The quality of elasticity is of considerable importance in a cement, especially where it is used for concrete work in footpaths and roads. Mr. Arthur Jacob, the borough engineer of Salford, has given considerable attention to the tensile testing of Portland cement. He has introduced cylindrical moulds. The shape is perfect, and by a careful filling of the moulds and exact measurement of the water used in each case, tests are made under conditions which seemed to him (Mr. Bailey) to be rigidly equal in every particular. Mr. Jacob's machine has the weight,—which consists of a long can into which a small stream of water flows,—placed at the end of a lever. This enables the test to be applied in a very gradual and nearly imperceptible manner, without any vibration; in fact, the operator may sit down and watch the machine, after the tap has been turned on, until the fracture is effected. The height of the water in the cistern is indicated by means of a glass tube similar to the water-gauge glass of a steam-boiler, the graduation being painted down the can or cistern. When the material is broken, a small trigger closes the tap, and prevents any further supply of water. So uniform are the tests by Mr. Jacob's system, that, with good cement, the figures obtained scarcely vary. On the 26th of September, six samples were taken from one bag, and were tested, with the following results:—810, 815, 820, 820, 820, 820. Mr. Bailey said he had had considerable experience of testing, but with any other form of clip, and under the most careful conditions, no results like these had ever come under his observation; and if tensile strain is the proper one to place on Portland cement, Mr. Jacob, he thought, had introduced the most perfect form of testing. But it was desirable to caution those who consider a high tensile strain the best, that this mode may result in the manufacture of a dense and treacherous cement, and elasticity was a quality which in future would have to receive quite as much attention. In past years Portland cement has been ill-treated. Ignorant and unscrupulous persons have sold and used cement under that name, and have brought it into undeserved disfavour. For workshop use it is invaluable. It preserves iron; indeed, it is used for preserving the insides of iron boats. Its uses and applications are innumerable,—tanks, walls, foundations, piers, solid lighthouses in one piece, are built of it. As its qualities become better known to mechanical engineers, it will be more extensively employed than at present.

Mr. W. H. Bailey, in replying to several questions raised in the discussion, said that sand intended to be used in the mixing should be dry, and the process of mixing carried out under cover. The quantity of water used in mixing was ¼ lb. to every pound of concrete. Too much care could not be taken in the mixing, and in many instances where cement had failed, such failure had been clearly traced to some want of attention in this particular. This had been proved by the entire destruction of a large breakwater in the South of England from the simple reason of a few rusty nails getting into the cement during the mixing.

Clarkson Memorial.—It has been proposed for some time to erect a memorial of Thomas Clarkson, in his native town of Wisbech, and we published a view of the design by the late Sir G. Gilbert Scott, R.A., which had been selected. About 2,000*l.* were required for its completion, towards which the sum of 1,400*l.* has been contributed. The want of a suitable site has occasioned delay, but this difficulty being removed, the committee have accepted a contract for the memorial (without the statue and bas-reliefs), and the first stone was laid on the 25th by Mr. Jonathan Peckover, the treasurer. Mr. Charles Gane (Wisbech), ex-mayor, or Mr. John Leach, will gladly receive subscriptions, so that the design may be completed.

"CLOSET" CONSTRUCTION.*

Great importance must necessarily attach to the deliberations of an Institute like this, which aims at disseminating information, and guiding public opinion on sanitary matters. It may, however, be questioned whether the real importance of a given subject is not shown less by the amount of talk to which it may give rise, than by the amount spent upon it in the production of an article the best fitted to meet advancing requirements.

The amount of brain-power and hand-labour expended for many years past in invention and experiment for the production of a perfect water-waste preventer and regulator, and an unexceptionable water-closet apparatus, is alone sufficient to testify to the paramount importance of investigation into the proper principles to be followed in their construction, with the view of arriving at some intelligible lines within which they should be restrained.

To all who have taken an active interest in sanitary matters, nothing can have been more evident than the dangers attending the old system of pans and valves, with D traps fixed out of sight, inside the house. At the annual meeting of the Parkes Museum, Sir William Jenner spoke of these last in no polite or measured terms. And truly the terms used by him were not exagerated. But the difficulties attending the amendment of an established state of things with the British citizen are almost insurmountable, especially if it be such as to touch his inner man, whether through his pocket, or (if there be one) some equally tender point. And unquestionably there are vast commercial interests which stand in the way. So far as we can be judged by outward appearances, under the present state of things even the value of the great bulk of house property is but little affected by the presence of sanitary or unsanitary arrangement in these respects. On a recent occasion in a house in which I have sojourned, and in which there has been constant ailment with one or more of the inmates,—to say nothing of several cases of blood-poisoning attributed by the medical attendant to sewer-gas,—I have endeavoured in vain to induce the landlord to provide a water service for domestic purposes, apart from the only one which is supplied from a cistern over the water-closet, this closet being served by the customary spindle valve, with water-box, which inevitably releases the bad air from beneath into the water at the bottom of the cistern. I appealed to him, further, to remove and to ventilate the decayed and constantly leaking lead soil-pipe (occasionally eaten through by rats from the drain), which runs down inside the house, adjoining one of the sitting-rooms, leaving it in an almost chronic state of stench. And, more than this, I appealed to the sanitary inspector, but could get no redress in these matters. This landlord, being also the agent of an enormous house-property, was imperturbable alike under threats of quitting and under appeals to authority. There is every reason to fear that such is no uncommon case. And in the great mass of speculative building hitherto, a few pounds per house of additional outlay, in these respects, has not been considered remunerative by way of investment. The houses must be had, and are often occupied almost before they are properly completed, irrespectively of these trivial considerations, about which it is said meddling people make so much fuss. People have become habituated to it. No death in their families has been traced to such causes. Almost all houses are alike in these respects. There is but little choice, and other occupants have lived on without complaining. Surely there cannot be so very much the matter, or we should hear more about it, and we can only go on as others do, and if we tried to examine into the matter ourselves, we should be no wiser. We must take what we can get, and either grumble or be thankful as the case may be. This, I venture to say, without exaggeration, is the prevailing state of feeling, and mode of action, or rather inaction, in these matters.

The remedies usually proposed for this state of things are, first, legislation for the enforcement of sanitary conditions; secondly, the education of the masses to understand and appreciate their own true interests, and to insist upon these being respected. Excellent remedies in their way, and they will doubtless effect much. But the difficulty of a general

* From a paper by Mr. William White, F.S.A., architect, read at the Exeter Sanitary Congress.

application of them meets us at every point. The great precedent remedy must be looked for mainly in the production of satisfactory sanitary apparatus and appliances, of the greatest simplicity, and at the most moderate cost; and then at imparting information respecting their principle, and their practical application, to the more educated classes of persons, and to those through whom such appliances are brought into use, rather than in any amount of crusade against mere recklessness, ignorance, or prejudice.

Let me now endeavour to give effect to the foregoing remarks by a few practical considerations as to water-closet construction. I would, in the first place, deprecate the use of all closets by which, on the pulling up a handle, the contents are dropped down by means of the withdrawal of a plug, valve, or pan, whether into a trap, or directly into the soil-pipe and drain itself. Apart from valves and plugs being liable to derangement, it is evidently possible, and in many instances of accidental deficiency of water extremely probable, that they may be used without water, to the great danger of corroding the pipes and choking the drains. Secondly, I would eschew everything but some description of hopper-basin or flushing-pan. The contents of those cannot be let down, to the great danger of soil-pipes and drains. In case of the water service failing, or being frozen up, or otherwise deranged, a pail of water poured down will carry everything away safely. Thirdly, I would have the best possible flush of water which can be obtained by a regulator or waste-preventer, constructed without any valve, except only the ball-valve which supplies the "feed" or serving cistern. Fourthly, I would, in all cases, insist upon the use of this feed-cistern, or other intermediate receptacle, for cutting off completely all contact between the closet and the main service, or house-cistern, which may then be placed at any convenient distance from the closet, whilst affording the opportunity of regulating accurately the amount of water to be used for each discharge. Fifthly, I would avoid all traps except the one which is formed in the construction of the hopper-basin; this being made to flow out into a ventilated or open soil-pipe, which, again may be carried up within an external ventilated flue, for protection from frost, or for carrying off the foul air more effectually. There have been several inventions which I cannot regard as wholly satisfactory, with a system of flushing which merely washes out the contents of the basin into the trap below, in which the contents commonly are only partially concealed, and which does not clear itself properly with any ordinary flush of water which can be let in upon it. They are, however, a wonderful improvement upon previous descriptions of hopper-basins, and of still greater value as aiding in the superseding of closet valves and pans. The old hopper-basin has in the main worked far better than these; but the small stream of water, through an insufficient nozzle, has been quite ineffectual for its proper cleansing. The "Shrewsbury" patent basin, made by F. Peirce & Co., is calculated to meet most of these objections. But invention has been rife in the direction of the valveless waste-preventers for the flushing of closets in the manner which I have indicated. Of these Hailstone's patent and Braitbwaite's patent appear to be excellent, if the stream discharged be sufficient. The water is discharged through a syphon, which is set going, in the one case by immersing a block of terra cotta, to raise the water to a sufficient height to fill the syphon; in the other, by raising a small quantity of the water in a cylinder. By the Shrewsbury patent the result is produced by the mere process of lifting out of the regulator, or feed-cistern, the requisite quantity of water in a pan or tray, and so tipping it into a funnel, thus securing the sudden and effectual flush which is required for the specially-formed basin or pan. It surely is to the fulfilment of such conditions as these that all our efforts must be turned, and the stream of invention directed, as, indeed, latterly it has been to a great extent. If there are principles in closet construction radically wrong and bad, and there are others which are essentially true and good, it is only by thoroughly sifting the one and the other that just conclusions can be arrived at, and advancement made. I have not been advancing theories without giving, as I conceive, good and sufficient reasons for the general principles which ought invariably to be followed. Let them be well weighed, and if they cannot be defended, let them be amended. Whether they be accepted as good and true or not, I cannot, I am sorry to say, conceal from myself the fact that they are not likely to be generally carried out, at all events for a long time to come, even with the most strenuous efforts of sanitarians to enforce them, either by precept or by law. The present state of things has too firm a hold on the people at large, and there are commercial principles at stake which will greatly stand in the way of such a general improvement.

I am not one to advocate interference with personal rights or vested interests, and I may therefore state freely what I believe to be the almost insurmountable difficulty attending it, even supposing a general agreement as to this system being the best. The best and largest firms necessarily live by advertising. And enormous is the good which they have effected by spreading the knowledge of improvements. Advertising is the only means by which such things can be brought before the public; and that which will pay, and will meet the public requirement, however bad in principle it may be shown to be, must not be omitted from the catalogue of the useful articles supplied. The good and the bad are *equally set forth, side by side*. The generality of people take the recommendation of a thing in this manner, and are only too glad to take what is thus brought before them, without further trouble or question. And so long as the great variety of opinion upon these matters exists amongst those who are supposed to be well informed, it is not to be wondered at that so little real result should be obtained. With all this, however, we are far in advance of our Continental neighbours. At Berlin, and at Rotterdam, they rest content, as it was described to me a few weeks since by well-informed persons, with merely a pan and a tap; and nothing could be more simple. At Dresden, Hanover, Bremen, and Hamburg, much more attention is now being paid to these mundane things; but one's reminiscences of Continental sanitation are by no means pleasant. I am not at all sure that the same remarks might not be made by a casual observer, as to the state of the case in our own country; for, as yet, I fear, we are, after all, but little in advance of them, and that typhoid fever, certain skin diseases, and much general debility and ill-health, will continue to be, as now, but too common; for up to the present time all that has been written and said by our most eminent physicians and sanitarians seems to have made but little practical impression on the educated, the heads of families, and house-owners generally.

RE-ARRANGEMENT OF MONUMENT YARD.

NEW BUILDINGS AND THOROUGHFARES.

The entire area of Monument-yard is at present being re-arranged, and so laid out as to convert a large portion of it into a new carriage-way, which is intended to be constructed between Fish-street-hill and Lower Thames-street, opposite Billingsgate Market. Hitherto the whole open space around the Monument has been flagged, and served only as an approach to the Monument itself and the buildings on the north, south, and east sides respectively, with the exception of a narrow passage at the south-east corner, leading into Pudding-lane. All this is now being changed. The old flags have been taken up, and the level considerably lowered, with the view of adapting it to the gradient of the intended new thoroughfare. There are to be new footpaths on the north and south sides of the Monument, with carriage-road approaches to the new thoroughfare eastward, which will intersect Pudding-lane, buildings there having been taken down for the purpose of opening out the new street. The new carriage-road around the Monument will be paved with granite, resting on a concrete bottom. It may be interesting to add that in making some necessary excavations for the new roadway, an old crypt was opened out at several feet below the level of the yard, in close proximity to the Monument. The old buildings on the north and south sides of the Monument, fronting Fish-street-hill, have recently been taken down, and on the site so cleared on the south side an extensive block of new buildings is in course of erection, which will have a frontage to Fish-street-hill of about 40 ft. in length, and be carried to a depth of 70 ft. eastward, the Fish-street-hill elevation, as well as that facing the south side of Monument-yard, being uniform in architectural design. The ground floor of the two frontages will consist of seven shops, five of which will be in the Monument-yard frontage, and two in Fish-street-hill. The building, which will be carried to a height of between 65 ft. and 70 ft., will have ornamental frontages in Portland stone and polished granite. The upper floors will consist of offices. Mr. W. Smith, of Gresham-buildings, is the architect; and Messrs. Lark & Son, of Fore-street, E.C., are the contractors. The site which has been cleared on the north side of the Monument in Fish-street-hill remains inclosed and not yet built upon. It belongs to the Fishmongers' Company, who, we learn, do not propose to erect any new buildings upon it until the Inner Circle Completion Railway project is finally settled.

THE PATENT LAWS.

In the Economy and Trade Department of the Edinburgh Social Science Congress, on the 11th inst., Sir U. J. Kay-Shuttleworth in the chair, the question set down for discussion was "The Effects of Patents on Science, Capital, and Labour."

The Rev. S. A. Steinthal, secretary, in the absence of its author, Mr. John Standfield, London, read a paper on the subject, in which the writer asserted that the three things which most required protection were science, capital, and labour. It was evidently our interest, he submitted, to afford inventors all the scope we possibly could, so that our trade and income might increase and our expenditure diminish. Contending that we had legislated so badly with regard to the development of science that the value of both capital and labour had been kept considerably below what it would otherwise have been, he remarked that the prosperity of a nation depended upon its scientific progress,—using these words in a wide sense to embrace all discoveries and improvements in our numerous and varied industries,—that scientific progress, in its turn, depended upon invention, and that the inventions of a nation were practically dependent upon its patent law. This was, perhaps, more particularly the case in this country than in any other. In the United States, a patent was granted for seventeen years, after careful examination by experts, for the small sum of 7*l.*; whereas a patent in this country was burdened with the heavy stamp-duties of 175*l.*, and was not subject to any examination. This enormous difference handicapped the British inventor by twenty-five to one in favour of the American, and thus, taking the average of the last ten years, there were 13,356 patents granted in the United States against 3,030 in this country. Mr. Standfield accordingly proposed that our stamp-duties should be so reduced that a patent in this country could be obtained as cheaply as in America. His proposal is to charge a stamp-duty of 2*l.* on application for a patent, and a further duty of 3*l.* when the patent is granted, and an annual stamp-duty of 1*l.*, 2*l.*, or even 3*l.*, so that the Patent Office may be more than self-supporting. He also proposes that patents should last twenty-one years, including provisional protection for one year.

Mr. E. J. Watherston said it was to be feared the Britisher was most unfairly handicapped in competition with foreigners. Most unwisely England omitted to raise up those sensible barricades of national and technical education; and farther, she failed to get rid of the "dead hand," the insane laws of our ancestors, by which many of our trades were sought to be governed. Thus it was that an excise was still to be found upon trade, in the shape of an oppressive tax upon "inventions." How foolish, he said, it seemed to be to fetter trades by so monstrous a charge for a simple patent as 175*l.*—a prohibitory charge, especially when a similar patent in the country that entered more closely into competition with us than any other cost but 7*l.*, and was shortly to be reduced to 5*l.* He maintained that, if it were desired to discover how not to encourage manufactures in this country, and to encourage imports at the expense and to the detriment of our manufacturers, an important factor might be found in our senseless patent laws. He held that we wanted a Minister of Commerce, whose duty it should be to relieve trades from all hindrances to progress, to let trades and manufactures be free, and, above all, to get rid as soon as possible of the shackles and hobbles upon inventors' brains.

Mr. R. A. Macfie opposed licence duty for patents, on the ground that it granted a monopoly, and that every monopoly was an impediment to trade and manufactures.

Professor Heinemann, London, opposed the abolition of patent duty, on the ground that it would discourage invention. He did not think the American system would do here.

Mr. Westgarth, London, contended that our patent duties were the greatest possible hindrance to invention. He did not, however, agree with the American system, but he regarded our present patent system as most gross and unjust. The Government should take in hand the training and restraining of inventors, should regulate the patent fees, and give the patent right to every applicant subject to those fees.

NEW MISSION-HALL, KILBURN-LANE.

The Queen's Park Hall, adjoining Queen's Park estate, was opened last week. The new building, the foundations of which were begun just three months since, comprises a hall 50 ft. long by 28 ft. wide, approached from Kilburn-lane through a side porch. The roof, which is lofty, and rests on stone corbels, is open-timbered, stained and varnished, and has a light and graceful appearance. The windows are constructed for ventilation, and are fitted with obscured plate-glass. The walls are painted a light violet, with a plinth 5 ft. high, of deep red. The platform is raised a few steps from the floor level, and has a moulded front and balustrade with massive polished mahogany handrail, the desk being raised and panelled in front. The doorways at each side of the platform lead to the inquiry and retiring room, with a lavatory, &c., conveniently placed in the rear, also to a room fitted up with boiler and other requisites for tea meetings. The seats in the large hall are of pine, stained and varnished, the ironwork (like the gas-fittings and straps, &c., of roof-timbers) are painted blue. The hall will seat upwards of 400 people with ease, a larger number being accommodated if necessary. The buildings, including heating, lighting, water-service, drains, seats, and all other matters, have been provided for the sum of 810*l*. Messrs. Hook & Oldrey, Cowley Wharf, Kensal Green, have done the work in a substantial manner within the short space of three months. The architect is Mr. Heffer, of Victoria-road, Kilburn, who designed the Albert Memorial at Hastings, the Mission Hall, New Ferry, and other public works.

SALE OF BUILDERS' WORKS, AND THIRTEEN ADJOINING HOUSES.

At the Auction Mart, on Tuesday, Messrs. F. Lewis & Co. offered for sale the extensive business premises, situated in Palace-road, Lambeth, facing St. Thomas's Hospital, which for several years past have been in the occupation of Messrs. G. Baker & Sons, builders and contractors. There was a large attendance at the sale, including several persons connected with the building trade. The premises occupy upwards of an acre in extent, and comprise several buildings, including large offices, deal-shed, saw-mill, joiner's shop, engine and boiler house, large engineers' and fitters' shops, 192 ft. long, and 40 ft. wide; three drying-sheds, with stabling for fifteen horses, and general stores. The steam power for driving the working machinery of the establishment was described as consisting of 16-horse power vertical engine, with a 60-horse power Cornish boiler. Included in the sale were likewise four gate-houses, in Palace-road and Paris-street, suitable for manager, clerks, and foreman, estimated together to be worth 145*l*. per annum. The property was stated to be held upon lease for a term of sixty-five years from June, 1844, at a ground-rent of 375*l*. per annum, and estimated to be of the net annual value, after deducting ground-rent, of 469*l*. The first offer made for the property was 3,000*l*., and by advances of 100*l*. at each bidding it was brought up to 3,800*l*., at which it was sold, it being stated in the room that it had been purchased by a firm connected with the building trade, by whom it would in future be carried on.

The several dwelling-houses in Palace-road were offered in thirteen lots. They were stated to be held on lease for a term of seventy-seven years from June, 1831, at an aggregate ground-rent of 115*l*., the ground-rent of each house being 9*l*. a year, with the exception of one of the houses, the ground-rent of which was 7*l*. a year. The rents of the several houses, all of which are let on yearly tenancies, range from 41*l*. to 46*l*. a year each, the aggregate annual rental being 531*l*. 4*s*. They realised prices varying from 460*l*. to 570*l*. each, fetching altogether 6,136*l*., the total amount realised by the whole of the property, including the builders' business premises, being 9,936*l*.

DEEDS AND TITLES OF LAND.

Sir Robert R. Torrens read a paper before the Jurisprudence Department of the Social Science Congress at Edinburgh, on the 8th inst., on the question, "Is it expedient that there should be one system of registration of deeds or of titles of land for the United Kingdom, on the basis of the system presently in operation in Scotland or on any other?" He said the benefits of the system in Australia had been that, through its operation, a saving of 19*s*. in the pound sterling had been effected in the cost of conveyancing. The wealth of the community had been increased by restoring to its intrinsic value as building sites land which, deprived of that special character by imperfect evidence and technical defects in title, lay waste and unprofitable. In answering the question how it came to pass that hitherto all attempts to apply this system to the lands of this country had completely failed, though taken in hand by three Lord Chancellors, he stated that the permissive use of deeds granted under the 63rd section of Lord Westbury's Act involved a combination of two incompatible principles,—"registration of deeds" and "registration of titles,"—producing a hybrid, unworkable measure. Lord Currie's Act was to some extent open to the same objections; but even if free from other defects, the result of giving nominally to the proprietor, but practically to his solicitor, the option to place land under the system, and the power to withdraw it again from that system, was in itself sufficient to ensure its failure, as had been demonstrated in the case of the Irish Act. It would be difficult, not to say impossible, to imagine conditions more favourable for introducing the system of conveyancing by registration of titles than those which existed in Ireland. But, unfortunately, the legal gentlemen who undertook to revise his Bill of 1863, preparatory to its re-introduction in the following session, deemed it politic, in order to propitiate Lord Westbury, and induce him to undertake the carriage of it through the House of Lords, to import into it certain provisions of his own measure, which were antagonistic to the principle of registration of titles, and his remonstrances were ignored.

Mr. R. Denny Urlin, of the Middle Temple, barrister, F.S.S., next read a paper on the same subject, in which he stated that the system of registration of title has several distinct advantages of its own; and it has been tried, though under heavy disadvantages, both in England and Ireland. Professional dislike led to the virtual rejection of a measure which was only optional; and only a few hundred titles are on the record of ownership. Still, the problem has been solved; for contracts can be made and completed within an hour, and dealings with the few estates on the record are enormously simplified.

NEW PUBLIC BATHS FOR LONGTON.

The foundation-stone of new public baths for Longton, Staffordshire, was laid on the 7th inst. by the mayor (Mr. George Bennion). The buildings are being erected on a site belonging to the Corporation, situated near the railway station, from plans prepared by Mr. Arden Hardwicke, C.E., the borough engineer, there apparently being ample provision made to insure convenience of arrangement in the many requisite sections of the building. While disposed not to lavish money in mere ornamentation, the Corporation wisely determined that the new baths should not be altogether devoid of exterior ornament. The style of the building is Gothic. There will be two main entrances, one for ladies and one for gentlemen, with a central ticket-office. The section devoted to gentlemen's warm baths will contain a number of both warm and vapour baths, and will have a large waiting-room attached. The dimensions of this part of the building are 38 ft. by 22 ft. There will also be a second-class bath-room, 30 ft. by 20 ft.; and it will be fitted up with eight baths. Provision is made for three swimming-baths, two for gentlemen and one for ladies. The first-class bath will be 70 ft. long by 30 ft. wide. It will be lined with white glazed bricks, fitted up with good dressing-apartments, and have a gallery, a diving platform being also provided at the deep-water end. The second-class swimming-bath will be of smaller area, 56 ft. by 30 ft., and it will be fitted up with all necessary conveniences. The ladies' swimming-bath will be 22 ft. by 17 ft.; and will be well fitted up, suitable dressing-rooms being provided. The roofs of the swimming-baths will be lighted from above by Shelley's patent system of glazing. Warm baths for ladies will be provided, and will be approached from the left of the entrance to the ladies' section of the building, and branching from the main entrance on their side. A waiting-room will be attached, and the baths will be of two classes, warm and vapour. The general Turkish baths will be on the first floor, over the ladies' section of the building, and will be suitably divided into compartments, the heating being done by a convoluted stove placed in the basement. The boiler-house will be situated in the rear of the main building, and will contain two powerful boilers, while the laundry will be fitted up with a six-horse power engine and have all requisite washing-machinery. The general work in this department will be done by Messrs. Bradford & Co., of Salford, under contract, for 750*l*. The tank-room is situated above the laundry, and will contain three large tanks. The superintendent's apartments will be on the first floor; and will be convenient in arrangement and fitting up. The builders are Messrs. H. & R. Inskip, of Longton, the amount of whose contract is 5,900*l*.

CHRISTMAS CARDS COMPETITION.

The offer of 500*l*., in fourteen premiums, made by Mr. Raphael Tuck for the best designs for Christmas and New Year cards, and the evidences of good faith given by the appointment of three well-respected artists as judges, led to the submission of a large number of designs; 925 frames are hung in the Dudley Gallery, many of them containing four designs each, and the large majority exhibiting a fair degree of skill. The decision has just now been announced, and it will be seen that the ladies have carried all before them, having taken eleven out of the fourteen prizes. The following is the list:—First prize, 100*l*., Alice Squires; second, 75*l*., Herbert Allobin; third, two of 50*l*. each, Harriet M. Bennet and Patty Townsend; fourth, five of 25*l*. each, Ellen J. Miles, Mary S. Story, R. J. Abraham, Mrs. Koberwein Terrell, and Rebecca Coleman; fifth, five of 20*l*. each, Marian Croft, Miss Balfour, Elizabeth B. Bayley, Geo. Clausen, and Kate Sadler.

THE BIRKDALE SEWERAGE WORKS.

The Birkdale Sewerage Works, which have been in course of construction since 1875, have just been formally opened by Mr. F. Hillé, the inventor and patentee of the system.

The Local Board did not determine upon Mr. Hillé's system before they had visited various towns where different ones were in operation, and were convinced that it was suitable. It was shown at the time that at Edmonton, at Tottenham, Windsor, and other towns, the process worked satisfactorily. The system consists mainly of two parts,—first, chemical treatment; and, secondly, filtration either artificial or through land. Chemical treatment has for its object the precipitation of all the suspended matter contained in the sewage and of whatever smaller proportion of the matter is held in solution. The liquid resulting from chemical treatment, commonly known as the effluent, is either discharged directly into the river or sea, or it is turned upon land for further purification. Where there are large rivers the effluent may be discharged directly from the depositing-tanks; but in the case of simple watercourses or streams chemical treatment is always desirable, so that the treated sewage may in no way be injurious either to vegetable or animal life.

The Birkdale Sewerage Works are situated at the top of Aughton-road, at the junction of the latter with Chatham-road. The sewage enters the works through screening-chambers, and from them into an underground reservoir, which will hold 500,000 gallons of sewage. From this

reservoir the sewage is condnoted into a pnmping-well, where it receives tbe chemicals, and is lifted by two ten-borse power engines into two depositing-tanks with a capacity of 370,000 gallons. From the depositing-tanks, after precipitation has taken place, the effluent, or purified sewage, passes on to filter-beds an acre and three-quarters in extent, which are divided into five separate beds that will be used in rotation, so as to insnre complete aëration or oxydation. Previonsly to the chemicals being sent into the pnmping-well they are mixed in tbe mixing-pan, whence they are delivered into two mixing-cylinders fitted with agitators, and thence pass into tbe well named. All the treated sewage before being discharged into the brook is passed over the filtering-beds. The extent of the gronnd covered by the seworage works approacbes five acres. The engineer is Mr. Fairbairn.

SMOKELESS TOWNS.

Sir,—May I offer a snggestion? To prevent tbe smoke of domestic coal poisoning tbe atmosphere is very desirable, and I venture to snbmit to yon that any row of bonses might be so altered as to the chimney ontlet, although new streets built to this plan would be mucb better, that all the smoke could enter a common flne leading to an exhausting fan and a fire. The fan should be so constrncted as to compel all the smoke arriving at tbat end of tbe horizontal flne to pass throngh a furnace and be destroyed. An engine would be required to work the fan, which might be utilised in another manner, namely, snpplying the electric light to all the houses. Large blocks of workmen's dwellings might be easily constructed on this plan, and the common flne might be so arranged as to give warmth to the building. This would effectually cnre smoky cbimneys, and would also ventilate every room wberein a grate was placed, if the inlet of the chimney remained open. The fire would also be nsefnl if made to consnme vegetable refuse, and possibly many otber valnable services could be found for it. Of conrse the furnace would be fed with a smokeless coal so as not to be in itself a nuisance, and the engine could supply power to the bonses for coal-lifts, dinner-lifts, &c.

Sunshine.

HOW PARISH AWARDS ARE TAKEN CARE OF.

Sir,—Whilst engaged in surveying an estate the other day, we had occasion to refer to the parish award, and accordingly sought out the clerk, to gain admission to the church, expecting to find the award there. He, however, informed us that the parson had it at the Vicarage. We therefore called on the worthy vicar, who most affably produced the award, and said he regretted he could not show us the plan which should accompany it, as he had lent the same for a few days to a man at the other end of the village, to make a tracing of it. Bidding the vicar "Good day," we went in search of the plan, which we found at the house of tbe man to whom it bad been lent, *nailed* to a table, to enable him to make bis tracing. The plan was evidently a most carefully prepared one, and certainly deserved better treatment.

Surely such plans and awards should be kept with more care, and as far as possible free from tbe danger of fire, &c., and not be lent promiscuously to any one who may think fit to borrow and take them off the premises of the person who has charge of tbem.

Maughan & Cuxson.

A HINT TO THE MIDLAND RAILWAY COMPANY.

Sir,—In a recent article in the *Builder*, headed "The Wreck of the Scotch Express," it is stated, "The London and North-Western, the Great Northern, and Midland Railways have twelve tracks of rails for more than twenty miles out of London," but although the two former have four tracks each out of London, the Midland Company have only two, making a total of ten instead of twelve. The travelling public have a very great deal to thank the Midland Railway Company for, and I have often been surprised that the Company do not do more for their local traffic between Luton and St. Alban's and London than they have done. If four tracks of rails were laid down as far as Luton or Bedford, it would give the Company a chance to keep their local trains more punctual, for it is a notorious fact that scarcely any of their local trains from Luton to London are ever in proper time, especially those in the early morning, which are used largely by business men. At several places down their line some large plots of building land have recently come into the market, and the Midland Railway Company would reap a great deal of benefit if they provided punctual accommodation to London from Luton and St. Alban's in the morning.

A Traveller.

ROAD FORMATION AND STREET PAVEMENTS.

Sir,—As the patentee of the asphaltic wood pavement referred to in your issue of the 9th inst., and in the letter signed "Fact," I trust you will allow me to point out that your letter correspondent might have stated his "facts" more clearly, at least one of them being misstated. In order to correct which, I may say that I am informed the Asphaltic Wood Pavement Company have laid in London over 85,000 yards on that system, and, I believe, 35,000 yards is a near approximation to that laid on Henson's system, making a total of about 120,000 yards on those systems, and not 10,000 yards, as stated by "Fact": thus showing the opinion of the authorities, though in a different manner to that he conveyed. This will be more evident when it is known that of the 200,000 yards, which I will take as correctly representing the quantity of wood pavement laid direct on concrete, a very large proportion (I believe, about 150,000 yards) was originally laid by the Improved Wood Pavement Company on their plank system, which has proved such a costly and utter failure as to rapidly require entire renewal; and, therefore, they have under their maintenance contracts relaid the greater part with wood blocks placed direct on concrete.

Now, as to the "fanciful bedding of felt or asphalte." It is acknowledged that the foundation forms the true road, the surface blocks in all systems being a mere covering to afford a foothold, and protect the foundation from the impact of, and loss by attrition from, the traffic. We have also to deal with the following facts, which do not seem to be clearly appreciated by your correspondent of last week:—1st. That the disintegration of the foundation in wood, as well as stone pavements, is due to the direct pounding action of detached or imperfectly connected blocks, assisted by the access of surface water. 2nd. That the cost of wood pavements is largely influenced by the proportion of timber employed, and as the price of suitable timber will continue to rise with an increased demand,—the supply being limited,—such pavement as requires the smallest proportion in original construction and renewals will always be the cheapest. The asphaltic wood pavement was designed entirely with a view to meet those conditions, and by the adoption of the impervious layer of asphalte the concrete is thoroughly protected from surface water, a less depth of foundation is thereby required, still retaining equal solidity. As regards economy in timber,—with wood paving generally, as with stone, a deep block is essential to stability; but in the above system the blocks are firmly held down to the asphalte layer, and agglutinated to each other by the asphalte, which is run half-way up the joints, and also enters the auger-holes, which should in all cases be bored in each, thus producing a compact parquet-like slab, extending from curb to curb, the strains from passing loads being in turn shared by neighbouring blocks, and transmitted to a largely-extended area of foundation, the result being that, whereas in other systems the block requires renewal when worn to within about 4 in. in depth, it is possible with the asphaltic wood pavement to wear them to within 2 in., or even 1½ in. of the base, without imparing their solidity. Blocks at least 2 in. shallower than are now employed in this country are thus sufficient for the requirements of the traffic.

The above are "*not the assertions made by any theoretical problems, but the actual experience*" obtained with the pavement, as laid over five years, under my foreign patents, in the streets of a Continental seaport town, over which a traffic passes from the shipping equal to the traffic of most average London thoroughfares. The following was the section:—concrete, 4½ in.; asphalte, ½ in.; sound red pine blocks, 3½ in. deep and 7 in. by 2½ in. on the surface, each block having two auger-holes bored to the depth of ½ in. near the base. The joints were run up half-way with heated asphalte, the remainder coarsely grouted. It has been in constant use to the present without repair, and is still in good condition, though the adjacent stone pitching has been thrice re-laid in the interval. The same section has been over twelve months in use for tramway traffic, and at the same time blocks only 2½ in. deep with ½ in. asphalte and 3 in. of concrete, were laid for light street traffic similar to that of most London squares. Both are in excellent condition, and there is every reason to expect continued good results.

It is unnecessary to remark that in this country the above sections should suffice for similar conditions of traffic, &c. That for very heavy traffic the depth of block need not exceed 4 in., with ½ in. of asphalte and 5 in. of concrete. That, far from being costly, all are cheaper than that advocated by "Fact," while retaining equal durability. Also, that the first cost of the shallower section is but little in excess of good macadam, whereas the annual cost of maintenance and cleansing would be considerably less.

In conclusion, I may add that it is evident from the facts I have adduced, an unnecessary quantity of concrete is required on the system advocated by your correspondent, and an average of about 30 per cent. of timber wasted, which might be saved by the judicious use of asphaltic wood pavement. That the cost of wood pavement is, therefore, generally about 2s. per square yard higher than is necessary for equal durability. And that, notwithstanding "Fact's" assertion that the asphaltic wood pavement is costly, it is capable of even more economic results than those contained in the table of your correspondent, to which he takes objection; for if the sections indicated above were generally adopted, a saving to the ratepayers of about 15 per cent. in the present cost of wood pavement would be effected, and for every three miles now paved with a given quantity of timber, about four miles could be paved in an equally serviceable manner.

Henry S. Copland, C.E.

Balsall Heath.—The new Church of St. Thomas-in-the-Moor, Balsall Heath, has just had its east window filled with stained glass. The principal subject, occupying three lights, is the Ascension. There are two minor subjects: on the right our Lord restores to health Peter's wife's mother, and on the left He gives sight to the blind. The window has been erected in memory of Mr Edward Townsend Cox and his wife, by their son, Mr. W. Sands Cox. It was designed and executed by Messrs. Camm Bros., of Smethwick.

ROYAL INSTITUTE OF BRITISH ARCHITECTS.

The first ordinary meeting of the new session will be held on Monday evening next, the 1st of November.

The usual certificates will be presented to Messrs. Gass, Goldsmith, Johnson, Kemp, Marvin, and Summers, passed candidates in the class of proficiency at the voluntary architectural examination, 1880. Afterwards the opening address of the session will be delivered by Mr. John Whichcord, F.S.A., president.

A special general meeting of members only will be held at the close of the ordinary meeting to elect an honorary secretary in place of the late Mr. Thomas Henry Wyatt, and Mr. John Macvicar Anderson, member of council, will be proposed as a fit and proper person to fill the office.

A voluntary examination in the class of proficiency will be held on the 14th, 15th, 16th, and 17th of June, 1881. All candidates will be required to go through the examination, as a whole, in both the scientific and artistic sections; but those who have previously passed in one section will be permitted in 1881 to offer themselves for examination in the other section.

CHURCH-BUILDING NEWS.

Swynbridge.—The parish church of Swynbridge, near Barnstaple, was re-opened on the 21st ult., after restoration. The church consists of nave, chancel, north and south aisles, south chancel aisle, north transept, vestry, with priests' chamber over it, porch, and tower containing a peal of five bells. The church dates from about 1460, with the exception of the tower, which is fourteenth-century work. Before the restoration an unsightly gallery crossed the west end of the church, completely blocking up the arch opening into the tower; this has been removed. The font has been removed from the second pillar on the north side to its present position, and the paint has been taken off, thereby showing the carving more plainly. The pulpit occupies the same place as formerly. The whole of the nave, aisles, chancel, and transept were blocked up with old-fashioned deal pews. These have been removed, and open sittings have taken their place. The benches are carved after the pattern of the old ones, some of which were found doing duty as props to the deal seats. The old carved benches that were found have been put together again, and once more occupy their proper position. The tiles in the chancel are encaustic, supplied by Godwin, of Lugwardine. When the plaster was removed from the east end wall of the transept, a piscina was laid bare, believed to have been that of a chapel dedicated to St. Bridget. The whole of the works have been carried out by Mr. Jonathan Marshall, of Plymouth, with the exception of the stalls in the chancel, which are the work of Mr. Robinson, London. The total cost of restoration (exclusive of the chancel, which is being done by the Ecclesiastical Commissioners) is 2,600*l.*

Chideock (*Dorset*).—On the 29th ult. the parish church of Chideock was re-opened, after restoration, which appears to have been much needed, the building having been allowed by neglect to get into a very dilapidated condition. Several of the heavy timbers in the south aisle roof were found to be completely rotten at the ends, and as soon as the lead was removed fell in of their own weight, showing that instead of supporting they were actually supported by the lead roofing, which, happily, was deeply embedded in the walls. The east and west walls of the transept were also very much decayed and out of the perpendicular, and an unsightly beam had been substituted for the transeptal arch. The restoration has included the removal of the gallery, the complete reparation of the belfry, the rebuilding of the north wall of the nave, and east and west walls of the transept, the insertion in the former of two new Perpendicular windows, the re-roofing, reflooring, and re-glazing of the entire church, covering the south aisle roof with new lead, laying a six-inch bed of concrete beneath the new wooden floor and providing for ventilation between the concrete and the wood, the building of the new transeptal, chancel, and side arches, with supporting buttress outside the south wall, fresh mortaring of the interior, and pointing and renewing the decayed stonework of the exterior, at a total cost of about 1,100*l.* The work has been done under

the direction of Mr. G. R. Crickmay, of Weymouth, the diocesan surveyor. One of Porritt's stoves has been adopted for heating purposes. Mr. Jno. Beer, of Wareham, has carried out the works. The stained-glass windows are by Messrs. Lavers, Barrand, & Westlake.

Banbury.—On the 29th ult. the new tower of Christ Church was dedicated by the Bishop of Oxford. The tower has been built, at a cost of 1,200*l.*, of Gibraltar stone, with dressings of Corsham Down Bath stone, and rises to a height of upwards of 80 ft. from the ground. The architects were Messrs. B. & E. B. Ferrey, of London, and the builder was Mr. Franklin, of Deddington.

Heythrop.—On the 28th ult. the Bishop of Oxford consecrated the new church just erected in Heythrop Park by Mr. Albert Brassey, the owner of the Heythrop Estate. The church, which is dedicated to St. Nicholas, consists of a nave and south aisle, with a tower forming a porch at the west end of the aisle, a chancel with an organ-chamber on the south, and a vestry on the north. It is built partly of the materials of the Roman Catholic chapel which formerly stood near the house, and partly of new stone from the quarry on the estate. Milton stone has been used where a material of finer and more even quality was required for carving, &c. The general dimensions of the building are as follow:—Nave, length 50 ft., width 22 ft. 4 in.; chancel, length 30 ft., width 20 ft.; height of tower, 94 ft. There is accommodation for from 180 to 190 persons. The roofs are of pitch pine throughout, and covered with Broseley tiles. The chancel and sanctuary are floored with a pavement of Italian marble mosaic by Messrs. Burke, of Newman-street. The stained glass in the east window is by Messrs. Burlison & Grylls, who have also executed the cartoon for the mosaic with which it is intended to fill the large panel over the altar; it is a representation of the Last Supper. The glazing, of three tints of cathedral glass, for the rest of the windows in the church is by Messrs. Brown & Boreham. The chancel seats, the altar, and pulpit, which are of oak and walnut, and the vestry screen of oak, were executed by the contractor, Mr. A. Groves, of Milton-under-Wychwood, who has carried out the whole of the works. The clerk of the works was Mr. Calloway, of Heythrop; and the foreman of works was Mr. Jos. Buckingham. The carving is by Mr. T. Earp, of Lambeth. In the tower are hung three bells by Mr. T. C. Lewis, of Brixton. The church is heated from a chamber under the vestry by Grundy's hot-air system. The style of the building is Decorated. The architect is Mr. A. W. Blomfield, M.A.

Rawtenstall.—In the Manchester Consistory Court, on the 1st inst., the Rev. James Norris, vicar of St. Mary's, Rawtenstall, applied for a faculty to take down the tower of the church, extend the church westward, increase the number of sittings, extend the chancel, construct a new vestry, and to make other alterations specified. It was stated that the cost of the proposed improvements would be 2,310*l.* A citation for the alterations was decreed.

Brynamman, Carmarthenshire.—The foundation-stone of the new church about to be built for the 200 seceders from the Welsh Congregationalists' communion was laid on the 7th inst. The new building will consist of a nave, 55 ft. by 25 ft., 18 ft. high to the plate, and 36 ft. to the ridge, the pitch-pine roof being open all the way up, and plastered between the rafters, the principals arched and supported on Bath stone moulded corbels; a chancel, 26 ft. by 16 ft., with arched, ribbed, and boarded ceiling; a vestry, with heating-vault below, and organ-chamber; also a porch, vestibule, and baptistery arranged side by side, forming a kind of narthex at the west end, which will have a suitable bell-turret above. The walls are to be built of local stone, with Westwood Ground dressings, and the roofs covered with grey Whitland Abbey slates. The pitch-pine seats will be of open description, on wooden platforms, the passages and chancels being laid with encaustic tiles. The whole outlay will be 1,500*l.*, the number of sittings provided being 300. The architect is Mr. E. H. Lingen-Barker; and the contractors are Messrs. Balcombe & Price, of Pembroke Dock.

Tamworth.—The committee for the restoration of St. Paul's Church have decided to get estimates from the architect, Mr. Basil Champneys, for the north and south-west windows, and for the three north aisle windows, and the preference has been given to local tradesmen.

Birmingham.—St. Asaph's Church, Birmingham, has been re-opened, after re-decoration by Mr. Heritage, of Marshall-street. The organ has been removed from the west gallery to the floor of the church, near the choir, and fifty-four pipes have been added to it.

Newcastle-on-Tyne.—It has been resolved to carry out certain alterations in St. Thomas's Church as soon as funds come in. It is intended to remove the present high pews, and to replace them by open oak seats, the cost of which, according to the tender of Mr. James Gibson, builder, will be 423*l.* It was also resolved to remove the glass from the great east window of the church, it being seriously out of repair, and to replace it by a new stained glass window, to commemorate the connexion of the Rev. Richd. Clayton with the church. The cost of the whole contemplated improvements is estimated at 950*l.* The work will be carried out under the direction of Mr. Arthur Gibson, architect.

Ipswich.—St. Clement's Church, Ipswich, was re-opened on the 7th inst., after alteration and redecoration. Altogether about 200*l.* has been spent, Messrs. J. B. & F. Bennett having done the builders' work, and Messrs. Stearn & Sons the painters' work.

Bathford.—The new tower of Bathford Church was opened on Michaelmas Day. It is the gift of Mr. H. D. Skrine, who some years ago built the north aisle. The former tower, built by Mr. Newman, the father of the builder of the present one, was of small dimensions, and intended to suit the conditions of low-pitched roofs, and a church of smaller area than the one since enlarged by the addition of a north aisle and other extensions with higher gabled roofs. The new tower is of much larger area on plan than that which it has displaced, and considerably higher, the style being that of the date of the chancel and other fragments of stonework discovered in taking down the old north wall of the nave, and which were of the Decorated period. The new tower consists of three stages in height of local freestone, the ornamentation being chiefly confined to the upper stage, which is pierced with large window-openings and crested by an open-work stone parapet with pinnacles at the angles, the south-west angle having a stone projecting staircase surmounted by a turret of considerably greater bulk and height than the other pinnacles, having a metal corona and weathercock on the summit of its spire. The tower is designed of sufficient height to allow of the nave roof being raised in the event of a clearstory being added. The former small bells have been exchanged for a new peal, furnished by Messrs. Warner & Sons, of London. On the west front is a canopied and crocketed niche containing a statue of St. Swithin, nearly life-size, and on the same front the arms and crest of the donor, Mr. H. D. Skrine. The carving and figure are by Boulton, of Cheltenham. The architect is Mr. Preedy, of London, who carried out the restorations of the church at two former periods. The builder is Mr. W. H. Newman, of Bathford.

DISSENTING CHURCH BUILDING NEWS.

Abergele.—A new Wesleyan chapel was opened here on the 26th ult. The architect was Mr. Richard Davies, Bangor, the contract being undertaken by Mr. James Copping, Abergele, for 2,600*l.* The new building, Renaissance in style, occupies a site at the junction of St. George's-road with Bridge-street, and provides accommodation for 500 worshippers. The entire cost of erection, &c., will not fall much short of 3,000*l.*

Low Fell.—The foundation-stone of a Primitive Methodist chapel and school was laid on the 25th ult. at Low Fell. The estimated cost of the building represented by the plans is 1,000*l.*, but it has been decided only to proceed with the chapel and the shell of the school at present, an arrangement which will only necessitate the expenditure of about 600*l.*

Wraysbury.—The Baptist chapel at Wraysbury has been re-opened, after alterations which have cost 450*l.* A tower and spire, in which is a three-faced clock, was the gift of Mr. Virgoe Buckland. Above the door in the tower is a bas-relief in terra cotta, by Tinworth, the subject being "The City of Refuge." This panel was the gift of Messrs. Doulton, of Lambeth.

Halifax.—St. John's Wesleyan Chapel, Halifax, which has cost 17,000*l.* or 18,000*l.* in erection, was opened on the 1st inst. The block of buildings comprises vestries and schools in rear of the chapel. On plan the chapel consists of a nave and aisles, without chancel. The principal front is to the north, and faces the junction of Prescott-street with St. John's-lane. The narthex, or porch, which is 12 ft. high, is entered by three arches springing from clustered columns. On either side is the octagonal base of the lofty pinnacles that form a leading feature in the design. A two-light window opens into the north side of each aisle. Over the heads of the arches to the porch runs a richly-decorated band of carved work. In the centre of the gable is placed the great seven-light window, its head filled in with rich tracery work of the Perpendicular period. A cluster of pinnacles finishes the gable end, and rises to a height of 50 ft. The two flanking pinnacles break into rich arcading after leaving the spring of the gable. They rise to a height of 57 ft., and are elaborately crocketed and carved. Internally the length is 77 ft. 4 in.; breadth, 50 ft. 8 in.; and height from floor to apex of roof, 42 ft. The aisles are divided from the nave by arcades of three bays each, the shafts being monoliths of polished Aberdeen granite, cylindrical in form, 8 ft. 3 in. in length, resting on octagonal bases of fine millstone grit, each base being 3 ft. 6 in. high. They stand clear of the seating. The spring of the transept arches is marked by the granite shaft being doubled, but each coupled shaft is in one piece. All the capitals are circular. The arches are equilateral. The span of each arch in the nave is 16 ft. 4 in. from centre to centre; while the transept arches are 24 ft. wide. Each of the eleven principals of the nave roof is filled in with Perpendicular tracery. The roofs to the aisles are sloped. All are in pitch pine, as are also the gallery fronts. The seats are low, open ones, with moulded tops. They are cushioned in dark crimson, supplied by Messrs. Jones & Willis, of Birmingham. Altogether there is accommodation for 800 or 900 worshippers. The windows are filled in with cathedral tinted glass. The gasfittings have been supplied by the Architectural Metal Works, Coventry. The pulpit is in Caen stone, octagonal in form, and richly worked upon every panel. It has been executed, from designs by the architect, by Messrs. Thompson, of Peterborough. The whole of the lofty wall space over the pulpit has been decorated in colour by Messrs. Powell, of London and Leeds. Neutral tints prevail. Five large recesses are formed, in four of which are inscribed the Lord's Prayer, the Creed, and the Commandments, the central space being filled up with a richly-floriated design. The wheel-window above has been filled in with stained glass, also by Messrs. Powell. The large openings in it are filled in respectively with the Calling of the infant Samuel, Solomon dedicating the Temple, our Lord blessing little children, and St. Paul preaching. The heating apparatus throughout chapel and schools has been supplied by Mr. Naylor. Mr. Henry Wilson has been the clerk of the works, and the following have been the contractors:—Mason, Mr. Jenkinson, Halifax; joiner, Mr. Townsend; plumber, Mr. Naylor; slater, Mr. Firth, West Parade; painters, Messrs. W. Lee & Son; ironwork, Messrs. Hirst Brothers. The architect is Mr. W. S. Barber, of Halifax. The organ in South Parade chapel is now in course of re-construction by Messrs. Forster & Andrews, of Hull, and will be placed in the new chapel in course of a few weeks. It is to be placed in a new case, designed by Mr. Barber, and the cost of its alteration and extension will be 600*l.*

West Hartlepool.—A new Wesleyan Chapel has been commenced here. The site is at the corner of Frederick-street and Corporation-road. The design is semi-Gothic, and the structure will be of red brick with stone facings, the aggregate accommodation being for about 600 persons. The total cost is estimated at 850*l.* Mr. Garry, of West Hartlepool, is the architect, and Messrs. Curry & Tuke are the general contractors.

Hereford.—Memorial stones of the new Baptist Chapel in Commercial-road, Hereford, were laid on the 27th ult. Accommodation is to be provided on the ground-floor for 400 persons, and on the gallery-floor for an additional 250 persons, making a total of 650 sittings, for each of which 20 in. are allowed. The façade is to be executed in purpose-made white bricks with Beer (Devonshire) freestone dressings. The style of architecture adopted is Italian, treated with simplicity. The amount of the contract is 2,665*l.*, and the work is being carried out by Mr. William Bowers, of Hereford, under the superintendence of his foreman, Mr. Henry Williams, and the clerk of the works, Mr. Lloyd,

from the designs and under the direction of Mr. John Johnson and Mr. George Cowley Haddon, joint architects.

ROMAN CATHOLIC CHURCH BUILDING NEWS.

Maidstone.—The new Roman Catholic church in Week-street was opened for worship on the 4th inst. The plan consists of a nave with aisles at each side, about 60 ft. long, and together about 42 ft. wide, and a chancel, side chapel, organ chamber, and sacristy, 25 ft. long and together 40 ft. wide, the end of the chancel being apsidal. A tower, which forms one of the entrance porches, is attached to the western-most bay of the south aisle, and another porch at the west end of the north aisle. The style adopted is Geometrical Decorated, the building being constructed of red bricks, with Bath stone bands and dressings. The west end of nave contains a large four-light window, with deeply-recessed jambs. The tower has an entrance doorway, deeply recessed. Over this doorway is a recessed niche, in which is placed a statue of St. Francis of Assisi, the patron saint of the church. At a height of about 30 ft. from the ground, the tower, which is square to that height, is formed into an octagon-turret with bold broaches at the junctions; the spire springs from this turret, the total height being about 100 ft. The chancel is not yet erected. Internally the nave is separated from the aisles by lofty arcades of four arches each, springing from massive columns, with carved capitals, and the chancel arch and arches at each end of the aisles correspond. The roof is constructed of pitch pine throughout, and consists of raised tie-beam queen-post trusses, with arched braces and struts, and wall-pieces springing from stone corbels; it is match-boarded under the common rafters and collars, which boarding is perforated in ornamental patterns for ventilation, and formed into panels by moulded ribs placed over them. The floors of the passages, &c., are laid with Wilkinson's polished concrete, with Maw's glazed encaustic tile borders. The windows are glazed with cathedral glass of various tints, arranged in patterns. The altar and reredos are of Caen stone, of simple design. Mr. J. G. Naylar, of Rochester, has been the builder employed, and Mr. Boulton, of Cheltenham, has executed the carving, except the altar, which is the work of Messrs. Vaughan, of Maidstone. Mr. E. Hill has acted as clerk of the works, and Mr. Thomas Cramp as contractor's foreman. The buildings have been designed by and carried out under the superintendence of Mr. C. G. Wray, architect.

Salford.—The new Church of Our Lady of Mount Carmel, Oldfield-road, Salford, was opened on the 29th ult. The church has been built in the Early English style, Mr. S. Harrison, of Prestwich, being the architect, and Messrs. Healey & Sons the contractors. The building, the total length of which is 128 ft. by 42 ft., gives accommodation for 700 worshippers. The structure is of brick, with stone and terra-cotta facings.

New Brighton.—The foundation-stone of the Church of SS. Peter and Paul, to be erected at the corner of Hope-street and Rowson-street, New Brighton, was solemnly blessed on the 29th ult., by the Rev. Dr. Knight. The plans, which have been prepared by Mr. Edmund Kirby, architect, Liverpool, include nave, porch, gallery, chancel, side chapels, and sacristy. The length is about 85 ft., and the width about 35 ft. The style adopted is Early English, in brickwork, with stone dressings.

York.—The Lady-chapel of St. Wilfrid's Church has just been decorated, from the designs of Messrs. Goldie, Child, & Goldie, architects, London. The decorations have been executed by Mr. Knowles, ecclesiastical decorator, Stonegate.

Walton-le-Dale. — On the 10th inst. a new church at Walton-le-Dale was opened by the Rev. Dr. Hedley, O.S.B. It consists of nave, chancel, side-chapels, and aisles, and the style is that of the Early Decorated period. It is built with hollow walls, the inside being of bricks, the outside faced with Yorkshire parpoints. The whole of the dressings, both exterior and interior, are of Stourton stone. The total length is 96 ft., the width across nave and aisles 53 ft., and the height to ridge is 52 ft. It has been erected from the designs of Messrs. Pugin & Pugin, by Mr. W. Hothersall, contractor, of Preston. It will accommodate over 500 people. The amount of the contract, including benches, was 5,223*l.* The altar and marble floor in the chancel have been executed from the designs of the architects by Mr. Isaac Sherratt, sculptor, of Preston.

SCHOOL-BUILDING NEWS.

Plymouth.—The first portion of the new building of the Boys' High School in Ford Park, Plymouth, is approaching completion. The entire design comprises fifteen large class-rooms, each capable of accommodating twenty-seven boys; an assembly-hall, 40 ft. by 75 ft.; a library and headmaster's room, 40 ft. by 27 ft.; spacious principal and secondary stone staircases, board-room, assistant-masters' room, and pupils' day-room; commodious drill-shed, three excellent fives courts, and large workshops, or chemical laboratory; a residence for the headmaster, a serjeant's lodge, and a dining-hall with all necessary culinary offices. The portion now in progress contains eight class-rooms, six being to the north, and two to the south of the central front entrance; the library over the entrance-hall and the back wing containing the board-room, &c. Of this portion the central entrance-block and the two class-rooms to the south of it are as yet but slightly above the foundations. The principal front of the building faces the south-west, and consists of a central entrance projecting 4 ft., flanked by a two-storied façade containing twenty-four large mullioned and transomed windows, lighting twelve class-rooms. At the southern extremity will be the headmaster's residence, extending over a carriage archway, which unites it to the main building; and at the northern end will be the assembly-hall—standing at right angles—octagonal turrets rising up at the points of junction at both ends of the front, and also at the south-west angle of the assembly-hall. The external walls are faced with lime-stone and Portland stone throughout. The works are being executed by Messrs. Blatchford & Son, of Tavistock, under the superintendence of the architects, Messrs. Paull & Bonella, of London and Manchester. Mr. Siddell is clerk of the works.

Pinxton (Derbyshire).—New schools are in course of erection here. The ground-plan comprises a school-room 54 ft. by 25 ft. 6 in., with class-room 15 ft. by 15 ft., with two porches, affording accommodation for 200 children. The roofs are open, with framed principals, stained and varnished. The walls externally will be faced with common bricks, relieved with bands of stock bricks; also to arches of windows, weatherings to buttresses, &c., and internally with common bricks. The roof will be covered with Welsh slate and red Staffordshire ridge tiles. The cost of the work, exclusive of the fittings and boundary walls, is 550*l.* Mr. John Bird, of Pinxton, is the builder. Mr. John Lowe, of Manchester, is the architect.

Bilston.—The memorial-stones of a new Wesleyan Sunday and Day School building were laid on the 22nd ult. The school is to be a plain-built brick structure, 57 ft. by 26 ft. outside, and 33 ft. in height, the total cost of its erection being about 700*l.* Messrs. Hickman & Johnson are the builders.

Kimberley. — The foundation-stones of a Baptist School and Mission-room, in Victoria-street, Kimberley, have been laid. The school and mission-room will be a plain structure, and intended to accommodate about 100 persons. The buildings will be completed at a cost of 300*l.*

Ordsall.—On the 9th inst. the foundation-stone of new National Schools for the parish of St. Clement, Ordsall, was laid. The schools will cost 3,600*l.*, of which sum Lord Egerton, of Tatton, gives 2,500*l.* Mr. Lord, of Manchester, is the architect.

Wolverhampton. — On the 16th inst. the corner-stone of the Wolverhampton new Blue-coat School was laid by the Hon. Mrs. Maclagan. The new buildings, which will cost 3,500*l.*, were recently described in the *Builder* (see p. 340, *ante*). Mr. T. H. Fleeming, of Wolverhampton, is the architect, Mr. Lovatt being the builder.

Architecture in Modern Civilisation.—Among the lectures announced to be delivered during the approaching winter season at the London Institution is one on "The Prospects of Architecture in Modern Civilisation," by Mr. William Morris. The date fixed for this lecture is in March, 1881.

VARIORUM.

A REVISED edition of the "Ventilation of Dwelling-houses and the Utilisation of Waste Heat from Open Fire-places"; with a chapter on the "Country Parson's Grate," and other modern fire-places, by Frederick Edwards, junior, is about to be published by Messrs. Longmans, Green, & Co. —— "Picturesque Europe" is getting towards its end. It improves with age. No. 54, just now published, treats of Belgium, and contains a number of illustrations which may justly be called beautiful. The letterpress of the part, by Mr. Percy Fitzgerald, is bright and pleasant.——Mr. Wyld, geographer to the Queen, of Charing-cross, will shortly publish an elaborate map of the gold fields and gold reefs of Southern India.——The *Garden* treats of every branch of its subject in the most thorough manner, and is so planned as to be a cyclopædia of information on flower gardening, fruit culture, trees, shrubs, stove and greenhouse plants, indoor decoration with plants, room and window gardening, garden design, town and city gardens, and cultivation of all kinds, both for the supply of the private house and the markets with flowers, fruit, and vegetables. The coloured illustrations, of which one is given every week, and the many engravings, are beautiful and suggestive. This journal, with a view to make it more accessible to all classes interested in the subject of which it treats, is now reduced from sixpence to fourpence per week.——We have received the first number of Ward & Lock's "Universal Instructor, or Self-Culture for All." It is to be a complete encyclopædia of learning, meeting the requirements of students of all classes, and characterised by such features as will, the publishers believe, give it a superiority over every similar undertaking. It seems a little too much like in intention a similar work published by Cassell & Co., but there is room for both.——The current number of *The Quarterly* includes an exceedingly interesting article under the title "Art-Collections." It should be farther elaborated and printed separately.——The new series of "The Magazine of Art" is published in monthly parts, and is enlarged by the addition of eight pages to each monthly part, commencing with part 19, which forms the first part of volume III. of the work. With the additional space thus given, the editor has been able to add many fresh features of interest.

Miscellanea.

The North London Hospital for Consumption. — On Saturday last the Duke and Duchess of Connaught visited Hampstead, and took part in the ceremony of laying the foundation-stone of the middle block of the new hospital for consumption at Mount Vernon. The site is on nearly the highest part of Hampstead, and the style of architecture adopted for the buildings is that of the French Renaissance of the seventeenth century. In plan the hospital is a compact rectangular structure, about 163 ft. long by 55 ft. 6 in. deep, and is intended for 110 patients. The wards on the first floor will be for women, and those on the second floor for men. On each of these two floors a day-room 35 ft. long is provided, and on the sunny side of the building are open arcades. The building is being carried out in sections, and the carcass of the western section, which embraces more than one-third of the whole, is now completed, and progress is being made with the internal finishing. The architect is Mr. T. Roger Smith, and the builders are Messrs. Higgs & Hill, of Crown Works, Lambeth.

Society of House Decorators.—On Tuesday evening last the first annual tea, *soirée*, and ball were held in Cleveland Hall, Cleveland-street, under the auspices of the Amalgamated Society of House Decorators and Painters, to help in establishing the principle of a superannuation fund for aged and disabled workmen, painters and decorators. There was a large attendance. The chair was taken by Mr. G. Shipton, general secretary of the society, who, speaking (as a vice-president of the Trades Congress Parliamentary Committee of the United Kingdom) of the Employers' Liability Bill, said that he hoped the employers would meet them in a friendly spirit, and, by subscribing to a fund voluntarily provided to meet cases of accident, render, if possible, an appeal to the law unnecessary.

The Nottingham Corporation Sewage Farm.—On the 14th inst. a number of the members of Nottingham Town Council, with some of the chief officials, by invitation of the Sewage Farm Committee, paid a visit to the farm at Stoke Bardolph, on the banks of the Trent, between Carlton and Burton Joyce. In 1872, the Leen Valley District Sewerage Board was created under an Act of Parliament, and this body combined Nottingham with the upper districts of the Leen Valley for sewerage purposes, and gave power to execute whatever works were necessary for a united system to deal with the sewage. The first act of the Board was to complete the system of sewerage of the Leen Valley, which was done at a cost of about 50,000*l.*, the sewage being thereby intercepted throughout the whole of the valley of the Leen from the north end of Bulwell to the south end of Nottingham, and cast into the river along with that of Nottingham. The next operation was to deal with the sewage so collected, and, in 1875, Mr. Tarbotton, the engineer to the Board, made a report, in which he recommended that the whole of the sewage should be dealt with by irrigation. About this time the extension of the borough was determined upon, and in 1877 the functions of the Leen Sewerage Board were merged in the Nottingham Corporation, who undertook the completion of the works which had been designed and determined upon by their predecessors. These works consisted in the construction of a gravitation outfall sewer from Nottingham to the land selected by the late Board and approved of subsequently by the Town Council, at Stoke Bardolph. The works consist of an outfall sewer from Sneinton to Stoke. Into this outfall sewer the higher portions of the town deliver their sewage by gravitation, but the lower portions of the town will deliver their sewage into it by pumping, which will be carried out in the Eastcroft, dealing with the whole of the sewage brought down the Leen Valley from Bulwell and Nottingham. The sewage will, therefore, be brought partly by gravitation and partly by pumping into the main gravitation sewer, along which it will flow down to Stoke fields, the large outfall sewer having been constructed at a cost of 35,000*l.*, commencing at Sneinton, and passing through the Colwick hills by means of a tunnel, two miles long, at the eastern extremity, delivering its contents upon the land at Stoke. This land consists of 638 acres 22 perches of porous gravel soil. The cost of the works already executed has been 70,000*l.*, but a further expenditure of 30,000*l.* is contemplated. The whole of the sewage will not be dealt with for some time, as the disposal of manufacturers' refuse is causing much difficulty. The present contributing population is near upon 200,000.

Yorkshire Association of Medical Officers of Health.—The annual meeting of the above association was held at Sheffield on the 19th. There was in connexion with it an exhibition of sanitary appliances and other objects of special interest to members. Among them were models and drawings of the desiccator, concentrator, and carboniser, as used at Manchester and elsewhere. There was also a great variety of disinfectants, as manufactured by the Sanitas Company and others. Before the meeting the members visited the works of Messrs. Charles Cammell & Co., where they witnessed the rolling of an armour-plate; and the Union grinding-wheel. The general meeting of members was held in the Council Hall, and was presided over by Mr. S. W. North, of York. The annual report stated that the society now numbered sixty-seven members, and the committee earnestly desired that if possible the association should include the entire body of medical officers of health throughout the county. At the general meeting which was subsequently held, Dr. Hime read a paper on the recent outbreak of diarrhœa at Sheffield. Dr. Drew, of Chapeltown, read a paper on "Sanitation in Utopia," and Mr. Swann, the architect of the New Fever Hospital, explained the internal arrangements of that institution. The members dined together at the Wharncliffe Hotel.

Measures Bros. & Co. — Changes have been made in this firm (iron contractors and engineers) by mutual consent, and from the present date the business will be carried on in the London office, by R. J. & R. H. Measures, under the style of Measures Bros. & Co., as heretofore, and in the Manchester office by R. Swarbrick, as R. Swarbrick & Co.

Glasgow Sunday Society.—The meeting at Glasgow on the 25th inst. was large and enthusiastic, and the resolutions we have already printed were carried unanimously. Professor Tyndall, F.R.S., in the course of an elaborate and cogent presidential address, said: Sabbatical rigour has been tried, and the question is, have its results been so beneficent, so conducive to good morals and national happiness, as to render criminal our attempt to modify it? The advances made in all kinds of religious knowledge in this our day are enormous, and the public desire for instruction which the intellectual triumphs of the time inevitably arouses is commensurate with the growth of knowledge. Must this desire, I ask, which is the motive power of all healthy progress, be quenched or left unsatisfied, lest Sunday observances unknown to the Early Christians, repudiated by the heroes of the Reformation, and insisted upon for the first time during a period of national gloom and suffering in the seventeenth century, should be interfered with? Are we so much better than other nations, who have neglected to adopt our rules, that we can point to the working of these rules in the past as a conclusive reason for retaining them immovably in the future? The answer must be, no. My Sabbatarian friends, you have no ground to stand upon. I say friends, for I would far rather have you as friends than as enemies. You possess a strength and earnestness with which the world cannot dispense. But to be productive of anything permanently good that strength and earnestness must be built on the sure foundation of human nature. This is that law of the universe so often and so eloquently spoken of by your illustrious countryman, Mr. Carlyle, to quarrel with which is to provoke and precipitate ruin. Join with us, then, in our endeavours to turn our Sundays to better account. Back with your support the moderate and considerate demands of the Sunday Society, which scrupulously avoids interfering with the hours devoted by common consent to public worship. Open the museum, the picture-gallery, the library, the public garden as competitors to the public-houses. By so doing you will fall in with the spirit of your time, and row with instead of against the resistless current along which man is borne to his destiny. On the motion of Mr. Mark Judge, seconded by Professor Caird, a hearty vote of thanks was given to the Professor.——At a meeting of the London committee on Wednesday, a telegram was received from the Manchester Branch to the effect that it had been decided to again open the Royal Institution Exhibition on Sundays for a period of eight weeks, commencing November the 7th.

The Late Baron Visconti.—Baron Pietro Ercole Visconti, who died on the 11th inst., was for many years one of the most prominent fignres in the archæological world of Rome. He was great-nephew of the celebrated Ennio Quirino Visconti, and nephew of the architect of the same name. Among the more important discoveries made under Visconti's directions as Commissioner of Antiquities, the *Times* correspondent in Rome mentions the temple of Cybele and Atys and other valuable results of the extensive excavations at Ostia; the guard-house of the seventh cohort of the Vigiles, near the Basilica of Saint Chrysogono; that portion of the ancient quays on the banks of the Tiber where the marble was landed and many hundred blocks lie buried where they had been disembarked; some very important tombs and the long-lost Basilica of St. Stephen on the Latin Way; and the completion of the excavation and clearing of the Appian Way.

The Whitby Jet Trade.—The Whitby jet trade, which has been in a depressed state for so many years, is again looking up. According to *Capital and Labour*, when the bad times came the Whitby jet ornament trade was one of the first of the fancy industries to suffer, and the fashion or the taste for jet ornaments as articles of mourning changed. Jet, however, now appears to be coming into favour again, not only for mourning purposes, but for ordinary adornment. On inquiry it would appear that the increased demand is by no means confined to England, but extends over France and Germany. The chief exportations, however, are to America. A few years ago endeavours were made, by the distribution of prizes, for specimens of superior work to improve the artistic character of works in jet produced in Whitby. We are curious to know what effect, if any, the steps then taken had.

Foot-Bridges over Streets.—The Society for the Prevention of Street Accidents are pursuing very philanthropic ends, but we doubt whether they are very practical in their aims. They lately waited upon the Lord Mayor for the purpose of urging upon him the importance of placing bridges at points in different thoroughfares where the traffic is very dense. We think his Lordship took a very common-sense view of the matter placed before him, pointing out to the deputation that very few persons would take the trouble of mounting and descending twenty or thirty steps when they could walk across a street, even at some personal risk. The Lord Mayor might have drawn the attention of the society to the fact that such a foot-bridge was tried about ten years ago in the Broadway, New York, and had to be taken down again, for the simple reason that no one would use it. The society would greatly promote its humane intentions by looking more closely after the principal cause of street accidents, reckless driving. Drivers, as a rule, will not budge an inch from their route when a foot-passenger is in their way, even if they do not drive too fast. —*Iron.*

The Chamberlain Memorial.—A memorial erected by public subscription to commemorate the exceptional services rendered to Birmingham by Mr. Chamberlain, the President of the Board of Trade, during his connexion with the Town Council, was publicly unveiled and presented to the town on the 26th inst. The memorial, designed by Mr. J. H. Chamberlain, takes the form of a monumental fountain in the Gothic style, consisting of a square stone shaft, springing from a low flight of steps and terminating at a height of 65 ft. in a richly-carved and crocketted octagonal spire. Octagonal projections form the upper part of the shaft, carrying four smaller pillars surmounted by gabled arches, with pinnacles at the angles of the gables. The spaces between the main arches are filled with ornamental panelling, partly in carved stone, and partly in mosaics of various designs. A medallion portrait of Mr. Chamberlain, executed in Sicilian marble by Mr. Thomas Woolner, R.A., fills a large circular panel on the south side, and round the base of the main shaft are grouped three large semicircular basins, the lowermost of which is from 15 ft. to 16 ft. in diameter. The material of the memorial is white Portland stone, and the cost is a little over 2,000*l.*

A Trade Book.—Messrs. Walker & Son, house-furnishers, of Bunhill-row, have issued a very good one. It contains nineteen page-views of different rooms, fitted up with much congruity and taste in the prevalent style. The price of every article is given in each case, to the extent of nearly 1,000 items.

TENDERS

For the erection of Smack Boys' Home, Royal Harbour, Ramsgate. Mr. Alfred R. Pite, architect. Quantities by Mr. Joseph Rookwood:—

Newby	£2,777 0 0
Paramor	2,320 0 0
Mitchell	2,300 0 0
Hooper	2,280 0 0
Evans	2,165 0 0
Nicholls	2,139 0 0
Shrubsole	1,948 0 0
Dennel	1,940 0 0
Martin	1,880 0 0

For various alterations at the Tally Ho public-house, No. 6, Willow-walk, Fortess-road, Kentish-town, for Messrs. Watney & Co. Mr. James Robert Furniss, architect:—

Hockley	£2,335 0 0
Whitelaw	2,045 0 0
Dixon	1,883 0 0
Lamble	1,867 0 0
Durnford	1,800 0 0
Taylor	1,777 0 0
White	1,754 0 0
Axley (accepted)	1,650 0 0

For the erection of new schools, at Farrance-street, Tower Hamlets Division, for the School Board for London. Mr. E. R. Robson, architect. Quantities by Messrs. Northcroft, Son, & Neighbour:—

F. & F. J. Wood	£10,860 0 0
Higgs & Hill	9,088 0 0
Shepherd	9,045 0 0
Harris & Wardrop	8,995 0 0
Boyce	8,989 0 0
Jerrard	8,827 0 0

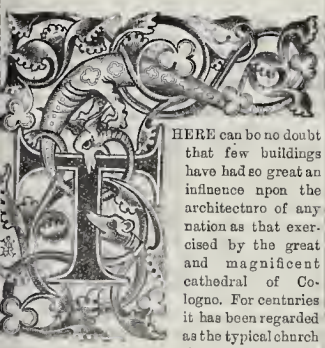
Cologne Cathedral, and its Influence upon German Architecture.



HERE can be no doubt that few buildings have had so great an influence upon the architecture of any nation as that exercised by the great and magnificent cathedral of Cologne. For centuries it has been regarded as the typical church of the German people, and the masterpiece of German architecture. The belief that Cologne Cathedral is the most perfect realisation of the Gothic style is so deeply implanted in the German mind that nothing will ever eradicate it. That a people should feel something akin to veneration for their greatest sacred structure is a sentiment worthy of the greatest respect, and we sincerely trust that we shall in no way wound the susceptibilities of our German readers when we point out certain facts which lead us to believe that the influence exercised upon German architecture by this vast and noble church has not been altogether a healthy one; and even if we suggest that before the erection of the choir of Cologne German architecture had given promise of developing into a nobler and more dignified style than it did after the achievement of that great work.

Perhaps it may be advanced that we are indulging in "insular prejudices," and that we judge Cologne Cathedral too much from an English standpoint; that our minds and tastes are too much influenced by the study of English churches and cathedrals; and that we do not take sufficient allowance for Continental architectural peculiarities.

Now we do not pretend, for a moment, that we are not influenced by a love for the noble examples of Gothic architecture bequeathed to us by our own English forefathers; on the contrary, we say boldly we firmly believe that the Continent can show no greater glories than the stately minsters of our native land. Lincoln, Canterbury, Ely, Westminster, and Durham will, we think, compare favourably with five great cathedrals taken from any country on the Continent. But in order that we may not be led astray by our preference for English Gothic, we shall not compare Cologne Cathedral with any English church, but shall make use of French and German churches where we find comparison necessary. The history of the cathedral of Cologne has been previously related in this journal, but for fear that the dates of its various parts may have escaped the recollection of our readers, we repeat them.

The foundation-stone for the choir was laid in the year 1248, but the choir was not completed until 1322. The nave was commenced about the latter period, and the greater portion of the aisles, together with the south-west tower, was probably erected between 1322 and 1400; for although the works were not entirely given up until 1499, yet the only portions which showed the peculiarities of the German Gothic of the fifteenth century were the buttresses between the north tower and north aisle, which have been now removed or altered.

The name Gerhard von Rile has been given as that of the probable or possible architect. Unfortunately, however, nothing is known about Gerhard von Rile; nor have we anything to guide us as to how far his work extended. An architect called Meister Johann is stated by Kügler to have commenced the nave.

Now the first thing which strikes us in studying Cologne Cathedral is the undoubted fact that the plan of the choir is a direct copy of that of the cathedral of Amiens; both consist of a nave with double aisles of five bays, closed by an apse of seven bays, with a chevet and seven radiating chapels, each forming an apse of five sides. The vaulting is identical in arrangement, and the only differences perceptible in the two plans are (1) that at Amiens the lady-chapel is prolonged one bay [it is by no means improbable that this was a subsequent alteration], and (2) the most western bays of the apse at Cologne are slightly wider in proportion than those at Amiens. Now, as the choir of Amiens was commenced before the year 1240, and Cologne not until eight years after that date, it is evident that Amiens was the original, and Cologne the copy. In 1258 a fire consumed the wooden roofs of the apsidal chapels at Amiens, and Viollet-le-Duc says that the triforium was commenced in 1258, the clerestory windows glazed in 1269, and the vaulting completed in 1288; that is, thirty-four years before the completion of the choir of Cologne. German writers tell us that although Cologne is later in date than Amiens, it is a higher development of Gothic than the French cathedral. In this, however, we must beg leave to differ from them. We do not regard the cathedral of Cologne as an improvement upon Amiens, and cannot help thinking that the attempt which was evidently made by the German builders to out-do the French cathedral resulted in a comparative failure. The extra height at Cologne, the increased stilting of the arches, and the lengthening the clearstory windows, are defects,* and the excessive richness and complication of the external buttresses rob the design of quietness and dignity. The apse at Amiens just misses looking wiry inside and confused externally, but the builders of Cologne fell into both faults. The English builders at Westminster saw the danger, and most carefully avoided it, for while making use of a French plan, like the Cologne builders, they did away with the stilting of the arches, simplified the buttresses, and decreased the proportionate height.

The apse at Amiens is such a splendid composition, and so thoroughly satisfactory in general effect, that it is ungracious to criticise it. However, if it possesses any defects, they are the stilting of the arches internally, and the breaking through the external cornices by the triangular canopies of the clearstory windows. Both features, however, are managed with skill and delicacy. But at Cologne both of these defects are so exaggerated as to become absolute faults in the design. Nor is the reduction of the triforium at Cologne any improvement upon Amiens; and we must say that we prefer the simple treatment of the piers at Amiens to the reedy appearance of those at Cologne, and although the statues, with their rich canopies and pedestals attached to the vaulting-shafts at Cologne, are beautiful features when taken alone, it may be doubted whether they do not disturb the harmony of the general design.

If the choir, which is by far the best portion of Cologne, falls short in beauty of its great French prototype, the nave bears no comparison with the corresponding portion of the French church; and the addition of a bay to the length of each transept is certainly no improvement; in fact, it is another of those exaggerations which injured the design of the great cathedral, and, throughout, German architecture in general. We fear it is impossible to avoid the conclusion that the wiry, drawn-out effect which became so marked a characteristic of German Gothic during the fourteenth century, was the result of the influence of Cologne Cathedral, and we have shown that that defect came about by exaggerating the peculiarities of the French architecture of the thirteenth century. We are led to this belief also by the fact that the Gothic churches in Germany which were erected before the choir of Cologne are entirely devoid of this defect, and that we shall find nothing to prepare the way for such a development either in the old Romanesque churches, in the Transitional churches, or in those few which show the more perfected Gothic. For instance, nothing of the kind is to be observed in such churches as Worms, Spiers, Mainz, or in the Transitional churches of Andernach, Bamberg,† Werden, Limberg,† Bonn, &c.; whereas the fully-developed Gothic churches are entirely devoid of this defect, and seem to give promise of a style singularly free from exaggeration or wiryness.

For instance, the splendid nave of the cathedral of Paderborn is singularly free from any kind of reediness. So also is the cathedral at Marberg, 1235-1283. In both of these cases the nave and aisles are of the same height; but the observation holds good of churches possessing clearstories; for instance, the exquisite Liebfrauenkirch at Trèves, 1227-1243, which is, to our mind, the most beautiful example of Gothic architecture in the whole of Germany, and a building which shows that Gothic architecture in Germany was in a much better road to produce a really grand and impressive style than it was able to effect after the work at Cologne had influenced its development and character. The choir and south transept of the cathedral at Wetzlar,‡ which were undoubtedly erected before the

* The treatment of the stained glass in the apse at Cologne shows that this defect was felt at the time, and the strong architectural lines introduced into the glass at about one-third the height of the windows was a clever attempt to remedy the evil.

* Illustrated in the *Builder* for 1879 (vol. xxxvii.), p. 179.

† Ibid., vol. xxxi. (1873), p. 287; vol. xxxv. (1877), p. 1225; and vol. xxxvii. (1879), p. 916.

‡ Ibid., vol. xxxi. (1873), p. 46; vol. xxxii. (1874), p. 969.

choir of Cologne, may be compared with the nave and north transept of the same church,—the latter, commenced in 1336, showing in a marked manner the influence of the work at Cologne,—in order to judge whether German Gothic had profited by the example of Cologne. The clearstory of the Abbey of Ecternach; the Dominican church at Coblentz, 1235-1239; the Cistercian churches at Marienstadt and Gnidenthal (1245); the western choir of the cathedral of Naumberg; the cloisters of the cathedral at Erfurth,—all serve to show the freedom of early German Gothic from wiryness and exaggeration.

The first church in which we trace distinctly the Cologne influence is the abbey church of Altenberg, commenced in 1255. There is a tradition that this beautiful building is a work of the same architect as the cathedral, and there is much to favour the supposition. The two buildings were evidently being carried out at the same time, and as they are only fifteen miles apart the greater church undoubtedly exercised much influence upon the design of the smaller though not less beautiful one. But the great influence of Cologne Cathedral upon German church architecture was not felt until after the first quarter of the fourteenth century, when we find its very marked peculiarities, both as to proportion and detail, copied over and over again, and imitated more or less exactly in a host of churches.

We have already alluded to the north transept of the church at Wetzlar, which is almost a reproduction of a part of the nave of Cologne. The nave of the church of St. Catherine, at Oppenheim on the Rhine, is a very remarkable example of the Cologne influence. Here we find the excessive complication of buttresses, the stilted arches, the lofty pierced angular canopies, or gables, over the windows, and all the peculiarities of the tracery of Cologne Cathedral almost exactly reproduced, and, as is generally the case, exaggerated in the copying. We also find here the large and somewhat clumsy finials, which are such marked features of the later portions of Cologne Cathedral.

The choir of the cathedral of Aix-la-Chapelle (1353) is another building which shows strong indications of the influence of Cologne, though chiefly as regards matters of detail.*

The chapel of St. Werner, at Bacharach, is so similar in much of its detail and treatment to the clearstory of Cologne that it is in all probability the work of the same architect. This beautiful chapel is said by Kügler to have been completed in 1293! and if this date is correct,—a matter which we feel some doubt about,—this chapel must have been in course of construction at the same time that the choir of Cologne was being erected, though finished twenty-nine years before it.

Amongst many other buildings of the fourteenth century which exhibit strongly the influence of Cologne, we will mention the cross at Goddesberg (1333); the Liebfrauenkirch, Oberwesel; the nave of the church at Xanten; the nave and choir clearstory at Magdeburg (c.1300); the exterior of the nave (south side) of the cathedral of Vienna (1359), St. Maria Stiegen, Vienna; and the two great Bohemian copies of Cologne,—the cathedral of Prague and the church of St. Barbara, Küttenberg. The resemblance of the two last-named churches to their great prototype is very remarkable. The cathedral of Prague, like that of Cologne, was left unfinished by its Mediæval builders, the choir alone being complete. Like Cologne also, the transepts were partly constructed, and one great tower, which is said formerly to have been covered with a spire of great height [as this spire was burnt down in 1541 it was probably of wood]. The cathedral of Prague was commenced in the year 1344, and consists of a noble choir, 157 ft. long, 144 ft. broad, and 116 ft. high to the crown of the vaulting. The plan of the choir is almost identical with Cologne. There are four bays in the length, closed by an apse of seven bays, with an aisle surrounding it, and seven radiating chapels. The only variations from the Cologne plan are that the two most western sides of the apse are nearly, if not quite, in a line with the side walls,—that is to say, they do not in plan form sides of the apse, but an extra bay of the nave portion; and the outer side aisles are sub-divided into chapels. The lower portion of the choir, as high as the great pier arches, is fair fourteenth-century work, though the columns are singularly reedy and the mouldings wiry; the window tracery is decidedly good. This portion of the building was erected from the designs of an architect called Matthias of Arras. The upper portion of the structure is the work of another architect, Peter Arler, of Gmünd, the supposed architect of the cathedral of Milan. The choir clearstory was completed, together with the vaulting, in 1386, and the tower in 1392. The walls of the transept, as far as they go, are probably of the same date. A singular feature in the church deserves notice: it is a chapel which forms the lower part of the south transept, so that had the transept ever been completed it would have been divided into two stories. This remarkable chapel is dedicated to St. Wenzel, king of Bohemia, and was completed in 1347, probably on the site of an older chapel, which will account for its somewhat singular position; it is rich fourteenth-century work, and the external walls are adorned with *pictures in mosaic*,—the only example, so far as we know, north of the Alps. The interior is adorned with ancient frescos, which are divided from each other by wide bands composed of coloured crystals.

The general appearance of the cathedral at Prague from the east reminds one singularly of Cologne (before its completion). There is the same treatment of the flying buttresses, doubled each way, giving the whole a wonderful effect of intricacy and richness; but, as is also the case at Cologne, at the expense of simplicity and dignity. Like Cologne, after having been left unfinished for many centuries, the cathedral at Prague is being completed by the addition of a nave and the completion of the transepts.

The other great Bohemian church which bears such a strong resemblance to Cologne is that of St. Barbara, at Küttenberg. Of this stately building the choir alone has been erected. In plan it is almost identical with Prague; but, if we recollect rightly, is a bay longer. Kügler, in his "Kunst Geschichte," says that the church of St. Barbara was commenced in 1380, but that the works were several times suspended. After remaining a long time *in statu quo* the building was taken in hand by an architect called "Meister Johann" (not the same Meister Johann who designed the nave for Cologne) in the year 1483, and the choir was vaulted in under the direction of Matthias Raisek in the year 1499. The tracery of the windows of the clearstory, and the flying buttresses, were, according to Kügler, not completed until 1510, under an architect called Meister Benesche von Laun. The works were carried on until the year 1541, when they were finally abandoned. Allowing for difference of date and certain eccentricities of detail, this church bears a wonderful resemblance to Cologne. Here, as at Cologne, we find the complicated arrangement of flying-buttresses, the glazed triforium (a very uncommon feature in Germany), immense loftiness, and, in fact, the great cathedral with all its defects exaggerated. The general view of Küttenberg, as seen from the river, cannot fail to remind one of Cologne half a century back. The great apse of the stately church of St. Barbara is seen towering over everything else, surrounded by the steeples of the smaller churches.

We have now described a few of the churches in Germany which strike us as showing, in a remarkable way, the influence of Cologne Cathedral, and we have pointed out what seem to us to be their defects; it must not, however, be supposed that we wish to close our eyes to the great merit of most of these buildings and of their great prototype. The richness, boldness of construction, and monumental character of these churches, the magnificent scale upon which they are carried out, the vast amount of labour expended upon every part of them, deserve the highest praise. They are, of course, vastly superior to anything we can do now, or shall probably ever see done again, in the way of church architecture, and in criticising them we are only doing so relatively; we wish it to be understood that what we point out as defects are merely so as compared with other buildings of their class and date. We will now speak about churches erected in Germany after the commencement of Cologne Cathedral, which do *not* seem to us to have been influenced directly by the erection of that great building.

The first work which attracts our notice is the nave of the cathedral of Freiburg, in Breisgau, inscribed with the date 1270. [Whether the vaulting is of the same date may be doubted.] The character of this part of Freiburg Cathedral is totally unlike Cologne. The proportions are far more quiet, and the relative height not greater than an English cathedral. The flying buttresses are single and free from complication. There is no triforium, but in its place a plain blank wall. The same treatment occurs in St. Lawrence, at Nuremberg, the nave of which church greatly resembles Freiburg. Freiburg is the only Gothic cathedral which the German Mediæval builders left complete, and it possesses what the Germans always seem to have longed so much to see,—three open-work spires; one at the west end, and the other two flanking the choir. That at the west end is by far the most beautiful spire we have seen in Germany.* Its general outline is singularly graceful and pleasing, and although very rich and sumptuous, the detail is so delicate as not to interfere with the general design. The huge finials and crockets which disfigure so many of the German spires,—those, for instance, of the cathedral at Meissen and the Pfarrkirche at Rothenburg, are avoided, and the pinnacles and buttresses are less confused and complicated than usual. The two other spires are far less satisfactory, but as they are quite subservient to the large one, their defects pass unnoticed.

The nave of the cathedral of Strasburg is so thoroughly French in treatment that it is difficult to believe it to be the work of a German architect, and the far-famed west front is one of those architectural tricks which teach nothing and lead to nothing. It may be classed amongst those works which are very wonderful until one knows how they are done; but directly it is found out that all these thin bars of stone are tied together with metal rods, the wonder ceases, and there is not sufficient dignity about the design to impress the beholder with any higher feeling than wonder. Nothing could possibly be less suited to the solemn grandeur of the interior of this great cathedral than the tiny and cut-up west front.

The cathedral at Metz is also purely French. But the church of St. Thomas at Strasburg is a charming example of Early German work, as is also the church of Hagenau. The church of Thann, in Alsace, is also purely German in design; it possesses a rather graceful spire, dated 1455.

Another group of churches which show little or no direct influence of the Cologne works are the Early Decorated churches in the neighbourhood of Dresden. The church of Haina is a beautiful example,—simple, graceful, and dignified,—but yet quite free from either heaviness or reediness.

The Westphalian churches, also, seem as a rule to have been little affected by the work at Cologne, if we except the Weisekirche at Zoest, which does certainly exhibit Cologne influences, especially about its west front. The spires have recently been added, we believe, upon the authority of an ancient design. We cannot admire this front; it seems to overpower the church, and is, moreover, hard and unpicturesque. The other churches of Zoest are remarkably interesting, as exhibiting good types of simple Geometrical Decorated work. The cathedral at Minden, a noble building, with three aisles of equal height, fine solid piers, and noble Decorated windows, of a type peculiar to Westphalia, is an excellent example of the early treatment of a "Hall-church," and is very local in character. It is evidently a later and more fully developed edition of the nave of Paderborn. It was in its turn taken as the model for many of the Westphalian churches.

The hall-churches ("*Hallenkirchen*") of Bavaria and Swabia do not exhibit the influence of Cologne, as far as their general plan and arrangements go; though in the tracery of their windows, doorways, &c., we can often discover traces of the Cologne style. There were evidently three schools, if not four, at work in Germany during the fourteenth century. There was, first of all, the Cologne school; secondly, the Westphalian school; thirdly, the Nuremberg school (which, however, only became influential towards the end of the century); and, last of all, the old Romanesque school, which lingered on in out-of-the-way places, especially in Austria and Hungary. We find Romanesque churches in these districts dating from quite the close of the fourteenth century; and even in the north, the style and peculiarities of Romanesque architecture are occasionally to be met with. The curious Pilgrimage Church at Ecternach is an example. Now it is difficult to point out what influences were at work in any building without

* See engraving in the *Builder*, vol. xxx. (1872), p. 867.

* See engraving in the *Builder*, vol. xxviii. (1870), p. 647.

careful examination, as it frequently happens that features of each school may be discovered in the same building; but we think the hall-churches of Southern Germany may be traced to a school which had its rise either in Nuremberg or in the neighbourhood. The finest examples are the choirs of St. Lawrence's and St. Sebald's, the nave of St. Mary's in Nuremberg, the three churches at Amberg; St. Martin's, Landshut; the great church at Ingoldstadt, the cathedral at Munich; St. Mary's at Würzburg, St. George's at Freising, Holy Cross at Gmünd, the two churches at Nördlingen, Ochsenfurth, St. Mary's at Etzlingen, Iphoven,* Kitzingen, and St. Stephen's, Vienna.†

The great minster at Ulm shows little Cologne influence except as to the details of some of the windows; its plan is purely German, and although nearly 400 ft. long, with a nave of 47 ft. span and 133 ft. high to the crown of the vault, its plan is remarkably simple, consisting only of a nave and aisles, with a single choir and a western tower. The aisles of the nave are double. The interior, though immensely lofty, looks bald and bare, from the entire absence of strings, and the great unbroken wall between the pier arches and the clearstory windows. This bald, ugly space is a great defect in many of the German churches, and certainly the Cologne architects deserve credit for getting rid of it.

We must now speak of a church which strikes us as uniting in a singular way the best features of the Cologne school, with elements of design purely German in origin. It is the beautiful cathedral of Ratisbon;‡ though less important as regards dimensions than Cologne, Ulm, or Strasburg, it seems, to our mind, to be a more perfect design. It consists of a nave and aisles, with shallow transepts, which do not break through the line formed by the aisle walls. There is a choir with aisles, terminating in three apses, the centre one divided into two tiers of windows, after the plan of Marburg and the Liebfrauenkirche at Trèves. The west front is the most striking in Germany, and the spires, which have been recently completed, seem to us to be rather better in proportion than those of Cologne. The height to the vaulting is 120 ft., but as the bays of the nave are very wide, and the span of the nave 50 ft., the whole looks good in proportion. The defect of elongating the clearstory windows, which is the fault of Cologne, is carefully avoided, and the great defect of Ulm, the bare wall above the pier-arches, here gives place to a triforium arcade. The window-traceries are well designed, and the mouldings and piers are free from wiryness. The great apse is a particularly beautiful composition; the triforium gallery is carried round it, supported upon arches, the spandrels of which are pierced, so that it forms a kind of double tracery arrangement. The arches are mostly equilateral, and there is throughout the building an entire absence of that stilting, which is to our minds one of the defects of German architecture. The whole design of this church bespeaks a master-mind,—unfortunately the name of its architect is unknown. Some people suppose that this noble church was designed by Albertus Magnus, who was bishop of Ratisbon when it was commenced in 1275. Whoever he was, we believe him to have been a greater genius than any of the architects employed at Cologne. The proportions of Ratisbon are far more pleasing than those of Cologne; it is elegant without that look of attenuation which is, to our minds, a defect in the larger cathedral, and, externally, it is rich without confusion. The buttresses are simpler and are better arranged than those at Cologne, and the west front is a far more powerful and infinitely more picturesque composition. In fact, out of France, we have seen no west front equal to it. The triangular porch is a remarkably splendid piece of design, and there is just variety enough about the details of the two towers to make them interesting. The kind of terrace or basement which surrounds this church is also a very fine feature, and we cannot help regretting that the modern builders of Cologne did not treat their terrace in a somewhat similar way. Altogether, we must say that we are of opinion that it is Ratisbon cathedral, rather than Cologne, which deserves to be considered the masterpiece of German architecture, and it seems singular that it should not have exercised greater influence upon German architecture. It is true we have the noble churches of the Minorites and Dominicans in the same town, which may be considered as belonging to the same school, and perhaps also the west front of St. George's, at Ansbach, and the churches at Nahburg, Sobenburg, Haahach, Sulzbach, and Abensberg seem to exhibit traces of the same style.*

We cannot help regretting that Ratisbon did not become the model for German builders to follow, because, as we have pointed out, it is really a far more national building in point of style, inasmuch as it retains nearly all the peculiar features of purely German Gothic, and avoids those exaggerations of the features peculiar to French churches which we cannot help regarding as the defects of Cologne. We must repeat that we do not wish it to be understood that we are finding fault with the great German cathedral, or with German architecture generally: on the contrary, we consider that the defects of Cologne arose from the architects copying and adopting French features instead of developing the Gothic which was already introduced into Germany into a purely national style. It may be said that, after all, the Cologne architects merely did what the architects at Trèves and Marburg had done, *i.e.*, they copied French works of their time. That may be true, but the earlier German architects, when they copied French works, never exaggerated them; on the contrary, they instilled into them a certain element of solidity, which was derived from their own Romanesque. This is distinctly noticeable at Paderhorn, Marburg, and the Liebfrauenkirche at Trèves, and we cannot help regretting that the Cologne architects ignored all that had been done up to their time, and went to France for inspiration, instead of continuing what, if fully developed, would have become a purely national and most magnificent style of Gothic architecture,—a style which, if we judge from the examples of its earliest efforts, would have been far more characteristic of German thought and German feeling than that introduced by the Cologne builders,—a more solid, severe, and dignified style,—a style exhibiting rather the breadth and sobriety of design than its intricacy and elaboration. If Marburg, Paderhorn, Trèves, and Ratishon had been taken as models, we should have found the German Gothic far more in accord with the German character than it became after the Galicisms introduced into it by the Cologne builders.

THE INSTITUTE AND PRACTICAL ARCHITECTURE.

We have much pleasure in noticing, and giving our cordial support to, the sensible and practical remarks on the present position and practice of architecture embodied in the opening address of the President of the Institute of Architects on Monday evening, and the pith of which will be found in another portion of our columns. It is to be hoped that the decisive tone taken by Mr. Whichcord in favour of the practical side of the profession of architecture is one among other indications of a reaction from the purely *dilettante* view of the profession which has been far too much emphasised by some of our most successful and popular architects of late, and which has done a great deal to create that distrust of the profession on the part of a considerable portion of the public, the existence of which we cannot ignore, however we may regret it, and however we may regard it as to a considerable extent prejudiced and exaggerated. That it is so we believe to be the case to a great extent. We believe there are really as many architects now as there have been in other apparently more practical days, who are fully qualified in the practical side of their profession. But it must be remembered that outsiders naturally judge of a profession by the character and utterances of that portion of its practitioners who are most prominent and irrepressible in public speech and action. Considering how very dull and prosaic the architectural taste of the country was in an earlier part of the century, it was both natural and desirable that there should be a reaction in favour of developing the artistic side of architecture. Reactions, however, are nearly always one-sided; and the art reaction has developed a small school of architects who have distinguished themselves more or less as draughtsmen and ornamentists, but have almost ostentatiously ignored and under-rated the practical side of the profession, and have in some cases even openly and in so many words expressed their indifference to it. They have reduced architecture to a mere indulgence in æsthetic sentiment, displayed in the adoption of special favoured forms of decorative building, followed out without very much regard to logic or principle even as far as design is concerned, and in the pursuit of which the practical suitability of buildings for their purposes, and the provision for the best schemes of ventilation, drainage, and other matters of sanitation or of convenience, of the first importance, have been very much left to take care of themselves. The novelty of a reaction always insures a considerable following, and the art-architects have for some time been exceedingly popular with the more cultured of the public. But sentimental fashions in building are never of very permanent interest, and already it must be evident to those who listen to conversation on the subject of architecture in general society, that the art-architect is becoming an object of distrust, and sometimes, as we can testify from observation, almost of derision. The President of the Institute has acted in every sense wisely in taking the opportunity of the opening address to prominently connect the aims of the Institute with the promotion of practical architecture.

The difficulty of uniting the two sides of architecture in the same person, of "combining the graphic with the scientific departments of the art," referred to in the President's quotation from Cockerell's address in former years, is, perhaps, over-rated. There have been tolerably numerous examples of the successful combination of the two elements, and the French architects are unquestionably able to furnish a higher average of men of this all-round training than we can show. The deficiency arises in great measure from the want of properly-directed study in this country, and from the want of judgment as to the objects of their profession which induces so many architects to take a one-sided view of what is required of them, and either to devote themselves to practical considerations and regard the picturesque as a mere gew-gaw, or to devote themselves to making picturesque buildings, and treat sanitation and construction as prosaic matters beneath their notice. There is, we honestly think, very little systematic effort to combine the two classes of study, and we really hardly know how much may be done by well-directed efforts to attain the intellectual equipment which should belong to a complete architect. As we have before pointed out, a very disproportionate amount of time is spent, by those students who are really most in earnest and wish to work, in the sketching of the details of ancient buildings. This is a most valuable and most fascinating phase of architectural education in its right place, but an over-indulgence in it to the exclusion of more practical studies leads to producing a class of architects who are exceedingly competent to produce beautiful drawings of new buildings which look like old ones, and to give detail drawings for their erection in accordance with the most admired models,—perhaps with some touches of modern or original detail founded on the old, but who are very inadequately trained in providing for the practical works of their own time. The pride of the young architect is to bring home his sketch-book full of charming sketches (and the average of "sketching-power" is probably higher now than ever it was) representing the prettiest bits of grouping and of detail which he has seen in his tours in search of the picturesque. If he would show equal interest in observing and making notes of what is wanted, or what is being introduced, in the way of practical improvements in modern buildings, in construction, in the use of new materials, in sanitary provisions and planning, well and good; the two classes of study would then fall into their right places. But the latter is mostly left to take care of itself. Draughtsmanship and sketching are the fashion, and carry the day; and as very few young men have independence enough to think for themselves and take a course of their own, the hard workers,—those who mean to get on,—throw their work into the accepted groove. The consequence is that the art-architect rises to the top, and that many of our greatest and most important buildings are erected by men of

* Illustrated in the *Builder*, vol. xxix, (1871), pp. 566, 568.

* The cathedral of Famagosta, in Cyprus, also bears a striking resemblance to that of Ratisbon, especially with regard to its apse and eastern end. It is, we believe, the only church in Cyprus which shows *German* influences. The great cathedral at Nicosea is thoroughly French in feeling and design. The abbey church of Delapais purely English, and St. Nikolaus, Nicosea, is evidently a Greek work.

great talent, no doubt, but who are simply the exponents and practitioners of a revived form of imitative architectural design. The more thoughtful part of the public are beginning to find this out now, and to see that they have spent great sums in the erection of pieces of architectural sentiment which are already beginning to pall on their taste as art-work, and which have never really fulfilled their practical demands.

One difficulty in the way of combining the functions of art-architect and practical architect arises really from the false view which is taken of what constitutes the art of architecture. The idea fostered by some persons that an architect is to be builder, sculptor, and painter in one, is almost entirely Utopian. Occasionally there may arise a very exceptional genius, such as Da Vinci, who seems capable of grasping everything; but taking the average capacities of even the more gifted of mankind, such an idea as to the requirements of an architect can only result in disappointment. The mastery of sculpture or of painting is enough, in itself, for the whole energies of most men who achieve real success in these arts; the attempt to combine them with the proper knowledge of the practical part of building can only result either in the erection of badly planned and constructed buildings, or in the execution of bad sculpture and painting. But it is not sufficiently recognised that the real and special art of architecture consists in expressive and decorative building. There is art even in a plan; one man will make a plan which answers its purpose, but which is entirely ineffective in its interior aspects; another will make one equally convenient, which provides an interior full of interesting and picturesque points of effect which arise naturally out of the requirements of the plan. Such a man is an artist in planning, and is much more truly an "art-architect" than one who merely covers a building with pretty details copied from old buildings, or cuts up its roofs into a confused and unmeaning assemblage of gables and spirelets. The decorative treatment of a building, in direct reference to the expression of its construction, carries this art of expressive building much further, and is a form of artistic expression quite worth special attention on its own account, without attempting to invade the province of the sculptor and painter. That it is so, and that it demands special study and a special organisation, is indicated by the fact that sculptors and painters who are their own architects invariably fail both in planning and in giving true expression to their plans; nor do painters and sculptors in general by any means understand decorative design. The large and interesting field presented by this class of artistic design may be entirely and fairly in the architect's province; and quite enough, too, for any man's time and thought, in combination with the practical side of building. This is the view of architectural art which the whole of Viollet-le-Duc's life-work embodies, and any man might be proud of such a repute as he has left behind him.

Two other practical points may be mentioned in connexion with the presidential address. Mr. Whichcord has decidedly repudiated what some people have called the trade-union theory of the Institute, as an institution for securing proper remuneration to the profession. Those who held this view were not, we imagine, numerous; and certainly nothing could be more at variance with the first object propounded in the Institute charter, "the advancement of the art of architecture." We draw attention to the fact that the President of the Institute has affirmed that the scale of charges sanctioned by the Institute simply represents the custom of the profession,—what a member of it is justified in standing up for and what the Institute will support him in,—but that it does not pretend to attach a stigma of unprofessional conduct to any man who chooses to work for less. So much the better. Such a pretence would have been a solecism, and is of course an exact parallel to some of the action of trade unions which is constantly complained of as hampering the liberty of individual members. Equally of course, the Institute does not pretend to discourage any architect from charging higher than its scale if his services are so much valued that he can command higher terms. It recognises a usual custom to which appeal may be made in case of dispute, and that is all it can reasonably and logically do. The other point we wish to touch on is the desirability of all architects of respectable standing, and who are desirous of raising the *status* of the profession, joining hands with the Institute. One statement made in Mr. Whichcord's address furnishes an exceedingly practical argument in favour of this. He mentions, in the first place, that while there are 1,300 professional architects in the kingdom, only 716 are members or associates of the Institute; and we have observed, in conversation with architects who are not members, that they usually give as a reason against joining,—"What are we to get by it, when every one knows that some of the most clever and successful architects are not members?" But there is the further statement that there are "nearly 3,000 persons professing to be engaged, in some form or other, in the practice of architecture," many of whom, probably, have a very shadowy claim to the title. But it is the good men who refuse to join the Institute who give the status to these pretenders. If all the properly-qualified architects would join the ranks of the representative body as members, and make it really representative, they would at once throw into discredit all those pretenders, who would have no chance of acceptance in the Institute. Let them say, if they like, that they do not care about the papers at the Institute meetings, that the proceedings are dull (sometimes they are); but for all that, if they want to stop the quack architect from practising, let them, in the name of common sense, strengthen the hands of the only body which, if properly supported, can effectually do so. To weaken the hands of the representative body by standing aloof and saying, "Oh, the Institute does nothing for us!" when the general joining of the whole profession in its ranks is exactly what is wanted to give it the power of being useful, is a most illogical mode of acting.

THE OCTOBER FÊTES IN MUNICH.

There is much in Munich to remind one of Italy. It is not because there are so many cold imitations of its noble architecture,—not only because we see engaged on its new buildings the skilful masons and plasterers of the other side of the Alps, and hear the not unfrequent sound of the Southern tongue; but just at present Munich is in the midst of its October rejoicings, which strongly remind one of the *Ottobrate* of Rome,—rejoicings not classic, as is the case in the Eternal City, at the more or less successful termination of the vintage, but rejoicings that coincide with the close of the business part of that enormous commercial interest in Germany, the in-gathering of the hops. The huge high-pitched warehouses of Nuremberg, and many other famous towns in the more southern districts of Bavaria, so little changed since the days of their world-wide fame, have been filled with their bulky stock, and busy, passing through the city gates, have been the wagons lightly laden with their bursting sacks of produce. In the country the hop-poles are stacked for the winter, and the season's work is done.

Not that the Munich fair, picturesque as it is, situated on the banks of the Iser, "rolling rapidly," and outside the old Isarthor, can compare in any way with the beauty of the Roman October *fêtes* in the gardens of the Borghese villa and on the banks of the Tiber; nor can the boisterous, ungraceful enjoyments of the Germans stand comparison with the good-natured and more genial merriment of the Romans. Even the *Ottobrate*, however, have lost their character, familiar to old residents of Rome of thirty years ago, when a traditional costume and a certain ceremony lent a classic charm to the rejoicing. The year 1848 is marked in the history of the *Ottobrate* as it is in that of Rome herself; for, in that autumn the costumes were worn for the last time,—costumes consisting alike for men and women in the familiar theatrical "brigand's hat," bedecked with artificial roses, and worn by a chosen number of handsome girls and young men perched high on wagons which bore them triumphantly on their merry *gita* outside the gates of Rome.

In Rome at one time, as we remember, every one seemed to rejoice alike in the October *fêtes*. In the year 1848, to which we have referred, owing to the early period, the grand people,—the earls and marquises of Great Britain, the barons of Europe, and the millionaires of America,—were conspicuous by their absence, owing to its not being "the thing" to arrive in Rome until considerably later in the year; but we can recall the familiar faces of more than one Roman notoriety, John Gibson, Wyatt, De Soulevy, George Mason,—whose brother served as a volunteer in the '48 war,—Father Prout, Charles Barry the elder, Waring, Penry Williams, poor George Thomas, Overbeck and his German admirers, and we know not how many other artists whose names are not so familiar. At that time Rome boasted of no regularly-organised English club; men were not afraid to be seen in the smoky cavern of the now practically defunct Café Greco, where many an *habitué* remembered where Thackeray sat and smoked the wretched Torlonia tobacco of the Papal Government, and when the massive seventeenth-century silver Roman lamps graced the counters of the famous old establishment.

Here in Munich the fair is a fair without the attendant pleasures, as they are termed, of the *Kermesse* of more Northern countries, but a genuine fair, such as explains the importance attached to these gatherings in the past, commencing during the first days with a display of agricultural products and a cattle-show, such as would recall to old Londoners the beginnings, forty years ago, in the late Baker-street Bazaar, of the huge Agricultural Hall shows of to-day; later on in the month succeeded by merchants and dealers collected from far and near, each with the wares peculiar to his district, but mostly predominating in crockery, hardware, and clothing, to satisfy the varied needs of daily existence such as have been supplied for centuries at this and similar fairs,—a national exhibition on a small scale, and arranged, too, in sections,—an assemblage of wares eagerly bargained for by the thrifty Munich housewives, who may be met streaming into town from the suburbs where the fair is held, bearers of heavy burdens of crockery, the rudely decorated pottery which fascinates so surely every artist and connoisseur who travels abroad. Happy hunting-grounds, too, for the bric-à-brac collector are the numerous dark stalls, in which are heaped odds and ends of every possible description, again reminding one of Italy.

Italy will soon be brought in even closer contact with us Northerners by the new means of communication through the St. Gothard Tunnel, of which recently such unsatisfactory accounts have been circulating. But the modern engineer's dictionary knows not the word "impossible," and so we hear that by next spring the tunnel will be completed. To more than one Italian and German workman here in Munich, at these October fêtes, and in many another part of Europe, will the termination of this great work recall the old Hospice which will disappear with the piercing of the tunnel. To how many thousands of industrious but poor artisans has not this charitable and venerable institution, during its five centuries of existence, afforded the succour so sorely needed when work was being sought? To how many a travelling apprentice has not this old Hospice formed a bright point of recollection in his hard-won career? What help must have been given in this difficult and always lengthy passage over the Alps may be judged when one learns that no fewer than from 18,000 to 20,000 needy travellers are annually received and obtain warm food and sleeping accommodation, and that often a hundred and more beds are occupied in a night. Such institutions are noble relics of the past, and it is with pain that one sees them disappear, but disappear they must; when, however, the old Alp passes have at length been doomed to be abandoned, there will probably remain no more interesting historical memorial of their existence than the noble line-engraving by John Landseer from the equally noble picture of the "Dogs of St. Bernard," by his son Sir Edwin.

But the necessity for the St. Gothard Hospice has passed, or will pass, rather, in a few months. There is little travelling now-a-days except by rail, and the times for the happy, even if obligatory, wanderings of the *Handwerksburschen*, the German travelling apprentices, who all know St. Gothard well, are drawing to a close. Here in Germany, as everywhere else, apprenticeship, its trials, its patient teachings, and its lessons, is not what it was in the past, a fact which perhaps may account far more than is generally acknowledged for the undoubted inferiority of too much work which is done in the present day, a fact of which one is characteristically reminded in a fair such as is at present being held in Munich, where it is difficult for the fastidious purchaser to find anything but what is old to please him.

Munich.

FRENCH ART PROGRESS AND ENGLISH EXAMPLE.

One of the most wholesome symptoms of progress among our neighbours is the awakening sentiment of self-reliance. It is felt, at last, that the State is not responsible for everything; that the people must watch over their own improvement, and seek themselves to supply what they most need. So far as arts applied to industry are concerned, the example of South Kensington has more than anything else at once alarmed and stimulated the French. It seemed extraordinary that so vast an institution should spring from private initiative, and that Government assistance should only follow and confirm the success already achieved by associations of private individuals. On a smaller scale, but equally emphatic in its moral lessons, the example given by the Belgian people was impressive; and now the words self-help, independent action, private initiative, are on the lips of all who in artistic circles of Parisian society discuss, how France shall hold her own against foreign competition. It is understood that the triumphs of the past have somewhat crippled the energies of the present; France has been resting too long on her laurels. She possesses, it is true, an admirable series of antique sculptures. The Museum of the Renaissance, the Sauvageot collection, the portfolios of drawings of the Louvre, the Cluny Museum, the Conservatory of Arts and Crafts (*Arts et Métiers*), the collections of models of the École des Beaux Arts, the stamp galleries of the Bibliothèque Nationale, and the collections of porcelain at Sèvres, afford elements of study, but these are scattered and disorganised: admirable in their way, but scarcely suited for a national school. Again, so far back as the eighteenth century, Bachelier and Descamps founded gratuitous schools throughout France, where young apprentices could acquire some knowledge of art. Then such men as Étienne Delaune, Cercean, Woeiriot, Légaré, Lepautre, Marot, Berain, Toro, Oppenord, Meissonier, Cauvet, Delafosse, and many others, published series of designs and models, which fed for several generations the imagination, not only of French, but of European artisans. This same country that produced Bernard Palissy, Leonard Limousin, Briot, Larmino, Nicolas de Lafage, Le Nôtre, Keller, Lefèvre, Jans, Audran, Cozette, Boule, Massé, Balin, Montarsy, Germain, Caffieri, &c., can hardly be suspected of falling behind the age, and allowing other nations to excel her in art decorations. Nevertheless, it is urged that the more looking backwards at former achievements and the mere mention of names that were great when foreign competition was less keen, is no sufficient guarantee for continued pre-eminence.

The collections exhibited at South Kensington are organised for a distinct purpose, and there are imitations of South Kensington all over Europe, with the exception, however, of France. There is in Paris the Museum of Cluny, but this can only be described as an archæological display; while, in the provinces, the Lyons collection is more especially devoted to the decoration of tissues, and that of Limoges to the ceramic arts. A general museum of the decorative arts which would form a central school for the study, in all its branches, of art applied to industry, is a want keenly felt in France, and this more particularly now that the competition of other countries is a force the French can no longer afford to ignore.

To meet some of these exigencies the "Union Centrale des Beaux-Arts appliqués à l'Industrie" was constituted in 1862, and, after considerable difficulties, this private body of distinguished patrons organised exhibitions which were held every two years, and consisted of objects illustrating the application of fine arts to industries. These displays attracted a great number of people, and have often been noticed in these columns. This, however, is not considered sufficient, and a second society was formed in conjunction with the first, known as the Société du Musée des Arts Décoratifs, for the purpose of creating in France a vast and special museum where the art-workmen might meet and classify in logical order the most perfect specimens attainable of the decorative arts. These choice works, or casts taken from them, should, it is also proposed, be sent round the country to local exhibitions and museums, so that the public taste of the entire nation might be further developed. This newer association, which in England we might call the museum committee, was constituted in April, 1877, and its influence is becoming daily more perceptible. Many months were spent negotiating with the Government, first with a view to the installation of the proposed museum at the Tuileries, when the palace should be reconstructed. Subsequently the Government conceived the project of converting the huge buildings where the International Exhibition of 1878 had been held into a National Industrial Museum, and the central and finest portion of the building would have been handed over to the committee for the installation of a permanent museum of fine arts applied to industry, and the creation of schools more or less founded on those of South Kensington. This project, however, fell through, and then the Government offered the Pavillon Flore, the wing of the Tuileries nearest the river, where a small exhibition was held, and many strenuous efforts were made to raise funds.

After some months, the Government took these premises back again, and gave them over to various officials connected with the Préfecture of Police, and the organisers of a national permanent museum were once more cast adrift. Ultimately the Government allowed this society to open a museum in the east wing of the Palais de l'Industrie. At the commencement of this year the Museum committee had obtained in all 10,000*l.* in subscriptions, and a great many gifts in kind, and the objects exposed, though somewhat modest and limited in number and variety, constituted nevertheless a good beginning. We are glad to note that the authorities at South Kensington lent willing help to this sister institution. All the books and catalogues that have been published, in all thirty-eight ponderous volumes and six portfolios of photographs issued at South Kensington, were offered as a free gift to the French Museum Committee of Fine Arts applied to Industry. These volumes were also accompanied by a certain number of casts of objects of art at South Kensington, and a cordial letter, promising that all works which in the future may be published will also be sent over to Paris. The letter announcing these gifts stated that the Lords of the Committee of the Council on Education had, on many occasions found cause to appreciate the assistance given by the various Paris administrations to the organisers of the South Kensington Museum, and were therefore particularly pleased to render any service to the French Museum of Decorative Arts. A hope was further held out that this might serve as the basis for international exchanges which would be of mutual profit to the two very similar institutions.

While the foundations of a permanent museum have been thus firmly laid, the Union Centrale has, on its side, continued to devote the same energy and ability in the organisation, every two years, of an Exhibition of Arts applied to Industry. These shows are now regular features of Paris life, but an outcry has recently been raised in favour of some sort of novelty. The committee felt that if they did not contrive some perpetual change, though still for the purpose of illustrating the same idea, the entire movement might be seriously compromised. The Exhibition of this year, it had been arranged, should be devoted to the glorification of metal, and it has recently been further decided that to make the Exhibition more useful and original, the raw materials required should be shown side by side with the tools the artisan employs, the model he copies, and the result he ultimately attains. The same rule will probably be observed in 1882, when the Exhibition will consist of tissues, paper, skins, and wood applied to the manufacture of furniture. In 1884, the exhibition will more especially interest our readers, as it comprises wood in its application to building and decoration, stone, and glass.

Finally, we should notice a third feature of the same movement, which is all the more welcome, as it will enable us to appreciate, in a great measure, the work that has been done without quitting our fireside. The Union Centrale and the Museum Committee have concluded an agreement with the well-known art-publisher, M. Quantin, who, at his own risk, issues a monthly publication, which is the organ of the two societies. It bears the title of the *Revue des Arts Décoratifs*, and besides publishing all the documents, minutes of meetings of the two societies, contains a number of articles by well-known critics, and three to six illustrations. Five numbers of this publication have already appeared, and contain reproductions of some of the finest objects displayed at the Museum of Decorative Arts.

THE FRENCH GALLERY.

The principal work in the Winter Exhibition of Mr. Wallis's Gallery, which opened this week, is the large painting by Luminais, "Les Énervés de Jumièges," one of the most powerful and one of the most repulsively painful pictures we have seen in the Gallery. It illustrates a story of a barbarous period; how Clovis II., having conquered the two sons who had rebelled against him, crippled them by destroying the sinews of their legs, and then placed them in a barge, and committed them in this helpless condition to the current of the Seine. The picture represents the barge with its unhappy occupants floating down midstream; it is life-size, the boat and the figures occupying the foreground. As an historical representation the picture is absurd; for it is not to be supposed that a man capable of such barbarity would have had his victims' wounds carefully bound up, and given them cushions and a mattress to make them as comfortable as possible under the circumstances; the object of the act (if it be really historical) was, of course, to ensure the death of the prisoners without taking the onus of actually giving them the death-blow. Apart from that, the power of the work consists in the manner in which the painter has succeeded in conveying the impression of utter bodily helplessness and pain combined with the indication of natural force of character in the countenances of the two princes. The figures lie like two logs on the boat, the sweat of pain and terror on their faces; with the expression, in the features of one at least of the two, of fierce passion and a strong will utterly unable to act. The swing of the boat turned sideways by the current is very well conveyed. No one who sees the picture will be likely to forget it, though most, like ourselves, would probably prefer to do so. With all the power displayed in it, it is doubtful what can be the use of painting a picture of so repulsive and cruel a subject, or who could possibly wish to possess such a work.

What struck us most in the room, after this, were the landscapes by K. Heffner, one of which, "A Flitting Gleam before the Storm," is a wonderful piece of realism in the portrayal of a transient but powerful effect in Nature: the gleam on the hill in the middle distance is like absolute light. There are three other works by the same painter, all portraying marked effects with more or less power, though none of them equal to this one. Munthe, the painter of snow scenes, has varied his materials a little in one or two works by choosing the margin of a river instead of the village roads and fields which he usually portrays, and seems better than ever. "Winter," a scene of cold twilight on the bank of an ice-bound river, is perfect in execution and feeling.

Perhaps the most satisfactory, though not the most striking work in the Gallery, is Madame Henriette Brown's "Preparations for the Festival," a young acolyte, clad in red serge, scouring a silver crucifix. The metal-work is very finely painted, and the whole has that kind of artistic interest which this artist succeeds in imparting to the representation of a mere common-place incident in the action of a single figure, simply by the force and truth with which it is represented; the painting tells no story, and yet compels the attention by its masculine power; if there were many such painters among women, we should have to say, by its "feminine" power; but Henriette Brown, fortunately for the men, has no rival that we know of among the painters of her own sex.

Priou's large picture of "A Satyr Family" contains some good painting, though it is an absurdity even as a mythological representation. He has grouped with a rough, goat-legged satyr, and his goat-legged child, a woman who looks, except as to the face, like a civilised lady with her clothes off: the utmost stretch of fancy cannot warrant such a *mésalliance* as that of this finely-turned creature with human limbs with him of the goat-shanks. A new exhibitor at the gallery is Max Todt, whose two small figures, "The Lover and his Lute," and "Can it be?" show very fine qualities of painting; they belong to the school which owes its existence to Meissonier. F. Thöne has two good boy pictures, and there is marked character, though with an awkward attitude of the figure, in Ulrich's "Retrospection."

The best known of the foreign contributors are not in force, and of the few English works there is little to be said.

THE PRESIDENT'S ADDRESS AT THE ROYAL INSTITUTE OF BRITISH ARCHITECTS.

Mr. Whichcord having first referred to the severe loss sustained by the Institute through the death of Thos. Henry Wyatt, Benjamin Ferrey, and Edward M. Barry, and remarked on some of the alterations proposed to be made in the conduct of the business of the Institute, proceeded thus:—I would not have it supposed that the purpose of the Institute is confined to the mere writing, reading, and discussion of professional communications, nor would I admit for an instant that its use is impaired because only a small minority of members attend these meetings. Many things combine at the present hour to diminish interest in the work done at them; the world is overburdened with papers, letters, lectures, discussions, and no small part of the load is sustained by this country. To carry on, at the recognised head-quarters of our profession, official duties affecting our interests as a corporate body; to promote and facilitate uniformity of professional practice; to secure, as far as possible, integrity of practice; to consolidate step by step the foundations already laid of that examination which I think will raise the character of an architect in public opinion, and debar unfit and ill-educated persons from the profitable exercise of our calling, whereby at the present moment incalculable prejudice is caused to the worthier members of a noble profession,—these form silent and efficacious work done by the Council and Committees.

The general scheme of that examination was tacitly approved by you at the annual meeting in May last; and it has since been worked out in detail by the Architectural Examination Committee. After nine sittings this committee presented an excellent report, which, with a few principally verbal amendments, has been adopted by the Council. It has consequently been proposed to devote our ordinary meeting for business, which occurs on the 3rd of January next, to this matter, in order that the general body of members may be afforded an opportunity of discussing the scheme,—the pressure of business at the last annual meeting having rendered any such discussion impossible. For this purpose, the regulations and programme of the examination under Bye-law XIV., as drawn up by the committee and approved by the Council, will be printed in the Journal of Proceedings, and thereby every member will be enabled to make himself acquainted with them before the meeting in January. Meanwhile, we have taken the necessary steps to form a Board of Examiners, and to obtain such a modification of the terms of the Ashpitel prize as will permit the prize to be awarded annually to that candidate who of all those examined during the year distinguishes himself most creditably in the examination. We have also decided to limit the voluntary examination, to be held in June next, to four days instead of six days as in previous years, but of this you have already been informed by the programme which was published some ten days ago. This, the twelfth that will have been held since their establishment, will be the final and concluding examination of a voluntary character. It consists of two sections: artistic and scientific. At the previous examinations a candidate has been permitted to pass one year in one section and another year in the other section. There are, consequently, a few gentlemen who, having passed in only one section, are not yet entitled to the usual certificate, and in order to qualify for it they must present themselves next June and pass in the other section; but all new candidates at the June examination will be required to pass in both sections. We shall thus be prepared to take our thirteenth examination,—the first under Bye-law XIV.,—in the month of March, 1882.

I may, perhaps, be permitted to revert to what I said on this subject in my address of last year. I asked whether the character of such an obligatory examination as we proposed should be general or strictly professional; I am glad that it is recommended to be one in reference to professional study and practice only. I said that the real difficulty lay in deciding upon the artistic capacity of a candidate; I am glad to know that the difficulty is reduced to a minimum. I maintained that, in my opinion, both geometrical and free-hand drawing were essential requirements for an architect; I am glad to know that not only does the programme of the proposed examination include practical tests of such requirements, but the probationary work required in the first instance from each candidate is likely to afford a very feasible means of testing a candidate's natural aptitude for the arts of invention and design. I maintained that an architect should be cognisant not only of the principles of construction, but of the nature, qualities, and value of building materials; and I am glad to know that it is proposed to devote an entire day to examination in such subjects. In fine, I have gone carefully through the suggested regulations and programme, which embrace requirements such as, I submit, every person seeking to be an architect should possess. Nor do I see in their general tenour anything Utopian, or, indeed, anything which might deter the heaven-born artist,—if artistic genius be purely and really a celestial gift,—from seeking admission to the Institute through the medium of an examination such as that we have decided upon recommending for final approval.

And here, gentlemen, I am induced to quote a passage from an address delivered from this chair by the first professional president who ever sat in it. I mean Charles Robert Cockerell. He was a man who, as the most artistic architect of the present day will admit, was, if anything, an artist. His words, uttered more than twenty years ago, when the graphic side of architecture was less understood and less followed than it is at present, merit your immediate attention. "So rare and difficult," said he, "is the union of the scientific and the graphic departments of this art in the same person, that theoretic writers are at variance as to the preference to be given to the one or the other faculty. Thus the learned Rondelet defines architecture as 'a science, the object of which is to direct the operations of every sort of building, so as to unite convenience, solidity, and beauty of forms. . . . . a vast science, the purpose of which is to provide for the security, the convenience, and the magnificence of nations, and to give them that lustre and prosperity which true civilisation implies. Most modern architects are rather decorators than constructors, aiming, like the painter and sculptor, chiefly to please,—indulging in captivating but often impracticable designs, induced by their associations with the imaginative arts of painting and sculpture, and . . . . . attracted by splendour and ostentation rather than by the graver merits of solidity, convenience, and durability.'" Now it is not I that am quoting a theoretic writer, it is the late Professor Cockerell who speaks, and who makes a pertinent quotation from a great Frenchman, the learned Rondelet,—that Rondelet who, at the very beginning of this century, described the architect of his day as a decorator rather than a constructor. Are we quite convinced in our own minds that Rondelet, if he lived at the present time, would define an architect in language more palatable to our own sense of what he should be? Are we quite sure that the cry for art, more art, in which I admit this country was long deficient, has actually provided us with what we required? Has not the tendency in England of late years been to unduly exalt the art at the expense of the science of architecture, so that architectural science is gradually becoming the specialty of men who are not, and who do not pretend to be, architects? The construction of aqueducts, roads, terraces, gardens, fortresses, bridges, seaports, viaducts, was once, and still lies, within the domain of architecture; yet few in England think of employing an architect on such works. In France, the best Parisian architects still think it within their province to edit works on the building legislative enactments of their country, and advise upon such subjects; here in this island there is a growing tendency to leave matters connected with building legislation to surveyors. In France, the planning of new thoroughfares, the laying out of public places, the daily charge of architectural monuments, the care of great estates both public and private, is retained by qualified members of our profession; here, in England, such duties are often relegated to all sorts of persons. I assert without hesitation that local governments and municipalities, indeed, many great owners of the soil, prefer to be advised by men who ostentatiously discard connexion with the picturesque and artistic elements of professional practice. We are more or less to blame for this state of things. Though thirty years ago there was plausibility in the successful efforts to stimulate the pursuit of architecture as an art, the necessity for such stimulus has now in some measure ceased, and the object of all thoughtful practitioners should be to reclaim much bonâ-fide practice diverted from its legitimate course,—to foster in younger men a regard for that scientific learning and mental excellence which Philibert Delorme preached, and which our own Sir Christopher Wren demonstrated to be worthy the pursuit of an artist.

But however limited may be the modern architect's connexion with the laying-out of cities, or even the design of new thoroughfares in this capital, he at least is afforded a doubtful satisfaction in viewing the disastrous efforts of others to accomplish work, the design of which would in earlier days have been entrusted to men of our profession. I am of course aware of the difficulties which beset all attempts at metropolitan improvements,—of the many legal and legalised impediments to public progress,—but I doubt whether the course pursued by the authorities, in facing those difficulties and removing those impediments, is either profitable or judicious. Take the West End of London, where the proposed line of new thoroughfares long-promised may be traced by half-demolished houses, empty tenements, and vacant plots of ground, and inquire whether these proposed thoroughfares are being executed in accordance with any well-considered architectural plan? There is little likelihood that the generation which is paying for them will enjoy the entire fruits of the enterprise. True, as mere thoroughfares, they may yet be made use of by living men, even of mature age; but that anything short of a miracle of accidents will render them things of beauty, or worthy of a great capital, I am constrained to doubt. Part of the system adopted, if system it may be called, is to connect a series of existing streets by removing blocks of old houses which divide them; by pulling down one side only of such existing streets, and driving a new thoroughfare along a necessary tortuous and irregular line,—a line formed by the untouched sides of streets, often of miserable dwellings originally erected without regard to either convenience or salubrity. Such is the mode in which the new street connecting Oxford-street and Old-street has been made; such is the mode in which the purlieus of Soho are about to be penetrated, with the intention of opening important thoroughfares, and I believe emphatically that this mode is dictated by financial necessity. The result will be, I venture to think, that there will remain on one side of the way for thirty and more years after the roadway of these new throughfares is completed, or at least until existing terms of lease fall in, an irregular line of disjointed blocks, huge and lofty; on the other side of the way rows of old and dingy tenements, with here and there a new building raised in the air over its squalid neighbours, and acquiring in due course prescriptive rights over the land on which such neighbours rest. Moreover, the squalid neighbours themselves, already possessing powers, acquired by similar prescriptive rights, are likely to be, in skilful hands, fertile of obstruction to individual improvement and public embellishment.

It must be admitted that the position of the Metropolitan Board of Works is one of unexampled difficulty. If even the powers vested in that body to effect improvements adequate to the scientific and artistic wants of the age were sufficiently broad, and if that system of liberal expenditure by which alone a satisfactory return is to be obtained were sufficiently understood; if even public opinion were educated enough to afford proper encouragement to the scientific re-arrangement of public places and streets in London, there would still remain the opposing complications and entanglements connected with vested interests and the abuses of the law of property. The systematic and organised obstruction which speculates upon the chances of exorbitant compensation would still issue triumphant from every fresh adventure. Moreover, there would still be found wanting, in metropolitan administration, that initiative faculty, that directing power, which sees, suggests, and plans the needed improvement,—the deficiency of which during recent years has been painfully conspicuous. Too much is England is left to chance and the happy-go-lucky encounter of conflicting interests, both personal and pecuniary. Take a recent case in the City of London, I mean the much-needed completion of the Inner Circle underground railway. There

were the two railway companies, the Corporation of London, the Metropolitan Board of Works, the various landowners and leaseholders,—all interested, but all at fault for a leader in a scheme of improvement which all admitted to be necessary. The probable cost of connecting the Aldgate station of the Metropolitan Railway with the Mansion-house station of the District Railway has been shown to be so enormous, in consequence of the value of land and tenements in the neigbbourhood, that the two railway companies dare not undertake the responsibility. It had been confidently expected that the Corporation and the Metropolitan Board would have co-operated in the scheme for the completion of the Inner Circle Railway, as it included the construction of a wide bandsome street in continuation of Cannon-street to Trinity-square. This proposed street would have given a great arterial thoroughfare in a crowded and almost impenetrable part of the city, and would have provided sites for blocks of offices and commercial buildings, for which there has long been considerable demand in the locality. But neither the new street nor the completion of the Inner Circle railway is yet a fact, though the postponement that has taken place is not due to any structural or indeed any difficulty of an insuperable nature. It is due solely to the difficulty of apportioning a just rate of contribution by the various parties interested to meet the enormous outlay involved. The railway companies, finding the cost of the land necessary to make their railway in the ordinary way would be a bar to any possibility of profit, unless the Corporation and the Metropolitan Board would undertake the construction of a new street simultaneously and incur the burden of the cost of the same, sought powers to burrow under the soil. The object of this was to avoid the obligation of constructing a new street over the railway. The companies offered to make compensation only for damage, without the necessity of acquiring the entire freehold of all the property touched by them. The Bill by which it was attempted to obtain such powers was, as might be expected, rejected by the House of Commons. It, therefore, still rests with the two railway companies and the two great governing bodies of London to make arrangements in respect to the cost of the superstructure,—that is, the new street and the new building sites,—so that the whole matter may be presented to the coming session of Parliament in a form which will enable a great and an absolutely essential public improvement to be commenced.

The educational part taken by the Institute in metropolitan business for the last twenty-five years, under the provisions of the Building Act, has recently been the subject of a communication from us to the Metropolitan Board of Works. The Council, acting on the advice of our Board of Examiners appointed by you, have taken steps to improve the character of the Examination for certificates of competency to hold the office of district surveyor in London. Instead of one sitting of four hours for the written examination there are now two sittings of three hours each, and in the latter of these the candidate's skill in making working drawings is tested. An oral examination remains as before. We have also, after consultation with the Metropolitan Board, determined to impose a fee on each candidate for examination,—a rule which will take effect at the beginning of next year.

The modern system of examination at home is closely allied to the extending fashion of international exhibitions abroad. Cousins at the Antipodes are returning the compliment which this country was the first to pay to colonial and foreign enterprise. The awards recently made to British architects at the Australian International Exhibition, held this year at Sydney, are numerous. I am indebted to Mr. Charles Barry for a book containing a list of these awards, and which is on the table for the inspection of all present. No official intimation has yet been made to the Institute on the subject of the architectural drawings exhibited at Sydney,—work with which we were immediately connected. I trust, however, that when this same exhibition is resumed next year at Melbourne, my successor will be enabled, in due course, to afford members fuller information about it than at present lies in my power respecting the Sydney gathering. The preservation of such official reports as the one to which I have alluded is part of the many functions of our corporate existence, and our library ought to contain all records of facts relating to British architects throughout the world.

The slight use made by members of our valuable library has been more than once touched upon by my predecessors, and I have sometimes asked myself whether its usefulness might not be extended, and the purposes for which it has been collected might not be advanced, by throwing it open to all *bonâ-fide* students of architecture. That this can be done without trenching upon the privileges of members is evident, for no one under the age of twenty-one can become an Associate, and practically very few gentlemen who are less than twenty-five years old offer themselves for Associateship. It therefore affords me great satisfaction to state that steps have been taken to open the library free to young men under twenty-three years of age, who are engaged in the study or even practice of architecture, and who produce satisfactory evidence of the fact. The legacy of 100*l.* bequeathed to the library by Thomas Henry Wyatt, is another instance of our deceased friend's goodwill and devotion to the Institute. A recent donation, made through the good offices of Professor Donaldson, of several original drawings by the late Owen Jones, whose portrait adorns this room, is no less welcome. The donation has been made by the two Misses Jones, sisters of our late esteemed colleague. I am further informed by Professor Donaldson that it is the intention of these two ladies to bequeath to the Institute such a sum of money as will found a studentship of the value of 50*l.* per annum, to be tenable for two years, for the purpose of assisting meritorious students to travel, in order to advance their knowledge of architecture and of colour applied to architecture. We shall, consequently, one day possess an Owen Jones Studentship,—one that will probably be not less popular among students than the medals and prizes we annually offer in connexion with the names of Soane, Pugin, Tite, Ashpitel, and others. Thus, slowly and surely, the promise of our founders is being fulfilled; and it may yet, perhaps at no distant period, become the pleasurable duty of some one in this chair to expatiate upon what has been effected, in your name, "for the general advancement of civil architecture," to quote our charter, "and for promoting and facilitating the acquirement of the knowledge of the various arts and sciences connected therewith."

It does not, however, come within the powers of the Council to do all that many well-intentioned practitioners think ought to be done. I have heard it seriously maintained that the only use of the Institute of Architects is to enforce observance of a uniform tariff of five per cent. commission to be charged by old and young, experienced and inexperienced, capable and incapable practitioners of architecture; and that nothing short of expulsion under the by-laws should await the youthful or diffident practitioner who places upon the value of his professional services a lower figure than that charged by his elder and more fortunate brethren. I cannot conceive anything more illogical or more suicidal. The clauses in the Institute paper, entitled the "Professional Practice and Charges of Architects" represent simply the custom of the profession in Great Britain and Ireland, in India and the British Colonies. Where doubts crop up as to the amount of charges due, where no previous agreement has been made and disputes occur, where death intervenes, when a Court of Law asks for information as to the custom of the profession, then the Paper of Professional Practice and Charges is rightly and necessarily cited. But no man signing the declaration of a Fellow or an Associate of the Institute, and in accepting the terms of our charter and by-laws, incurs the obligation to abide by any restraints of professional charges. All such commercial and professional restraints are opposed in more ways than one to the laws of the realm; and would, at the best, encourage action on our part not dissimilar of its kind to that of ill-advised trade-unionists. I admit that there are questions of professional practice requiring a great deal of thoughtful consideration,—questions which may very fitly be discussed this session,—particularly the complications connected with the taking-out of quantities, and the best means of obtaining a fairer adjudication in architectural competitions than appears to exist. These are matters that should occupy the serious attention of the conference to be convened in May next, when I trust that a large number of those architects who signed the memorial on competitions will do us the favour to be present. I also hope that the numerous quantity-surveyors now practising in London and some provincial cities will afford us assistance in the discussion of several important points which are likely to be raised on the subject of quantities: the division of labour connected with them, and the present mode of paying for them.

Perhaps nothing about the memorial on the subject of competitions presented to the Council by Mr. Street afforded me more astonishment than the fact that there are in the United Kingdom more than 1,300 professional architects, for at the present moment the Fellows and Associates of the Institute together only reach a total of 716. Indeed, at the close of the last session the numbers stood thus:—

	F.	A.
Australia	4	2
Colonies and abroad	4	12
English Counties	110	82
Indian Empire	3	3
Ireland	6	3
London and Suburbs	209	253
Scotland	15	4
Wales	0	6

351 Fellows, 365 Associates, making a total of 716.

But I am still more astonished to find, from a list issued every week in a professional newspaper, there are nearly 3,000 persons professing to be engaged in the practice, under some form or other, of architecture. It is there stated that in Birmingham there are 49 architects, of whom only 7 are members of the Institute; in Bradford, there are 22, of whom 2 are members; in Bristol, 25, of whom 4 are members; in Edinburgh, 41, of whom 3 are members; in Glasgow, 60, of whom 19 are members; in Liverpool, 57, of whom 13 are members; in Manchester, 113, of whom 20 are members; in Sheffield, 31, of whom 7 are members; in Wolverhampton, 11, of whom 1 is a member; in York, 10, of whom 1 is a member; in London and suburbs, more than 750, of whom only 462 are members. The cathedral towns of Chester, Lichfield, Lincoln, Peterborough, Ripon, and Salisbury are not represented in our ranks by a single Fellow or Associate. In Hull, Sunderland, and Wolverhampton, which contain together, it is said, 38 architects, and in the principality of Wales, which is also said to contain 38 architects, there does not reside even one who has formally accepted the obligations of a Fellow of the Institute. Now, I know, of course, that a vast number of the gentlemen whose names are put down in directories as architects, and are so called by their neighbours, could not and ought not to become members of our body. But when you consider that of the many memorialists on the subject of competitions less than a third are members of the Institute; when you look at the long array of architects' names printed in the last-issued number of our "Journal of Proceedings,"—architects who have memorialised the Council, and who are not members of the Institute,—the very pertinent question arises, for what reason do these practitioners stand aloof from the corporate body of the profession? Are they unable or do they fear to incur the obligations which we have accepted? Some, no doubt, are prevented from entering our ranks by the expense, slight as it is, of so doing; a few others, perhaps, by caprice. But that the majority are ostracised in consequence of conscientious reasons I cannot for one moment suppose, nor do I think that there is anything in the declaration of a Fellow or of an Associate, or anything in our charter and bye-laws, which an honourable practitioner, having at heart the good of his profession and of himself, ought to refuse to accept. Indeed, it is only due to the public, as well as to ourselves, to direct serious attention to the fact that the number of architectural practitioners who submit to no recognised professional discipline, who take no obligation designed to secure integrity of practice and eliminate all pecuniary interest in building materials or participation in the commerce of building, is Legion. It is only due to myself, as your president, to state that the published names of such practitioners in this island alone exceed, by much more than 2,000, those on the roll of the corporate body. I shall, doubtless, be reminded that those of them who are members of local societies do accept obligations and do combine to resist evils and abuses which, at the very formation of the Institute, it was the object of our founders to root out, and which they largely succeeded in abolishing; but I need no such reminder. I am aware that the constitution of two or three of the provincial Insti-

tutes and Associations does not seriously differ from the purport of our own; but are such societies endowed with the powers which the corporate body of British Architects possesses? I doubt it. I venture to maintain that the interests of the public, not less than of the honourable practitioner of architecture, are linked with the prosperity and influence of the Royal Institute of British Architects. Such interests are linked with the legitimate control the Institute exercises over the conduct of those who accept the systematic discipline it is authorised to impose.

ROYAL INSTITUTE OF BRITISH ARCHITECTS.

THE opening meeting of this Institute for Session 1880-81 was held on Monday evening last, Mr. John Whichcord, president, in the chair. Among the new members presented to the President as attending for the first time since their election, was his Serene Highness Count Gleichen, Honorary Associate.

The Secretary (Mr. William H. White) announced the decease of Mr. John Henry Brown, Associate, on the 18th of October; and of the Marchese Giovanni Pietro Campana, of Rome, Honorary and Corresponding Member.

Several donations to the library and collection were announced, including some drawings by the late Owen Jones, presented by his sisters, the Misses Jones. A vote of thanks was accorded to the several donors.

The following passed candidates in the Class of Proficiency of the Voluntary Architectural Examination were then presented with the Institute certificates, viz.,—Messrs. J. B. Gass, — Goldsmith, — Johnson, H. H. Kemp, P. J. Marvin, and L. G. Summers.

The following gentlemen were balloted for and declared to be duly elected, viz., as *Fellows*, Mr. C. N. Beazley, of Guildford-street, W.C., and Mr. James Allanson Picton, F.S.A., of Liverpool. As *Associates*,—Mr. G. W. Watson, of the Department of Public Works, Melbourne, Victoria; Mr. Alfred Aitchison, of Harley-street; Mr. Augustus Rovedino, Craven-street; Mr. C. W. Reeves, Guildford-street; Mr. Arthur Ashbridge, Leadenhall-street; Mr. H. L. F. Guermonprez, Beaufort-street, Fulham-road; Mr. Sydney Vacher, Stanley-crescent; Mr. J. E. Bale, Sierra Leone; and Mr. Hugh Stannus, Kennington Park-road.

The secretary gave notice of an alteration in the conditions already issued by the Council with respect to the competition for the Soane Medallion for 1881, the subject chosen being a county court for a provincial town of 30,000 inhabitants. By the alteration thus made the area of the site to be covered is limited to 10,000 square feet.

The President having delivered his opening address, which we print on other of our pages this week,

Mr. Charles Barry, in moving a vote of thanks to Mr. Whichcord, referred to the address as one of an eminently business-like character, dealing ably with professional topics of great interest to, and deserving the careful and thoughtful consideration of, every member of the Institute. The President had lucidly explained a number of what he very properly spoke of as experimental measures in the administration of the business of the Institute, all of which had received very careful and anxious consideration on the part of the Council, whose sole desire in initiating them had been to give effect to the wishes and views which they thought were held by the majority of the members. It would be for some future president to sum up and analyse the results of those experiments. That relating to the compulsory Architectural Examination was the most important experiment that had ever been attempted by the Institute. The President was very sanguine as to the great good which it would be to the public, and the still greater good it would be to the profession itself. He (Mr. Barry) was sure that all present shared the hopes of the President, but it was a very great experiment to make, and he ventured to think that the members of the Institute must not be wholly unprepared for a certain measure of ill-success, or for only a partial success of the scheme,—at any rate, in its earlier days. The measure had been most carefully debated and discussed, and had undoubtedly received the approval of the large majority of the members of the Institute. That would be an earnest, he hoped, of their not being faint-hearted if the scheme did not at once succeed. The next subject to which the President alluded was the realisation, owing to an unexpected stimulus, of a desire long expressed that the Institute, like many other professional bodies, should have a charitable fund of its own for the relief, when necessary, of unfortunate members of the profession. The President had explained the terms of the bequest left to the Institute conditionally on its having a benevolent fund of its own, and although it would in all probability be some years before the Institute inherited the bequest, that was no reason whatever why donations, and, still better, yearly subscriptions to the fund, should not be given and allowed to accumulate at interest until the time when the bequest should be received, so that the fund might become one affording means to do a great amount of good. Having feelingly acknowledged the President's reference to the late Mr. Edward Barry, the speaker went on to observe that another subject touched upon in the address was that of reducing the number of meetings at which papers should be read, and appropriating the evenings so gained to the discussion of professional questions. That was a change which might with care be made an engine of great good; but, on the other hand, it might prove to be an engine of great mischief. The Council, however, trusted that members who should meet to discuss such questions would approach them with calmness and temper, and with a due sense of the responsibility which they would incur in dealing with them. One hoped-for advantage of such discussions would be that, from time to time, the hands of the Council would be strengthened, and their responsibility in dealing with professional questions somewhat lightened. Into the very large question of the relative importance to be attached to science and art in the work of the architect he did not propose to enter. The President had quoted some interesting words by Professor Cockerell, who in his turn had quoted Rondelet, but he thought it should be borne in mind that both these authorities were speaking of times now passed away. With regard to the mode in which public improvements are effected in this country, particularly in the metropolis, he fully concurred in the remarks made by the President, but thought that there was no hope for a favourable change in that direction unless we were prepared to accept the authority of some such autocratic administration as was formerly presided over in Paris by Baron Haussmann. As to the subject of professional remuneration, he did not think that anybody who had studied the scale of charges authorised by the Institute could find fault with it on the ground that it too highly rewarded any of the duties therein specified, and he could, therefore, see no reason for reducing any of the charges sanctioned by it. The scale was of great value in promoting uniformity of practice and of preventing undue rivalry between the members of the profession. In conclusion, Mr. Barry referred to the assiduity with which Mr. Whichcord had fulfilled the duties of his office during the past year.

Mr. C. L. Eastlake said that as a former officer of the Institute, it gave him great pleasure to second the vote of thanks proposed by Mr. Barry. The President had shown great tact in dealing with the different questions to which he had called attention. He cordially echoed the wish expressed by him that many of the large number of architects who, for some reason or other, held aloof from the Institute, could be induced to join its ranks.

The President, in reply, suggested that it would be but graceful on the part of the meeting to convey to the Misses Jones, through Professor Donaldson, the thanks of the Institute for the announcement received through him of their munificent intention to bequeath a very considerable sum of money to the Institute. He therefore moved:—"That the Royal Institute of British Architects beg to express their deep and grateful acknowledgments to the Misses Jones for their kind and generous intentions in regard to endowing a scholarship in remembrance of their brother, the late Owen Jones, whose talents and personal character endeared him to his professional brethren. The members feel that at the same time such a memorial will not only be a graceful tribute to his honoured memory, but will also contribute essentially to the advancement of the study of art in those branches of architecture which he himself had illustrated so successfully in his brilliant work and publications."

Mr. Barry seconded the motion, which was carried with much applause.

A special general meeting of members only was then held for the election of an honorary secretary, in the room of the late Mr. T. H. Wyatt. Mr. John Macvicar Anderson, member of Council, was unanimously elected, and in returning thanks paid a graceful tribute to the services of his predecessors in that office,—Professors Donaldson and Hayter Lewis, and Messrs. Frederick Pepys Cockerell and Thomas Henry Wyatt.

The meeting then terminated.

INTERFERENCE WITH THE FLOW OF AIR TO BUILDINGS.

MR. JUSTICE FRY has recently decided a case,—that of Hall *v.* The Lichfield Brewery Company (49 *Law Journal* Reports, Chancery Division, p. 655),—upon the question of the right to air, which is of so much importance that it is impossible to refrain from commenting upon it in these columns. Nor can it be touched on without discussing briefly the whole question of the right to air. Now, bold though it may seem, we are unable to think that Mr. Justice Fry's decision is correct, considering the current of previous judgments in the English courts. First of all, we venture to lay down two propositions, which, if they are correct, form, without doubt, the key to the decision of disputed facts which relate to air. The first is that no man can acquire an indefeasible right to the flow of air to or into a building, and consequently that no action can be successfully maintained to prevent a person from building so as to interfere with such flow of air. But this general proposition is subject to the qualification that if the flow of air is so interfered with as to cause an actual nuisance,—as, for instance, if it is likely to cause injury to health,—then that a right of action does exist. The second proposition is that every man has a right that the air which flows to his house, or to any other building, shall be reasonably free from pollution. We say "reasonably free," because regard must be had to surrounding circumstances, and in a town like Birmingham or Wolverhampton it would be impossible to have the pure air which circulates round a Highland village. As Vice-Chancellor Knight-Bruce observed in the case of Walter *v.* Selfe, "meaning by unpolluted and untainted air, not necessarily air as fresh, free, and pure as at the time of building the plaintiff's house the atmosphere then was, but air not rendered to an important degree less compatible with the physical comfort of human existence,—a phrase to be understood of course with reference to the climate and habits of England." This last proposition we do not intend now to examine further; to do so would lead us into a long discussion of the various cases which have dealt with the pollution of air,—a distinct branch from the right to the flow of air, though the distinction is not always kept properly in mind.

To return to the case which was decided by Mr. Justice Fry. The claim was, so far as the judgment was concerned, for the obstruction of air to a slaughter-house in consequence of the erection of new buildings by the defendants. Mr. Justice Fry decided that the plaintiff had a right to the relief which he claimed. He seems to have considered that there had been a breach of an implied covenant "not to interrupt the free access of air suitable for the purposes of a slaughter-house, just as salubrious air is suitable for the occupation of a dwelling-house."

Now at this time of day it is an extraordinary thing to observe a legal fiction of so obvious a character resorted to for the purpose of forming the basis for a claim as this of an implied covenant. The slaughter-house had, it is true, been in existence for more than thirty or forty years, but it is obvious that the right cannot be one arising from any implied covenant. Air and light are more or less on the same footing, and, as the words of the Prescription Act show, length of enjoyment is what constitutes the basis of the right to light. The Prescription Act governs the question of light, and the right to air must rest, if it exists at all, on the same principle, not under statute, but by common law; and we may say that in a case decided in 1824, that of Moore *v.* Rawson (3 Barnwell & Cresswell's Reports, p. 332) there is a passage in the judgment of Mr. Justice Littledale in relation to light and air which no doubt gives some

countenance to an existence of such a right. Again, there is no analogy between the access of salubrious air to a dwelling-house and the access generally of air to a slaughter-house. As we have pointed out, if salubrious air is changed into polluted air, that is a positive nuisance, but if you stop the flow of air to a slaughter-house, though a nuisance may arise, it arises from the nature of the house, and not from anything connected with the air. A man erects and keeps his slaughter-house at his own risk, just as a man builds a house at the extremity of his land at his risk, and if he wishes to have a free stream of air he should negotiate with his neighbours for that purpose. In Mr. Goddard's work on "Easements," he states that "from the earliest times a right of action for obstruction of air, which would have entered a window, has been recognised by law if a right that the air shall be uninterrupted has been acquired." For this proposition he cites Aldred's case (9 Coke's Reports, 58) decided in the reign of James I. But when this case is examined we find that the head-note is as follows:—"An action in the case lies for erecting a hog-stye so near the house of the plaintiff that the air thereof was corrupted." And the rest of the note amplifies the statement. When we look into the case, we find also that the whole facts bear out the note. "One ought not to have so delicate a nose that he cannot bear the smell of hogs," is one ground of defence, though it does not appear to have been successful. A still older case is mentioned in the judgment, to the effect that "an action lies for stopping as well of the wholesome air as of light." But here we have the qualifying adjective "wholesome," the obvious meaning of the remark being that the air should flow unpolluted to a building. Coming down from the times of the Stuarts to our own days, we find, in 1866, a case decided by the present Lord Hatherley, namely, Dent *v.* The Auction Mart Company (Law Reports 2, Equity, p. 238). In the course of the argument, the Vice-Chancellor asked,—"Is there any authority for interference in cases of obstruction of air as distinguished from light?" To which counsel replied, "Probably not." And in the judgment we find this short but important passage: "Another part of the case is this,—there is a staircase lighted in a certain manner by windows which, when opened, admit air. The defendants are about to shut up these windows as in a box with the lid off by a wall about 8 ft. or 9 ft. distant, some 45 ft. high; and in that circumscribed space they propose to put three water-closets. There are difficulties about the case of air as distinguished from that of light, but the court has interfered to prevent the total obstruction of all circulation of the air; and the introduction into a confined space of this description is, I think, an interference with air which this court will recognise on the ground of nuisance. *This is perhaps the proper ground on which to place the interference* of the court, although in decrees the words 'light and air' are often inserted together as if the two things went *pari passu*." The passage which we have placed in italics seems to show conclusively that on the ground of nuisance, and nuisance only, will the court interfere with an obstruction of air. In the case before Mr. Justice Fry, the nuisance likely to arise came, as we have pointed out, from the nature of the plaintiff's building, not, as in the case of Dent *v.* The Auction Mart Company, from anything done by the defendant. Again, in the case of Cell *v.* Abbot (8 *Jurist*, N.S., 987), decided in 1862, the court interfered with the obstruction of air into a back kitchen, and again the judge (Vice-Chancellor Kindersley) remarks, "It was therefore such a *nuisance* as this court would protect against." The obvious result of the defendant's obstruction was to close the back kitchen entirely and leave it totally without ventilation, and this would, it is clear, be an injury to the health of the inmates of the house, and quite a different matter from the prevention of air through a window or aperture, if it did not cause an injury to health. These decisions are still further strengthened by the case of Bryant *v.* Lefevre (4 Law Reports, Common Pleas Division, p. 172), decided in the course of last year, and upon which we made some remarks after it was decided (*Builder*, vol. xxxvii. pp. 354, 678). There was in that case a claim for a free flow of air to the chimneys of a house, but much of the reasoning of the judgment is applicable to more limited claims. For example,—"When it has been said that there is a right to air, there is good ground for supposing that the wholesomeness of the air had been interfered with, or that there was some peculiarity in the land or building which made the air necessary in a definite place."

The latter part of this sentence, no doubt, might give some countenance to Mr. Justice Fry's decision, but we think it is really pointed to some such fact as a back kitchen, as in Abbot *v.* Gale, and not to an unusual construction such as a slaughter-house, which, had it been an ordinary building, would not have been interfered with by the obstruction in question. This view is borne out by another passage in the same judgment, "No doubt there is a nuisance, but it is not of the defendants' causing. They have done nothing in causing the nuisance. Their house and their timber are harmless enough. It is the plaintiff who causes the nuisance by lighting a coal fire in a place the chimney of which is placed so near the defendants' wall that the smoke does not escape, but comes into the house. Let the plaintiff cease to light his fire, let him move his chimney, let him carry it higher, and there would be no nuisance." Apply the reasoning of this passage to the case of a slaughter-house and it is clear that Mr. Justice Fry gave a wrong judgment. It does not appear, indeed, that the case of Bryant *v.* Lefevre was brought to his attention, which could hardly have failed to have influenced his judgment. The reason of such a view as we have pointed to is obvious. A man has a right to do with his own what he will, so long as he does not injure another, but each adjoining owner has to give and take, and to prevent a man from building because he obstructs the flow of air is to prevent his doing what he will with his own. When my neighbour darkens my house so as to prevent its being properly used, when he builds so close as to stop *all* circulation of air, then he causes a nuisance injurious to health; but if a man chooses to exercise a trade which requires a special amount of air, he must go and do so in a place fitted for it, and not prevent the legitimate enjoyment and use of his neighbour's property. If this idea is properly grasped, it becomes evident that,—especially having regard to the Prescription Act,—light and air stand in the eye of the law on a very different footing, and that, in spite of the judgment of Mr. Justice Fry, the obstruction of the latter element only gives a right of action when it has caused what the law calls a nuisance.

HIGHER TECHNICAL EDUCATION AND COOPER'S HILL COLLEGE.

All those of our readers who are interested in the training of young men for any branch of the great technic profession, including engineering, architecture, and survey, should pay attention to the change announced to be impending in the conditions under which pupils will henceforth enter Cooper's Hill College. At present the door of entrance is narrow. It is guarded by a competitive examination of some severity. But once inside, the future of the pupil is in his own hands. Employment in India is assured him at the close of his college course, so that he conducts himself well.

It is now proposed, we are told, at the same time to widen the gate of entrance, and to take away from the College the great privilege of certain provision for its pupils. For the competitive examination at entrance, a pass examination is to be substituted; the pupils being admitted in order of application, and the limit of age at entrance is enlarged from nineteen to twenty-one years. The effect of this will probably be to obtain more pupils from the more wealthy classes, rather than to secure the pupils most likely to distinguish themselves. The cost of the education and maintenance of a young man from nineteen to twenty-one is more than that for any other two years of his life, and those parents and guardians who can afford this additional outlay will only be found among the wealthier part of society. These "late men" will,—or may,—be of two kinds. There will be those who, having repeatedly tried, and as often failed, to pass various examinations, will come thus late in the day to Cooper's Hill. But there may also be those who desire to make sure, and who may have enjoyed even a university training. Against these men, if they have worked for their two extra years, the ordinary student will have but little chance. The public school men,—who now take their fair share of entrances,—will be distanced, and the educational character of the place will be altogether changed.

But this is not all, nor nearly all. The competitive examination is to be shifted to the close of the course. This means that the posts to be given to the pupils will be limited,—and other information leads us to anticipate narrowly limited,—in number. Indeed, it may with much probability be suggested that the fact that the college is now supplying an unusual number of engineers for whom there is really no room or need in India is the real meaning of the change. But, if so, how much better simply to announce that, in future, only a certain number of appointments would be annually given.

It may have been thought that such an honest bit of truth would have reduced the number of pupils. Very likely so; but does the college exist for the pupils, or the pupils for the college? It is very likely that the new arrangement, if carried into effect, will for a time increase the number of pupils, and the profits of the establishment. But we do not think such an increase likely to be permanent. When what we anticipate to be the necessary effects of the change become gradually patent, a revulsion will set in. What is required by the country, and what is best for its service, must, in the long run, be also best for our great educational establishments. There are certain points in which change was desirable at Cooper's Hill, and in which, in the due course of things, change has come to pass; but we seriously deprecate the present plan of turning the establishment into a trap for pupils.

EDUCATION IN SPAIN.

It is satisfactory to feel, and agreeable to be able to state in these columns,—where the interests of hygiene and sanitation have long been advocated,—that the consideration of their importance is spreading to countries where but a short time since their existence was almost ignored. A Parisian journal, the respected *Débats*, in a recently-published letter from a Madrid correspondent, has given some interesting details regarding a new educational institution opened in the Spanish capital. In the list of studies followed, hygiene finds a special place by the side of the varied branches of literature, science, and art. In many other respects, too, is this an excellent institution. One general rule regulates the whole system, the education is effected as much as possible without the aid of books, which, indeed, during the first years are almost completely absent. The book is used merely as a secondary or auxiliary means of instruction; in lieu of the old system, in which the memory of the pupil is tortured to retain what has been mechanically learned by rote, his eye and mind are made to appreciate what the book can never explain. The system, it will be seen, resembles much what in our modern art education has led to such excellent results, drawing from the round instead of from the flat; the intelligence is exercised and strengthened. But not here does this process stop in the institution to which we are referring; indeed, it may be said that it is only at this point that commences the veritable innovation. The education is completed by means of excursions made by classes, under the direction of their professors, with a view to examining and studying what cannot be learned in the institution. Extending beyond the walls of the capital, visits are often made in the provinces. In town these are made to the museums, art-collections, the Observatory, the Botanical Gardens, the various great factories, and even shops, new buildings, or engineering enterprises in progress. In the provinces the visits are made to sites interesting from an archæological, artistic, and geological point of view. From their observation, and the information they have gathered, the pupils on their return are called upon to prepare an account of what they have seen,—an account corrected by their professor. Excellent exercise for the eye, the mind, and the power of reflection and of expression, it can be understood how invaluable may be the result of this method in practically educating men for the business of life such as it is in the present day, so different to that of the past, for which the existing system of education was formed, and has been so faithfully handed down to us. How practically the system has already been set to work, may be judged from the fact that in July last considerably more than 200 excursions and visits were made under the conditions above specified. It is many centuries since the world has

looked to Spain for the initiative in the progress of culture, for the first steps towards which, in modern times, we owe so deep a debt of gratitude to the Moorish conquerors of the Peninsula, over which, after their departure, so black a night slowly fell. But again, the hope is promising that Spain may take its rank worthily with the other nations of the civilised world in the endeavour with them to advance the sum of human health, wealth, and wisdom.

THE DEATH OF SIR THOMAS BOUCH.

Those of our readers who have taken an interest in the circumstances attending the destruction of the Tay Bridge, which have been so frequently referred to in our columns, must have read the announcement of the death of Sir Thomas Bouch with a feeling of melancholy regret. Whatever view may have been taken with regard to the amount of personal responsibility which rested upon the engineer in relation to the calamity of last December, the sorrowful ending of so successful a career carries the mind beyond the range of technical fault-finding, and ought to lead us to contemplate rather the bright than the dark side of a life that has terminated so sadly. Any one who saw the late Sir Thomas Bouch moving to and fro during the inquiry into the disaster with which his name must for ever be associated, could not help seeing that he was a stricken man. The tear and wear of his professional life, mixed up as it had been for many years with ventures in which he had a deep pecuniary interest, had already begun to tell their tale. When, in addition to all this, he suddenly found himself thrust out of the position of trust and responsibility which his abilities had rendered apparently secure, and placed in an attitude of defence towards the work of his own intellect, and the anxious labour of years, the strain that was thrown on his constitution could be read by the passer-by.

The circumstances, in the mere aspect of their human interest and as a commentary on the vanity of human affairs, appear to us to afford the materials for a tragedy, the motive of which is peculiar to the times we live in. In the climax, when the fates have come with the shears, the end, instead of being a culmination of the sorrow, is rather of the nature of a kindly remedy for evils that could not longer be borne. It is very questionable if any opportunities that might have been afforded by the prolongation of life, even beyond the common span, would have so altered the aspect of what has passed as to have removed the causes of mental anxiety and suffering. We hope, that now he has gone, the lesson he has left to the living may never be taught at the expense of a kindly regard for the dead.

The curtain has fallen on a human tragedy, which we have already spoken of as having a motive peculiar to the times we live in. It is true that in its external aspect there is not much to strike the mind as different from the exigencies of an ambitious career in all ages. The successful general who, after having conquered his enemies, has himself been conquered, is a familiar subject for the dramatist. But with him each action of his life has to be judged from the individual circumstances surrounding it. If his enemies were fighting for their rights, success could never justify the object of his labours. But in this nineteenth-century tragedy we find a general in the army of labour, fighting in a noble cause, who has fallen a victim to the inexorable watchfulness of natural laws that are ever ready to revenge themselves upon mistakes. The foes with whom he fought were never encountered in support of an evil cause. Let us not, then, think of Sir Thomas Bouch as one who destroyed the Tay Bridge, as might have been done by the leader of an invading army. He did his best, in circumstances surrounded by trial and difficulty, to make it secure. In his battle with the elements, it was at least his sincere wish to succeed in the interests of progress and civilisation. Even those who were ready to quote the sad death of the sufferers from the accident as a ground for indictment are silenced by the mournful event that has followed. Sir Thomas has died of a broken heart, and gone to join the multitude of the rank and file of the army of labourers whose lives, in the great vortex of modern civilisation, have met with an untimely end. In spite of the sad termination to his career, we can still look back on his previous work, and deplore the loss of a great builder.

Requiescat is a sentiment that all men, even those who felt most keenly and spoke most loudly about his responsibilities, will now be ready to express. Rest from such afflictions appears the most merciful interpretation of death when hope has ceased to secure a hearing.

LANGNESS LIGHTHOUSE, ISLE OF MAN.

Two years ago (vol. xxxvi., p. 952) we gave an account — somewhat popular in its nature —of the Chickens Lighthouse in the Isle of Man, and the remarkable marine scenery by which it is surrounded. A comparatively short sail or steam in a northerly direction brings the mariner off Langness, a low, rocky promontory, which projects into the sea nearly three miles from the mainland. Its very lowness partly constitutes its danger to navigation, as in foggy weather a vessel may touch the rocks before they are perceptible, and even on a comparatively calm day an angry current, a continual seething and foaming of the waves, surrounds the promontory some distance from the land. Scarcely a winter passes without two or three vessels ending their days on these treacherous rocks. It is therefore none too soon that the Commissioners of Northern Lights have just completed the erection of a lighthouse on this spot. The engineers were Messrs. Stevenson, and the actual buildings are now nearly completed. The lighthouse is 59 ft. high, and is surrounded by a square enclosure, within which are comfortable houses for the keepers, whilst at the back are yards and piggeries, the whole forming an exceedingly complete set of buildings, having regard to the purpose for which they are to be used. Being on the mainland, it should be a favourite station, for it is no little addition to their actual duties for the lightkeepers to spend weeks of a lonely existence caged within a narrow structure surrounded by the sea, as are those who have charge of the Chickens and Skerryvore lighthouses. The buildings are all of greystone, and in addition to the warning which this light will give in stormy or thick weather, it will be a useful guide for the fishing-boats and trading-ships which have to enter Castletown Bay. The beacon will be lighted on the 1st of January next, and from that day it may fairly be hoped that no more wrecks will be heard of on this treacherous spot, and that Langness, from being a terror to the passing sailor, will become a guide to those who have to navigate these northern but frequented seas.

CONVERSION OF COOK'S BUILDINGS, LUDGATE-CIRCUS.

A NEW CITY CLUB.

The extensive new buildings forming the north-west side of Ludgate-circus, which, a few years ago, were erected by Mr. John Cook, at an outlay of about 60,000*l.*, are to a great extent about to be utilised as a new City club on a very comprehensive principle. The ground and mezzanine floors will still be occupied by Messrs. Thomas Cook & Sons, the well-known excursionists, but the upper portions, which have hitherto chiefly been used as the offices of London representatives of several of the leading provincial daily newspapers, are henceforward to be appropriated to club purposes, and are at present undergoing the necessary alterations. There will be altogether upwards of twenty rooms forming the club, several spacious rooms on the first floor consisting of a library and reading-room, well supplied with newspapers and periodicals. The second and third floors will be set apart for *restaurant* and dining purposes, whilst the floor above will be fitted as billiard-rooms, with provision also for other games. There will also be smoking-rooms, whilst some of the apartments are intended to be used for conversational purposes by members of the club. The *cuisine* department will be at the top of the building, with lifts communicating with the several floors, and the manager's apartment will likewise be on this floor. Special accommodation is intended to be provided for members of the press who may choose to connect themselves with the club. A room will be set apart for their exclusive use in preparing manuscript for the several newspapers with which they are connected, and this room will be open the whole of the night under the care of an attendant. The club is to be conducted on strictly temperance principles, no alcoholic drinks being permitted.

The alterations in the interior are being carried out under the superintendence of Mr. Cundry, the architect of the building.

DECORATIVE SUGGESTIONS FROM NATIONAL FORMS.—No. 5.

The plant figured in this number, *Solanum jasminoides*, is remarkable, not only for its great elegance and grace of form, but for the fact that it combines two forms of leaf, a one-lobed and a three-lobed form, the latter being (in the specimens we have observed) mostly developed in the upper portion of its growth. The blossom has five white petals very symmetrically arranged, to which the stamens form a yellow centre. It is a climbing plant, having some resemblance, as its specific name implies, to the jasmine, but not found in northern latitudes of Europe. This combination of the single and triple leaf is one point observed in the designs here based upon it, for a wrought-iron grille, a wall-diaper, and a decorative tile. The lines of the natural plant, both in its general growth and in the form of the leaf, are so clean and precise that they are susceptible of being applied in ornamental design with much less conventionalism than is necessary with many natural types. The iron grille is perhaps more naturalistic than is usually desirable in such a material, the character of the plant forming the excuse for such a treatment. The slightly waved or serpentine line of the main uprights is directly derived from the manner of growth of the stalk, which shows a prevalence of slightly sinuous lines. Such a treatment is in keeping with the ductile nature of wrought iron, and aids, in fact, in expressing the character of the material; in cast iron it would be out of place.

TRIUMPHAL MONUMENT, FREIBURG, BADEN.

Breisgau, which for 200 years formed the extreme south-west frontier of Germany towards Elsass, from the time the latter was taken by the French, was in great danger in January, 1871, of being overrun by Bourbaki's army. The struggle which was maintained for several days by a German force against an enemy who outnumbered it more than three times, has been compared with that of Thermopylæ, with this difference, however, that the modern Spartans successfully resisted the equally modern Persians, and thus saved their frontier-land from being ravaged by an exasperated foe. This glorious fight, with their back to the wall, determined to conquer or to die, was sustained by the Fourteenth German Army Corps, under their able leader, General von Werder. The three days' battle on the Lisaine, on the 15th, 16th, and 17th of January, which completed the defeat of Bourbaki's army, saved Baden, and in the first place Breisgau, from threatened devastation and ruin. In thankful remembrance of the conspicuous bravery displayed by the troops engaged, the principal city of Breisgau, Freiburg, has erected a monument to her saviours, which was unveiled in the presence of the German Emperor and Crown Prince, members of the reigning house of Baden, General von Werder, and many deputations from the Fourteenth Army Corps. The monument (of which we give a view), certainly one of the most imposing of the many trophies lately erected in Germany, has been executed by Professor Moest, of Karlsruhe, after his prize design; it is erected on the Kaiser-Wilhelms-Platz, formerly Casernenplatz; and bears four inscriptions. The principal one may be thus Englished:—

TO THE
XIVth GERMAN ARMY CORPS
AND ITS LEADER,
GENERAL VON WERDER,
THE GRATEFUL BADEN PEOPLE.

The artist has, in an appropriate manner, expressed the principal characteristics of that great struggle by the defensive attitude of the four soldiers placed on the projections at the four corners of the base. Their duty was, not to act offensively, like their opponent, but to defend the open gate of their unprotected fatherland to the last man.

Thus three German men of eminence have been honoured in Freiburg by monuments, viz., Rotteck, the liberal historian; Berthold Schwarz, the inventor of gunpowder; and Werder, a veritable modern Bayard.

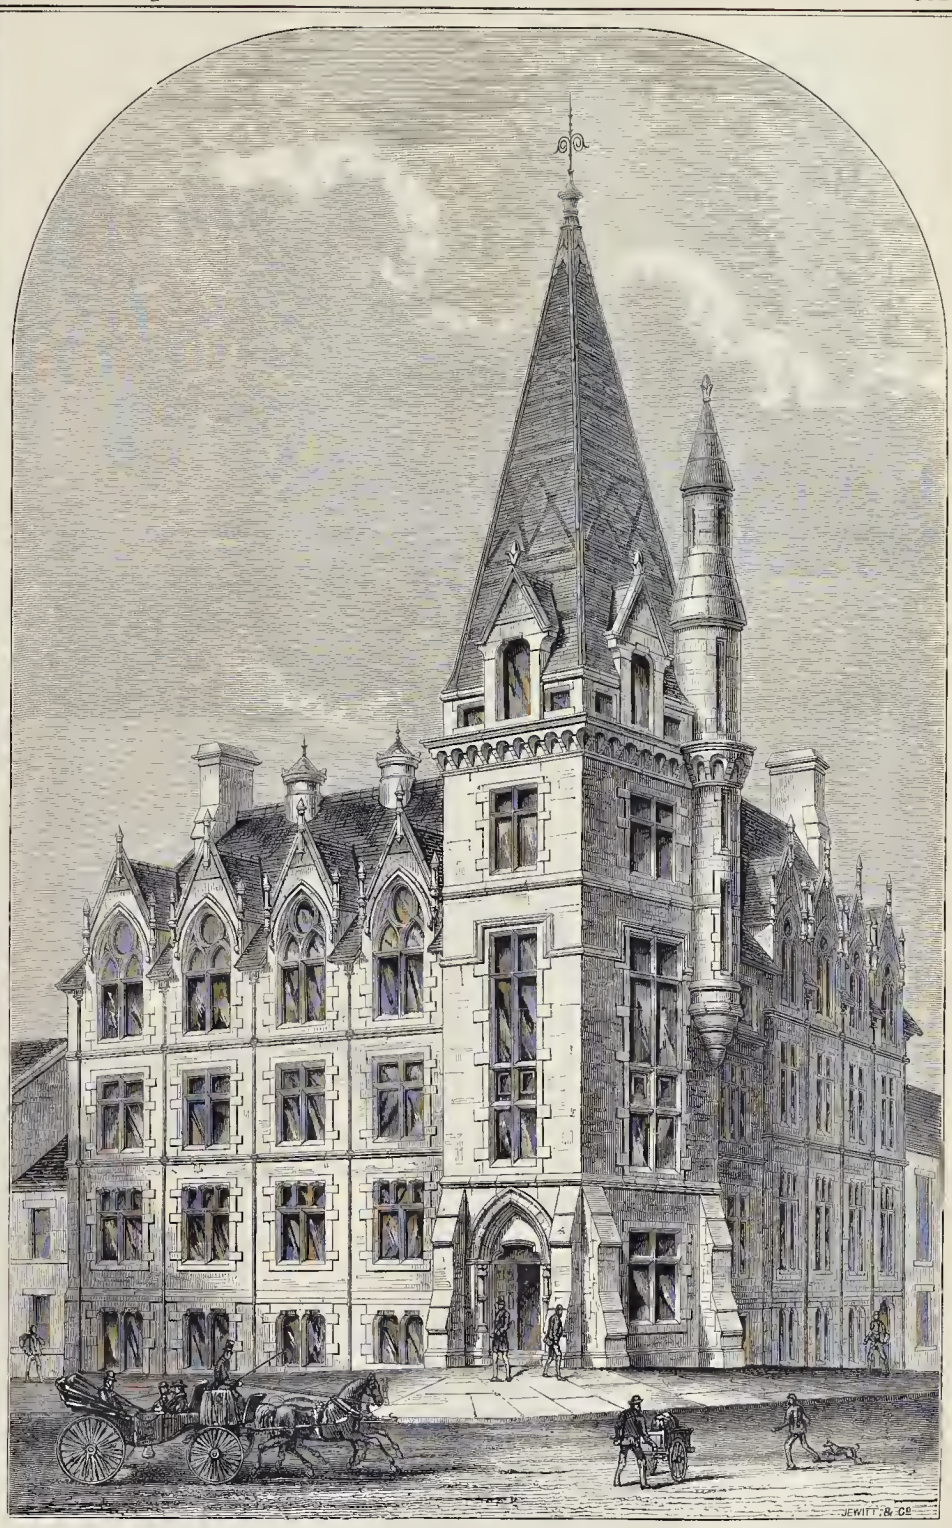
DECORATIVE SUGGESTIONS FROM NATURAL FORMS. — No. 5.

THE TROPHY, FREIBURG IN BREISGAU.—Professor Moest, Karlsruhe, Sculptor.

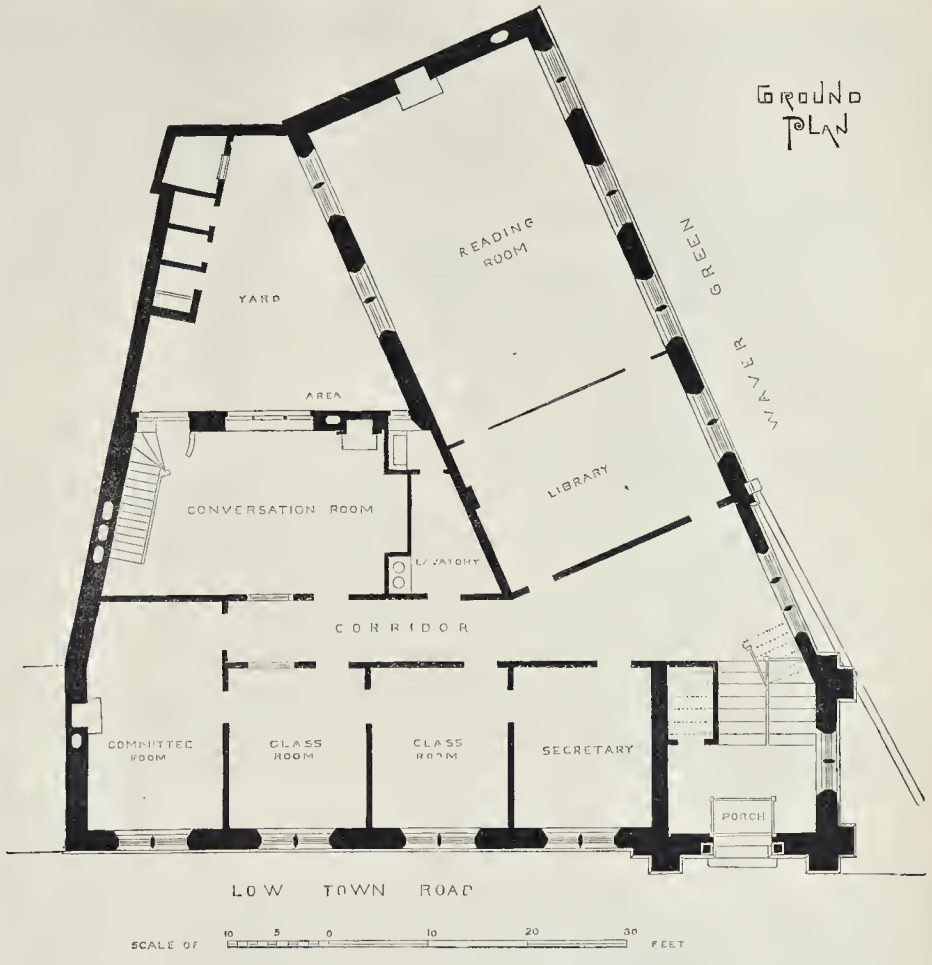


PUDSEY MECHANICS' INSTITUTE.—Messrs. Hope & Jardine, Architects.

Whiteman & Bale Photo Lith. 256 High Holborn

Wyman & Sons, Printers, 74 Queen St.

RESIDENCE AT BLUNDELLSANDS, NEAR LIVERPOOL.—Mr. T. Mellard Reade, Architect.



MECHANICS' INSTITUTE, PUDSEY, NEAR LEEDS.—*Plan of Ground Floor.* [For View see p. 561.

MECHANICS' INSTITUTE, PUDSEY, NEAR LEEDS.

About the middle of last year the committee of the Pudsey Mechanics' Institute invited architects to submit designs in competition for a new building. In response to the invitation, several sets of plans were received, and after these had been examined, the design of Messrs. Hope & Jardine, architects, Bradford, was selected as first in order of merit, and consequently these gentlemen were engaged to carry out the works.

The new institute, which is now about to be opened, occupies one of the best sites in the town, being at the junction of Low Town-road and Waver-green, two of the principal streets. It contains on the basement-floor a large room, intended to be used for public tea-parties, or similar gatherings, with the necessary kitchen accommodation adjoining, a number of class-rooms, lavatory, &c. These rooms are all well lighted, and the staircase arrangement is such that this floor can be used without interfering in any way with the upper ones.

On the ground-floor are a spacious reading-room and library, a conversation-room, a committee-room, two class-rooms, a secretary's room, and a lavatory.

On the first floor, which is reached by a staircase, are a large public hall, situate on the Low Town-road side of the building, capable of seating 600 persons,—a ladies' cloak-room, and a smaller lecture-hall, to be used for science-lectures, &c.

The public hall has a gallery round three sides, which is entered from the second-floor level, and it has also connected with it two ante-rooms for the use of the lecturers or those engaging the hall.

On the second-floor,—over that part of the building which fronts Waver-green,—are large, well-lighted rooms, for the use of the art classes connected with the Institute.

A good stone obtained from the quarries in the neighbourhood was used in the erection of the building, and the different works were let as follows:—

Mason's work, Mr. James Smith, of Bradford; joiner's work (including library-fittings and seats to the public hall), Messrs. A. & J. Briggs, Bradford; plumbers and glazier's work, Mr. J. Wilcock, of Pudsey; plasterer's work, Mr. Wm. Tattersall, Bradford; slater's work, Mr. Jas. Smithers, Great Horton; painter's work, Mr. Wm. Simms, Pudsey; ironwork and heating apparatus, Messrs. Taylor & Parsons, Bradford. Mr. J. T. Boothman was clerk of works.

The total amount of these contracts is about 3,200*l.*, and will not be exceeded. The amount allowed to be spent, according to the instructions to competing architects, was 3,000*l.*

RESIDENCE, BLUNDELLSANDS, NEAR LIVERPOOL.

The subject of our illustration is a residence built for Mr. Joseph Gardner on the Blundellsands estate, situated on the coast about seven miles from Liverpool by the Liverpool, Crosby, and Southport Railway.

The west front faces the sea, having views, over the entrance to the river Mersey, of the Cheshire and Welsh coasts as far as the Great Orme's Head. The Crosby Channel, by which most of the numerous ocean steamers and large sailing-vessels enter and leave Liverpool, lies just outside, and at high water the sea presents a very fine aspect.

The materials of the walls are local grey brick, with moulded Ruabon red brick quoins and other dressings. The upper part of the house is half-timber work filled in with cement. The outside timber is all Baltic fir; the inside joiners' work is of pitch-pine. The contractors were Messrs. Wells & Son, of Bootle, and the architect is Mr. T. Mellard Reade, of Liverpool.

The cost has been about 2,500*l.*

The Case of Mr. Strachan.—In addition to the sums mentioned last week, we have received 10*s.* 6*d.* from Mr. William H. Pipe, of Tottenham, and 1*l.* 1*s.* from Mr. Robert J. Johnson, of Saville-place, Newcastle-on-Tyne.

"DRINKING-WATER AND ENTERIC FEVER AT LLANDUDNO."

With reference to a paragraph under this heading, in a previous number of our journal (p. 513, *ante*), we have received letters from, *inter alia*, the engineer and clerk to the Llandudno Improvement Commissioners, Mr. T. T. Marks; from a member of the Board, and the solicitor of the Board, Mr. Chamberlain. It will be sufficient to print the last-named:—

Sir,—I am instructed by the Llandudno Improvement Commissioners to call your attention to a paragraph in your paper of the 23rd inst., headed "Drinking Water and Enteric Fever at Llandudno," in which it is stated that fever was due to the drinking of polluted water at Llandudno. A statement of this kind going the round of the newspapers is very injurious to a health-resort like Llandudno. The medical gentlemen practising here, and the occupiers of houses, are under statutory obligation to give notice to the commissioners of any case of infectious disease, and are subject to heavy penalties for not doing so. (See Sect. 14, Llandudno Improvement Act, 1879.)

Now, the commissioners know of no case of enteric fever occurring here during the present year, and they are quite ignorant of the facts (if facts they are) contained in the paragraph in question.

Under these circumstances I am instructed to *demand* of you the name and address of the author of the paragraph. I may add that our water is peculiarly pure, as the copy of an analysis, by an eminent chemist, sent by this post shows.

You will, I am sure, appreciate the importance of supplying my clients with all the information in your power, as, if the statement is untrue, proper publicity should be given to a refutation of it, or should there be any doubt about its truth, no one is more interested than my clients in thoroughly investigating the matter.

R. S. Chamberlain.

Llandudno, 29th October.

Of course, Mr. Chamberlain may "*demand*" (the italics are his), if instructed to do so, but we are not bound to comply. We should be quite willing to aid the Board in making the desired investigation,—anxious, indeed, to do so; but we cannot subject a family scarcely recovered from serious illness to the correspondence which would follow. It will be seen, on referring to the paragraph, that no slur was cast on the water as supplied from the waterworks; for we do not even know if the house occupied was supplied from the waterworks, or by a well, or rain-water cistern. We merely stated what we know to be a fact, namely, that three of the family who drank water while at Llandudno were attacked with enteric fever within a few days of their return home. The object of the paragraph was to put the sanitary authorities of Llandudno on the alert. Since the paragraph appeared, moreover, we have received letters from two other persons whose families have fallen ill after a visit to Llandudno, and as the writer of one of them desires that his name should be given, we print it:—

Sir,—Having had your paragraph in the *Builder* forwarded to me respecting the water and enteric fever at Llandudno, I lose no time in adding my testimony to that of your correspondent. I and my niece were staying at the above place for a month; she during her visit being a "water-drinker." On returning home she complained of illness, which in due course developed itself into a decided case of "enteric fever." Her medical man is convinced the poison was contracted away from home, and, of course, could only be traced to Llandudno. She is now slowly recovering, after nearly two months' illness, and I think, with your correspondent, that no time should be lost in having the matter thoroughly investigated by the sanitary authority, or else people seeking health and strength may unsuspectingly find their graves.

Thos. Harding.

P.S.—Kindly insert this in your next issue.

Fair Lawn, Weston, Bath, 29th October.

Sir,—The local authority of Llandudno may imagine that they supply pure drinking-water, and analyses of samples in bulk may warrant the opinion; but if water-drinkers who have been resident in Llandudno suffer from enteric fever, and medical men give it as their opinion that the fever must have arisen from the water drunk, neither indignation nor official threats will alter the facts. The wisest thing the local authorities can do will be to cause a house-to-house investigation to be made in the manner now described. Ascertain if or not the domestic supply is drawn from cisterns situate within the house. Are these over water-closets or middens, or near to them? Are the cisterns open or covered? Are they ventilated? Is the over-flow pipe severed from the house-drain? Water may be rendered impure and poisonous by sewer-gas passing from a drain up the overflow-pipe, if the tank or cistern is covered and unventilated. Cisterns over or near water-closets or middens may become tainted by the water absorbing sewage-gases. Dirty cisterns may render water impure.

The Llandudno officials had better set their inspector of nuisances to work rather than their solicitor. They may depend upon it that the old proverb will prove true in their case,—namely, where there is smoke fire may be strongly suspected. So, where there is enteric fever amongst water-drinkers there must be a strong suspicion of impure water, and it is the duty of the Local Authority, and the interest of the ratepayer, that this suspicion should be removed.

Civil Engineer.

THE OPENING *CONVERSAZIONE* OF THE ARCHITECTURAL ASSOCIATION.

The thirty-ninth session of the Architectural Association was opened with the usual *conversazione* on Friday, the 29th ult., in the galleries in Conduit-street. Owing to the galleries being occupied by the exhibits of the Institute of Art, the Association was unable to make its usual display of drawings, &c., with the exception of a few laid on the tables in the large gallery, among them being some good water-colour drawings of architectural subjects in France and Italy by Mr. Aston Webb and Mr. F. T. Baggallay. We must also make mention of a large and noteworthy view of St. Alban's Abbey as it now stands, with the new high-pitched roofs over the nave and part of the south aisle,—as seen from the rising ground on the south of the river. This, a boldly-executed water-colour drawing in grey and white, was lent by the artist, Mr. Wyndham Hughes, and is likely to prove of interest and value on various grounds as time wears on. The drawings submitted for prizes offered by or through the Association were exhibited in the meeting-room of the Royal Institute of British Architects, kindly placed at the disposal of the Association for the evening by the Council. During the evening the band of the Royal Engineers performed a selection of music in the large gallery, and the Museum of Building Appliances was, by permission of Mr. D. V. Boyd, open to the inspection of the company.

Shortly after nine o'clock, the President, Mr. Ernest C. Lee, took the chair in the meeting-room of the Institute, and before proceeding with the distribution of prizes, mentioned that letters from several architects of eminence apologising for their inability to attend the meeting had been received, including one from Mr. Decimus Burton, who expressed regret that in consequence of age and infirmity he was precluded from being present, and enclosed a cheque for ten guineas to be added to the prize fund. The President announced that the *Essay Prize* would not be awarded this year, only one essay having been sent in,—a production which was not considered by the judges to be worthy of the prize. With regard to the *Architectural Union Company's prizes* for measured drawings, those sent in under the motto "Gipsy" had been adjudged the best, but it was doubtful whether the first prize could be awarded to them, they having been submitted elsewhere on some other occasion. The decision, therefore, remained in abeyance until the question raised had been settled. The second prize in the same competition was awarded to Mr. J. L. Houston. The *Architectural Association's Silver Medal* and a sum of 5*l.*, were taken by Mr. Vaughan. In the *Class of Design*, the first prize was carried off by Mr. M. J. Lansdell, and the second prize by Mr. R. J. Lovell, honourable mention being made of Mr. Burrows. The *Elementary Class of Design* prizes were awarded as follows:—First, to Mr. H. C. Stock; second, to Mr. G. Blizard; the work of Mr. C. C. Bradley being mentioned with honour. The first prize offered to members of the *Class of Construction* went to Mr. Sbilcock, the second prize to Mr. Clifton, and honourable mention was made of the work done in the class by Mr. Yetts. In the *Class for Colour Decoration*, the first and only prize was taken by Mr. S. R. Smith.

The President then delivered a brief address, the first part of which reviewed the early history of the Association, and contrasted its at one time languishing condition with the prosperity and usefulness that have of late years distinguished its operations. It has now upwards of 800 members, and an attempt is being made to institute an annual prize, worthy of the Association's position as an educational body, in the shape of a travelling studentship for the younger members of the profession. The sub-committee charged with the consideration of the matter have resolved to recommend to the general body of the Association that a scheme he set on foot for raising the sum of 400*l.* to endow a travelling studentship named after the Association, and that this sum be raised among the members, past and present, of the Association. To avoid apparent competition with other travelling studentships, it is recommended that the age of candidates be fixed at twenty-three. Secondly, it is proposed to nominate a special prize fund committee with the view of raising funds to increase the value of the existing annual prizes. Having dwelt on some of the vagaries of fashion in architecture and internal decoration, Mr. Lee concluded by remarking that the great exponent of art in its domesticity is woman; to her we look to provide us with those externals which are pleasing to the eye and soothing to the artistic sense. It is she who holds the power of making the house a garish waste or an abode of pleasure. It is to her we trust to inculcate the lesson that extravagance is not art; that the simplest materials may, by means of thought and discretion, be transformed into objects far more satisfactory to the sight than the costliest if handled by the unwise. To woman, again, we look to point out the way to the young idea. Let good taste be cultivated in the nursery; let the receptive eye of childhood have its lesson in colour and in form; give it the advantage of becoming familiar with the works of such genial masters as Caldecott, Miss Greenaway, and Walter Crane. We all know a "Philistine" when we meet him: the rising generation should be saved from becoming such as he. We do not want prigs, Postlethwaites and Cimabüé Browns; but we do like an appreciative and discriminating audience, and we desire something more,—we want a public who by their outside pressure will eventually bring England to the first place in art, as in most other matters she already is, and to that end we ask the continued co-operation of the ladies.

Mr. Roger Smith congratulated the president on his occupancy of the chair of the Association, and further congratulated the members of the Association on the fact that they were then assembled in the meeting-room of the Institute. It was gratifying and an augury of good for the future that the two societies which might be said to have architecture in their keeping, while distinct,—and long might they remain so,—could yet heartily co-operate with and encourage one another. He was very glad to see that the anticipations upon which he and others ventured some years ago with regard to the question of a diploma for architects were being justified by the examinations established by the Institute, and he reminded the young members of the profession that in 1882 admission to the Associateship of the Institute could only be by examination, which would then be compulsory instead of voluntary as at present. He trusted that the result would be, before very long, that those entering the architectural profession would generally avail themselves of the opportunity of obtaining what would be to them something like the real and authoritative diplomas without which the members of some other professions could not practise. He thought that the Institute and the profession at large were to be heartily congratulated on having arrived at so important a point, and the Association, by carrying on with unabated vigour its classes and other work as an educational body, was capable of doing much to ensure the success of the compulsory examination, in which its members would now have an additional stimulus in the pursuit of their studies.

Mr. Chatfeild Clarke also addressed the meeting, observing that the question which lay at the root of the work of the Association was how best to fit its members for entering and remaining in the architectural profession with honour to themselves and satisfaction to the public under the conditions of competition and depression amidst which it had now been for some time carried on. The architectural practitioner, young or old, should, he need hardly say, maintain a high sense of honour and professional honesty, both towards his clients and his brother practitioners; and not the least of the claims of the late T. H. Wyatt and Benjamin Ferrey on the remembrance of the profession was that they had always conformed to a high

standard of honour. Not long ago he (Mr. Clarke) had ventured in that room to protest against some dangerous advice given to the younger men of the profession by an able and eminent member of another profession, the tendency of which was that individual architects should think of themselves only and not of the welfare of their profession. They might depend upon it that they would best consult their own interests in the end by pursuing an undeviating course of honourable conduct towards their professional *confrères*. The times of depression which had operated so disastrously to the profession were, he hoped and believed, passing away, and he thought he could discern good prospects in the future for all who would pursue their work with energy and high integrity. All such might hope to reap in due time the rewards of a profession which was not only highly honourable in itself, but the pursuit of which offered everything that could gratify the artistic taste of a cultivated mind.

Mr. Phené Spiers having made a few observations, the formal part of the evening's proceedings was brought to a close.

THE TOPOGRAPHICAL SOCIETY OF LONDON.

The inaugural meeting of this Society was held in the Long Parlour of the Mansion House on Thursday afternoon, October 28th, when Mr. Robert Harrison, librarian of the London Library, presided, in the unavoidable absence of the Lord Mayor. Letters expressing interest in the Society were read from Mr. Lowell, the American Minister; Lord George Hamilton, M.P.; Mr. Fawcett, Postmaster-General; Mr. Alderman and Sheriff Fowler, M.P.; Sir John Lubbock, M.P.; the Right Hon. J. G. Hubbard, M.P.; the Earl of Rosebery, Alderman Sir Sydney Waterlow, Mr. J. A. Froude, Mr. W. Morris, and other gentlemen.

Mr. H. B. Wheatley, F.S.A., said the want of some general organisation by means of which the constantly changing phases of "the world of London" should be registered as they passed away had long been felt; and, in fact, in a country like England, where materials were abundant in almost all departments of knowledge, the great want was a centre to which the different atoms might gravitate. Every day landmarks were swept away, often with little present notice, and generally with total forgetfulness on the morrow, so that the society was not formed a day too soon. The points to be taken up by the society were numerous, but the following were, perhaps, some of the most important, viz., the collection of documents, deeds, &c. (original and copied), and of extracts relating to the history of and associations connected with places in and around London, arranged in an accessible form; the collection of information relating to the etymology of London place-names, and preparation of a record of changes in London nomenclature; the preparation of maps and plans showing the position of public buildings, streets, &c., at various periods; the preparation and publication of a bibliography of London topography; the preparation and publication of an index of London drawings, prints, antiquities, tokens, &c., in various collections; the publication of copies of old London engravings, and also of unpublished drawings. In order to keep the members informed as to the work of the society, it would be necessary to prepare a full annual report; and as one means of obtaining trustworthy information it was proposed to appoint local committees to watch over the topographical changes and demolitions in the several districts. The scope of the Society's work would, as he had said, be very large, for it would include the preparation of maps and views of London during the Roman, Saxon, Norman, and Plantagenet periods; the publication of interesting records from the State papers, and monographs of buildings about to be swept away. There was reason to believe that many of the ancient institutions of the city had much valuable topographical information in their possession, which they would be willing to impart to the Society. Mr. Wheatley added that the committee had discussed the advisability of uniting with one or another of existing and kindred societies, but had decided that it would be better to found a new organisation, though one that would be on the most friendly footing with other institutions.

A letter was read from the London and Middlesex Archæological Society, protesting against the formation of the Topographical Society on the ground that all their objects were already undertaken by that institution.

Major-General Baillie moved that the objects of the Topographical Society were worthy of the support of all those interested in the present and past of the metropolis.

Mr. E. Solly, F.R.S., in seconding the resolution, regretted the tendency of the age to destroy everything.

Mr. Winkley suggested that much valuable information could be culled from the old parish registers of the City; and

Mr. Furnivall described how the City teemed with reminiscences of Chaucer, Spenser, Shakspeare, Hogarth, Johnson, and others.

The resolution was carried; and the meeting separated after deciding as to the amount of the annual subscription and other details, and after passing a vote of thanks to the Lord Mayor for his courtesy in placing the Mansion House at their disposal.

ARCHITECTURAL ASSOCIATION: LIST OF PAPERS.

The following is the syllabus of papers for the ensuing session:—

November 5.—Address from the President (Mr. Ernest C. Lee).
November 19.—The Use of Cements. Mr. Gilbert R. Redgrave.
December 3.—Furniture. Mr. C. G. Vinall.
,, 17.—The Architectural Treatment of small Staircases. Mr. Aston Webb.
January 7 (1881).—A Week in Norfolk. Mr. C. R. Pink (Hon. Sec. Excursion Sub. Com.).
January 21.—Parsonages. Mr. Lacy W. Ridge.
February 4.—The Sanitary Work of an Architect. Mr. Ernest Turner.
February 18.—In Lombardy with the Architectural Association. Mr. Edward J. Tarver.
March 4.—Cheap Churches. Mr. William White, F.S.A.
,, 18.—Holland. Mr. R. Phené Spiers.
April 1.—Swimming Baths. Mr. L. C. Riddett.
,, 29.—Members' *Soirée*.
May 13.—Queen Anne Architecture. Mr. W. Burges.
,, 27.—The Use of Marble and similar Materials in English Architecture. Mr. T. G. Jackson, M.A.
June 10.—Colour Decoration as applied to Architecture, from a Painter's Point of View. Mr. R. Corbett.

EDINBURGH.

The department of the new medical class-rooms devoted to the study of anatomy in the new University Buildings, has been completed, and is now in use. This department occupies the east side of the south quadrangle, the class-room, measuring 58 ft. by 42 ft., with a height of 46 ft. 6 in., is seated for 500 students, the desks being formed of iron. There is a workroom, 29 ft. by 20 ft.; a house-room, 39 ft. by 38 ft.; and a retiring-room for the professors, 14 ft. by 20 ft. The upper floor of the south side of the quadrangle is occupied by a dissecting-room, 108 ft. in length, by 39 ft. wide, and 27 ft. high. The roof of this department is formed in ridges, and glazed towards the north, so as to afford a steady light; but there are also six large windows which augment the light at certain points, and are useful for ventilation. The room is fitted up with a number of wash-stands which will be supplied with hot and cold water, and there is other necessary accommodation attached, comprising cloak-room, &c. There is also a demonstration-room, 21 ft. by 10 ft., with an ante-room, and a smaller dissecting-room, 39 ft. by 20 ft. Adjoining the anatomy class-room is one 40 ft. by 17 ft. for microscopic observations, a laboratory, &c. The lighting and ventilation of these apartments has received special attention.

The great ventilating-shaft and chimney, regarding which so many disparaging remarks were made, when it was in course of erection, is now, when completed, generally acknowledged to be a picturesque and ornamental addition to the architectural features of the city. It consists of an outer cone of white brick, and within this is placed an iron tube, which is used as the smoke-flue. There is a space between these which will receive the heated and vitiated air and carry it upwards. This structure is about 180 ft. high, 18 ft. in diameter at the base, decreasing to about 12 ft. About 30 ft. from the summit are a series of narrow openings, with slender pilasters between, rising from an ornamental base, and capped by a cornice; it is surmounted by an elongated bell-shaped summit, with an opening at the top, which receives the termination of the inner iron tube.

Attached to the new infirmary was a class-room fitted to accommodate 120 students; but this has been found to be quite inadequate, and it has been resolved to extend the buildings so as to accommodate 300 students. Operations are being actively pushed on, and the building will be ready for the roof in a short time. The original plan of a semicircular auditorium has been adhered to, and the external elevations partake of the same character as the rest of the infirmary. The rebuilding of the class-room will entail a cost of about 1,300*l*.

St. Stephen's Parish Church, the exterior of which is considered one of the most successful efforts of the late Mr. Playfair, has undergone several important alterations in the interior. This interior was extremely bald and uninteresting, and the acoustic qualities were wretched. The latter defect will, it is expected, be modified by the alterations, and the harmonies of the interior enlivened. To make room for a new organ, by Willis, of London, the pulpit has been brought forward, and the choir platform entirely remodelled. Mr. David Rhind, architect, has carried out the new arrangements.

The new churches in course of erection at Morningside, Dumbiedikes, Canon Mills, and Gilmore-place, are progressing rapidly towards completion, and that at Rosehall is almost ready for occupation; in regard to all of which more hereafter.

At a meeting of the Guildry to elect a dean, more than usual interest was taken in the proceedings in consequence of the office being contested, a most unusual occurrence. The Council of the Guildry had, it appears, nominated Mr. William Macgregor, a well-known builder, for the office, but it was objected to him that, being engaged in active business, and, as he had often had cases before the court over which he would have to preside, it would scarcely be expected that he could perform the duties with the same impartiality as a gentleman not engaged in business. Mr. Robert Hutchison, of Hillwood, a retired builder, was accordingly brought forward, and, in spite of strenuous opposition, was elected over the nominee of the Council by a majority of eleven. This result is nothing short of a revolution in the proceedings of the Guildry; and a final blow is aimed at the old system of nomination by a motion of Mr. Stevenson, a member of the Corporation, to frame a code of rules for future guidance, embracing amongst these the election of office-bearers by a popular vote.

NEW BUILDINGS IN GLASGOW.

The new Theatre Royal, opened by Miss Marie Litton, is the third that has been built in Glasgow in as many years. It is not more than twenty months since the old Royal succumbed to the flames, and as another theatre, the Royalty, sprang up in the interval, it was doubtful for some time whether the building would be restored. About a year ago, however, the matter was set about in a practical way, the result being that Mr. C. J. Phipps, of London, was engaged to prepare plans. The new building is on the site of the old one, and the chief external alteration is the main entrance being changed from Cowcaddens-street to Hope-street. Quite close to each other are four entrances,—one for the dress-circle, one for the stalls, a third for the upper-circle, and the fourth as an extra opening to the stalls and boxes. The old main entrance is made available for the pit and amphitheatre, while the gallery door is that formerly used for the amphitheatre. Besides these, there are other means of exit from all parts of the house which can easily be brought into requisition in case of emergency. The stalls are laid out in five rows, affording accommodation for 100 persons; while immediately behind is the pit, capable of accommodating about a thousand. Overhanging the pit, at a judicious height, is the dress-circle, reached by a double flight of steps. This part of the house is seated for 312. At the back nine boxes, each for six persons, are curtained off, and behind these again are the ladies' and gentlemen's cloak-rooms and lavatories. The upper-circle rises above the dress-circle, while the uppermost parts of the house are, as usual, devoted to amphitheatre and gallery. The upper-circle accommodates 300, the amphitheatre 366, and the gallery from 900 to 1,000,—the whole available auditorium being thus capable of seating over 3,000 persons. The stalls and dress circles are fitted up with the folding chairs invented by the architect, and made by Mr. Wadman, of Bath. All the floors and passages are of concrete, while the inner

walls are of brick and Portland cement. The proscenium is 31 ft. wide by 36 ft. high, and behind the act-drop the stage measures 72 ft. in width, and from the foot-lights to the back wall 58 ft. The internal decorations are being carried out on an elaborate scale. The general character of the architecture of the interior is that of the French Renaissance, the roof terminating in a coved ceiling with a sun-light in the centre. An allegorical study representing the various arts allied to the drama is painted by Hartford, of London, over the proscenium. The decoration and gilding are being carried out by Mr. Edward Bell, of London, while Messrs. Jackson & Co., London, are constructing the box-fronts, proscenium, and ceiling with their patent fibrous plaster. Messrs. Burke & Salviati, of London and Venice, have laid out the vestibule in marble mosaic. The following Glasgow tradesmen have also been employed in the reconstruction of the building:—Stevenson & Sons, masons and bricklayers; Ross & Son, carpenters and joiners; Morrison & Son, slaters and concrete builders; McGregor, Gilmour & Co., and Stevens, ironworkers; Bremner, plasterer; Rae, plumber; Chalmers & Tosh, gasfitters. Mr. Wm. Browne acted as clerk of works.

In the course of a few days a new public building just erected in Adelaide-place, Bath-street, will be opened for the joint accommodation of the Glasgow Philosophical Society, and the Engineers and Shipbuilders of Scotland, who hitherto had suites of rooms from the Glasgow Corporation in Sauchiehall-street. The architects of the new building were Mr. T. L. Watson and Mr. W. J. Millar, C.E.; and the total cost does not exceed 6,000*l.* The architecture is of the Classic style, in harmony with the other buildings in the street. Of four stories, the basement will be occupied by the curator's house, museum, and heating apparatus. The street floor consists of library and reading-room, the first floor is set apart as a hall seated for 300 persons, with council-room adjoining. On the upper flat are two large rooms, to be used for sectional and other meetings. The Geological and Natural History societies of Glasgow intend to take rooms in the building.

A number of churches are in course of erection in Glasgow at the present time. The most important of these are the Woodside Established Church in Great Western-road, for the Rev. David Watson, which is to cost 9,000*l.*; a new Free Church at Dowanhill, Partick (the estimates for each are about 5,500*l.*); a Wesleyan church at the junction of West Nile and Sauchiehall streets to supplant the church in John-street, bought by the Corporation for the site of the new municipal buildings; and a new Evangelical Union church at Govan. Mr. Henry Higgins, jun., is architect of the Woodside church; and the designers of the Wesleyan building are Messrs. J. McKissack and W. G. Rowan. The architect of the Dowanhill church is Mr. Petrie, and the contractors for the work are:—Masons, Messrs. Gordon & Hamilton; joiner, Robert Carmichael; slaters, John Morrieon & Sons; plumber and gasfitter, Robert Russell; plasterers, Regali & Tonner; glazier, Messrs. Keir; heating, Combe & Son; brackets, Wm. Ramsay & Son.

LIVERPOOL ENGINEERING SOCIETY.

The usual fortnightly meeting of this society was held at the Royal Institution, Colquitt-street, on Wednesday in last week, Mr. A. Ross, president, in the chair. A paper entitled "The Combination of the Block and Interlocking Systems on Railways" was read by Mr. H. A. Dibbin, M. Inst. C.E. The author commenced with a brief review of the progress of railway signalling from its first introduction on railways, and thence the various improved methods in use at present were considered, chiefly in respect to the block system, and its vital relations to modern railway traffic-working. Diagrams were exhibited illustrating the main argument of the paper, to the effect that although the block and interlocking systems are in themselves pushed to every possible degree of perfection, they are as yet uncombined, and can, therefore, be actuated in antagonism to each other, through the fallible human agent who works them, and thus permit of disaster. Many methods, more or less successful, had been devised to overcome this great defect in railway working, but in order to effect a thoroughly safe and correct combination of the diverse elements, viz., the train, and the electric and out-door signals and the pointsman, they should each actuate but one electric current. This circuit should be so devised that its closing and unclosing permit no adverse element to intrude, and the train itself thus rule the road.

SANITARY RULES FOR PUBLIC BUILDINGS.

The following rules, to be observed in the construction of all buildings erected under her Majesty's Office of Works, have been prepared and issued by the Secretary to the Office of Works:—

1. All water-closets and urinals shall be constructed so that one wall at least of such closets and urinals shall be an outer wall of the building.
2. All soil-pipes shall be carried outside the building, and ventilated by means of pipes leading the foul gases above the highest point of the building. Such pipes to be carried to points removed from chimney-stacks.
3. Separate cisterns shall be constructed for the water-closets and for the general purposes of the building. No tap or "draw off" shall be affixed to any pipe communicating with a cistern supplying a water-closet or urinal.
4. All waste-pipes and overflow-pipes of cisterns shall terminate in the open air, and be cut off from all direct communication with drains.
5. Great attention shall be paid to insuring through ventilation in all rooms. Rooms so high that their ceilings shall be more than 2 ft. above the top of the windows, corridors, staircases, and other open spaces shall be specially ventilated so as to prevent the accumulation of stagnant air.
6. All main drains should, where practicable, be formed outside the building. In the event of its being necessary to carry a main drain underneath a building, it must be trapped immediately outside the main wall, and a ventilating-pipe must be carried from that point to the highest part of the roof, as under Rule 2.

THE PHOSPHATES IN WHEAT AND FLOUR.

Attention is being once more drawn to the impoverished condition of the finest end whitest flour, and to the superior nutritious power of "whole" or "entire" meal. These views have, for many years, received the warmest support and advocacy from the highest chemical and physiological authorities. But, notwithstanding these recommendations, the general public make only the most sparing use of whole meal bread, while the entire meal is, we believe, almost unusable for all other purposes. We have, therefore, no hesitation in recommending to the attention of our readers a process which has recently come under our notice, both theoretically and practically, and which presents two conspicuous advantages. It consists in restoring to the fine white flower, which the public so universally demand, those very important nutritious constituents,—the phosphates. Three-fourths of these salts contained in the wheat grain are rejected with the bran in the ordinary milling processes, yet they enter largely into the composition of the blood, brain, &c., while phosphate of lime forms eighty per cent. of the bony frame. The second advantage of this flour is that the phosphates are restored in such a form that the flour is "self-raising." Hence, for those who prefer the flavour of unfermented bread, yeast, &c., can be dispensed with, and the entire nutriment of the flour retained; while the pastry, cakes, and puddings, made with the flower are exceptionally light and digestible, and an economy is effected in butter, eggs, lard, and similar adjuncts.

An interesting pamphlet on this subject, which is issued by Messrs. McDougall Bros., of 10, Mark lane, informs us that the process is the joint invention of Mr. McDougall, well known in connexion with disinfectant preparations, and Professor Horsford, an equally well-known American chemist.

NEW MARKETS, ST. HELIER'S.

Extensive new markets are about to be built at St. Helier's, Jersey, on the site of the present Meat Markets, the old building and stalls of which are about to be swept away. Temporary stalls have been erected for the butchers in the Vegetable Markets, St. Helier's, and the contracts for the new markets have been let:—Masons' and excavators' work to Messrs. Fallaize & Tostevin, of Jersey; ironwork and painting to Mr. Dyson, of Elland, Yorkshire; carpenter's and joiner's work, plumber's and glazier's work, slater's and plasterer's work, and cement flooring, to Mr. David Nichols, of Leeds; and the roof is to be executed on Helliwell's patent system, of Brighouse, Yorkshire.

The total amount of the contracts is about 12,000*l.*

WATER SUPPLY FOR COLLIERY VILLAGES.

The Hexham Union Rural Sanitary Authority is now considering the question of providing a supply of water for a large section of its district, including Prudhoe, West Wylam, Mickley, and other villages. Plans and report have been received from Mr. John S. Hodgson, C.E., Hexham, showing the total estimated cost of a gravitation scheme by which water can be supplied from Minsteracres to a total population of 5,000, to be 11,216*l.* This scheme involves a total length of 12¾ miles of piping, of which twelve miles would be cast-iron pressure mains. A separate scheme having been suggested for the supply of Prudhoe village independently, the estimated cost of this project is stated to be 1,588*l.* The source in this instance would consist of two springs at a sufficient altitude. The want of water in the district is becoming urgent, owing chiefly to the drainage operations of the extensive coal workings.

PUBLIC BUILDINGS IN INDIA.

An inhabitant of Bombay thus writes to us:—"I take the liberty of forwarding to you a Bombay paper containing a criticism on one of our Bombay buildings in particular. The subject of architecture in India is one that is not sufficiently thought of at home, although we are crowded yearly by engineers from England, both in the Public Works Department and railways, as well as a few private men who are the minority; and, as I need not tell you, more than merely outward design is needful in a building. This fearful overdone Gothic architecture in our Bombay buildings should be a warning to all architects; the unsuitableness of such a style for India is apparent to all who study the question. Mr. Stevens was the architect for the Sailors' Home,—the building in question. He is in the Public Works Department."

The paper sent (the *Bombay Review*) contains part of a correspondence criticising the arrangements and architecture of the Sailors' Home in that city. The critic, after commenting on various points of a reply which had been given to previous strictures, says:—

"The building in question looks handsome; but a sailors' home needs to be something more than what an ornamental sugar-top is to a bride-cake. An architect is no architect if he cannot utilise his space, and still have ornament,—beauty without common sense is only skin deep. It is not likely that Jack will complain to his superiors, and he is not competent to articulate on architectural and financial waste. But I have no doubt he feels rebellious at being hemmed in on all sides by spike railings, so as to make him feel as if he were in a prison, and not in a 'home.' In conclusion, to go back to the point, let it be asked whether or not a building costing 2½ lakhs of rupees should not have been a complete building? Had it been turned into a hospital, as was once proposed, it would have simply been a species of misappropriation to have used the public contributions (by subscription and a fancy bazaar), for the purpose of putting in stairs, floors, windows, and a roof, into a building that had already cost over 2 lakhs of rupees. It does seem a little ridiculous that a structure costing so much, and with walls sufficiently strong to keep out a bombarding enemy, should seldom have more than eight or ten sailors in it. Happy Thought! These useless thick walls must have added to the cost; but it is so easy to play ducks and drakes with public money.

P.S.—Is it too late to overhaul the design of the new railway-station? That also abounds with turrets, and greater and lesser domes and minarets, overdone altogether. His Excellency the Governor should step in and curtail what may be found unnecessary and inappropriate, not to say anything that will be waste of money."

The editor of the *Review* adds:—"We are sorry if these criticisms of our architectural correspondent have caused undue annoyance to those concerned; but it must be remembered that this is an important public question, and increasingly so in India. With the ever-distressing spectacle of the New High Court before us, we are bound to lose no suitable opportunity of drawing public attention to architectural experiments unsuited to the climate and the purpose for which buildings are intended. Above all, there is in this matter one popular fallacy which needs to be rooted out, namely, that when the architect has produced a handsome elevation and designed the outward form of a building, his work is as good as done. Fitness, proportion, and, if there be funds to spare, beauty, also, we must have; but the final test of an architect's skill lies in the adaptation of inner arrangements to the purposes of a building, and with these, its outward presentment must harmonise. If this essential condition be wanting, towers, turrets, and pinnacles are but a vain show, and even if there be added 'storied windows richly dight,' these will not make an architect of the designer

of an incongruous building in which usefulness and fitness have been sacrificed to outward effect."

SOUTH NORWOOD DRAINAGE.

For a number of years past the sewage of South Norwood has been utilised upon a sewage farm of 60 acres of clay land located in the parish of Beckenham. The lease of the larger portion of the land have expired, and as the leases of the remaining portion will shortly terminate, and the district is increasing at a rapid rate, some permanent provision is necessary for dealing with the sewage. In order to determine what was best to be done, the Croydon Local Board, who are the Sanitary Authority of the district, in June last, invited Messrs. Bailey Denton & Co., Mr. E. Eachus, Mr. Baldwin Latham, and Mr. Lundie, to submit schemes for disposing of the sewage of the district.

After careful investigation, by various committees, of the schemes submitted, the Local Board, on Friday, the 29th ult., determined to adopt the scheme prepared by Mr. Baldwin Latham, C.E., which consists of a gravitation outfall sewer conveying the sewage from Norwood on to the sewage farm at Beddington, and the lifting the sewage from the small area which cannot be dealt with by gravitation, into the gravitation outfall sewer, by means of a pair of gas-engines, the estimated cost of the undertaking being 26,000*l*. The Croydon Local Board have recently acquired the freehold of the sewage farm at Beddington, where they have upwards of 500 acres of land capable of dealing, by filtration, with the sewage of 500 people to the acre. The population of the district of the Croydon Local Board is estimated at the present time at about 70,000, so that they have a large margin provided at Beddington for dealing with the future sewage of the district.

THE DANGER OF PLASTER CEILINGS.

Sir,—In your valuable article in last week's *Builder*, on "A Sanitary Aspect of Construction," you speak with some force on the disadvantages of heavy ornamental plaster ceilings, and I feel it to be a duty to draw the attention of your readers to the risks which are often run by individuals and the public generally, to obtain them.

Having been called in to advise in the case of Bedford Chapel, I have had the opportunity of making a critical examination of one of the last-century ornamental flat ceilings, which were so common prior to the introduction of open timber roofs in church and chapel construction, and during the prevalence of classic taste in architecture. I am quite at a loss to imagine how the ceiling at Bedford Chapel lasted so long, and I cannot but think that many other ceilings must be in an equally dangerous condition. The facts are these:—

The general thickness of the plaster was just upon 2 in., and the well-designed floriated ornamentation was worked on this base with the setting coat, and was not otherwise sustained than by the cohesiveness of the material, except that in places where cherub faces, or heavy mouldings were run, some nails were introduced into the body of the plaster, but no bracketing of any sort existed, and the whole weight of the ceiling, viz., about twenty-five tons (each square yard weighing over a hundredweight), was sustained by the plaster key which was squeezed through the laths. The laths were single laths, very thin, the ends lapping each other, and being secured by one nail.

The roof is sustained by double queen-post trusses, very well designed, and in good condition, situated 10 ft. apart; the tie-beams are 12 in. by 9 in., between which 8 in. by 6 in. binders are fixed 6 ft. apart. The ceiling-joists, 3 in. wide and 12 in. apart, come between the binders, the under side of the tie-beams, the binders, and the ceiling-joists being all flush with one another. The laths were secured by cast nails, about ⅞ in., but never more than ¼ in. entered the beams to which they were attached. But no fillets intervened to keep the laths a little free of the timbers, so that the laths were laid flat against the under-side of the beams, thus reducing the area by at least one-fifth, over which it was possible to secure a key for the plaster, and consequently about five tons of the weight was unsupported by any key.

This was alarming enough, but having hung so long, it might have held longer if the remaining key was sound. To ascertain this, the dust was brushed away with a light hair-brush, and with it came much of the key which had perished, and on further examination it appeared that nearly half of the key had gone, and that from twelve to fifteen tons of the plaster ceiling had no apparent support.

The plaster which fell was under the centre of one of the trusses, but the laths were, with few exceptions, left behind, and no key was visible above them.

I had, therefore, no hesitation in condemning the whole ceiling as most dangerous, and that the first fall was in all probability the precursor of many more, which the vibration of the moving multitudes who thronged the church might at any moment bring down upon the heads of the people.

On removing the ceiling to put a new one of canvas and paper for temporary continuance, my judgment was confirmed in a remarkable manner, for it came down in large pieces with little or no trouble on the workmen's part except where, at some distant time, it had been slung up to bearers laid upon the ceiling-joists by iron rods, $\frac{3}{16}$ in. diameter, passed up through the plaster from below, a piece of thin metal about 6 in. long by 1 in. wide being secured to the lower end, and a nut being fixed to the screw end of the upper part of the rod, by which means the bagging ceiling had been held up when it was ready to fall from want of key. The fine coat had been scraped away to admit the metal and finished flush, so that no indication of the presence of these ingenious suspenders was visible from below.

I think these facts are sufficiently alarming to be a warning to others, and to cause the investigation of similar ceilings to be made by competent persons in the interest of the public.

Edward C. Robins.

THE SCULPTURE ON BLACKFRIARS BRIDGE.

Sir,—It would appear that the proposed decoration of Blackfriars Bridge is of a magnitude and of an importance unfortunately of rare occurrence in this country, both as regards scale and remuneration, for the groups must necessarily be colossal, and their cost thousands. It is an opportunity of a kind which ought to occur oftener in a great country, and in a city the greatest commercial centre in the world. The means for obtaining an artist equal to the occasion ought not to be a matter of difficulty. As such an opportunity,—to the shame of these realms,—seldom does occur, it would, perhaps, be ungracious to too severely criticise the proceedings of a committee uninitiated in such affairs, or to overhaul and pull to pieces their *naïve* advertisement, in which they have attempted to enumerate every mode of drawing, some of which no artist would ever think of availing himself of in such a competition.

The most hopeful feature in the advertisement is the announcement that the President of the Royal Academy has consented to guide the committee in the selection of an artist; that is, if, after selecting so competent a guide, they will be guided. The time has, perhaps, come for the whole profession to repudiate the decisions of non-professional committees in such competitions. The writer would be content to accept Sir Frederick's decision in the matter without any intervention on the part of the committee. But were a frequency of such competitions imminent, it would not be wise to tax, in every case, the kind offices of one competent judge. It would, therefore, be well at this juncture to advocate the institution of a professional committee of taste, whose function it should be either to adjudicate in all art competitions, or to select artists for employment on public works. It would be an institution far preferable to that sometimes proposed, viz., a *dilettante* Minister of the Fine Arts, who would only afflict the metropolis with evidences of his individual artwhims. It would, in reality, be a Ministry of the Fine Arts without the drawback of that so frequently proposed. Each member of such a committee ought, of course, to be selected for his freedom from bias, for his catholicity of judgment; or it might again happen, as it often has in art competitions, that even professional judges, having some decided bias, have selected those designs which would best perpetuate their own vagaries, setting aside the most suitable and best calculated to elevate art.

There is yet another matter in which the uninitiated are liable to be led astray. It has been possible for men of ingenious tact, and without having the slightest claim to be considered artists, to pass themselves off, by means of hired labour, for sculptors. With a professional committee, such deceits would be useless.

W. Cave Thomas.

THE MATERIALS OF THE FLOORS AT BRADING.

Sir,—A visit to the recently-unearthed Roman villa at Brading suggests numerous questions, of much interest to persons at all versed in building matters.

The tesseræ composing the chief pavement are very thin, barely ½ in., which would suggest that they must have been well laid on a prepared and hard cement floor, and cement run in between them. But this does not appear to have been the case, for within 1 in. from the surface of the tile is the soil of the country; and the cement, now quite white, and with all the nature gone, appears to have been the common white chalk lime of the district.

But this same lime mortar must at the time of its use,—at the very least fourteen or fifteen centuries since,—have been very good, and set very hard, for close by this principal hall, wherein the most perfect pavement lies, is the heating chamber for the whole house, and in which stand a number of small columns to support the arched or groined floor, covering the flues or fire; and they are constructed alternately of about 3 in. of concrete mortar (now crumbling) to one 1-in. red tile. As at present, they could not possibly carry the weight of the floor, which must have been great, judging by the arched stones of which it was constructed.

And again, the shaped stones used as roof-tiles are from Purbeck, where in the immediate neighbourhood are *concrete* remains, wherein the cement from the local cement-stone is as hard as the shingle that is held together by it, and we may fairly conclude that this would come under the notice of the builders of this villa, who must have considered the chalk cement which they made at Brading *superior*, at that time, to the cement of the blue lias near Purbeck; for obviously no consideration of expenses nor trouble has weighed in the construction of these buildings.

Thus the cement which was presumably the strongest at the period of these villas being erected, has proved the least durable when exposed to the test of time. And how far is this to hold with regard to the artificial hydraulic limes, having chalk lime as their basis, which the past thirty or forty years have brought into such very extensive use, in very important works?

It appeared to me something of a puzzle, how the tesseræ were formed, so remarkably uniform in size, and out of varying stones of widely-varying density. Blake's stone-crusher was probably unknown and undreamt of in the fourth century, and the use of only such appliances as we are aware of, or can fancy, as being within the reach of quarriers of those days appears scarcely sufficient for producing such good results. If "Flint Jack" were living he might throw some light on the matter. An archæological friend,—one of the committee of the archæological society which has these remains in charge,—suggests the splitting-up of the stone into lengths, which were then cross-cut into tesseræ, similarly to the method adopted in the modern and beautiful Italian glass mosaics. This would not apply all round, however, for we cannot conceive flint, or, at all events, "chert," being thus treated.

Possibly some of the readers of the *Builder* may throw light on these questions.

Feldspar.

Stratford.—St. John's Church, Stratford, which has been closed for some weeks, for repairs, was re-opened on the 3rd ult. The walls have been cleaned and re-coloured in neutral tint. The windows have been filled with stained glass of different colours, and the old system of gas-lighting has been superseded by coronæ suspended from the crown of the arches. The work has been carried out by Messrs. T. Norton & Sons. The repairs to the tower, which are not yet completed, are being carried out by Mr. J. Morter.

PIOUS (?) FRAUDS.

SIR,—In wandering round the world, by making use of something more than our eyes, we constantly stumble upon, and are mentally hurt by, examples of shams which are something more than may be understood by the term "pious frauds." I could mention several, but will content myself with one.

Last week, wandering into our grand old church dedicated to St. Paul, Peter, and Swithin, in the historic city of Winchester, the feeling came uppermost that whatever might be the "professional" opinion as to the appropriateness of the Gothic or the Classic form for church architecture, there is always something inexpressibly soothing to the mind in passing from the bustling world outside into the cool, solemn, and generally beautiful interiors of our Gothic cathedrals; a spare hour is never lost in wandering around and about them, and on this particular occasion an intelligent verger incited a desire to wander over it. Up a corkscrew staircase to the gallery below the clearstory, from which fellow mortals in the nave below looked like wandering bottle-stoppers, up again to the leads, and into the space between the external leaden roof and the stone vaulting, where it is a sight to see the great tie-beams, one of which spans the entire width, probably 50 ft. or more without a splice, all cut many a year ago from giant trees in the New Forest, before the railway lent a helping hand, and when the roads were simply shocking; into the lantern-tower which, with its thirty-two richly-carved Norman headed windows, has been turned into a belfry, and then again over the choir with its great stone r——. Hullo! Am I awake or dreaming? Has the fiery glass of sherry at the pastrycook's disagreed with me? No! it is all right. "Be careful how you tread, sir," pipes out the thin voice of the elderly guide, "that ain't stone" nor plaster, but it is beautifully done in wood. A certain mythical, happy, and easily-satisfied gentleman, named Toots, would have overcome the sensation this "pious fraud" had evoked, by a remark the public may endorse, "It's of no consequence whatever"; but sitting beneath the great patched window of many but harmonious colours, gazing along the glorious vista of the nave, listening to the swelling anthem, the eye will surely hereafter rest upon a shady spot upon the arched and gilded roof, where Heaven's light should flood the choir and God's service instead of being clean shut out, and the lantern darkened with a wooden lie.

WILL WATCH.

LONDON WATER SUPPLY.

SIR,—Referring to the remarks in last week's *Builder*, on the London Water Supply, mention is made of supplies from the chalk.

From beds of chalk, intermingled with gravel and sand, about sixteen miles from London, in the parish of Stone, Kent, there is an enormous quantity of water. It may be seen rising out of the ground and running in streams to the Thames, on the estate of the Stone Court Chalk Company, situate a short distance from Dartford. It has been computed that 18,000,000 gallons run through this ground daily,—waste, into the river. This water has been pronounced to be pure and excellent.

This quantity would greatly augment the present supplies for the south-eastern district of London, and could be utilised at no very extravagant outlay. J. M. B.

HARD WATER.

SIR,—Can you or any of your numerous corrospondents tell me how to make my spring-water less hard and corroding? I have a circulating boiler by which hot water is conveyed to the top of the house; but the water is not only comparatively useless for cooking or washing purposes, but is a constant expense. The taps are invariably leaking, the pipes are continually choking with a hard rocky substance, and the boiler, in spite of a periodical cleaning, burns out on account of the same rocking. Can anything be done to improve the water without discolouring or spoiling it for any purposes? The water is pumped into a large slate cistern at the top of the house, and this cistern fills the supply cistern for the boiler by means of a ball tap. I shall be very grateful for any suggestions.

F. MEADE KING.

*** Inquire what could be done by the Porter-Clark process.

Mr. J. T. Newton, of George-street, Westminster, has been selected from amongst various candidates for the post of architect and surveyor to the Incorporated Society of Licensed Victuallers.

A NORMAN KEEP.

MR. J. H. PARKER has drawn attention in the *Times* to what is called St. Leonard's Tower, at Malling, in Kent, and which he pronounces to be the earliest Norman keep in existence, and in all probability "the earliest that ever was built, the construction of the walls being of earlier character than any Norman keep in Normandy itself or in Britain." The manor on which it stands was given by William the Conqueror to one of his Norman followers, Gundulfus or Gundulph; he found himself placed in the position of a settler in a hostile country, the king of which had given him a donation of a large tract of land, but he must get possession of it in the best way he could. His first object was naturally to secure an abode for himself, in which, with a small band of followers, he could be safe against any number of assailants. He was a brave man and a clever man, and an architect, and, not daunted by the danger of his position, he saw how he could secure this object. This was by building a house on an entirely new plan; the walls were built of rubble-stone, found on the spot or near at hand; the lower part was built solid, so that no battering-ram could have any effect upon it, and the doorway was 10 ft. from the ground, with a short ladder, which could be easily drawn up. This was exactly such a house as was wanted by all the Norman settlers in Britain; it was very soon copied in all directions. The fame of Gundulph spread far and wide, and a few years afterwards he was employed by the Conqueror to build the Tower of London, a Norman keep on the same principle, only on a much larger scale, and built of good ashlar masonry, instead of rubble. Mr. Parker goes on to say, "the popular notion that the Normans brought their keeps with them from Normandy, as things well known and long in use there, is entirely a delusion"; and states that M. de Caumont, the leader of the Archæological Society of Normandy, and others, made a tour to the sites of all the castles of the Norman barons who had gone over to England with William the Conqueror. Their object was to ascertain the character of the construction of stone walls of the first half of the eleventh century as distingnished from that of a later period. "To their amazement and annoyance they found no masonry of that period in any one of them. Magnificent earthworks, enormous fossæ or trenches, and lofty earthen mounds, were found everywhere; the additional defences had been wooden palisades only and no stone walls." Mr. Parker adds that when he showed M. de Caumont a careful engraving of St. Leonard's Tower, De Caumont acknowledged at once that this construction was of earlier character than any keep in Normandy.

This statement puzzles us considerably. In hot youth we tramped Normandy (had some pleasant interviews, by the way, with the venerable De Caumont), and have very distinct recollections of the castle at Falaise, visited more than once. We have before us now a rough sketch made at that time of the stone-room, in that stone castle, in which William, the so-called Conqueror, was born; and can see with the mind's eye the printed statement of the fact hanging on the wall. From the window of an adjoining room it was, as every one is told, that Robert, William's father, saw Arlette, the tanner's daughter, afterwards William's mother. Well, all this, of course, happened years before the followers of the Conqueror began to build keeps in England. Mr. Parker knows all about this as well as we do, or better, and we will not venture to say he has made a mistake, but we shall be very glad to have a little explanation, and to know if we are henceforth to pronounce Falaise *fallacy*.

A SANITARY ASSURANCE ASSOCIATION.

A MEETING was held on Monday, November 1st, at the Langham Hotel, to consider the desirability of forming a Sanitary Assurance Association "for the purpose of securing to its members at a minimum cost those advantages which the progress of Sanitary Science has made available." The chair was taken by Sir Joseph Fayrer, K.C.S.I., and the proceedings were opened by Mr. Mark H. Judge, who said that this was an attempt to bring medical men and architects together on the great question of house ventilation. Letters strongly approving the formation of the association were read from Dr. Andrew Clark, Mr. Spottiswoode, president Royal Society, Dr. Playfair, Mr. Arthur Cates, F.R.I.B.A., Dr. Lauder Brunton, Dr. Ferrier, and others.

The Chairman said he recognised in such an association as that proposed the fulfilment of a great want in respect to house sanitation. The richer classes undoubtedly had facilities for rendering their houses healthy which were not possessed by those beneath them; but there was, on the part of the great mass of the public, a general want of faith in sanitary science and sanitary law. He believed, however, that the idea was growing that improved sanitation meant additional value to life, and certainly an increase of the domestic comfort and well-being of the people.

After a discussion, in which Mr. Edgecombe Venning, F.R.C.S.; Mr. Chatfeild Clarke, F.R.I.B.A.; Mr. Edwin Chadwick, C.B.; Dr. Longstaff, and Professor Corfield took part, the following resolution was unanimously passed:—

"That we cordially approve the formation of the Sanitary Assurance Association; that Professor de Chaumont, F.R.S.; Professor Hayter Lewis, F.R.I.B.A.; Mr. H. Rutherfurd; Professor W. H. Corfield, M.D.; Mr. George Aitchison, F.R.I.B.A.; and Mr. Mark H. Judge, be appointed a Provisional Council, with Professor Corfield as chief sanitary officer, and Mr. Judge as surveyor, *pro tem.*; and that they be requested to organise the Association on the basis of the prospectus which had been issued, and to report to a future meeting."

THE RIGHT OF SUPPORT FROM ADJOINING HOUSES.

WOOD *v.* GILBERT.

THE plaintiff in this case (Common Pleas Division, before Lord Coleridge and Justices Lindley and Lopes) had kept a coffee and eating house in the neighbourhood of Oxford-street, and the defendant had an adjoining house. Both houses were upon the estate of the Duke of Portland, and they were about 100 years old. The defendant pulled down his house, leaving the party-wall between the two, however, standing. He shored this wall up, but it gave way and came down. The plaintiff claimed damages for the loss which he had thus sustained, and at the trial before Lord Coleridge the jury found that the plaintiff's house came down in consequence of being deprived of the support of the defendant's house, and that there was negligence in the way in which the defendant had taken down the house. Upon this finding the verdict was for the plaintiff for 545*l*.

Mr. Talfourd Salter, Q.C., now moved for a rule to enter judgment for the defendant, contending that the plaintiff had no right to lateral support from the three walls of the defendant's house, which were taken down. It was also contended that the verdict was against the weight of evidence, and that, in fact, the wall probably came down in consequence of the lower part of the wall having been burnt to powder upon the plaintiff's own side of it by an oven which had been there.

Mr. Justice Lindley said that these houses were probably originally so constructed that one could not stand without the other, and therefore there was no ground for saying that the plaintiff had no right to lateral support from the defendant's house. He also thought that the verdict was not against the weight of the evidence.

Rule refused.

CASES UNDER THE METROPOLITAN BUILDING ACT.

MOATAB.

AT Wandsworth, Mr. John Synnett, a builder, was summoned by Mr. Woodward, district surveyor, for using mortar composed of earthy matter in the building of houses in Rollo-street, Battersea Park-road. The complainant said that after receiving notice of the building of the houses, he inspected the mortar, and found an absence of sand. He wrote a letter to the defendant giving him notice that the mortar must not be made with earthy matter. He inspected the mortar again, and found it very bad, no alteration having been made. In cross-examination, the witness said there was lime in the mortar, but it contained a large proportion of earthy matter.

Mr. Hanson, the district surveyor of North Battersea, produced samples of the mortar which he had taken from the buildings. He said he had dried one sample, which he found contained one portion of lime, and the remainder earthy matter and grit. Better mortar was used outside in the pointing of the walls, but the mortar used inside had not any sand in it.

Other evidence was given to the effect that proper mortar should contain two-thirds of sand and one of lime.

Mr. Haynes, who defended, said the witnesses were mistaken. He should be able to show that the mortar used contained half lime and half grit and and sharp sand.

A witness for the defence said road grit was quite equal to sharp sand.

Mr. Paget said it was shown by the defence that the mortar used was composed of mud. He imposed a penalty of 3*l*., with 2*l*. costs.

THE RIGHT TO WORK OVERTIME.

At Marlborough-street, Mr. Mansfield has given judgment in a case, Squires, a journeyman painter and house-decorator against Mr. Pontis, a house-decorator, of Euston-road. Mr. Mansfield said the question was whether a workman who was sent by his employer to work in the country was entitled to work overtime, and be paid for so doing, as of right. The question narrowed itself down to a point of law—namely, whether a custom had been established in favour of the complainant's claim. In his opinion, no custom had been established sufficient in point of law. It appeared that the gentleman for whom the work was done objected to the men working overtime, and he (Mr. Mansfield) regarded the employer as a middleman between the customer on the one hand and the workmen on the other. As it was clear Mr. Pontis could not have charged his customer with the overtime, and the men could not look to Mr. Pontis, as their employer, for it, he dismissed the summons; but, as he considered it a very fair question to have been discussed, he should not give any costs against the complainant.

Mr. Lewis asked to have an appeal.

Mr. Mansfield asked whether the proper course would not be for Mr. Lewis to ask him to state a case for the opinion of the Court?

A long and technical argument ensued, and Mr. Mansfield said, instead of dismissing the summons, he would adjourn the case for a fortnight to enable Mr. Lewis to consider what course he would pursue.

CHURCH-BUILDING NEWS.

Southport.—On the 14th ult. the Bishop of Liverpool consecrated the chancel and transept of All Saints' Church, Churchtown, Southport. Originally the church was erected as a chapel of ease to St. Cuthbert's, the parish church for Churchtown, and was consecrated in May, 1877. The population of the district, however, increased so rapidly that it was ultimately deemed necessary to constitute All Saints a parish by itself, and to enlarge it to supply the requred accommodation. The architects engaged in this work were Messrs. Garside & Johnson, of Lord-street, Southport. Previously to the addition of the chancel and transept the church would seat 400 people, now 1,050 can be accommodated. The total cost of the work is 5,000*l.*

Frant.—The parish church of Frant has been re-opened, after restoration. Externally the roof has been new leaded, and other repairs have been effected. In the interior the windows, with the exception of that over the Marquess of Abergavenny's pew, and in the chancel, fresh glass has been put, which has lately been found in some lofts and stables in close proximity to the church. The glass is of English make, and is said to date from the thirteenth to the sixteenth centuries. The church has been redecorated from drawings by Mr. John O. Scott, architect, and the work has been carried out by Mr. Milner Allen, of Fulham-road, London. The church has been re-pewed by Mr. H. Bond, from special designs by Mr. Scott.

Watford.—The new church of St. Matthew, South Watford, was consecrated on the 12th ult. by the Bishop of St. Alban's. The building is 104 ft. in length, and consists of a nave 67 ft. in length, in four bays, north and south aisles with western entrances, the tower and spire rising to a height of 120 ft., and placed at the north-west corner of the building. The chancel is of apsidal form, and is lighted by five windows. The architect is Mr. W. H. Syme, and Messrs. Waterman were the contractors. The new church will accommodate 500 persons.

Stratford-on-Avon.—The vicar of Stratford-on-Avon, in responding for "The Clergy," at a banquet given by the mayor of Stratford the other day, intimated that he was about to engage in the work of restoring the ancient parish church, for which work thousands of pounds would be required.

Plaistow.—On the 16th ult. the memorial-stone of a new chancel for St. Mary's Church, Plaistow, Kent, was laid by Lady Scott, of Sundridge Park. The work of constructing the new chancel has been entrusted to Mr. J. C. Arnaud, builder, of Bromley, and the contract price is 1,792*l.* The architect is Mr. W. R. Mallett.

Southburgh. — The church of St. Andrew, Southburgh, was re-opened by the bishop of the diocese on the 7th ult. after restoration. Prior to the restoration, nothing but a heap of rubbish remained of the tower, which had fallen, apparently, from 100 to 150 years previously, the two bells, together with the solid oak framework which supported them, having been first removed and placed under a thatched shed in the churchyard. The church itself was in a deplorable condition, and so insecure that when the old lead roof was removed the walls began to show signs of falling, in spite of every precaution having been taken to shore them up with strong timber supports. It was, therefore, found necessary to remove at once the stone tracery of the windows, and to rebuild the church throughout, with the exception of a small portion of the west wall, which had been made secure. The total cost of the work so far has amounted to little short of 4,000*l.* Of this the Gurdon family, who are the chief owners of the soil, have contributed the greater part. The rebuilding of the church has been carried out on the old lines under the supervision of the architect, Mr. J. A. Reeve, of London. The contractor was Mr. John Goss, of Shipdham. The objects of interest found during the restoration included a mural painting of St. Christopher bearing the infant Christ, on the north wall of the nave, and another painting on the north side of the chancel, of which the design was not clear.

Bradley. — St. Martin's Church, Bradley, Bilston, was re-opened on the 26th ult., after restoration and renovation (rendered necessary by a serious gas explosion in April last), at a cost of about 750*l.* The chancel windows, three in number, again represent the Nativity, Crucifixion, and Ascension, by the same artists (Messrs. Gardner, St. Helen's, Lancashire). The chancel floor has been re-laid with tesselated tiles, by Messrs. Craven, Dunnill, & Co., and the choir-stalls have been altered and improved by Mr. Sansome, Bilston. The whole interior of the church has been renovated and coloured. The old organ has been replaced by a larger one, purchased from St. Paul's Church, Balsall Heath, at a cost, including reconstruction, of 260*l.* A series of slate tablets have been placed between the chancel windows. The tablets (the gift of Mr. Edward Pugh, of Wolverhampton) contain the Twelve Commandments, the Lord's Prayer, and the Apostles' Creed, written in Old English characters, with illuminated capitals.

Abbot's Bromley.—The chapel in connexion with St. Anne's Middle-class School for Girls, Abbot's Bromley, which at present consists only of the choir, is to be enlarged, and the foundation-stone of the new buildings has been laid by the Hon. Mrs. Maclagan. The Provost (Canon Lowe) said that to complete the chapel 1,500*l.* was wanted.

Wynyard Park.—On the 3rd ult., the new private chapel at Wynyard Park, one of the seats of the Marquess of Londonderry, was opened by the Lord Bishop of the diocese. The chapel is built adjoining the Monumental-room, is 86 ft. in length by 24 ft. in width, and is described as being of the "Roman-Corinthian style" of architecture, in keeping with the rest of the mansion. The plans have, however, not yet been carried out in their entirety, and many of the decorations remain to be added. The principal feature of the building is the chancel arch, of various rich marbles. At the entrance to the chancel is a dwarf screen of red Devonshire marble, inlaid with mosaics, panels of Mexican onyx being on the reverse side. This, as well as the organ, is the gift of the Marchioness. The chancel steps are of Derbyshire fossil marble; the paving throughout of Italian mosaic, in patterns designed by the architect (Mr. James Brooks), and executed by Minton, of Stoke-upon-Trent. The choir-stalls and benches are of oak, relieved by shafts and panels of walnut-wood.

Bedford.—Holy Trinity Church, Bedford, has been re-opened, after redecoration. The pulpit has been cut down some 14 in. or 18 in., and the old panels removed, leaving the tracery only. The font has been removed and refixed near the south door. The whole of the works have been carried out under the direction and personal supervision of Mr. John Day, architect. The painting and decorative works were carried out by Messrs. Clarke & Carling, of Bedford; the gasfitting and re-lighting by Messrs. Kilpin & Billson, of Bedford; paving, by Maw & Co., of Broseley, Salop; the prayer-desk, lectern, and other woodwork, by Mr. John Hull, of Bedford. The cost will be something over 300*l.*

Hungerford.—The parish church of Hungerford was re-opened on the 12th ult., after undergoing renovation. The old-fashioned pews have given place to open seats. New arcades, clearstory walls and windows, have been built, the latter being filled with foreign glass. The new gas-fittings and iron-work on doors are by Mr. C. Leaver, of Maidenhead. The vestry fittings have been supplied by Mr. Frnen. A new organ has been erected by the well-known makers Messrs. Forster & Andrews, of Hull, at a cost of 510*l.* The alterations and improvements have been carried out by Messrs. Morris & Stallwood, architects, of Reading, Messrs. Wooldridge & Son, of Hungerford, being the contractors. The total estimated expenditure, including the cost of the organ, is 2,917*l.*

Dorchester. — The restored chancel of the parish church of Piddletrenthide, near here, has been formally reopened; Mr. Ewan Christian, of London, is the architect for the Ecclesiastical Commissioners. The work of restoring the church has been in process off and on for twenty-seven years.

DISSENTING CHURCH BUILDING NEWS.

Swanwick.—The memorial stones of a new Primitive Methodist Chapel at Swanwick, near Alfreton, Derbyshire, were laid on the 5th ult. The cost of the new building will be 750*l.* There will be accommodation for 300 persons. The architect is Mr. J. Wills, of Derby, and the contractors are Messrs. Brown & Simpkin, Eastwood.

Shifnal.—On Sept. 29th the new Wesleyan chapel which has been erected at Shifnal from designs by Mr. J. H. Fleeming, architect, Wolverhampton, at a cost of about 3,000*l.*, and giving accommodation for 350 sittings, was opened. The new building is Geometric Gothic in style. The walls are of red brick, relieved with Grinshill stone and red terra-cotta dressings, and the roof is covered with Broseley tiles. Internally the chapel is 62 ft. 6 in. long, by 38 ft. wide, and will accommodate 350 adults on the ground floor. An end gallery yet to be constructed, over the entrance-lobbies, will give accommodation for 100 more. The building is roofed over in one span, the main front, facing New-street, consisting of a central gable, with a large tracery-headed window and moulded and gabled doorway. A stone turret, 80 ft. high, is placed on the western side of the main gable, set back from the gable to suit the inequality of the site. The side-walls are pierced with tracery-headed windows, divided by massive buttresses. The new building is heated by hot air, the apparatus being supplied by Mr. Truswell, of Sheffield; the gasfittings are by Mr. Eaton, of Wolverhampton; and the general work has been carried out by Mr. Yates, builder, of Shifnal, under the superintendence of Mr. Fleeming.

Carron (N.B.).—On the 2nd ult. the memorial-stone of Carron United Presbyterian Church, Falkirk, was laid. The proposed building is of Early English design, and will, when completed, be seated to contain about 440 people in the area, and 100 in the gallery. It is intended to be heated by hot air. The entire cost is estimated at 1,700*l.* The architect is Mr. James Boucher, Glasgow; and the builders are Messrs. Taylor & M'Fadyen.

Nacton.—On the 6th ult. a new Congregational Chapel, in connexion with Tacket-street Chapel, Ipswich, was opened at Nacton, about five miles from that town. The new chapel replaces one which has been in existence many years, and has cost about 400*l.* Mr. Coe, of Ipswich, has built the chapel, from designs by Mr. A. Conder, of London. Sittings are provided for 170 persons.

Ipswich.—On the 7th ult. the memorial-stone of a new Wesleyan Chapel, in Alan-road, Ipswich, was laid. Mr. Hubert is the architect, and Mr. A. Coe is the builder, the amount of the contract being 1,077*l.* The chapel will be of red brick, with white brick and stone dressings, and will provide sittings for 400 persons.

Welshpool.—A new Congregational Church has been opened at Welshpool. The architect of the building is Mr. H. Rider, of Welshpool.

Birkenhead.—On the 12th ult. the memorial-stone of a new chapel, in connexion with the United Methodist Free Church, which is in course of erection in Claughton-road, Birkenhead, was laid by Mr. Arthur J. Williams. Mr. Edward Legge, of Birkenhead, is the contractor, and the architect is Mr. R. H. Roberts, of Everton. The building will accommodate about 500 worshippers, and there will be large school-rooms and vestry underneath. The cost of the land has been about 500*l.*, and that of the building will be upwards of 2,000*l.*

Broxburn (N.B.).—The foundation-stone of a new United Presbyterian Church, at Broxburn, has been laid with Masonic honours. The buildings have been designed by M. Hippolyte J. Blanc, architect, Edinburgh, and consist of a church of parallelogram plan, measuring about 62 ft. by 30 ft., with a gallery at one end, affording accommodation for upwards of 400 sitters;

a hall capable of accommodating about 100 persons, a vestry, ladies' waiting-room, and minor apartments. Externally the church presents a gable-front to the main road, a gabled projection with pointed and richly-moulded arch forms the principal entrance, the main gable being pierced by a large wheel-window filled with cusped tracery, besides twin-pointed arched lights on each side of the doorway. On one side the gable is flanked by a tower and spire, the former containing the stair to the gallery. The accepted tender for the works amounts to about 3,000*l.*, which includes the erection of a manse.

Conway. — The memorial-stones of a new English Wesleyan Chapel have been laid at Conway. The site is in Rosehill-street, in close proximity to the old parish church. The style is Gothic, the external materials used being freestone from the Bryncoraeb quarries, with random-work. Accommodation will be provided for some 150 worshippers, but the schoolroom is so constructed as to be opened out to form a transept, to be utilised during the summer months, when there is a large influx of visitors. This will afford accommodation for another fifty. The approximate cost is about 1,000*l.*, and the contract is being carried out by Messrs. Hugh Thomas & Ellis Hughes, Mr. Fraser acting as clerk of the works. Mr. Curwen, jun., is the architect.

Llansamlet.—The new Bethel Chapel here was opened on the 9th inst. Its architect is Mr. J. Thomas, of Mumbles, Swansea, and the contract was given to Mr. R. Llewellyn, Birchgrove, for 2,400*l.* The chapel has sitting accommodation for 900 people. It is heated by Grundy's patent apparatus, fitted under the superintendence of Mr. George Daniel.

Newcastle-on-Tyne.—A new Congregational Church, to accommodate 500 persons, is about to be commenced at Heaton, near Newcastle. The church will, when completed, consist of a nave with double transepts, and there will be a small west-end gallery. At the east end will be a school-room, class-room, vestry, with other conveniences. The materials to be used are stone with ashlar dressings and slated roofs. It is in contemplation to eventually erect a tower and spire. Messrs. Oliver & Leeson, of Newcastle, are the architects.

Carnforth.—A new Congregational Church was opened at Carnforth on the 28th ult. The new structure seats 200 persons on the ground-floor, and a gallery is provided over the class-rooms on the south side. The mason-work has been executed by Mr. M'Farlane, and the carpenter's and joiner's work by Mr. Grime, of Settle; the remaining works have been executed by local tradesmen. The new structure is in the Gothic style, and has been designed and carried out under the superintendence of Messrs. Hetherington & Oliver, architects, Carlisle.

STAINED GLASS.

South Africa.—Messrs. Wailes & Strang, Newcastle, since fitting up the Catholic Cathedral at Durban, Natal, with stained-glass windows, have been commissioned to provide windows for three more churches in South Africa, viz., Bloemfontein, Kimberley, and Pretoria.

Dublin.—Four transept windows in Christ Church have recently been filled with stained glass, introducing figures of the four Evangelists. The windows have been executed by Heaton, Butler, & Bayne, of London, under the supervision of Mr. J. Rawson Carroll, architect, of Dublin.

Plymouth.—As a memorial of the twenty-fifth year of the episcopate of the Rev. Dr. Vaughan, R.C. bishop of Plymouth, the window at the west end of the Catholic cathedral in that town has been filled with stained glass, illustrative of incidents in the life and work of St. Boniface. The window consists of three large lights, each upwards of 23 ft. long, with tracery over. The middle light, which is the broadest of the three, contains in the centre a full-length figure of St. Boniface, vested in chasuble, mitre, maniple, and pallium, with crosier in the left hand, and in his right hand a sword, piercing a book. In the two side-lights and above and below the centre figure the story of the life and work of St. Boniface is told in a series of fifteen designs in chronological order. At the extreme top of each light are the arms of the bishop and diocese *per pale*, in the middle the arms of Mayence, and on the right the arms of Plymouth. In the tracery above are large heads of figures representing St. Willibald, bishop; St. Winibald, abbot; and Sta. Wallburga, nun, relatives and companions of the saint. The work has been entirely executed by Messrs. Fouracre & Watson.

Docklow.—Docklow Church, near Leominster, just re-opened after restoration, contains a new stained-glass window, by Mr. W. Done, of Wyle Cop, Shrewsbury. The window is in the chancel, and has three lights. The central compartment contains a representation of our Saviour on the Cross, and the side compartments contain the Virgin Mary and St. John in devotional attitudes. All the other windows in the church are filled with rolled cathedral leaded glass, by Mr. Done.

Hungerford.—A three-light stained-glass window has been placed in the parish church of Hungerford. The subject represented is the "Sermon on the Mount," our Lord occupying the centre light, with figures of His disciples in the two side lights. The upper and lower parts of the lights are filled with architectural canopies. The window was designed and executed by Messrs. Heaton, Butler, & Bayne, of London.

Wellingborough.—A stained-glass memorial window has recently been placed at the east end of the south aisle in the parish church of his native town, Wellingborough, by Mr. Henry Septimus Gill, of Tiverton, to the memory of his parents, whose remains are interred in the churchyard, just under the window. It is a window of Perpendicular tracery with five lights, and the subject is our Saviour as the Good Shepherd, holding a lamb in his arms, for the central figure; the other lights are occupied with figures of the four evangelists. The work was done by Mr. Drake, of Exeter.

Crawley, Sussex.—Mr. John Davies, of Wyle Cop, Shrewsbury, has just completed a series of stained-glass windows, intended to be placed in Crawley church, Sussex, which has recently been restored. The windows are for the aisle, and consist of thirteen compartments, each one containing some Scriptural subject. They derive some additional interest from the fact that among the individuals commemorated by them is the late Mark Lemon. Not long ago Mr. Davies executed the stained glass for the chancel window in the same church.

SCHOOL-BOARD SCHOOLS.

Plymouth.—The new girls' school, Wolsdon-street, is now occupied. The building, which is in the rear of the infants' school erected a few years ago, is for 250 girls. It includes a central schoolroom, 70 ft. by 20 ft., with spacious class-rooms, lavatories, cloak, and retiring rooms in the east and west wings, forming altogether one of the most complete suites of rooms for school purposes in the neighbourhood. The style is Early English. The walls are of tooled lime-stone with Portland stone dressings, and the roofs are all open-timbered. A dado of pitch-pine surrounds the rooms, and the fittings and furniture are generally of that material. Boyd's hygiastic ventilating-slates are used throughout, and the lavatory and closet fittings are by Macfarlane. The entrance to the new school is under an arched gateway of wrought stone. Mr. Hine, of Plymouth, has been the architect, and Mr. Blowey, of Buckland Monachorum, the contractor.

South Shields. — Two Board Schools for infants have been recently been opened by the School Board. In each case, accommodation is provided for 350 infants. It is intended shortly to erect boys' and girls' schools in extension of both these groups, and for which the preliminary arrangements have been made. The contractors were Mr. Robert Allison, of Whitburn, and Mr. John Grisdale, of Newcastle-on-Tyne. Messrs. Oliver & Leeson, of Newcastle, were the architects.

Miscellanea.

The Largest Vinery in the kingdom is being built by Mr. George Bashford, of St. Saviour's, Jersey, the eminent grape-grower. It is to be 1,100 ft. long and 30 ft. wide. It takes 42,000 ft. of glass, and is to be glazed on Helliwell's patent system of glazing without putty. This vinery is to be heated with hot water, and will take 10,000 ft. of 4-in. pipes. It is intended for the production of early grapes for the London market.

Closing a Main Thoroughfare.—At the Kensington Vestry a letter was read from the Metropolitan Board of Works sanctioning the closing of the Kensington-road for the purpose of repairing the carriageway, and stating that the Board had been surprise and regret that part of that thoroughfare had already been entirely closed without the sanction of the Board having been previously obtained, and that it is imperative on all future occasions the sanction of the Board shall be obtained before any road is closed. Mr. Campbell observed that there were extenuating circumstances. The vestry clerk wrote for permission, and received a reply from the engineer to the Metropolitan Board stating that the Board had adjourned, and he had no authority to make any order. He (Mr. Campbell) thought that when a chairman of a Board was paid 2,000*l.* per annum out of the rates, some arrangement ought to be made to answer the communications of vestries. Mr. Freeman, the member for Kensington at the Metropolitan Board, thought that the less that was said about the matter the better. The engineer to the Metropolitan Board had authority to give permission for small works, but he did not feel justified without the consent of the Board to give permission for the closing of the great western thoroughfare. The matter dropped.

South Kensington Museum.—The Director of this institution has just returned from an official visit to the museums, and to the Imperial and other collections at St. Petersburg and Moscow, undertaken by desire of the Lord President of the Council, in order to ascertain what examples of gold and silversmiths' work in these collections might be reproduced, to add to the large number of fac-similes of art treasures, both English and foreign, already existing at South Kensington. The Emperor of Russia ordered unreserved compliance with the request for permission to copy in electrotype from objects in the Imperial collections, and a selection was made of about 250 objects, ranging from goldsmiths' work of early Greek art exhumed at Kertch, through Mediæval times to English plate of the sixteenth and seventeenth centuries, and pieces of French art of the period of Louis XV. Provincial museums and local art exhibitions are largely interested in the advance of this branch of the operations of the Museum, by which fac-similes scarcely distinguishable from the unattainable originals are either lent on loan, or may be purchased, at a very moderate cost, for permanent display.

The Electric Light.—Among the electric light appliances now on view at the Glasgow Philosophical Society's Exhibition at Burnhank, is a collection of exhibits by Messrs. R. E. Crompton & Co., including a number of Mr. Crompton's regulating lamps, which have been adopted in many parts of the United Kingdom, in America, and on the Continent. On the same stand are shown instruments for measuring the electric current, as well as commutators, switches, resistance-coils, and other apparatus more interesting to the technical observer than to the general public. A complete set of portable apparatus for supplying four large lights collectively at 24,000-candle power is placed at the end of the Drill Hall. This set of apparatus is capable of lighting thoroughly and brilliantly a hall or railway station 400 ft. long by 150 ft. wide. It consists of a six-horse-power portable steam-engine, specially made for Messrs. Crompton & Co., Gainsborough. After preliminary inquiry, the directors of the North British Railway have resolved to adopt the electric light as the means of illumination for their new station at Queen-street, and within the last few days they have concluded a contract for the lighting of the station on the Crompton system.

Ventilation of Caius College, Cambridge.—The patent self-acting air-pump ventilators of Messrs. Boyle & Son having been recently applied to the chapel of Caius College, Cambridge, under the direction of Mr. Waterhouse, experiments were made to test their efficiency, and though subjected to very trying conditions, we understand they were found to be acting in a most efficient manner, the air being exhausted through each ventilator at the rate of about 700 cubic feet per minute, whilst there was not the slightest down-draught experienced during the whole time the experiments lasted. We hear that Messrs. Boyle are about to apply these ventilators extensively to another college in Cambridge. This system has been selected from competition plans submitted for the ventilation of the Town-hall, Yeovil.

The Roman Villa near Brading.—Up to the present time eighteen chambers have been thoroughly excavated, and the angles of the walls of a nineteenth have been discovered, in addition to which walls in direct connexion with the parts opened have been traced by Messrs. J. E. Price and F. G. Hilton Price (who have been conducting the operations), to extend eastwards a distance of between 60 ft. and 70 ft., and walls have been likewise observed more to the southward of the present diggings. The mosaic pavements of some of the rooms are remarkably fine, more especially the one in the largest room, which measures 40 ft. long by 18 ft. broad at the western end, and 15 ft. broad at the eastern end. Many other rooms with simple floors of concrete have been found. One of the most interesting is a large hypocaust containing fifty-four pillars of tiles 2 ft. 6 in. high; the tiles are about 8 in. square; they are cemented together with mortar in wide joints. During the excavations a quantity of plate-glass for windows has been collected. This last is a discovery of considerable interest; for although what is known in glass-making as pillar moulding was (after having been allowed a "patent" for many years) shown to be no recent invention, the fact that sheet-glass polished on one side and ground on the other was in use with the ancients appears to have been unknown until the present discoveries. The coins range from Severus Alexander (A.D. 221) up to Constantius (A.D. 337), proving that the villa was occupied as late as the fourth century.

Gas versus Electric-Light.—For a considerable time past the gas-committee of the borough of Birmingham have been experimenting with a view to the adoption of some system of gas-lighting which will compete with the electric light, for the purpose of illuminating large public squares. Trials have been made at the Windsor-street gas-works of all the improved forms of gas-lamps which have been tried at London and Paris, with the modifications suggested by their own engineer and the various lamp-makers. The aim has been to ascertain two points,—the most effective burner relatively to the gas consumed, and the form of lantern which best diffuses the light afforded. Upon the former point the committee have decided in favour of a triple cluster of Bray's flat-flame burners. The burners are fitted on to a special form of tap, designed by Mr. Hunt, the engineer at the Windsor-street Works, by whom the trials have been principally conducted.

Value of Property in the City.—The value of a piece of land upon which are two shops, one with a frontage to Gracechurch-street, and the other facing Half-Moon-passage, known as 89, Gracechurch-street, and lately in the occupation of Mr. Birrubaum, an india-rubber manufacturer, has been the subject of litigation. The sum asked was 13,842*l*. On the part of the plaintiffs, Mr. Fox, with Mr. Thorne, Mr. Andrew, and Mr. Collins, surveyors, estimated the property, which consisted of a superficial area of 786 ft., at 1*l*. per foot for the premises facing Gracechurch-street, and 10*s*. per foot for that part facing Half-Moon-passage. On the part of the Corporation, Mr. Farmer, with Mr. Vigere, valued it at an average of 12*s*. per foot, and said that 9,653*l*. was sufficient. The jury gave 11,900*l*.

Minster Church.—The Queen has contributed 50*l*., through the Hon. Charles Gore, secretary to the Commissioners of Woods and Forests, towards the fund which is being raised for the restoration of the ancient abbey church of Minster-in-Sheppey. The church is one of the most ancient in Kent, and possesses features of deep interest to the antiquary. It should receive most careful handling.

The Cabinetmakers in Paris.—The strike has ended, the masters having acceded to the request of the men, whose chief demand, it will be remembered, consisted in asking for a payment of 80 c. an hour, instead of the 60 c. they have long received.

Kelly's "English" Lamp, for streets, railway platforms, barracks, and avenues, comes to us with a good character. It burns petroleum without using a glass chimney, and gives a pure white light for eighteen hours. Its economy as against gas is said to be very considerable.

The United Asbestos Co., whose advertisement will be found in our present number, claim to possess nearly all the ascertained sources of supply of asbestos in Italy. The company has been formed to acquire the businesses of three existing firms.

Church Institute, Maidstone.—This proposed new building is to be erected on a site lately purchased in Union-street, and will have four floors. The basement will contain rooms for the caretaker, a gymnasium, 33 ft. by 29 ft. and 14 ft. high, and lavatories for the younger members. On the ground floor there will be a reading-room, 30 ft. by 20 ft., a spacious hall and vestibule, a library, 22 ft. by 18 ft. 3 in., a dining-room and recreation-room, 22 ft. 6 in. by 14 ft. each, and offices. The first floor will contain a large committee-room, 26 ft. by 20 ft., and a smaller one, 20 ft. by 12 ft., and a large assembly-room, 49 ft. by 29 ft., and 22 ft. high. On the second floor an additional committee-room for ladies, and bedrooms for the caretaker, will be provided. The building will be Gothic in style, with arcaded windows, and an entrance with clock-tower at the angle. The assembly-room will be lighted by side windows of the same style, will have a groined roof of pitch-pine, and will be fitted with a stage for lecturers or persons taking the principal part in any meeting. The general fittings inside will be arranged with due regard to comfort. The trustees have entrusted the planning of the building to Mr. E. W. Stephens, architect, Maidstone.

Birmingham Master Builders' Association.—At the annual meeting of this Association, on Wednesday last, Mr. W. H. Parton presiding, the report read by the secretary referred to the passing of the Employers' Liability Act, and stated that the Council of the National Association of Master Builders had decided to defend actions brought against members under the provisions of the Act at the expense of the Association, so far as the legal costs only were concerned, in such cases as the Council considered ought to be defended. This course would be adopted until January 23, 1881, after which the future action would be determined by the general meeting at Manchester. Members were therefore requested, if proceedings were commenced against them, at once to communicate with the secretary. At the annual dinner, held in the evening at the Great Western Hotel, Mr. G. Shelley stated that notices had been received from the carpenters and bricklayers for an increase of wages, the former asking for an additional three farthings, and the latter for one farthing per hour. He considered this action ill-timed, very injudicious, and calculated to do great injury, just as they might reasonably look for improvement in trade. The demand would be opposed by the committee to the very uttermost, and he hoped successfully.

New Banking Premises have been erected at Haltwhistle, for the Carlisle City and District Banking Company (Limited). The buildings comprise, on the ground-floor, banking-room and County-court office, &c., and above a residence for bank-manager. The contractor for mason-work was Mr. George Westgarth, the joiner-work being done by Mr. J. McAdam, both of Shotley Bridge; Mr. Ormerod was the plasterer, Messrs. Thompson & Sons were the plumbers, Messrs. Smith & Son the slaters, and the painter was Mr. Canning; all the last-named being Carlisle tradesmen. Messrs. Hetherington & Oliver were the architects, and the building has been erected under their immediate superintendence.

Hampton Court Palace.—In continuation of the restorations which of late years have been effected in and about the Royal Palace of Hampton Court, the handsome groined ceiling at the foot of the Great Hall staircase is now undergoing a process of renewal rendered necessary by the gradual decay of the old ceiling, some portions of which had become so rotten and defective as to be in danger of falling.

South London Working Men's College, Upper Kennington Lane.—Professor Tyndall will preside at a general meeting of the College, on November 8th, at eight p.m., when the prizes and certificates awarded to the students will be distributed. We are asked to say that tickets can be had at the College.

The First Stone of the Smack Boys' Home, Ramsgate, was laid by the Marchioness Conyngham on Tuesday last. The building is arranged to accommodate sixty boys. The contract is being carried out by Mr. Martin, builder, of Yalding, under the superintendence of Mr. Alfred R. Pite, architect, London.

Messrs. Baker & Sons' Premises, Lambeth.—The purchasers of the yard and four houses are Messrs. Gwynne, the well-known engineers, of the Thames Embankment.

TENDERS

For the erection of dwellings in flats, stables, &c., at Islington. Messrs. Tunley & Boyle, architects. Quantities by Mr. Henry Lovegrove:—

Kirk & Randall	£3,758 0 0
Macey & Sons	3,515 0 0
Woodward	3,493 0 0
Brass	3,396 0 0
Sabey & Son	3,314 0 0
Morter	3,161 0 0
Outhwaite & Sons	3,095 0 0

For alterations at the Lord Southampton, Southampton-road, Maitland Park, for Mr. W. J. Wetteuhall. Mr. James Robert Furniss, architect:—

Anley	£1,170 0 0
Palmer	995 0 0
Edgley	896 0 0
White	887 0 0
Bodeu (accepted)	875 0 0

For rebuilding, after fire, the Sutton Steam Flour Mills, for Messrs. F. & D. Napper. Mr. Frederic W. Ledger, architect:—

Nightingale (accepted)	£898 0 0

For building wing and alterations to the Duke of Edinburgh Tavern, Queen's-road, Bayswater, for Mr. G. Harris. Messrs. Bird & Walters, architects:—

Anley (accepted)	£1,970 0 0

For Board schools, to seat 680 children, at Newington, Hull. Mr. William Freeman, architect. Quantities supplied:—

Garbutt	£4,254 0 0
Gootes	4,181 16 0
Oxen & Bramham	4,167 0 0
Sanderson	4,165 0 0
Blackburn	4,142 3 9
Robinson	4,098 0 0
Habbershaw & Son	4,045 0 0
Morrell	4,034 6 0
Drury & Harper	4,007 0 0
Marsden & Hodgson	3,990 12 9
Sargeant	3,982 0 0
Brown	3,978 0 0
Stephenson	3,970 0 0
Beilby	3,952 17 9
Hockney & Liggins	3,930 0 0
Southern	3,884 14 3
Berry	3,865 0 0
Lison	3,831 0 0
Skinner	3 830 0 0
Wilson Bros. (accepted)	3,770 0 0

For new buildings, for the City of London School, proposed to be erected on the Thames Embankment. Contract No. 2,—Superstructure. Messrs. Davis & Emanuel, architects. Quantities supplied by Mr. F. Downing and Mr. H. P. Foster:—

		Granite Columns, &c.*
Ashby & Horner	£87,810 0 0	... £285 0 0
Ashby Bros.	86,990 0 0	... 390 0 0
Conder	86,840 0 0	... 675 0 0

Mowlem & Co	75,972 0 0	... 498 0 0
Peto Bros.	75,239 0 0	... 468 0 0

* Red Aberdeen granite columns and pilasters, in lieu of Portland stone.

For the erection of Board-room, living-rooms, stables, van lodge, forge, stores, &c., for the directors of the Crays Gas Company. Mr. G. St. Pierre Harris, architect. Quantities by Mr. Billing:—

Wiltshire	£1,329 0 0
Lowe	1,269 0 0
Wright	1,188 0 0
Eldridge & Gee	1,189 0 0
Haisman	1,172 0 0
Chafen	1,160 0 0
Taylor & Son	1,150 0 0
Watts & Davies	1,143 0 0
Brett & Son	1,120 0 0
Arnaud	1,119 0 0
Banks	1,095 0 0
G. & S. Fisher	1,095 0 0
Cox	1,040 0 0
Higgs	1,030 0 0
Beale	958 0 0

For the rebuilding of Manor Farm, St. Mary Cray, for Mr. R. B. Berens. Messrs. W. Hodsoll and G. St. Pierre Harris, architects:—

Wood	£1,610 0 0
Brett & Son	1,300 0 0
Wright	1,195 0 0
Taylor & Son	1,065 0 0
Eldridge & Gee	1,038 0 0

For the construction of new roads and drains at Pagegreen, Tottenham, under the superintendence of Mr. W. Eve:—

Palmer	£2,150 0 0
Rutty	1,875 0 0
Taylor	1,722 0 0
Potter	1,495 0 0
Irons	1,495 0 0
Porter	1,477 10 10
Hunt	1,314 0 0
Pizzey	1,277 0 0
Bell, Wood-green (accepted)	1,172 0 0

For proposed new warehouse, Cursitor-street, Chancery-lane, for Mr. Frederick Chifferiel. Mr. Joseph Lavender, architect. Quantities by Mr. J. G. Raynes:—

Macey & Sons	£3,150 0 0
Greenwood & Co.	3,130 0 0
Holland & Hannen	3,125 0 0
Perry & Co.	3,106 0 0
Brass	3,073 0 0
Colls & Co.	3,050 0 0
Langmead & Way	2,995 0 0
Patman & Fotheringham (accepted)	2,985 0 0

For raising the tower and spire of St. George's Church, Forest-hill. Mr. W. C. Banks, architect:—

Tarrant & Son	£1,635	0	0
Sharp & Everard	1,219	0	0
Taylor & Son	1,203	0	0
White	730	0	0

For the erection of new Board and Committee rooms and alterations at the Barnsley Union Workhouse. Messrs. Dixon & Moxon, architects. Quantities by the architects:—

Brailsford, Clay-cross	£2,357	19	6
Robinson & Sons, Barnsley	1,850	0	0
Bustard, Barnsley	1,836	0	0
Bycraft, Barnsley	1,784	10	0
Hinchcliffe & Moore, Barnsley	1,774	3	0
Taylor & Sons, Barnsley	1,770	0	0
Carr, Barnsley	1,725	0	0
Lawton & Schofield, Barnsley*	1,711	0	0

* Accepted.

For the erection of an additional school-room, offices, &c., at the Elementary School, West Molesey, for the West Molesey School Board. Mr. Thomas Goodchild, architect. Quantities supplied by Mr. H. P. Foster:—

Wood	£1,081	0	0
Prout	999	0	0
Havell	970	0	0
Garrud	957	0	0
Bonell	950	0	0
Seal	933	0	0
Julian	920	0	0
Harris	899	0	0
Wart	891	10	0
Angood	890	0	0
Pack Bros.	889	0	0
Wheatley	887	15	0
Sanders	837	0	0
Beale	828	0	0
Piller	827	0	0
Synelch	820	0	0
Waite	723	10	0

For alterations and extra floor at 123 and 125, Queen Victoria-street. Messrs. Gordon & Lowther, architects:—

Larter	£642	0	0
Taylor & Parfitt	497	0	0
Dyer	489	0	0
Steel Bros.	459	0	0
Richardson (accepted)	443	0	0

For stables at Kingsland-road, for Mr. Carter. Mr. Dunch, architect:—

Conder	£207	0	0
Bowden	193	0	0
Alston	185	15	0
Taylor & Parfitt (accepted)	175	0	0

For new roof, &c., at Messrs. Holt & Co.'s Brewery, Ratcliff. Mr. Dunch, architect:—

Curtis	£390	0	0
Palmer	325	0	0
Taylor & Parfitt (accepted)	319	0	0

For conservatory, &c., at Mr. Margetson's, Chipstead, Surrey. Mr. R. Shaw, architect:—

Weeks	£198	0	0
Taylor & Parfitt (accepted)	179	0	0

For alterations to shop, &c., 49, Hackney-road:—

Taylor & Parfitt (accepted)	£199	0	0

For additions, Slough-place, Cuckfield, for Captain Sugison. Mr. Holloway, architect:—

Cook	£1,375	15	3
Deacon	1,192	0	0
Knight	1,067	0	0
Clark	1,066	0	0
Hollidge & Stuart	1,029	0	0

For the erection of a warehouse at Bethnal-green, for Mr. R. Letchford. Messrs. Hammack & Lambert, architects:—

Hyatt	£1,883	0	0
Wire	1,777	0	0
Cubitt	1,645	0	0

For the erection of two dwelling-houses in the Willow-road, Hampstead, for Mr. F. D. R. Copestick. Mr. T. Milbourn, architect. Quantities not supplied:—

Linzell	£2,100	0	0
Harper	2,090	0	0
Conder	1,980	0	0
Bishop	1,910	0	0
Cross	1,855	0	0
Hambly	1,815	0	0
Reid	1,598	15	0

For a villa in the Station-road, Forest-gate, for Mr. G. Roberts. Mr. Edward Brown, architect:—

Salt	£476	0	0
Birch	408	17	0
Hawkins	388	10	0
Dyer & Son (accepted)	345	0	0

For a cow-house in the Station-road, Forest-gate, for Mr. G. Roberts. Mr. Edward Brown, architect:—

Hawkins	£196	0	0
Birch	159	0	0
Salt	150	0	0
Dyer & Son (accepted)	145	0	0

For pewterer's work at the Old George, Bethnal-green, for Mr. F. Brien. Mr. Edward Brown, architect:—

Rogers	£131	9	0
Heath	123	0	0
Thompson (accepted)	106	0	0
Gasfitter's Work.			
Garnett	178	0	0
Steadman	154	0	0
Christian (accepted)	144	0	0

For Westerham Waterworks, Kent. Mr. J. W. Grover, engineer:—

Botterill	£2,980	0	0
Julian & Co.	2,396	0	0
Painter	2,315	14	9
McKenzie & Co.	2,032	0	0
Pontifex & Wood	2,009	0	0
Bingham (accepted)	1,895	3	10
Jones	1,893	15	9

For alterations at 107 and 109, Leadenhall-street, for Mr. J. T. Morton, under the superintendence of Mr. W. Eve:—

Lascelles	£385	10	0
Hall, Beddall, & Co.	374	0	0
Heiser	275	0	0
Wilson & Exton	249	0	0
Harris & Wardrop (accepted)	248	0	0

For roads at Turnham-green:—

Martin	£1,580	0	0
Rose	1,549	0	0
Pizzey	1,535	10	0

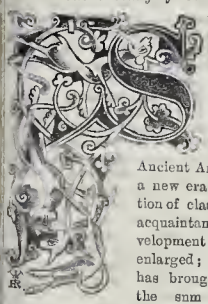
The Modern Study of Classic Archæology.



SINCE Winckelmann, justly esteemed the father of classic archæology, published, now nearly 120 years ago, his "History of Ancient Art," which marked a new era in the appreciation of classic antiquity, our acquaintance with the development of art has been enlarged; almost every year has brought its discoveries, the sum of which has seriously modified the views expressed four generations ago by the worthy German antiquary. The history of this advance within the century that separates us from the enthusiastic but strangely incorrect surmises of Winckelmann is an interesting one, and has recently been ably told by M. George Perrot in the pages of the *Revue des Deux Mondes*. M. Perrot's name has long been known to the archæological world in connexion with the exploration of Asia Minor, while to those who have attended the pleasant lectures at the classic Sorbonne, his erudition is familiar.

In reviewing the late lamented Dr. Stark's "Manual of Archæology," M. Perrot has taken an opportunity to concisely tell the story of the modern study of Classic archæology, in the development of which it is interesting to feel how appreciable a share has been taken by England. But to Germany falls the greatest share of honour. With Winckelmann, a German, archæology took its rank among the sister sciences; it is in Germany that the study of archæology has been pursued with the most consistent and methodical effort. The rest of Europe has supplied the ranks with eminent archæologists, but, remarks M. Perrot, there does not exist elsewhere, as in Germany, a school of archæology fostered by a systematic attention to the necessities of the understanding of its lessons, as afforded by the numerous collections of casts that exist in the chief universities throughout Germany.

Within a comparatively short space of time our supposed acquaintance with antique history has been disturbed and corrected by the discoveries made in Egypt, Chaldæa, and Asia Minor. The cuneiform inscriptions, those speaking records of the past, after having lain buried during centuries, were at length to see the light, and in the hands of experts be deciphered and made to deliver up their secrets. All this knowledge was undreamt of by Winckelmann and the race of archæologists who immediately succeeded him. Egypt and its still mysterious civilisation, before his death, had been but partially revealed; and since Bonaparte's disastrous expedition to the banks of the Nile, what discoveries have not been made? The later school of archæologists have lived to see recently a fresh civilisation evoked from a long sleep, when but a short time since General di Cesnola and Mr. Lang revealed to the learned world the art of Cyprus. These, and many other discoveries on the mainland of Asia Minor,—in which M. Perrot himself has taken an active part,—have strangely modified the views of modern archæologists on the history of the development of art which Winckelmann had pictured, the self-wrought creation of the land which was to see the perfection of art,—Greece. As for his knowledge of Egyptian art, it was confined to the study of the debased figures of Cardinal Albani's Museum (so well known to English visitors to Rome), of which he was long the faithful curator; while to his inquiring mind that vast field of study and research, the painted vases, still remained as they had lain for so many a century, in the cities of the dead, scattered over ancient Etruria and the Campagna. To him even the great art of the sculptor, the art which he most deeply reverenced, was but imperfectly known, and his admiration was unfortunately bestowed on copies of earlier masterpieces of that great fifth century before the birth of Christ, the age of Pericles, of Phidias, of Alcamenes, and of Polycletus, and which alone appealed to him through the pages of history, whose clearest allusions could never have possessed the suggestive meaning of the smallest fragment impressed by the artist's hand. The statues of the pediment and the friezes of the Parthenon, the temple of Ægina and many other great edifices, were still in their original places under the forbidding guardianship of the Turks. Without a knowledge of the art of this period,—the zenith of Greek refinement, how was it possible for the archæologist of that day to understand the archaic or primitive art which had slowly led up to the perfection of the age of Pericles?

The real service rendered by Winckelmann was, therefore, not so much to have thrown a lasting light on our knowledge of classic antiquity as rather to have reduced it to method. The study of his precepts was further developed by Zoega and Ennis Visconti. A mass of facts was in this manner gathered and classified, and the sketch traced by Winckelmann filled in in its outlines. This methodical system of the study of classic art was soon to be put into practice when, with the commencement of this century, numerous excavations brought to light thousands of the treasures of the classic days. The Great Unknown, so little dreamt of by the prime mover of the enthusiasm, was soon to become more familiar. As M. Perrot has figuratively put it, a curtain seemed to be suddenly drawn aside, and behind the rich and brilliant scenery of the Græco-Roman civilisation glimmered faintly the real antiquity, the East,—the father of all religions, of all useful inventions, of the alphabet, and of the plastic arts.

Champollion was to open the road to the deciphering of the long-locked hieroglyphics, and the later discoveries were to show that Egyptian art, like that of every human nation, had had its infancy, its maturity, and its old age; its periods of abeyance, of decay, and of revival. Botta and Layard were to continue these discoveries under the sand which choked the site of Nineveh, and in their hands Assyrian civilisation was to tell its tale of wonders. Babylonia, Lower Chaldæa, Susia, the ruins of Persepolis, so long known but ill-studied, were, by the efforts of Porter, Texier, and Flandrin, to aid in the general fund of information that was now pouring in on a civilisation that had long preceded that of the Greeks; artists, antiquaries, travellers, searchers, and philologists mutually assisted each other in the task. Comparison of the results led to the conclusion that two great centres existed in those distant days: the older in the venerable valley of the Nile, the other probably commencing its influence in Chaldæa, but at a date far more recent than that of Menès, the first of the sovereigns of Egypt. Through the Phœniciana these two powerful centres mutually affected each other. One obscure point in this strange development has only been settled within a few years,—the direction followed, the surroundings through which had passed these two great influences before reaching the eastern and northern shores of the Mediterranean to sow the seeds of cultivation among the still barbarous tribes, the ancestors of the Greeks and the Romans.

Phœnicia has been really known only within a few years, when M. Renan brought home the curious remains he found in Syria, and which now form some of the most interesting treasures of the Louvre, and from the study of which the part played by the Phœnicians in the transmission of the great art-traditions of Egypt and Assyria to Greece, commenced to be understood. Hamilton, Fellows, and the French traveller, Texier, had thrown out, in the early part of this century, some vague hints of the Phœnician influence in the development of Greek art; but their uncertainty became confirmed when the several exploring expeditions specially sent abroad to study the question had completed their researches. And here let a word be said of the services rendered by M. Perrot, who formed so important a member of the expedition, and whose work on the archæological exploration of Asia Minor* justly received on its appearance no small attention. The Phœnician theory received a further support when, within a short time only, the discoveries of Mr. Lang and General de Cesnola in our newly-acquired colony of Cyprus showed another of the stepping-stones in the passage of the art of Egypt and Assyria to Greece.

Together with the progress of our acquaintance with the early civilisation of the East, our knowledge of classic antiquity was receiving fresh impetus. The appearance at the British Museum, in 1816, of the Parthenaic Marbles, which bear so universally the name of their

* Exploration Archæologique de la Galatie, de la Bithynie, etc., par MM. Perrot, Guillaume, et Delbet. 2 vols., folio.

sponsor, Lord Elgin, was to work a miraculous change in the opinion of the artistic world in the merits of Greek art. A new standard of beauty, almost a new type, was suddenly held up, and the artists,—foremost among whom let us not forget the name of Haydon,—came forward in unanimous worship of the marvellous acquisition of the British Museum, which showed the art of Athens in its purest development, freed from the last traces of archaism before its very perfection, to last so short a time, was to lead it to the inevitable decline, the end of which was, it is true, long in coming. Once the attention of the artistic and archæological world was turned in this direction, discovery followed on discovery. Under the skilful guidance of our own revered Cockerell, the Eginetan marbles were, in 1811, to be dragged from the ruins of the temple they had adorned, and after passing through the hands of Thorvaldsen, be ons among the many gems of King Louis' collection in the Munich Glyptothek. The British Museum was to acquire the friezes of the Temple of Apollo Epikounios and the still more familiar Phigalian marbles, and which, as provincial productions, inferior as they might be to the works of the metropolis directed by the master-hands of Phidias and Alcamenes in person, were to show clearly the freedom and variety of Greek art at its noblest period, untrammelled by the tyranny of school or the deadening influence of formula.

M. Perrot has taken care to point out how invaluable were these discoveries in showing at this, the most prolific and most original period of Greek sculpture, how intimately that great art was connected with its sister, architecture. The early example of Stuart and Revett * was to be followed with fruits when Greece, after the memorable Battle of Navarino, was freed from the benumbing influence of the Turks. Each ruin was measured and drawn with religious care by enthusiastic artists, among whom more than one English name stands foremost; the French pupils of the Villa Medici even left their quiet home and the many inspiring subjects for study in Italy, to cross the Adriatic and seek at the fountain-head, if not at the source, the origin of Roman art.†

Studied with this minute care, the architecture of Greece was soon destined to have its secrets revealed. Every professional reader remembers how Penrose made clear the skilful artifice by which the architects of the Propylæa and the Parthenon added, by a slight curve in the lines which to the eye appear straight, a subtle and inexplicable beauty.‡

At the same moment, further discoveries were to be made. Hittorf, during his minute study of the ruins of Sicily, was to proclaim to the world the theory of polychromatic decoration in Greek architecture. Loud were the protests against this supposed heresy, but later discoveries have entirely shown Hittorf and his partisans to have been right.§

While in this manner the sister arts of sculpture and architecture were the object of such fruitful study, the companion art of painting properly so-called had received but small attention. Here all was conjecture, and the reputation of Polygnotus, of Zeuxis, and of Apelles was merely one of historical tradition. In the explorations at Pompeii and at Rome, numerous specimens of classic paintings—all purely wall decorations—were to be discovered, but these paintings were far from being satisfactory; they were Italian work, though from Greek models, and all, in spite of their beauty, were stamped as belonging to an art in its decline.‖ But Winckelmann, though he and his followers had seen the first Pompeian frescoes unearthed, was destined to remain unconscious of the finest period of the painter's art in Greece, and the knowledge of which we owe to the discovery of the thousands of painted vases,—ignorantly termed Etruscan by too many people,—which, within the last half-century have been brought to light. In 1831 Gerhard published his famous Report on the Vases of Vulci, and immediately this new and rich field of archæological research was crowded with reapers; and now, thanks to the labours of these toilers, the harvest of information is somewhat more exact than that possessed by the earliest seekers. We know now that these vases were made in a large number of places, at Athens, at Corinth, in the Greek colonies of Africa, in Sicily, in Italy; that the renown they enjoyed was such that the Greco-Scythians of the wild Crimea and the polite Etruscans of Italy eagerly sought their possession. The Etruscan even imitated the original Greek models, for the art of vase-painting was essentially Grecian,—an art, as remarks M. Perrot, born with the first dawn of its plastic genius, and which alone died out towards the second century before the Christian era, when that genius had ceased to be really prolific and creative.

By the study of these vases, it is certain that no incomplete idea may be formed of the contemporary state of the painter's art. Compared with the literary criticisms, these vases enable us to form some idea of the style of the great painters, of Polygnotus, of Zeuxis, of Apelles, and of Protagoras. But this side of the refined life of classic times remains yet, as probably it ever will, dark and unlighted. M. Perrot is expressing a widely-felt sentiment when he regrets the loss of all traces of the noble sister of the faithful trio. If there is, he remarks, in the shipwreck of antiquity a loss for which the cultivated find it most difficult to be consoled, it is the complete annihilation of the work of all those great painters whom the ancients did not hesitate to place on a par with the most famous of their sculptors and architects.

To the archæologists of the last century the existence of the interest contained in the innumerable objects which form the hook of study of the educated classic antiquary of the present day was unknown. The very number of these objects, their power of escaping the destruction which overtook more important works, has placed in the hands of the student a fund of information; and, in many cases, fragile objects have been preserved through ages, as if to show us the forms of antique art and modes of life and thought in the past, which, without their existence, would have remained ignored by us. What sources of information have been supplied by the delicate little terra-cotta figures of which every museum in Europe possesses some copies! *

In this manner, the study of classic archæology gradually extending its field of inquiry year by year, the need for methodical arrangement was again felt; and from this necessity have sprung the numerous archæological associations which exist in every country, and at the head of which stands foremost the Roman Institute of Archæological Correspondence, founded at Rome by Bunsen, Gerhard, and the Duc de Luynes, as far back as 1827.† Wisely allowing a freely international spirit to pervade its doings, in its ranks it has counted all the more eminent scholars of Europe. Its monthly bulletin has recorded for many years past all the important discoveries made in Italy, while the pages of the Annual are occupied with the description and illustration of more abstruse problems.

Each country has, through the members of its own learned societies, additionally assisted in the work; many unknown paths have still, however, to be explored, and the students of the numerous unread inscriptions that still exist have yet to reveal to us much that remains at present unexplained. Already with Boeckh and Borghesi epigraphy showed its importance, and since their time its services have been even more clearly shown. As for figured archæology, its task, as M. Perrot remarks very truly, is still heavier; the language of form is less clear than that of words, while a further difficulty arises in the very abundance and variety of the materials, which are every day increasing in number. Order is necessary in the arrangement of these scattered facts, and this difficult task it has been the endeavour of more than one patient student to carry to a successful conclusion. When the Roman Archæological Institute was formed, now fifty years ago, the necessity for making catalogues and inventories, and determining the limits of the information which then had accumulated, was clearly felt. But to carry out this vast scheme, a man of an exceptional organisation had to be found,—a student of a more than ordinarily extended course of reading,—a *savant* whose taste the toil of the workroom would not injure,—an artist and a scholar. Everything is not to be learnt in books, as observes M. Perrot very justly. If you wish to speak with any competency, commence by studying closely the productions of the plastic arts; open with them, as it were, a friendly and familiar intercourse, cultivating in yourself the sentiment of form and the love of beauty. Without this education of the eye, the fruit of long practice, how is it possible for the student to seize the slight shades which distinguish the styles and the schools?

The first half of this century saw such a man, who seemed formed for the task by a union of qualities rarely found in one individual,—Ottfried Müller. The pupil of Niebuhr and of Boeckh, none among his contemporaries made such a powerful effort to embrace in his vast researches the whole extent of antiquity, to represent it and revive it under its various aspects. A philologist, he finds a singular charm in the most minute analysis of a science which weighs words and syllables and compares the lessons of manuscripts; a poet, in his leisure hours he appreciated keenly the charm of ancient and modern letters.

With the vast learning at his disposition, he hoped to be able to trace the outline and colour the picture, into which he was to introduce the whole history of ancient Greece, and place it under our eyes in all the indivisible unity of its artistic and literary, its social and political, existence. Death, in striking him down at the early age of forty-two, shattered this noble dream, and his work was never achieved. But during the elaboration of this immense programme, his activity did not allow him to be idle, and during the years that he held his chair at Göttingen he kept in charmed expectation his numerous listeners, while the magazines were filled with his facilely-penned studies; with his contributions to current literature alone, a Berlin publisher has recently formed a large work, in five volumes. But of all his works, his "Manual of the Archæology of Art," which appeared at Breslau in 1830, was that which was destined to render the greatest service to the study of antiquity. Translated into French, into English, and Italian, the book became an indispensable guide to all those who wished to acquire a knowledge of antique art.

To those interested in the story of Classic art, Müller's handbook, for it was in this form that he judged it most convenient to publish his work, is familiar, and once its apparent intricacies are mastered, the ease with which it can be used as a book of reference cannot be too highly praised. When the reader is desirous merely to acquire a summary notion of some point, the voluminous footnotes need not disturb him; but when he is desirous to enter more fully into the matter, the footnotes will supply him with a valuable series of reference to books and other sources of information.* Want of space forbids our following M. Perrot in his analysis of the arrangement of this work, the only fault of which lies in its having been published so many years ago.

In 1835 Müller himself saw through the press a second and revised edition of his work, but since that date how many important discoveries have there not been made in the field of inquiry in which Müller was so versed? Since those days the East has yielded up secrets unguessed by Müller, and Egypt, Phœnicia and its great Libyan colony, Chaldæa, Assyria, Asia Minor, Cyprus, and Rhodes have been explored. It was three years after Müller's death that Botta commenced to unearth the monuments of Assyrian art, and since them we all know what has been learned. Müller's ideas were conceived in the

* The Antiquities of Athens Measured and Delineated. By J. Stuart and N. Revett. London, 1761, in folio.

† In 1872 the collection thus made contained no less than sixty-one restorations, comprising 691 original drawings on double-elephant paper. The publication of the fifty-two volumes, in which these drawings are bound, was commenced under the direction of M. Charles Blanc; but only four parts have appeared. Among these the most interesting is the Restoration of the Temples of Paestum, by Lahronste; the remaining studies will, unfortunately, from all appearance, be left unpublished for some time to come.

‖ In the *Revue* of October 1, 1879, M. Gaston Boissier reviewed the learned work of Herr Wolfgang Helbig, on the wall-paintings of the Campagna, *Untersuchungen über die Campanischen Wandmalerei*. Leipzig, 1873.

* Among the seekers in this refined branch of antique art, M. Heuzey has particularly distinguished himself, and his works on the terra-cotta fragments and figures of the Louvre Museum are some of the most interesting of the recent additions to the science of archæology. M. Heuzey is at present publishing an illustrated catalogue of the terra-cotta figures of the French National Collection.

† This Institute, now the German Archæological Institute, celebrated in 1879 the fiftieth anniversary of its foundation, when a history of the Association was published by Herr Michaëlis in Italian and in German.

* The English translation of Müller's handbook, "Ancient Art and its Remains," is by John Leitch. The first edition was published in 1847, and a new edition in 1850.

early years of the century, and he is one of the warmest upholders of that now exploded theory that the Greek genius was of purely native origin. To him the part played by the Phœnicians was but vaguely pictured; the discoveries of Fellows, of Hamilton, and of Texier, were unknown; and while he was to die in his beloved Greece, these patient explorers were to call the attention of the learned world to the wondrous monuments of Asia Minor, the art displayed in which resembles so strikingly that of Upper Assyria.

With this fact borne in mind, excuses may be made for the deficiences that are so glaring in Müller's handbook; foremost among these, the author's misconception of the part played in the formation of Greek art by their Oriental predecessors, to whom, however, a few short and concise, but above all ill-placed, paragraphs are devoted.

The modern historian who would attempt a history of Greek art would be obliged to prelude his labours with the history and study of Oriental art. Egypt would necessarily be the point of departure, and in its historical succession Egyptian art in its various manifestations, according to their bearing on the art of Greece. To the people of the East a large share would have to be devoted to show how, as M. Perrot remarks, by the processes they invented and the forms they created they contributed to prepare the early rise of Greek art and its brilliant zenith. The field for the labours of the modern historian of art is somewhat vaster than that toiled in by Winckelmann and Müller. Our century is essentially, as our author truly remarks, a century of historical research. In the consideration of an individual or of a people, of a religion or of a philosophy, of a literature or of an art, we seek the earliest origins to the point where they disappear in uncertainty or are lost in the haze of a distant commencement.

In the history of Greek art, to reach its true origin we must push farther in our research, and leave far behind the narrow limits of Greek history. Greece, which has long been in "antiquity," comes in reality late in the development of civilisation which had already run a long race of centuries. In comparison with Egypt, Chaldæa, and Phœnicia, Greece is almost modern. By its geographical position it was easily open to foreign influence, and particularly to that of those ancient Asiatic countries teeming with tradition. With the first upward movement from barbarism, the neighbouring East was to furnish Greece with models and examples by which it was greedily to profit. Thus, as remarks M. Perrot, the further the progress of the study of the past is carried, the more surely we recognise the truth of the traditions and myths which speak of the influence on Greece of Egypt, of Syria, and of Asia Minor. The student, in his research, will be struck by the fact that the Greeks borrow from their predecessors all the elements of that industry which is not yet an art, but without which art cannot be formed,—the processes of metallurgy, of ceramics, weaving, the laying of building materials, all those technical secrets which appear so simple to those who have long possessed them, but the discovery of which represents the accumulated effort of how many unknown generations? To the East, Greece owes her "alphabet of art," which she applied to the expression of her own sentiments. Hence, in Greek art, even in its highest perfection, so many traditional details, whose origin can be traced to the banks of the Nile or the Tigris, and transmitted down to our days. But it is something more than the mere adaptation of the traditions of their predecessors that the Greeks were to produce. Two or three centuries elapse, and Greek art is to become original, an art superior to all that has preceded it, one which alone merits the appellation of "Classic," being able to furnish rules susceptible of being transmitted by instruction. In what this superiority consists, and the reasons of its existence, is the task of the future historian to determine; and this inquiry can alone be satisfied by a study of the art of those people who formed the art of Greece: then that art will be understood. For, as M. Perrot concisely puts it, "beyond the obelisks and the pyramids of Egypt, beyond the stepped towers of Chaldæa, the domes of Nineveh, the tall colonnades of Persepolis, the fortresses and tombs hewn in the flanks of the mountains of Phrygia and of Lycia, beyond the huge walls of the Syrian cities and the ravines where gape the yawning entries of their funerary grottos, beyond all this architecture, beyond all this strange colossal sculpture, stands clearly visible on the horizon the sacred rock of the Athenian Acropolis; and as we advance in this review of the past, we see it rising before us in the clear blue southern sky, with the dazzling whiteness of its marbles, the severe elegance of its porticos, and the majesty of its pediments, in which live and breathe the gods of Homer and of Phidias."

The story of Classic art has yet to be traced on, and if the exigencies of the study oblige the student to leave behind the Athens of Cimon, of Pericles, of Lycurgus, to cross the sea to Veii and to Clusium, to explore the Etruscan cemeteries and the strange lavishness of the decoration, if he at length reaches imperial Rome, with its gigantic edifices, how often in the midst of all this wealth of splendour will he not feel inclined to turn with regret to the memory of the past? The archæologist will still trace with curiosity the changes by which new peoples and new needs will influence the types created by Greece. The decadence continues to be interesting in the efforts made to remain faithful to the bygone traditions, but another influence more interesting is already shadowing forth the advent of another art, of Christian and modern art, which closes the study of the strictly Classic archæologist.

We have a quarrel with M. Perrot for the slight mention he has made of the remarkable achievements of Dr. Schliemann, and his omission altogether of any mention of Mr. Newton's labours in the field of Classic archæology, but we will not now pursue it.

CHURCH PLANNING AND CLERICAL CRITICISM.

When the revival of ecclesiology in this country took place, about a generation back, clerical critics had a flourishing time of it. The whole duty of the architect was to study the plans and arrangements of the pre-Reformation edifice, *donec templa refecerit*, until he could produce exact and orthodox copies of its arrangements, and what might pass for exact and orthodox copies of its architecture. The latter was the less easy task of the two; some of it involved not only the study of the facts of a style, but the imbibing of its spirit, and the discovering of workmen (if so it might be) who had also imbibed it, or into whom it could be instilled; and many examples of churches in the supposed true Mediæval style remain to attest how difficult was the accomplishment of success in such particulars. But the Mediæval plan and arrangement, and the Mediæval church furniture, and its names, could be more easily recovered, and in such matters the clergy, spurred on by their personal interest in a movement which promised to bring them into more conspicuous place and influence, were rather before than behind the architects, and assumed the position of teachers and reprovers of the latter. No practical question of the suitability of this or that form of building was at stake. It was simply the knowledge of ecclesiological precedent which was required; and under the hands of the clergy, who had most sedulously studied this knowledge, the church architect was compelled to do penance, unless he were one of the very few who had acquired even more learning on the subject than the clerical amateurs, or was able to persuade them that he had done so.

Less formal stress is laid by the clergy on this ecclesiological exactness now, partly because so many architects took it up for themselves, and it became so much a matter of course in many quarters that there was the less need for special protests and proselytising in the cause. At the same time, the extreme rigour of the ecclesiological party was somewhat abated of its pristine zeal, and there crept in a certain perception that the practical side of building did also affect churches as well as habitations; that it was desirable to have them properly warmed and ventilated; and that there was even something to be said in favour of contriving that the worshippers should be able to see and hear the clergy. The first point may be said, however, to have hardly got beyond theory, save in a few very exceptional instances. A church properly warmed and ventilated is certainly one of the rarest phenomena to be found. The latter point, the innocent desire on the part of lay members of the community to see, if not to hear, their spiritual pastors and masters when in the exercise of their office, took practical shape so far as to lead to a popular conviction sometimes acted upon, that long transepts were inconvenient features in a modern church, and to a very few attempts to reduce the side aisles to places of passage only, so as to interpose no piers between any of the congregation and the chancel, lectern, or pulpit. This latter bold innovation received the sanction of one or two of the chosen architects of the ecclesiological party, but the experiments which have been made in putting it into practice are not numerous. For any improvements in the warming and general comfort of churches that may have been made we are indebted not so much to architects, certainly not to clergymen, but mainly to heating engineers anxious to push their inventions. Even congregations make little or no stir on this point. People who would complain viciously if they had to sit shivering and with feet half-numb in a theatre or a concert-room, will put up with this in a church with hardly a murmur, beyond the customary remark after morning service in winter, "Dear! how cold the church was this morning:" a touching example of the elevation of moral sentiment and the triumph of spirit over matter which attendance at church induces, or, perhaps, of the tendency of mankind towards resignation to any evil recognised as general and unavoidable.

Our attention was drawn to the subject the other day, in connexion with the large and handsome parish church at Whitechapel, which was recently burned out (we do not say burned down, as the walls are nearly all standing), after only two or three years of existence. There has been, of course, some talk as to rebuilding it, in connexion with which a well-known clergyman of the Broad Church school, the new vicar of Greenwich, wrote the other day to one of the daily papers, protesting against the church being re-constructed on its old lines, on the ground that, as his personal experience enabled him to judge, it was so utterly bad acoustically that it was next to impossible for any preacher to make himself properly heard in it; the tone of his letter conveying a general innendo against architects for building churches in which no one could hear. This was replied to by a letter from the Rector of Whitechapel, denying that there had been any formal determination to rebuild the church as before, and admitting fully that the non-acoustical qualities of the building seemed to necessitate some departure from its original model if it were rebuilt. This clergyman also wrote in a somewhat injured tone in regard to those who designed churches, observing that it was to no purpose to tell him that the acoustic qualities of the church were bad, but that he wanted architects, or others who ought to know, to tell him why they were bad,—whether it was the height, or the materials, or the shape, or what it was.

This would be a reasonable position enough if the clergy generally really wanted churches conveniently planned and good to hear in. But the fact is that the onus of this part of the matter rests with the clergy and the clerical party themselves. If those who promote the building of churches really wanted churches constructed for the practical aim of providing comfort and promoting easy hearing, they would get them. Theatrical proprietors demand these qualities, and obtain them, not always as completely as might be, but still very fairly, even in ordinary cases, and sometimes very completely. But the fact is that a practically-designed church is the very last thing that clergymen or church-building committees really want. If an architect gave his mind to such a problem, and evolved a church which he believed to be the most practically suitable for seating a congregation so that all should hear well and to be comfortable in regard to the provision of warmth and fresh air, quite independently of architectural precedent, not one clergyman in a hundred would look at it, and in all probability the architect would be scoffed at for his pains, as a "Philistine" with no proper understanding of the orthodox proprieties of church architecture. The manner in which this has come to be the case is, of course, simply this: the great move for church-building in this century was inaugurated mainly by the zeal of the modern High Church party. They gave the impulse, and they also gave to it its characteristic direction. In their view the revival of ecclesiasticism meant a revival, as far as possible, of the privileges of the clerical caste in the pre-Reformation period, and consequently of the revival of the pre-Reformation church. The

ritual significance of the building was to be emphasised; the idea of its use as a place for preaching in was discouraged. The short chancel, which practically sufficed for the celebration of the Communion during the Low Church period, was to give way to the long Mediæval chancel with stalls on either side for the clergy apart from the lay worshippers, and this separation was eventually further emphasised by the revival of the screen separating the chancel more distinctly from the church; although in all cases at first, and in most cases still, the stalls which in the Mediæval church were occupied by the clergy are now occupied merely by choristers simulating the clerical garb. The addition of the long chancel was a definite and in one sense a logical practical result of the new view (or the old view, if they prefer to look at it so) of the clerical office, which the church revival brought up; but there was also the influence of revived Mediæval sentiment, which affected the whole architecture of the churches, and led to the idea that nothing could satisfy the revived ecclesiastic feeling but the revival of the ecclesiastical building, and the general object held before the architects was to produce churches which should represent the Mediæval church in all its architectural expression and details as completely as possible. The architects were, as has been often observed, a good deal tyrannised over at first by their clerical preceptors; but in the end they learned their lesson: they found the ecclesiological party were, after all, their best patrons, were the party most eager to build churches and most ready to spend money over them, and they adapted themselves to the circumstances; so that now "a church architect" means a man who can build an effective church on the Mediæval pattern. The idea of the proper form of church thus accepted, was soon tacitly followed even by those who had no connexion with the ecclesiological movement. If a Low Church clergyman went to an architect for a church, he got a building on the model which the High Church party had set up, and which has become *pro tem.* the accepted form of church. There would be differences in the details of internal arrangement and furnishing, no doubt, according as the building was for a High or Low Church client; but both would get the same general form of church; and, indeed, the architect, in the present state of public feeling or habit of thought on the subject, would scarcely venture to propound any other, nor probably would the clergyman, to whatever section of the Church he might belong, think of proposing anything out of the way, on practical grounds. A church is a building in the Gothic style, with three aisles and a long chancel; that is the accepted opinion: and so it comes to pass that the Rector of Whitechapel, who, we believe, is what is usually called a Low Churchman, had an absolutely Mediæval church built for him, in which neither he nor his friends could make themselves heard from the pulpit without discomfort and exertion both to preachers and listeners; and then he and his friends wish to know how it is that the church should be so "dys-acoustic" (to coin a word from Greek), and why it was built so.

The latter part of the question we have answered already: the other portion of it should be put the other way. We should not ask, why should such a church be had for hearing in, but, why should it be expected to be otherwise; and in some few cases, we might add, why should it unexpectedly turn out to be good for hearing in? For there are such cases, to our knowledge. We never were in Whitechapel parish church during service, but we knew the building: a lofty, three-aisled church, the centre aisle nearly 80 ft. to the apex of the open-timber roof, the walls internally as well as externally of brick. No such building could possibly be expected *à priori* to be good to hear in or to speak in. Two of the first conditions for a good acoustic apartment are that there should not be a superfluity of height, and that the walls should be of materials which sympathise with and reinforce sound. Brick, and other such hard substances, do the very reverse. They do not assist sound in any way, but they do reflect or echo it very sharply; consequently, instead of the voice being at all helped by the building, it is, without reinforcement, split up and confused by a number of echoes from hard surfaces at various angles. Add to this that a portion of the congregration are seated under side aisles, lower than the portion of the church from which the preacher's voice is emitted, and that all experience proves that it is very difficult to get sound to travel clearly from a more lofty into a lower and more confined space; add further, that by refusing the system employed in most other public buildings, of seating part of the audience on different levels, they are all spread out on the ground-floor over a considerable area, and that part of that area is partially shut off by stone piers which both intercept sound, and contribute further to produce confusing echoes; and that the form of open-timber roof, producing a kind of inverted trench over the building, is further calculated to lose and confuse sound. All these considerations are mere commonplaces to any one accustomed to study the acoustic properties of buildings; and no one would think of building a meeting-room, concert-room, or theatre in this way, or of these materials. But we really do not see that the architects are to blame in this, and so many similar cases. If the architect is an unprofitable servant, it is only in the Scriptural sense, that he has confined himself to doing what he was told to do. The architects may quite fairly turn round on the clergy and say,—"Reverend Sirs, you, or the most irrepressible section of your body, demand churches on the Mediæval model, as a matter of sentiment: there they are. They are not built for practical purposes, but for sentiment. If you *will* have them, you must take them with all their practical defects."

The ultimate solution of the problem, of course, depends on the judgment which the clergy and people at large ultimately arrive at, as to what they want churches for. Are they to be places for the performance of a ritual mainly, or mainly for addressing and leading a body of people? And if for the former object, is the ritual to be regarded as congregational, participated in largely by the people, or is it to be mainly clerical or priestly, witnessed only by the people? Which it ought to be we do not undertake to suggest here; we may have our own strong opinion, but we are not going to introduce theological or ritualistic discussions, of course, into these columns. We may observe, however, that if the latter, the priestly ritual, be what is wanted, then, and then only, is the strictly Mediæval form of church a practically fit type of building for the purpose. If, on the other hand, the church service is to be regarded mainly as an opportunity of addressing a number of persons collectively, then, and then only, is it necessary to regard the building in as purely practical a spirit as we employ in the case of a theatre or a lecture-room.

We desire to say that we do not ourselves go so far as this, more especially in a day when opportunities of addressing the public through the press are so multiple. Speaking generally, we are not in favour by any means of a purely utilitarian view of church-building. On the contrary, we are inclined to think that it is very desirable to preserve the idea, especially in crowded towns, that the church is the one class of large building left to us in which we may aim at effect and sentiment, at architectural beauty of interior expression, for its own sake, as a thing grateful and soothing to those especially who usually see around them only comparatively squalid buildings and murky streets. In such neighbourhoods a large church, with a fine and impressive interior, seems to afford the kind of relief to the mind suggested in the verses at the commencement of Kingsley's "Saints' Tragedy," where the child-heroine muses on the steps of the cathedral,—

> "All without is mean and small,
> All within is vast and tall;
> All without is harsh and shrill,
> All within is hush'd and still."

But it does not necessarily follow that from the Mediæval model alone can such architectural effect be obtained, or that we might not combine this with practical acoustic properties, at all events much better than the Mediæval model can usually afford. People must not, however, expect that they can get both qualities combined in a high degree. If they do they will be disappointed. No building on a large scale which is absolutely good acoustically, can, it is to be feared, rise to anything very fine architecturally, not in the most impressive and monumental style of architecture. The two things seem to be incompatible. If perfection either way is wanted, it is for the clergy to say which they want. Do they want preaching-rooms, or do they want buildings for prayer and impressive celebrations, or do they want to combine both? If either of the former, they can have them if they will make up their minds which they want; if the latter, they must be content with a compromise, securing as much architectural effect with as good acoustic properties as can be devised. They are not likely to have both together in perfection; but the combination may, no doubt, be realised much more successfully than it ever has yet been.

We may perhaps return to the consideration of the subject more in detail; in the meantime, we will make one suggestion. The Institute of Architects have shown an intention of promoting the element of discussion more at their meetings; why should they not get up a discussion as to the best form of church-building for the worship of the church of the present day, inviting a few leading clergymen or church dignitaries to state their views as to what is wanted? It would need the hand of a resolute chairman to keep down any possible ebullition of *odium theologicum*, not only on the part of the clergy, but of some of the architects; but an animated and interesting discussion might be safely promised, and perhaps some useful conclusions might be arrived at which would prevent the wasting of large sums of money on buildings which some of those who use them only complain of as unsuited for their purpose.

THE HOLYROOD FLINT-GLASS WORKS.

The tourist who chances to visit the royal palace of Holyrood in his wanderings through Scotland will observe, on his way up the south back of the Canongate of Edinburgh, a congeries of chimneys and cupolas flanked by a certain bold and rather conspicuous frontage (embellished with some curious bas-reliefs), which, his guide will tell him, with an air of mystery, is the Holyrood Glass Works. Having a dislike of all manner of mysteries, and having, moreover, always had a curiosity about the manufacture of glass in all its phases, we obtained the necessary permission to visit the works, and the few remarks which follow are the result of our observations.

How a manufactory of flint glass should be established, as it has been for upwards of a century, in the immediate vicinity of the greatest historical palace in Scotland, is beyond our province to inquire. The times, in fact, are changed. Edinburgh is full of such mutations,—a brewery here, a brass-foundry there, a Free Kirk, and a public school,—such buildings now occupy the sites of the once-celebrated town mansions of the old nobility of Scotland. In the present instance, however, the proprietor (to whom our acknowledgments are due for his courtesy) does his best to support the historical character of the neighbourhood; that is to say, he has spent a deal of money in beautifying, castellating, corbelling, and so forth, the back elevations of all the property he possesses which abuts on the Queen's Park,—one of the most romantic and beautiful public parks, we need scarcely say, in this country.

The Holyrood Flint-glass Works have, therefore, a claim on our attention, and we have no doubt that some of our readers will be glad to hear even the little we have to say. Glass is proverbially a difficult subject to handle, in more than one way; and flint-glass is the most difficult part of it. All we can just now offer are a few hurried observations, and we shall begin by asking a question.

What is flint glass? That is the first question. But this involves a second. What is flint? Very few of our readers, we suspect, will be able to answer this question satisfactorily to themselves. The geologists will tell us that nodules of flint are found embedded deep in the bowels of the limestone rocks, likewise in the coralline deposits at the bottom of the sea. The mineralogists, who are always ready with profound definitions, say that it is a variety of quartz, a sort of intermediate substance between quartz and opal. The chemists, on the other hand, who, from their analytical nature, are more precise in their determination, give us this general formula of its composition: silica, lime, oxide of iron, water, carbonic acid, and sometimes traces of organic matter. We must not, however, enter upon this very wide subject. Our best plan, perhaps, is to say that flint is flint. The mass of our readers will probably recognise and remember flint as a certain hard, obdurate substance, used by all the poets, since the days of Homer, as a metaphor indicating

obstinacy; and, long before the days of the Greek poets, by our own ancestors, who dwelt in caves, for implements and weapons; and finally by our own immediate progenitors, as a means of striking a spark of fire in a gun-lock,*

"In our hot youth,
When George the Third was King."

It may be added that flint is a species of Nature's glass,—somewhat obscure, no doubt, unless it be cut thin enough,—but still entitled to rank in this respect with opal and the gems. We need not, however, dwell any longer on flint, for the fact is that although flint-glass was originally made, as fine earthenware and porcelain are at this moment, from calcined and pounded flints, the modern method of manufacture simply employs various descriptions of fine siliceous sand; in other words, of flint that is pounded by Nature.

How this obdurate and opaque material came to be transformed into a beautiful and transparent, or it may be translucent, form of glass, carries us back at one tremendous leap to the graves of the Pharaohs. Egypt was always pre-eminent in the manufacture of glass, the sand of Alexandria being indispensable for the finest qualities. It retained this supremacy even during the Roman era; for it is a well-known historical fact that the Emperor Hadrian, on his visit to Egypt, was profoundly struck with the nature and extent of the manufacture; and he sent as a present to his friend the consul Servianus, one of those beautiful opalescent vases which the Roman writers mention with such unqualified admiration. The Romans themselves made both crown and flint glass, and knew how to make use of soda and lead as fluxes. We dare not, however, enter on the tempting field of archæology, nor even allude to the Venetian and Bohemian schools of art.† We shall just add here that flint-glass was first manufactured in England at Crutched Friars and in the Savoy about the year 1565. The Holyrood Works, to which we now invite the reader's attention, have been established, as we have said, over a century, and were the first, as they are certainly the largest, of their kind in Scotland.

The process of making flint-glass, like that of any other sort of glass, is simple enough theoretically, but in practice it is extremely difficult in every stage of the operation. The materials usually consist of the finest white siliceous sand; that is to say, the silicate of alumina; a strong alkali,—the bicarbonate of potash; a small quantity of the nitrate of soda; and lastly, the oxide of a metal by way of *flux*, which either consists of red lead or litharge,—*i.e.*, the red oxide or the vitrified protoxide of lead. To these ingredients are added a small per-centage of the protoxide of manganese, and also of arsenic, for the purpose of obliterating the action of iron in the sand (which is always present in more or less quantity). Of course, every manufacturer *differentiates* these quantities. Roughly speaking, flint-glass is composed of the same materials as every other glass,—certain silicates, certain alkalies, and certain metallic oxides. But we may add that it is possible so to vary or to adulterate these materials that a pot of good flint-glass may differ from a bad one something in the same degree and ratio (the comparison will, we are afraid, go no further!) that a specimen of Honduras bay-wood differs from a plank of fine Spanish mahogany!

In the Holyrood works the first thing we are naturally directed to after a bird's-eye glance at the singular buildings, is this raw material, which we find strewed about in great heaps on the floor of the mixing-house. The raw material we saw looked uncommonly like a heap of worthless rubbish, such as one may see emptied any day into what the Scotch call a "toom" as builders' offscourings; and is certainly not nearly so picturesque as the gravel we may see collected at the sea-beach for the purpose of adorning our garden-walks. But after the mixing comes the transformation; and in order to illustrate this, since we cannot find, in the whole range of modern manufacture, a transformation so singular, so complete, and so beautiful, we are compelled to fall back on the time-honoured comparison of the crawling caterpillar with the beautiful butterfly.

The next process, then, after admixture is what we shall term combination. After this heterogeneous material,—this mass of wretched rubbish, as one might suppose,—is properly mixed with all the necessary salts of potash, &c., and all the other ingredients, it is conveyed to the melting-house, where it is put into a pot, or rather a number of pots. But we had better explain, perhaps, what this pot signifies,—that is to say, a pot of glass.

In the centre of a large lofty, brick-built, stone-flagged, and well-ventilated melting-house, probably 140 ft. square on plan, stands a fiery furnace which roars night and day, surmounted with a cupola chimney and dome, and containing within its lurid bosom several enormous pots of a peculiar construction, made of Stourbridge fire-clay. The construction of these furnaces is a special branch of the building trade; and on some other occasion we may describe their construction. It is enough to say at present that they are so constructed as to stand the most enormous heat that it is possible by such means to produce. We have seen copper smelted at Swansea; and iron at Merthyr Tydvill; and we confess to the impression that these glass pots were more intense in their heat, until we were informed by the intelligent manager, Mr. Gilbert, that such was not the case. In point of fact, however, the heat (and glare) of the furnace is something tremendous. It is, we believe, nearly impossible to estimate the temperature of the white heat necessary to reduce this obdurate stuff to a liquid,—stiff, viscous, yet homogeneous. Even Wedgwood's pyrometer can give no really philosophical estimate of the great heat necessary to produce this liquid vitrification. But the singular thing about the process is that it is possible to overdo the heat, and actually to burn the glass, just as you might overheat an oven and burn a loaf. Indeed, it is one of the chief difficulties of the business to estimate and control the heat of the furnace. The fuel consists of good coal. But somehow all the various ingredients assist in feeding the combustion, or chemical combination, and the time required to produce this pot of liquid glass, technically termed "metal," ranges from two to three days and nights. We ought to add here that every pot of metal is not brought to maturity with invariable success. Sometimes a hitch occurs in the operations which renders the metal less workable, and sometimes spoils it altogether.

When this pot of metal is ready or "ripe," then begins the action of the "journey"-men glass-blowers. The singular and beautiful process of glass-blowing (which, thanks to the progress of our modern educational literature, is known to every schoolboy) is certainly one of the most ingenious and *dexterous* in the whole range of the useful arts. Several half-naked men, armed with long malleable iron tubes, select each an opening in the furnace, and dipping their tubes into the pot attach a definite quantum of the red hot, or rather white hot, metal; and blowing through this tube by an orifice in its upper extremity they can produce by the most surprising manipulation, actually any shape or form that is needed for the required drawing. A glass, or globe, or claret-jug, or vase, or, in short, any form of the various beautiful articles to which flint-glass may be applied, gets here its first and final form.

We made some inquiry at this stage on a subject with which we are always more or less concerned; and found to our astonishment that although glass-blowers are perhaps not the longest-lived tribe of artisans, still that their handicraft is not an abnormally unhealthy one, not nearly so much so as that of a tailor, for example, or a stonemason. Some years ago, we were informed that as a class they were notoriously intemperate in their habits; but that this feature in their character seems to have gradually disappeared as sanitary laws became better understood, we may speak to from our personal knowledge. And it is due to the British manufacturers of glass to say that they have done more to elevate the social condition of their working-men than almost any other employers of labour connected with the great staples of our national industry.

But we must hurry on. This flint-glass vase, shall we say? which has now reached its first and rudimentary stage in formative art, has next to be annealed,—"attempered," as our grandfathers used to say. Glass, we are sorry to repeat, needs "tempering," like human nature and fine steel; and many a good specimen of glass-blowing ingenuity cracks in the process, which is simply a more or less gradual reduction of the hot fragile vase to the ordinary atmospherical conditions. This is accomplished in what is termed the annealing oven; that is to say, a form of reverberatory furnace.

Hitherto we have been dealing with what we shall take leave to call the "hot" manipulators; we now come to speak of the "cold" ones,—*i.e.*, those artists who in place of using fiery furnaces and vitrified fluxes, work among cold water, emery, and putty. In this department resides the most artistic of all the processes, namely, that of glass-cutting, which is now one of the most important and highly-paid branches of art in Great Britain and the Continent, as well as the United States. The design, of course, precedes everything; and we are bound to say that we have seldom seen better designs in glass-cutting than we saw at Holyrood. After this, drawings are made on the glass (which, by the way, is first of all obscured). We now enter a long rectangular room, well lighted from the roof, in which we are almost bewildered by a congeries of lathes and wheels whirling and revolving at a great speed. All these wheels are really miniature grindstones, plentifully supplied with sand, emery, and putty-powder, and with these implements and materials the workmen engrave with astonishing rapidity on the exterior surface of the glass the requisite design. It is very like lapidary work on a large scale,—a process, in fact, of "diamond cut diamond," and the results are equally beautiful and exact. After leaving the cutting department, the flint-glass goods are carefully washed, and then removed to the packing-room, where they are carefully packed in tissue-paper, then in crates filled with straw; after which they are ready, as the signboard says, "for home use and for exportation."

We will not attempt to enter upon a catalogue of the sometimes magnificent and always beautiful articles. We have only to add that within the last five-and-twenty years no country in the world has made such progress as Great Britain in this splendid department of our national industry. Such are a few of the observations which occurred to us in connexion with the Holyrood Flint-glass Works.

CONSOLS AT PAR, AND LANDS THAT WANT HANDS.

The attainment of par by Consols, which took place on the 3rd inst., is an event of no little interest to all those engaged in building, or in any industrial investment. The quotation of 100 to 100⅛ is the highest touched by the Funds since 1853. It is only the third occurrence of such an event since our National Debt attained its present magnitude. In 1844, for the first time, Consols rose above par, and stood for a time at 101¾. The Railway Mania of 1845, almost, if not quite, unequalled in its inflation of prices and of hopes since the time of the famous Mississippi scheme of Law, closely followed. In 1852 Consols touched 102, the highest point they had ever reached. The world was then under the the influence of the golden promises of perpetual peace and brotherhood between nations, to which a sort of dream-like reality had been given by the brilliant success of the Crystal Palace of 1851. The then recent discovery of the gold-fields of California and Australia formed a powerful factor in the buoyancy of the public faith. The Russian invasion of Turkey, and the Crimean war, prevented a sequel to the fine-weather barometer-mark of 1852 such as that which occurred in 1845. Without trespassing beyond our prescribed limits, we may say that there is not, at the present moment, so unclouded a horizon as to promise an immediate era of rapidly-increasing prosperity. At the same time, the results of the late harvest,—which, whatever they have been positively, are magnificent in comparison with those of the harvest of the preceding year,—are reflected in the quotations of the Stock Exchange. Perhaps not less potent as a factor is the general absence of opportunities for investment. The prices attained by our Railway Stocks are not such as to tempt the prudent investor. London and North-Western are quoted at 157. On the 6th of November, 1879, they were 146½, and paid 4*l.* 5*s.* 9*d.* per cent. if purchased at that price. Brighton are quoted now at 145; last November they stood at 133, paying 4*l.* 3*s.* 11*d.* at that price. Midland stand at 137⅝, or 1½ higher than in 1879, when they paid 3*l.* 19*s.* on the

* Our readers who wish to pursue this subject should consult Mr. Evans's work on "The Flint Implements of the Drift."

† We may refer on this subject to the learned and beautifully illustrated work of the French antiquary, M. B. de Perthes. Fol. ed. Paris, 1852.

purchase-money. Metropolitan are only a half per cent. higher than they were a year ago. Metropolitan District are 2½ lower. Thus while it is difficult to obtain more than 4 per cent. by railway investment at the market price, there is no sign of such an inflation of the prices of these securities as to lead to anything like a repetition of the eagerness of 1845.

Some outlet, however, must form itself for the accumulating growth of capital if the terrible outlet of war is avoided. The *Builder* was, for a time, almost alone in the press in the anxious warning it raised against investment in foreign loans. "The foreign loans," says an able contemporary, "which absorbed so much of our wealth during the golden years of 1872-73 have utterly collapsed." No new opening for financial investments has occurred. We may point to the rapidly-increasing debt of our rural and urban authorities. No doubt, that is a safe investment so far as the lenders of the money are concerned; but we fear that, from the ratepayers' point of view, it will be found, to a great extent, to have been a wasteful and extravagant outlay. The luxury of some of our municipal authorities has attained a pitch that is little short of scandalous. The misery of the pauper, and the cruel pressure under which many of our crowded city populations yet live, if it may be called life, afford a grim contrast to municipal luxury. The point which will strike many of our readers is this: How is it that, while money is thus seeking for investment,—while we have so many idle hands in the United Kingdom,—while we have great towns in sore need of thorough drainage and disposal of the sewage, and while we have hundreds of thousands of acres of ground left untilled, or nourishing only furze and heath, dotted with a few pinasters, as along the course of the South-Western Railway for long miles of its course from London to Bournemouth,—no one arises to put these factors together into a remunerative sum? We have not only lands that want hands, but lands that would well repay well-directed labour. We have labour enough and to spare. We have city and urban refuse for which the land hungers, which is yet left to breed pestilence in the towns; and we have, which is the feature of the day, capital crying out for employment. The one thing which, some time ago, was the only deficient requisite, is now ready. How is it that a little of the superfluous capital, of which the accumulation is signified by the quotation of Consols at par, is not utilised in such a thoroughly remunerative manner as by taking, for example, the sewage of Guildford to fertilise some of the waste ground to the south of Woking? We cite but one example; hundreds may be found. But the great expanse of the tertiary sands of Hampshire and of Surrey seems to offer the most tempting field for improvement.

THE PICTURESQUE AND THE USEFUL.

Every man of taste feels a pang at any invasion of the romantic scenery of England by any of the disfiguring works of the industrial pioneer. To a very great extent, owing to geological reasons, the heaven-defying chimneys of the factory, and the smoke and flame vomiting mouths of the furnace, have been reared amid scenes that were, before the introduction of the industry of the mines, bleak and desolate. The sudden contrasts between crowded city and bleak moor, to which the attention of the traveller over such lines of railway as the Manchester and Sheffield is so often called, are of a nature that was only to be witnessed in dreams before the pathway was laid for the iron horse. But that portion of our scenery which is at once bold and rich, where the heights are wooded with timber of secular growth, and the valleys laugh with corn or rich meadow pasture, is, for the most part, at present safe from conversion into streets or brickfields.

Thus it is with a ready sympathy that the cry of distress of a resident in the lovely neighbourhood of Derwentwater Lake will be heard by many of those to whom our home Alpine scenery is dear. He writes to lament the completion of a survey for the construction of a tramway from the Honister Crag Quarries, above Borrowdale, to Braithwaite, on the Cockermouth, Keswick, and Penrith Railway. Commencing in the wild vale of Borrowdale, the line skirts the western side of Derwentwater Lake; and, descending by the lesser Cat Bel, crosses the opening of the famous vale of Newlands. The objection of the resident to this line is, that it is sought only to enrich the pockets of the promoters; and he holds that it should be resisted by all those who wish to preserve inviolate the beauty of the lake scenery.

In reply, one of the proprietors of the Honister quarries refers to their vast extent and excellence, tested by working for centuries. The facility for expediting the slates which they yield that it is now sought to provide is a small-gauge tramway, 27 in. wide, on which a small locomotive will draw a train of small wagons twice each way daily, with the exception of Sundays. And it is to be observed that this mode of communication will free the narrow winding roads, or rather lanes, that now conduct the wayfarer or the tourist along these valleys (in many of which it is only here and there that two carriages can cross) from the intolerable nuisance of the slate-carts. Twenty horses and carts are now employed; and it is in the prospect of the employment of four or five times that number for the transfer of slates that the construction of the tramway is proposed.

When the issue is fairly joined between the taste and the pocket, the latter is doomed to win, as a general rule. Without going into any nice details, we may take it that the conveyance of the slate by the proposed tramway will be effected at one-third the cost of conveyance by road. And as building *will* go on, and houses *must* be roofed, and Honister may fairly claim to be the source of the local slate supply, we cannot regard the completion of the tramway as anything but a question of time. Instead, therefore, of commencing a warfare of which the upshot is foredoomed, why do not the residents of the vicinity lend their energies to secure a picturesque, or, at all events, a not hideous, set of designs for the works? There is no reason why a tramway, *per se*, should be more ugly than a road. There is no reason why any bridges or other buildings needed for its use should not possess some architectural claims to admiration. Some of our quaint old road and river bridges are among the most picturesque features of many an English county. Who does not know the river-bridges at Maidenhead and at Chester? The fact is, that we ought to learn the true lesson conveyed by the triumphs, first of Brindley and of Telford, and then of Stephenson and his contemporaries, over the peculiarly opposition of landowners and corporations. The consent of the then Earl of Essex to the passage of the Grand Junction Canal through Cassiobury Park was not obtained without a long and costly struggle. But in truth the canal is now, in portions, a great ornament both to this and to the adjoining park, the Grove, the seat of the Earl of Clarendon. What is truly lamentable, no doubt, is the miserable squalor and unsightliness of Telford's canal bridges. And many of Stephenson's railway bridges are little better. But why should these things be so? Why should not the counsel of an architect, of sufficient eminence to give weight to his opinion, be sought by the landowner?

At but slightly increased cost, public works may be rendered ornaments, instead of disfigurements, to a neighbourhood. If there is, then, to be fighting,—and we confess to some sympathy with the invaded party,—let it take the form of an appeal to taste, rather than a flat negative to the demands of commerce. Let the Derwentwater residentiary proprietors choose a man of admitted taste, whether an architect in practice or otherwise, and make their opposition to the Bill depend, or at least make their withdrawal of opposition depend, on the satisfaction of their referee as to the architectural design, or picturesque execution, of the proposed new works. Every one will be the better for such a plan. Money will be properly spent, instead of being wasted in Parliamentary fighting. In fact, we can conceive of but little opposition to our recommendation, except on the part of those who take a natural interest in the maintenance of this kind of warfare.

The Case of Mr. Strachan.—We have received 3s. in postage stamps from "Benson," and must now close our list. Mr. Edward Ashworth (17, Dix's Field, Exeter), writes to say he will willingly receive any further aid that might be offered. The Committee of the Architects' Benevolent Fund would probably assist if properly applied to.

ARCHITECTURAL ASSOCIATION.

The first general meeting of this Association for session 1880-81 was held on Friday, the 5th inst., Mr. Ernest C. Lee, president, in the chair. Votes of thanks having been passed to several gentlemen for services rendered in connexion with the opening *conversazione*, upwards of fifty gentlemen were nominated for election as members, including Professor Hayter Lewis.

The President expressed the satisfaction which he felt, and which would be felt by all the members of the Association, at the fact that such a patriarch in the profession as Mr. Hayter Lewis should desire to join them. It was a great honour to them, and he therefore begged to move that Professor Lewis be at once elected, waiving the usual interval between nomination and election. This was seconded by Mr. R. C. Page, one of the honorary secretaries, and carried by acclamation.

The President then proposed the adoption of the annual report, which contained the following passages:—

"The Committee, in submitting the report of the past session, are gratified in feeling that the prosperity of the Association in its different branches continues to increase; as is testified by the successful results of the work, and the efforts of its members to develop what has now become a recognised society for the professional education of young architects.

The numerous opportunities offered for study and improvement during past years have been turned to good account by many, and, judging from the numbers who have attended the classes and fortnightly meetings, and the merit of the work, the Committee feel fully justified in stating that the Association is in a very healthy condition.

Visits to buildings of interest were made on alternate Saturday afternoons from January until the end of the session, and were well attended upon all occasions, those present evidently appreciating the opportunities of acquiring practical information and studying contemporary architecture. The thanks of the Association are due to those architects who accorded permission, and in some instances met the members and conducted the visits personally, thereby adding much to their utility and interest.

The library has been well attended, especially by the new members. Several donations have been made, notably by Mr. George Godwin, F.R.S., Mr. H. L. Florence, and others. A catalogue of additions to the library will be issued shortly.

The Committee have much pleasure in announcing that negotiations are pending by which the Association will receive on loan from the Royal Institute of British Architects a number of valuable books, many of which duplicate those already in our library.

The Council of the Royal Institute of British Architects having invited the Association to be represented on a committee engaged in preparing a general scheme for an examination for membership of the Institute, Messrs. J. D. Mathews and H. L. Florence, Past-Presidents, were chosen to fulfil those duties.

The Birmingham Branch continues to work efficiently in connexion with this Association, and has availed itself fully of all the privileges of membership.

Amongst the honours taken by members of the Association during the past year have been:—

Royal Academy.—F. Bageallay, Gold Medal; J. Ince, Medal of Merit in same competition; R. Gibson, Travelling Studentship.

Royal Institute of British Architects.—L. Stokes, Pugin Travelling Studentship; F. Hemings and M. J. Lansdell, Medals of Merit in same competition; E. Harper, Soane Medallion; L. B. Broun, the Tite Prize; G. H. Blagrove, Prize Essay."

Mr. J. Douglass Mathews seconded the adoption of the report, referring especially to the steps which had been taken by and in the name of the Association in connexion with the Compulsory Examination Scheme. As stated in the report, Mr. Mathews and Mr. Florence were chosen by the Association to represent that body on the committee formed to consider the question under the auspices of the Institute, and from the statement made by Mr. Mathews it appeared that he and Mr. Florence, as representing the Association and the younger members of the profession generally, prepared, at the request of the committee, a scheme of what the examination should, in their opinion, be. That scheme was adopted by the committee, and afterwards by the Council of the Institute, with scarcely any alteration. Another committee had since been appointed and was now engaged in considering the best means of giving effect to the scheme of Examination, and on that committee the Association was well represented, their representatives including, besides himself and Mr. Florence, Messrs. T. H. Watson, Lacy W. Ridge, Roger Smith, and others. It was earnestly to be hoped that the Compulsory Examination, which would commence in 1882, should be a success. He and others of its promoters had long advocated the assimilation of the architectural profession in some degree to other professions dealing with the life and property of the public, by the establishment of diplomas to be granted only to those who should by examination demonstrate their fitness and competence to practise, but it was felt that they could not go

to the Legislature and ask for a diploma without first proving their earnestness by establishing such examinations as it was in their own power to do. With a view of making the Compulsory Examination as successful as possible, the Association,—which was to a far greater degree than any other society the nursery of the Institute and, indeed, of the profession at large,—would, he thought, do well to at once form classes for its more advanced members with the view of fitting them to pass the examination with credit to themselves and the Association.

The motion for the adoption of the report was then put and carried.

The balance-sheet, submitted by Mr. J. Douglass Mathews, and adopted on his motion, showed that the financial position of the Association is satisfactory, notwithstanding several heavy items of exceptional expenditure connected with the recent alteration of the premises in Conduit-street. The total receipts for the year were 655*l.* 5s. 2d., including 127*l.* 17s. 8d. balance in hand from last year, 51*l.* 13s. withdrawn from investment, and 426*l.* 6s. 6d. members' subscriptions and entrance-fees. The total expenditure was 603*l.* 11s. 4d. (including 139*l.* 10s. for rent; 106*l.* for alterations and improvements in new class-room and library, and for new furniture; and 28*l.* 9s. for law expenses in connexion with lease), leaving a balance in the hands of the treasurer of 51*l.* 13s.

The presentation of the many reports from the various classes and other agencies for carrying on the work of the Association was next proceeded with. They showed that what may be called the departmental work of the Association had been fairly well sustained during the past year, although hardly commensurable with what might be expected from so long a muster-roll of members and so many facilities as are afforded by the Association. The reading and discussion of these reports always occupies a very considerable time, and this year a discussion arose as to whether it would not be possible, in future, to print them in the Association's Brown Book, by which plan every member would have them, and they could then be "taken as read" at the first business meeting of the session, which is always the opening meeting. This suggestion was opposed by some members on the score of the extra expense which would be involved, but it was urged by others that the necessary outlay would be well expended, seeing that these reports gave detailed accounts and statistics of the work done in the various classes, and, indeed, described an integral and a very important part of the business of the Association. It was understood that this suggestion would be followed in future, but when the reading of the reports was about half-way got through, it was moved that that business be shunted for a time in order that the President might read his address. This was carried *nem. con.*

The President then delivered his inaugural address. After reviewing in detail the work of the last session (which, he said, thanks to the energy of the late President, Mr. S. Flint Clarkson, and to the indefatigable labours of the secretaries and committee, and those of the officers of the various classes, had not been retrogressive, although the number of members attending the classes was not so satisfactory as could be wished, considering that the Association numbered more than 800 members), he proceeded as follows:—On the question of prizes I have something to say. First, with reference to the too often unsatisfactory character of the drawings sent in for the open prizes, we cannot suppose (with the list of prizemen for the last year [all members of this Association] figuring in our report), that there are not enough, and to spare, of good men and true who are capable of competing and producing drawings which we should be proud to hang on our walls in exhibition. But the fact remains that they do not compete. Why is this? I think we must, however unwillingly, come to the conclusion that the prizes in themselves are not of sufficient value, and that the honour of taking the prize is too often gauged by its monetary worth, not by the students only, but also by the public. If this be the case, you will all be glad to hear that an attempt, perhaps too bold, but, for all that, a determined attempt, is, I hope, on the eve of being made to rectify this defect; and that the prize sub-committee have convened a meeting, and will submit the following report for the consideration of your committee at their next meeting. This is so important a matter that I shall take the liberty of giving it you *in extenso*:—

"*Architectural Association Prize Sub-Committee.*

At a meeting of this committee, held at the President's (Mr. E. C. Lee's) rooms, on October 19th, 1880, the members present being Messrs. Adams, Batterbury, Lee, Shuffrey, and Webb, it was unanimously decided to recommend the following suggestions for adoption and approval to the committee of the Architectural Association:—

1st. That a scheme be set on foot for raising a fund sufficient to endow a permanent annual prize, to go by the name of the 'Architectural Association Travelling Studentship.'

Taking into consideration the immense increase in the members of the Architectural Association of late years,—its importance as an educational body, and the laxity of competition for its open prizes arising, as the committee consider, from the small value of the prizes offered, the committee consider that the raising of the necessary funds to endow a Travelling Studentship would not present insuperable difficulties.

It is considered that an amount to produce annually the sum of 20*l.*,—say 400*l.* or thereabouts,—would be required, and the committee suggest that they should be empowered to take such steps as may appear to them advisable to raise this amount among the members of the Architectural Association.

In order to avoid the appearance even of competition with similar prizes offered by the Royal Academy and the Royal Institute of British Architects, it is proposed that the Studentship should be open to those members who are not more than twenty-three years of age, and further, that the election of a student be based not only on his draughtsmanship, but also on his powers of design, and that the drawings sent in should be limited in number. And the committee desire to express their opinion that the institution of such a Studentship would greatly benefit and raise the status of the Architectural Association.

2nd. That a special Prize Fund Committee be formed in connexion with the present Prize Sub-Committee, for the purpose of obtaining annual subscriptions sufficient to considerably increase the present amounts offered for open prizes, the committee fully believing that the comparative failure of the existing Prize Fund is largely owing to the want of any organised effort to raise the money required adequately to endow the medal, essay, and any other open prizes, which are from time to time set on foot."

I trust that this project will appeal to every member as one of the first importance, and that each one will subscribe in some form or other to enable it to become a reality. If we cannot get the whole of the amount this year, we shall strive to complete it in the next. It is a great work and a valuable one, and in after-years each of us will feel proud to have added his mite, and to be able to lay claim to have been one of the originators of the "Architectural Association Travelling Studentship," and to have raised the standard of the Association by giving a proper status to its prize fund. The library, in the very efficient hands of its present officers, continues to carry on its work most thoroughly, and arrangements for the extension of its usefulness are at present in negotiation with the Royal Institute of British Architects. And now I must say a few words to you concerning the Architectural Examination. You are most of you aware that the Royal Institute of British Architects propose in 1882 to make the Associateship attainable only by the passing of a Compulsory Examination, and I think you will most of you agree that it is a step in the right direction,—a step towards the architectural diploma period which we hope eventually to attain to. It will at once raise the status of the profession and the standard of education,—the social and artistic position of the architects of this country. It will, I trust, be the means eventually, though naturally by slow degrees, of eliminating those practitioners who take our name and enrol themselves under our banner simply for trade purposes. While we are legally powerless to prevent what is morally an infringement on our rights, at present there is nothing to prevent any small builder, auctioneer, or house-agent from tacking-on "Architect" to his name; nor can we, without an Act of Parliament, hope to have protection from this sort of piracy. Freedom from this, however, may come, and will, if the Compulsory Examination scheme is thoroughly carried out. We do not want to prevent people building houses,—if they are so ill advised,—without an architect; but we do object to having the profession dragged through the mire by ignorant tradesmen who have no claim or right whatever to our name. These, however, gentlemen, are higher matters than properly come within our province, though we must all, individually, feel the greatest interest in them, and strive to further the objects sought to be attained, as far as lies in the power of each one of us, as members of an association of students formed for mutual help in self-education. Let the task we set before us be to strengthen the hands of the Royal Institute of British Architects, by proving that among the younger members of our profession there is a large body of men able and willing to think and work and act together, and, who will not be afraid, when the time comes, to submit the result of their labours to the test of an examination. . . . . During the last session there has been sitting a committee, under the auspices of the Royal Institute of British Architects, on the vexed question of architectural competitions. What conclusion they have come to, and what advice they are prepared to give with regard to future procedure, we do not at present know; but we may well hope that a code of rules, based on the principle of paid limited competitions and professional adjudication, will be the result. In conclusion, gentlemen, I hope and trust that in the present session the harmony of the Association, notwithstanding its increasing ponderosity, will still be maintained; that in our social connexion we shall all be ever ready to extend a helping hand to our less successful brethren; and that in our labours together here we shall strive by all means in our power to fulfil the aspirations of our motto, and learn so to order our ways that posterity will at least allow that the architects of the nineteenth century, whatever else their shortcomings, did, to the utmost of their power, "Design with Beauty and Build in Truth."

The reading and consideration of the reports from the classes, &c., was next proceeded with, and this business having been disposed of,

Mr. Lacy W. Ridge moved a vote of thanks to the President for his address, which he characterised as extremely practical, and full of interest to the members of the Association. He urged that, in future years it would greatly facilitate the business of the opening meeting if the reports of the classes were printed in the Brown Book of the Association. The members would then have the advantage of seeing them in advance of the President's address.

Mr. Thomas Blashill, in seconding the motion, said he had been struck by the variety of subjects which the widening operations of the Association had rendered it necessary for the President to mention in his address. It was very desirable that members should join the various classes which were carried on under the auspices of the Association. With regard to the proposed Travelling Studentship, 400*l.* was a large sum to raise, and he ventured to suggest that pending the full realisation of their desires in that direction, the treasurer of the Association might, as the funds allowed, be permitted to make a grant in aid of the travelling expenses of the student who might be deemed most worthy of it, so that the proposal might take effect at once. Upon the members generally Mr. Blashill urged the importance of spending a few weeks abroad occasionally, as a useful auxiliary to home studies and travels, and he pointed out that the facilities now existing for foreign travel enabled students and others to get over a great deal of ground at a very small expense.

Mr. S. Flint Clarkson, in supporting the motion, said, with reference to the proposal to raise 400*l.* for endowing a Travelling Studentship, that he did not see why it was stipulated that that sum should be wholly contributed by the members of the Association. The Institute was not above receiving special gifts from non-members in aid of similar objects; why, then, should the Association lay down a different rule of procedure? He hoped this and other points would be well considered; for he believed that the proposed Travelling Studentship, if made sufficiently different from those already existing, would be a great success.

Mr. Riddett having said a few words, the motion was carried *nem. con.*, and Mr. Lee having briefly replied, the proceedings terminated.

THE PRINCESS'S THEATRE.

THE new theatre was opened on Saturday last, the 6th, with "Hamlet," Mr. Edwin Booth, the American actor, playing the principal character. Before giving a few particulars of the new house, we are impelled to say that the representation was unsatisfactory. The newspapers, properly anxious to show kindness to a visitor from afar, have sought to say what they could in favour of Mr. Booth's performance, but the truth may be read between the lines. It was mannered and monotonous, and never once "fetched" the house. We shall be glad to see Mr. Booth in another part, and to find ourselves able to admire. There is little to mention specially in respect of the acting in the other parts, except as regards Miss Gerrard, who, as Ophelia, though somewhat weak and colour-

less at first, in the mad scene achieved a genuine and well-merited success.

The architectural scenery that has been provided for the play is the worst that has been seen on the London stage for a long while. As the tragedy is to be played but a short time, if Mr. Gooch had brought together a number of old and inharmonious canvasses, surprise would scarcely have been expressed. But that such scenes as are exhibited should have been painted for the purpose at this time of day is surprising. The Norman period having been selected, the painter had nothing to do but to go to known examples of the style to ensure something like correctness; instead of doing which, he has chosen to burlesque every detail. Such a Norman interior as that in which the interview with Ophelia takes place, with two staircases and four fearsome beasts sitting on the newels, was never seen before out of a pantomime. And this, too, on the spot where for years, under Charles Kean, the scenery was always artistically beautiful and archæologically correct. Such a scene as that to which we allude exposed night after night before an audience is a public injury.

The new theatre has been erected from the designs of Mr. C. J. Phipps, architect, Mr. Mark Manley being the builder. The other contractors engaged were Messrs. Geo. Jackson & Sons for the proscenium, box-fronts, and other ornamental plaster work; Messrs. C. Drake & Co. for concrete floors and stairs; Mr. Edward Bell for painted decorations and gilding; Mr. D. Jones for the gaswork; Messrs. Strode & Co. for the sunlight; Mr. Wharton for the stage; Messrs. Gregory & Co., Regent-street, for the upholstery; Mr. Wadman for the stalls and dress-circle seats; Messrs. Cottam & Co. for the ornamental iron gates; Messrs. Wills & Co. for the waterfall and fernery; and Messrs. Burke & Co. for the mosaic pavements. Mr. E. Nightingale was clerk of the works.

The audience to the stalls, private boxes, dress circle, and upper boxes, enter the theatre from the new frontage in Oxford-street, by a vestibule, 20 ft. wide, opening into a crush-room at the foot of the grand staircase. The audience to the pit, amphitheatre, and gallery enter the theatre from the new entrance in Winsley-street, a few doors out of Oxford-street. The Royal and stage entrances are in Castle-street. A commodious room is provided for the Royal box.

On the first tier, the balcony or dress-circle has five rows of seats to hold 140, and behind these nine private boxes. The balcony advances nearer the stage than we have ever noticed in so large a theatre.

The upper circle, or second tier, has six rows of seats, and will hold 400 persons. The pit holds about 800. The dimensions of the auditory will be seen from the following measurements:—

	Ft.	In.
Curtain line to dress-circle front	32	0
Ditto to upper circle front	39	6
Ditto to amphitheatre front	41	6
Ditto to gallery	45	0
Ditto to the back wall of the pit	61	0
Ditto to the back of the stage	40	6
Ditto to the footlights	4	0
Width of the stage and scene docks	118	0
Height of the stage to the gridiron-floor	56	0
Depth of the stage to the cellars	19	0
Height of ceiling above pit	55	0

A special feature of the arrangements is a separate transfer-staircase from the highest level of the gallery to the ground-level of the pit. So that on crowded nights the overflow from the gallery can transfer down to the pit without mingling with the persons still ascending by the main entrance staircase; also from the pit, a passage at the back affords a means of transferring to the front entrance vestibule, where access is at once obtained to the several higher tiers of the auditory.

All the entrances and staircases are fireproof, and the stage is separated from the auditory by a solid brick wall carried up above the roof. A saloon and smoking-room are provided on the level of the dress-circle; the latter extending over the entrances and facing out into Oxford-street.

The proscenium opening is 30 ft. wide and 36 ft. high, flanked on either side by three tiers of private boxes, very lofty, as the custom now is. Above, in the tympanum of the arch, is an allegorical figure subject satisfactorily painted by Mr. Ballard, representing the various arts allied to the drama. The two spandrels supporting the ceiling contain figures of "Poetry" and "Music."

The general tone of the decoration is light cream colour, deepening in colour towards the lower parts of the auditory, and the whole of the ornament is gilded. The hangings to the private boxes are of figured silk,—a deep crimson colour. The act-drop, by Mr. William Beverley, represents a tapestry curtain with the Royal Arms in the centre, and, strange to say, is very unsatisfactory.

Mr. Phipps is an experienced theatre-architect, and, as might be expected, the arrangements for seeing and hearing appear to have been well attended to; the public staircases are of the right kind, short flights and no winders, and the vestibules and approaches are capacious; but from an art point of view the new Princess's is decidedly inferior to some of his other works.

THE TEMPLE BAR MEMORIAL.

The memorial at the commencement of Fleet-street was unveiled on Monday, the 8th, by H.R.H. Prince Leopold, in the presence of an immense and not altogether friendly crowd,—unfriendly, that is, to the memorial, not to the Prince, who was received enthusiastically. We have done our best to avoid joining in the common cry against this erection. But it cannot be done; the more the structure is looked at, the more clear the fact becomes that its position is a dire mistake, and that it must inevitably be removed before long. It stands immediately opposite to the entrance to the Law Offices, and will during some hours of the day absolutely prevent carriages from setting down at that door.

Although the memorial has already been illustrated and described in various quarters, we are bound, probably, to repeat some of the particulars, though very briefly. It consists of a basement of blue Guernsey granite and pedestal of red granite, the angles being protected by four spur stones of Shap granite. In the pedestal are four panels in relief executed in bronze, that on the south side depicting an incident in the life of her Majesty the Queen, on her visit to the City after her accession. On the north side the relievo represents the Queen, with the Prince and Princess of Wales, passing through the City to St. Paul's on Thanksgiving Day, 1872. The figures and accessories are so much in relief that when they get clogged with mud it will be impossible to clean them without damage. The best thing that can be done will be to put glass over them. The tablets at the ends are much smaller. That on the east end gives a representation of the old gate, with the strange intimation above that it was erected by Sir C. Wren, and removed by Horace Jones. Why the City Architect should thus unnecessarily hand himself down to posterity as an Iconoclast it puzzles us to say. The superstructure consists of four piers, with capitals, or rather eight pilasters of Craigleith stone, with the necessary architectural accessories, and with niches between them on the north and south sides in Ancaster stone. The whole is surmounted by a small pedestal with a dragon, holding the City shield modelled by Mr. C. B. Birch, A.R.A., and cast in bronze by Mr. Moore, of Thames Ditton. The vigour and power of this part of the work deserve praise. The niche on the south side is filled with a statue in Sicilian marble of the Queen, in her state robes. In the northern niche there is a statue of the Prince of Wales in Field Marshal's uniform,—singularly unlike his Royal Highness. Both these statues are by Mr. Boehm, A.R.A. The whole height of the memorial is 31 ft. 6 in., and the width of the base of the pedestal is 5 ft. 1 in. by 7 ft. 8 in., exclusive of the spur-stones. The pilasters are filled with carved cameo panels, emblematic of Peace and War, Art and Science, together with the rose, shamrock, and thistle. There are two portrait medallions on the east and west sides of the memorial, one representing Prince Albert Victor of Wales, and the other the late Lord Mayor, Sir F. Wyatt Truscott. We should have mentioned that the frieze above the pilasters is inscribed "MDCCCLXXX. Temple Bar formerly stood here." The carving and modelling were executed by Mr. H. Mabey, with the exception that the relief facing the north was modelled by Mr. Kelsey. Messrs. John Mowlem & Co. executed the masonry, the granite work being supplied by Messrs. Alex. Macdonald, Field, & Co. As regards the work of the City Architect, we have no hesitation in saying that if the site had been unobjectionable, the memorial would have obtained praise. The rapidity with which the work has been done, considering its character, is remarkable.

Those who have seen the memorial as it now stands will have noticed that only a portion of the space intended to be devoted to the purposes of a "refuge" for persons crossing the road is curbed and paved and provided with the ornate lamp-posts at the angles. That portion of the refuge, three or four square yards in area, is on the City side of the structure. With a view, perhaps, to make the memorial as little of an obstruction as possible, the western face of the masonry has been carried up right on the very confines of the western boundary of the City, and consequently the few square yards of space required for the refuge at the western end of the monument must be taken out of the roadway of the Strand. Somehow or other, those most concerned in the erection of the memorial seem to have acted in such haste as to omit to ask and obtain beforehand the sanction of the Strand District Board of Works for permission to encroach upon their domain. Only when the monument was nearly completed was the requisite permission sought, when lo! the Strand District Board passed a resolution refusing to accede to the request, and condemning the structure as an impediment to vehicular traffic. Subsequently, a deputation, consisting of Mr. Bedford and other representatives of the Corporation, waited on the Strand authorities to endeavour to induce them to rescind their resolution, and to give their sanction to the completion of the memorial. A motion made to that effect was, however, lost by 18 votes against 12 for it. To this determined rebuff is due the present incomplete state of the memorial. The dispute affords an apt illustration of the way in which the local authorities of London can thwart each other when conflicting interests prompt them.

THE METAL SPIRE OF ROUEN CATHEDRAL.

COPPER AND IRON.

The spire of the Cathedral of Rouen is legendary. This "unluckly manufactory chimney" has served a number of writers for a long time as a butt for sarcasm and laughter. And this work of Alavoine's, who was, nevertheless, one of the architects of the column of July, had up to the present only found detractors.

The lantern had been set up, and for long years stood in an adjoining courtyard. Put into its place, this last portion of the spire has considerably modified its aspect, and the gigantic *flèche*, 150 mètres in height, has since then been more justly appreciated. To-day, the work commenced in 1827 has entered into its last phase, as our sketch shows. The nakedness of the base was most unsightly. The artist had projected to overcome this by the aid of large turrets around it, and these are found effectual. They are nearly 25 mètres in height. For a long time previously a model in timber work, carefully worked out, painted lead colour, had given an idea of the importance of the intended addition.

The whole of the works have been under the direction of M. Barthélemy, diocesan architect. The frame-work of the turrets, executed in iron by M. Filleul, is covered in copper *repoussé*, with ornaments modelled and framed by M. Marron. A portable scaffolding, established by M. Gambier, was transported successively to the four angles of the tower for the building of each turret. The whole of the *repoussé* work in copper is isolated from the iron by ties and rings of hardened wood. It is composed of leaves hooked to each other, and not soldered, and is the most important work of the kind that has been executed in France up to the present time.

A colossal statue of Bartholdi, which was recently to be seen at the Paris Exposition des Beaux Arts, is the only work which can at all compare with the construction of these turrets, which are of enormous dimensions, but nevertheless appear very fitting at the great height at which they are placed.

These are, in fact, the last complement of the work of Alavoine, and nothing now remains to entirely finish it but some touches of gilding, which by this time, indeed, may have been given.

The sketch of the cathedral which we publish is taken from a roof in the Rue Grand Pont. It gives an idea of the effect of the spire as improved by its turrets, and from which the cross rises in the air to a prodigious height.

THE METAL SPIRE OF ROUEN CATHEDRAL.—From the Design of the Late M. Alavoine, Architect.

DECORATIVE SUGGESTIONS FROM NATURAL FORMS.—No. 6.

THE leaf of *Sterculea*, which forms the basis of the two capitals here given, bears, as will be seen, some resemblance in general style to the acanthus leaf, but is broader and rounder; the circle is, in fact, very predominant in the design of the leaf, both the points and inner margins of the indentations touching for the most part on the arcs of circles drawn from the point of departure of the leaf-ribs. If this leaf were used in flat or inlaid design, this circle element in it should be emphasised in the setting or background of the design: in carved ornament it can hardly be so without producing too stiff an effect.

The two designs here given are intended partly to illustrate what was observed in our leading article on the subject (*Builder*, October 9th), as to the double use which may be made of each suggestion by treating it in either picturesque or symmetrical style,—in other words, in the Gothic or the Classic type. Some features of Gothic and Classic capitals have, however, been purposely interchanged here; in the Gothic capital the central leaf under each projection of the cap is carried up and turned over under the abacus somewhat as in the usual treatment of the conventional acanthus in the Corinthian capital; and in the other more Classic form the scroll of the volute is inverted, a suggestion borrowed from the well-known type of Transitional capital found almost all over Europe during a portion of the twelfth century. The distinction between design for stone or for marble carving is also kept in view; the very conventional treatment of the leaf in the Classic design, with a small fillet carried round the margin, and the filleted scroll-work above, being only fitted for execution in a fine and hard material which will take and retain a very high finish. The eyes of the scrolls are supposed to be set with coloured stones or heads, a practice undoubtedly employed by the ancients in the Ionic capital, if not in other forms.

We have given the first six of these "suggestions" in consecutive numbers: in future we hope to continue to give others, perhaps more elaborated than these, from time to time as may be convenient.

BERMONDSEY TOWN HALL.

IN 1878 the Vestry of Bermondsey, having resolved to erect a public hall, board-room, and offices, in order to provide for the necessary requirements of the district, took steps to obtain a suitable site for the purpose. Early in the following year they purchased the tanyard and premises originally occupied by Messrs. John Barrow & Son, in the Spa-road and Neckinger-road, adjoining the public baths and washhouses.

The site, containing upwards of 49,000 ft. superficial, comprises not only the space necessary for the intended public hall and offices, but also a suitable dwelling-house for the resident clerk of works, and a warehouse building three stories high, the ground-floor of which has been converted into stabling for twenty horses, the upper floors being available for stores. The remaining portion of the land will be appropriated as a stone depôt. The property is situated within a convenient distance from the Vestry's wharf and dock abutting on the river Thames, the two establishments thereby enabling the Vestry to provide for carrying on the whole of the public business connected with the parish.

The following statement from the census return of the parish will indicate the rapid increase which has occurred of late years, viz.:

	No. of Houses.	Population.	Rateable value.
1801 ...	3,203 ...	17,169 ...	£34,387
1811 ...	3,505 ...	19,530 ...	59,873
1821 ...	4,691 ...	25,235 ...	65,141
1831 ...	5,388 ...	29,741 ...	72,593
1841 ...	5,963 ...	34,947 ...	76,633
1851 ...	7,556 ...	47,836 ...	123,876
1861 ...	8,523 ...	58,212 ...	150,216
1871 ...	11,073 ...	80,429 ...	281,902

The population at the present moment is estimated at 98,000, and the rateable value is 364,855*l.*

The extent of streets and roadways under the jurisdiction of the Vestry is upwards of thirty-two miles, being nearly doubled since the Metropolis Local Management Act came into operation in 1856.

The new Town-hall fronts the Spa-road. The principal elevation and portions of returns are faced with Portland stone, and the rest of the building is of picked stocks, with white Suffolk arches and bands. The ground-floor, as the accompanying plan shows, contains accommodation for the several officers of the Vestry and of the Boards of Governors and Directors under a local Act. The board-room is 46 ft. 9 in. by 29 ft. 6 in. in the clear, and 20 ft. in height.

The public hall is 80 ft. by 52 ft. 9 in. in the clear, and 37 ft. 9 in. in height, with galleries on each side, and an additional gallery at the south end over the first floor landing. The hall and galleries are estimated to hold 1,200 persons. Provision is made for a platform or dais and retiring-rooms at the north end, with separate access.

The front portion of the structure contains entrance-hall, lobbies, and staircases, besides gentlemen's and ladies' retiring-rooms, lavatories, &c., so that the public hall may be used at any time without interference with the ordinary business of the Vestry.

The front portion of the basement will be fitted up with apartments for caretaker, strong rooms, heating apparatus chamber, coal-cellars, and kitchen departments (if so required) in connexion with the hall.

The rear part will be separately approached as a cart store, &c., from the depôt.

The whole of the floors are fire-proof, on Dennett's principle, the corridors paved with stone, and the entrance-hall and lobbies with ornamental tiles.

The works are being carried out from the designs and under the superintendence of Messrs. George Elkington & Son, architects, 95, Cannon-street. The contract for the buildings, amounting to 21,200*l.*, is in the hands of Messrs. Perry & Co., Tredegar Works, Bow. Mr. S. Ford is clerk of the works.

It is intended that the first stone shall be laid on the 23rd inst. by Mr. Porter, churchwarden of the parish.

MR. EDMUND SHARPE'S WORKS.

THE Architectural Association has brought nearly to completion the volume to be dedicated to the memory of Mr. Edmund Sharpe, completing one of his projected tasks,—the illustration of the twelfth-century architecture of Charente. The volume will contain a memoir, and a full list of Mr. Sharpe's publications, and it has been represented to us that good service would be done by our printing a list in the *Builder*, and inviting our readers to find out gaps or errors in it, and to communicate with the secretary of the Publication Committee,—Mr. J. S. Quilter, 10, Brunswick-square, W.C. We gladly do this, and hope that the list will be as perfect as care and skill can make it. The books are dealt with this week; the minor works, pamphlets, and papers read before societies, &c., will be given in another number. It looks like a pleasant piece of hero-worship,—this thinking of even the sweepings of his workshop as of gold,—it is, besides, a view not far from the true one.

LIST OF BOOKS.

I. Decorated Windows, a series of Illustrations of the Window Tracery of the Decorated style of Ecclesiastical Architecture. London: Van Voorst. 1849.

Demy 8vo. (8½ in. by 5½ in.). Without pagination,—one page of text to each plate. Sixty steel engravings, dated 1848. 1*l.* 1*s.*—This work was issued in monthly parts each containing eight steel plates, in single leaves with explanatory letterpress. The work was classified in chronological order, by a list of plates issued with the last part. It was at first intended that the concluding part should be "a review of the whole subject, illustrated by woodcuts." This review was expanded so as to form the volume which stands next in the list. (?)

II. A Treatise on the Rise and Progress of Decorated Window Tracery in England. Illustrated with ninety-seven woodcuts and six engravings on steel. London: Van Voorst. 1849.

Demy 8vo. (8¼ in. by 5½ in.)

III. Architectural Parallels; or, the Progress of Ecclesiastical Architecture in England, through the Twelfth and Thirteenth Centuries. Exhibited in a series of parallel examples selected from the following abbey churches:—Fountains, Kirkstall, Furness, Roche, Byland, Hexham, Jervaulx, Whithy, Rievaulx, Netley, Bridlington, Tintern, St. Mary's York, Guishorongh, Selby, Howden. London: Van Voorst.

a. Large paper proofs, folio (24¼ in. by 18⅞ in.) 1848. 15*l.*

b. Small paper, tinted, folio (21¾ in. by 14¼ in.), 1848. 12*l.* 12*s.*

Small paper, plain, ditto. 10*l.* 10*s.*

Dedication to the Earl of Derby, January, 1848. No text; but two lists of the plates are given, in order to convey suggestions for binding the work. The illustrations comprise one group of plans on wood, and 120 lithographs,—the geometrical drawings on stone by R. J. Withers and T. Austin, and the views by H. Fielding; all printed by Maclure, Macdonald, and Macgregor, of Liverpool.

IV. Supplement to "Architectural Parallels," containing the full sized mouldings of the following abbey churches, Furness, Roche, Byland, Hexham, Jervaulx, Whithy, Fonntains, Netley, Rievaulx, Bridlington, Tintern, St. Mary's York, Guishorongh, Howden, Selby. London: Van Voorst. 1848.

Folio (21½ in. by 14¼ in.). No letter-press beyond a list of plates. Sixty plates, lithographed by R. J. Withers (fifty-seven) and T. Austin (three), and printed by McKie & Lawson, of Lancaster. 2*l.*

V. The Seven Periods of English Architecture Defined and Illustrated.

Super-royal 8vo. (9¾ in. by 6 in.).

a. First edition. London: G. Bell. Preface dated 1851. Text, pp. i. to xiii.—1 to 37. Twelve plates, drawn by T. Austin, and engraved on steel by G. B. Smith,—also seven woodcuts. 10*s.*

b. Second edition. London: Spon. 1871. Pp. i. to xiii.—1 to 37. Twenty steel engravings and woodcuts. 15*s.*

VI. The Architectural History of St. Mary's Church, New Shoreham. Chichester: Mason. 1861.

Imperial 4to (12¾ in. by 8¾ in.). Text forty-seven pages. Two steel engravings by G. B. Smith, six lithographs by H. Fielding, one by R. J. Withers, fifteen woodcuts.

Supplemental sketch of the Collective Architectural History of Chichester Cathedral, Boxgrove Priory, and St. Mary's Church, New Shoreham, as indicated by their mouldings.

Text thirty-two pages. Sixty-two woodcuts. These works by Mr. Sharpe form part of a volume which also contains "The Architectural History of Chichester Cathedral, &c.," by the Rev. R. Willis, M.A., F.R.S., and "Boxgrove Priory" by the Rev. J. L. Petit, M.A., F.S.A. Issued at 1*l.* 10*s.*

VII. An Account of the Churches visited during the Lincoln Excursion of the Architectural Association, August 22nd to 27th, 1870. London: Spon. 1871.

Sup. royal 8vo (9¾ in. by 6 in.). Preface dated June 1st, 1871. Text 152 pages. Sixty-five lithographs, mainly transferred to stone by Mr. William Henman, and printed by Kell Bros., also four woodcuts. 1*l.* 1*s.*

VIII. The Mouldings of the Six Periods of British Architecture from the Conquest to the Reformation. London: Spon.

Imperial 4to (12¾ in. by 9¾ in.), lithographed by Kell Bros.

a. No. I. Preface (2 pages), dated May 1st, 1871. Sixty plates, wholly devoted to Pier Arches. 1*l.* 1*s.*

b. No. II. 1871. No text. Sixty plates (nineteen of Pier Arches, forty-one of Doorway Arches). 1*l.* 1*s.*

c. No. III. 1874. No text, but a chronological arrangement for the whole of Nos. I., II., and III. Sixty plates (twenty-five of Pier Arches, thirty-five of Doorway Arches). 1*l.* 1*s.*

The author's intention was that the three numbers should be broken up, and the plates arranged according to the "chronological arrangement" issued with *c*.

IX.—The Ornamentation of the Transitional Period of British Architecture, A.D. 1145–1190. London: Spon.

Imperial 4to (12¾ in. by 9¾ in.)

a. No. I. Introduction (ten pages), dated Feb. 1st, 1871. Description of Plates (to page 32) completed as far as Plate XIV. Forty-two plates (thirty-seven of pier capitals, three of doorways, and two of arcades), lithographed by Kell Bros., also three woodcuts. 1*l.* 1*s.*

b. No. II. Part I. No text. Twenty plates (fifteen of pier capitals, three of doorways, one of arcades, one of corbel-shafts), photo-lithographed by Whiteman & Bass.

c. No. II. Part II. No text. Twenty-two plates (sixteen of pier capitals, three of doorways, three of arcades), photo-lithographed by Whiteman & Bass.

d. No. III. The lithography of the remainder was nearly finished when Mr. Sharpe died. The letterpress cannot be completed; but it may be possible to publish a sufficient number of drawings to make the work fairly complete, and to issue "directions for the rearrangement and the numbering of the plates, and the binding of the whole in one volume," as proposed by Mr. Sharpe at the first. The parts were issued in indiarubber bindings, so that they might be broken up and the whole of the plates rearranged.

X. The Architecture of the Cistercians. London: Spon.

Imperial 4to (12¾ in. by 9¾ in.)

a. Divided into:—

Part I. General Plan.

(Preface dated June 20th, 1874.) Text, twenty-eight pages (Lancaster printed). Plate I., photo-lithographed by C. F. Kell.

Part II. The Domus Conversorum: containing the Day-room and Dormitory of the Conversi of a Cistercian Monastery.

(Preface dated June 30th, 1874.) Text twenty-three pages, five plates photo-lithographed by C. F. Kell.

a. Re-issued as Illustrated Papers on Church Architecture. No. I. April, 1875.

b. Illustrated Papers on Church Architecture, No. II. April, 1876. Cistercian Architecture.

Part I. General Plan (continued).

Text (Lancaster printed), pp. 29 to 87; appendix, pp. i. to xx. Seven plates, photo-lithographed by C. F. Kell.

c. Part III. Development of Choir, announced, but never completed. Plates IV., V., VI., VII., and VIII. of *b.* were prepared for the "Development of Choir."

XI. The Ornamentation of the Transitional Period in Central Germany. London: Spon (Lancaster printed). 1877.

Note.—The title on the cover reads "Illustrated Papers on Church Architecture. No. 3. November, 1876."

Imperial 4to. (12¾ in. by 9¾ in.). Introduction two pages; descriptive letterpress, eight pages. Twenty-one plates engraved by G. B. Smith, "from drawings made upwards of forty years ago."

This work was the last actually published before Mr. Sharpe's death, on May 8th, 1877. The next "Illustrated Paper on Church Architecture" was, however, ready to receive his last touches, most of the lithographs being actually printed off. "I have already published, in a separate work, Illustrations of the Ornamentation of the Transitional Period of British Architecture. In the next and following numbers of this series will appear illustrations of

the same period of Mediæval Architecture in the North and in the West of France." (Introduction to XI.)

Queries.

Was Part I. of "Decorated Windows" really issued on November 1st, 1844, as at first proposed?

What was the date of the issue of "Architectural Parallels"?

How was it issued to subscribers?

Is the date 1846 correct for any completed large paper copies?

Has a prospectus of the work survived?

How and when were the illustrations of Tynemouth Priory Church (4 plates) published?

A paper was read on Tynemouth by Mr. Sharpe at the Newcastle-on-Tyne meeting of the Royal Archæological Institute,—where was this printed?

THE NEW CHURCH AT SPALDING.

THE dedication of the new church of St. Paul at Spalding took place on Wednesday, the 27th of October, and the readers of the *Builder* will no doubt, be interested in a description of what must be called a posthumous work of Sir Gilbert Scott. The edifice is the gift of Miss Charinton, of Spalding, who has, in addition, also built parsonage and school, and endowed the living. The cost of the whole has been about 30,000*l*., and the church will accommodate 500 worshippers.

It is Early English in style, and consists of a nave of three principal arches, sub-divided into six arches on each side, with north and south aisles. The principal entrance is the south porch. At the west end of the nave, and connected with it by a corridor, is a well-proportioned campanile, carrying a broach spire, 135 ft. high. The walls of the campanile are 4 ft. thick to the full height of the tower. It contains a peal of eight bells, by Lewis, of Brixton, hung in iron cages; the tenor weighs 16 cwt. On the north side of the church is the priests' vestry; over this is the organ-gallery. Adjoining this is the choir vestry, from which a spiral staircase leads downwards to the heating apparatus and upward to the organ-chamber. The dimensions of the edifice are as follow:—

	Ft.	In.
Entire length of interior ...	133	3
Nave (length)	69	6
Nave (width) including aisles..	49	0
Chancel (length)	35	0
Priests' vestry ...	16 6 × 13	0
Choir vestry ...	16 6 × 10	6

The materials used in the structure are red brick and Ancaster stone. The clearstory arcade consists of a continuous row of arches, supported on detached columns; six of these arches are pierced for windows. The whole of the roofs are covered with lead. The interior of the church presents a pleasing picture, from the peculiar treatment of the main arcade of the nave, which is supported on each side on three principal piers, with detached columns carrying the three semicircular arches. Each of the principal arches is divided into two pointed arches, springing from more slender columns between the main pieces. This unusual treatment may be seen in St. Thomas à Beckett's Church at Portsmouth, and at the church of Boxgrove, near Arundel, where the origin of this treatment is traceable in the Norman portion of the structure, and it was perfected in the subsequent Early English style. The stonework of the interior has been relieved by the introduction of stone with a red tint, also from Ancaster. The carving of the foliage throughout, and the various corbel-heads, are well executed. A very good likeness of the Bishop of Lincoln is carved in the north corbel of the hood of the chancel-arch. The windows of the chancel are set in deeply-splayed jambs, with clustered columns engaged, detached, and banded. The floor is elevated about 3 ft. above the ground-level, and is carried throughout upon Dennett's arching, thereby being protected from damp arising from the soil. The ironwork of the chancel-screen and the bandrail of the pulpit are by Skidmore, of Meriden, Coventry. The pulpit, in carved oak on a stone base, is by Farmer & Brindley, Lambeth; as is also the carved work in the chancel. The altar-table is of oak, carrying a thick slab of Mansfield stone rather more than 8 ft. long by 2 ft. 6 in. wide. It is raised seven steps above the floor-level of the nave, the steps within the sacrarium being grey fossil marble, polished. The stalls and screens are of carved English oak, very massive. The sedilia and piscina are hooded, and recessed in the thickness of the south wall. The font is in its form similar to the font in the cathedral at Lincoln, but in Mansfield Woodhouse stone, with Purbeck marble shafts. Mr. Hannaford was clerk of the works.

The contract for the whole of the work was undertaken by Messrs. Pattinson, Brothers, of Ruskington, near Sleaford, who must be congratulated on their work.

At the consecration, the venerable prelate of Lincoln congratulated the vicar of Spalding on the acquisition of another beautiful church to his parish, and remarked that, during the period of his incumbency more than 80,000*l*. had been spent in his parish in church restoration, building, and endowment, and that three new churches had been built in the same time within the period of his episcopate.

NOTES FROM BRISTOL.

THE building trade is not at all in a flourishing condition in Bristol or the neighbourhood, and, if the statement of one of the leading builders may be accepted, the operatives engaged in this branch of industry will, during the winter, have to pass through a hard time, for which most of them are ill-prepared. Speculative house-building, which a year or two ago seemed the rage on all sides, is now not nearly so active. The falling-off may be attributed to two causes: the house market is already oversupplied; most of the available building areas within an easy walking distance of the centre of Bristol have been used up; three or four large estates in the suburbs, however, are marked out for the erection of small and medium-sized houses, so that work in this department is not brought to a complete standstill.

Amongst the public buildings still in hand is St. Peter's Church, Clifton. Old St. Peter's was found too cramped for the congregation, and a fine new structure is being built on a convenient site only a few yards from the old edifice.

The Knowle Baptist Chapel, the foundation-stone of which was laid in the middle of the summer, is in an advanced state of progress, and will be before long ready for use. The place is internally light and convenient, and provides for some 500 or 600 worshippers, besides having spacious class and school accommodation. Mr. Beaven is the builder, and Mr. A. Hanford the architect. The cost is estimated at about 2,000*l*.

The Parochial Hall at St. Philip's,—a parish with between 30,000 and 40,000 inhabitants,—promises to be a fine one. It will meet a long-felt want of a large hall for public meetings in the centre of the district, and also provide room for the transaction of various matters of parish business. Messrs. Wilkins & Son are the builders.

A week ago the Mayor of Bristol laid the foundation-stone of a new Mission Church at Eastville,—a growing suburb of Bristol. The design is Early English in style, and the front of the building will be of Pennant stone, with Freestone dressings. The cost of the work is expected to amount to 1,700*l*. Mr. H. Williams is the architect, and Messrs. Eastabrook & Sons have taken the building contract.

A simple and inexpensive Mission-hall has been commenced in the heart of St. Philip's.

Mr. Kranss is just finishing the laying of a tramway line to Bedminster, after completing another branch of the same system which extends to Horfield. The Horfield line will be worked by steam, this being intended as an experiment to see how far the cheaper power can replace horse-flesh. One or two short bits of line have still to be laid to complete the tramway system, which will then supply nearly all parts of the city.

Instructions have been given to a committee of the Town Council to erect a bridge over the New Cut in place of a light iron one erected at the beginning of the century. The present bridge is manifestly insufficient, and the new one will be on a much more modern principle. The cost is roughly estimated at 8,000*l*.

Instructions were given last week for laying out a small public pleasure-ground at Cotham, presented to the city, at a cost of 800*l*.

The new police-courts in Bridewell-street, which cost some 15,000*l*., and have been in use several months, are a great improvement on the old Council-house, as far as ventilation and accommodation are concerned, but have two serious defects. The chief court has such peculiar acoustic properties that it is difficult to hear in it, and the smaller one is terribly draughty.

A new chapel is being added to the Borough Lunatic Asylum at Stapleton. The style of architecture is Norman Gothic, and accommodation will be found for about 350 patients and their attendants at a cost of 2,600*l*. Mr. Edwards has prepared the designs, and Messrs. Forse & Ashley have obtained the contract.

THE EARLIEST NORMAN KEEP, AND THE CASTLE OF FALAISE.

SIR,—As to the objection which you make to my statement,—that the earliest Norman keep is in all probability the one at Malling, in Kent, cannot be reconciled with the usual tradition in Normandy, that the *present castle* of Falaise is the one from which "William's father saw Arlette, the tanner's daughter,"—the explanation is, that although the present castle is on the same site, the existing building is certainly not of the time of the Conqueror, still less of his father, and is probably fifty years later than either. It is the old story. People consider the date of foundation as necessarily the data of the existing building, and make no allowance for the frequent rebuildings that took place everywhere, especially in the twelfth century. It is, perhaps, sufficient to say that Falaise was certainly one of the places visited by De Caumont and his friends in search of masonry of the first half of the eleventh century, and could find no masonry of that period in any one of the places they visited. This fact opened the eyes of De Caumont to the delusion which he had previously been under, in common with all the other antiquaries of Normandy. De Caumont himself never hesitated to acknowledge this; others were not always equally ready to acknowledge it. English people are often deceived by the name of the Norman style, which is quite correct in England, but in France this style is called the "Anglo-Norman" style. The style was, in fact, developed after Normandy became a province of England. There are quite as many Norman buildings in England as in Normandy. Few Englishmen know the architecture of Normandy better than I do. About fifty years ago I visited all parts of it, and was there many, many times. I was introduced to De Caumont by Dr. Buckland, the geologist, at Caen, at the meeting which De Caumont had called for the purpose of forming an Architectural Society. This was in the year 1834; two or three years after this, when I went again to Normandy for the purpose of going about and seeing things with my own eyes, I was accompanied by my friend M. Bonet, the excellent artist, whom De Caumont always gave up to me when I was in France, and we had instructions from De Caumont himself what places to go to. I have some scores of M. Bonet's drawings for which the sketches were taken on that occasion, amongst others the existing castle of Falaise, also of the church of St. Étienne, usually called the *Abbaie aux Hommes*, at Caen, of which my friend Bonet afterwards wrote and published the history; but this was not until after I had convinced both him and De Caumont that the existing vault and clearstory are of the time of Henry II., seventy years after the time of the Conqueror. The church originally had a wooden roof only, and, like all the other churches of the eleventh century, of the same width. When I first told this to my French friends, they would not believe it, for they had known the building all their lives, and must know it better than I did; but when I had persuaded them to go up to the clearstory gallery with me, they acknowledged that I was right; and Bonet has acknowledged this in print, both in the *Bulletin Monumental* and in his history of the church. The explanation of this is that I have profited by the teaching of Rickman and Professor Willis, that the history of any building can be best ascertained by comparison with others of the same period; they had not had the same opportunity.

Experienced eyes can often read off the history of a building almost at first sight, from having seen a score of others of the same kind, and therefore see the history of a particular building better than those who have studied it carefully, but have had no opportunity of comparing it with others.

For the same reason, beginners often cannot see the history at first, even when it is pointed out to them by those who have had experience, and afterwards wonder how they could have been so stupid as not to have seen it before.

English travellers in Normandy generally take

the dates of the buildings from Murray's "Handbook," and unless they have the latest edition this is very likely to mislead them. In the latest edition that I have seen, Gally Knight's "Tours in Normandy" was the authority for all the architectural history. The ideas of Mr. Gally Knight were rather in advance of his time, and he was assisted by Mr. R. C. Hussey, certainly one of the best-informed persons on this subject at that time, but that time was sixty years ago, and during the last half-century Architectural History has made great progress. JOHN HENRY PARKER, C.B.

*** The modest intimation that all who do not agree with Mr. Parker are ignoramuses, is characteristic, and not to be admired. There is no evidence whatever to disprove the general belief that William was born in the existing castle at Falaise. Is it reasonable to suppose that William's companions in England should forthwith proceed to erect structures such as the Tower of London, if they had known and seen nothing but earthen mounds and trenches in their own country? Some years have passed since we saw Falaise, but our recollection, aided by memoranda made at the time, tells us that it exhibited such work as might have been the precursor of that at the Tower.

We have not leisure at the moment to go fully into the question, but may mention, for what it is worth, the account of the siege which Falaise withstood in 1027, as given by a contemporary, Guillaume de Jumièges. Robert, the brother of Richard III., who was then Duke of Normandy, had rebelled against him and taken refuge with his adherents in the castle of Falaise, and the chronicler relates how that the Duke plied the battering-ram so long and so vigorously to the walls that Robert gave in. In other early writers also the walls of the castle are expressly mentioned.

HERTFORDSHIRE CONVALESCENT HOME, ST. LEONARD'S-ON-SEA.

THIS building stands on the crest of a hill near the West Marina Station, St. Leonard's, with an uninterrupted view to the sea, and a south-west view extending to Beachy Head. It was opened on the 28th ult. by H.R.H. the Princess Christian.

An endeavour has been made to avoid the character of an institution, and to give, both in the architecture and internal arrangements, as much the character of a home as was consistent with its uses.

The home is entered on one side to the men's department, and on the other to the women's, and the upper floors are approached by distinct staircases, the communication only being by a pass door, to be used by a matron. The sitting-rooms face the sea, and are sheltered by a continuous verandah. In the rear of the hall, and approachable from each side, is the dining-hall, and in direct communication with it is, in the rear, the kitchen, scullery, and other domestic offices, the dinner being served by a butlery-hatch.

On the right, as you enter on the women's side, is the committee-room, the matron's room, stores, and other accommodation. On the first and second floors there are dormitories, fitted to take forty beds, designed with a view, as far as possible, of securing cross ventilation to each room. Separate sick-rooms are provided for each sex, with lavatories and bath-rooms, there being also accommodation for the matron, the servants, and provision for stores of linen.

Provision has been made, on an average, for a space of not less than 1,000 cubic feet for each bed, and under no circumstances will more than seven persons sleep in one room, the average being less. Air is admitted under the sills of the windows, by hit-and-miss brass gratings, from bent flues, and the extraction is by means of ventilating-flues taken up beside the chimney-flues, fitted with "Eyre's" ventilators.

As regards the drainage, all contact with the main sewer is intercepted by a Doulton's trap, the sinks and bath wastes discharging in the open air with trapped gratings. All the soil-drains are without the building, and in every case ventilated at the top.

The rain-water has been preserved by a separate system of pipes, and is taken to a large tank available for house use. Internally, the building has been fitted with Lloyd's ventilating and warming stoves to the principal rooms, and the chimney-pieces are of wood fitted with tiles, the gift of a lady.

The principal entrance-door has some stained glass, given by Messrs. Shrigley & Hunt, who also gave some tiles for the chimney-pieces. The corridors have tiled floors, and the walls are finished with hard surfaces.

The whole of the works have been executed by Mr. Ebenezer Lawrance, of Wharf-road, City-road, London; and the designs have been prepared by Mr. Thomas Chatfeild Clarke, architect.

NEW FREE LIBRARY FOR DUNFERMLINE.

CONTRACTS were lately signed for a new library building presented to Dunfermline by Mr. Carnegie, a native of the town, and to be called the Carnegie Free Library. The sum gifted is 8,000*l.*, of which 5,000*l.* or so are to be spent on a new building, and the remainder on books. The plans were prepared by Mr. J. C. Walker, architect, Edinburgh, and the style is the Domestic Tudor. The new building will have a frontage to St. Margaret-street and Abbot-street, and it will be in close proximity to St. Margaret's Hall, recently built from designs by Mr. Starforth, architect, Edinburgh. The front to Abbot-street is 82 ft. in length, and two stories in height; while the St. Margaret-street elevation is 70 ft., and of the same height. The principal entrance is near to the corner of the Abbot-street frontage, and has been designed so as to give the appearance of a square tower. This part of the elevation is carried a story higher than the rest of the building. The doorway is finished above as a gablet with carved stone finial. The third-story of this part has oriel windows, and the interior is to be set apart as a smoking-room. The oriels are to be supported by boldly-moulded corbels, and surmounted by small turrets. The plans show a library-room, 57 ft. 3 in. by 25 ft. 6 in.; recreation-room, 26 ft. 6 in. by 25 ft. 6 in.; gentlemen's reading-room, 34 ft. 3 in. by 25 ft. 6 in.; ladies' reading-room, 22 ft. 6 in. by 18 ft. 10 in.; smoking-room, 28 ft. by 16 ft.; and a keeper's house, consisting of three rooms and a kitchen. Lavatories will be provided, and decorations are to be adopted in keeping with the general design of the structure.

FURTHER SALES OF BUILDING LAND.

THERE have been several sales of building sites in the suburbs within the last few days, in addition to those which from time to time have already been reported in the *Builder*. On Monday evening in last week Mr. W. H. Collier submitted for sale at Myddelton Hall, Upper-street, Islington, 122 plots, situated in Hornsey-lane, belonging to the British Land Company, on an estate which the company has recently purchased. The sites have frontages to a number of new roads which have been constructed, leading from Hornsey-lane and Hazelville-road, and are close to Highgate Archway, and within a few minutes' walk of the Crouch-end Station of the Great Northern Railway. Twelve of the plots have frontages of 20 ft., with a depth ranging from 127 ft. to 137 ft.; the remaining plots having also frontages of 20 ft., and a depth of from 80 ft. to 85 ft. Of the entire number of plots offered, 101 plots were sold, the larger plots realising an average sum of 132*l.* each, and the smaller ones 110*l.* each. The entire proceeds of the sale amounted to 11,110*l.*

On the same evening, Messrs. Baker & Son offered for sale, at the Victoria Tavern, Edgware-road, Kilburn, the second portion of the Stonebridge Estate, at Willesden, close to the Harrow-road Station of the Midland Railway, and the Willesden Junction of the London and North-Western line. The number of plots exhibited was 76, the plots having frontages of 16 ft. each, and a depth of from 90 ft. to 100 ft., and described as well adapted for small dwelling-houses. About one-half the number of plots offered were sold at prices averaging 34*l.* each, the total amount of the sale being 1,154*l.*

On Thursday evening, the 28th of October, Messrs. Protheroe & Morris offered for sale, at the Eagle Inn, Snaresbrook, 76 plots of freehold building land at Wanstead, having frontages to George-lane, which are reserved for shops, and other frontages to three new roads, to be called Mansfield, Camden, and Sydney roads, stated to be specially adapted for cottage property. The property is immediately adjacent to Epping Forest. Amongst the restrictions contained in the conditions of the sale, it was provided that the trade of an innkeeper or victualler is not to be carried on upon any lot on the estate, nor is any lot to be used for the erection of a school, church, or chapel, or as tea-gardens, or as a place of public amusement or resort. It is further provided that no trade or business is to be carried on on any lots except those fronting on George-lane, nor is anything to be carried on on any part of the estate which may be a nuisance or an annoyance to the adjoining property, that of the trustees of the Earl of Cowley; neither are any bricks or tiles to be made, nor is any clay or lime to be burnt. There was a large attendance at the sale, and a few lots only remained unsold. The shop lots facing George-lane realised from 5*l.* to 5*l.* 5*s.* per foot frontage, and those lots fronting the other roads 3*l.* per foot frontage; the total proceeds of the sale amounting to about 2,500*l.*

The second and last portion of the Harringay New Park Estate, Green-lanes, was also sold last week, at the Queen's Hotel, Wood-green, by Mr. R. J. Collier. It consisted of 139 lots. The first lots offered were stated to have frontages to the Green-lanes of 25 ft., with a depth of 280 ft., and were sold for 20*l.* per plot. A tavern site realised 550*l.*, and other plots of less important frontages were sold for proportionately good prices. The total proceeds of the sale amounted to 11,275*l.*, which, added to the sum realised by the first sale, makes the aggregate sum realised for the estate, fifteen acres in extent, 22,450*l.*, or about 1,500*l.* an acre. We are informed that the estate, when purchased by the vendor, did not cost more than 10,000*l.*, and that the profit on the re-sale, after deducting the cost of roadmaking and other expenses, will be about equal to the original purchase-money.

VALUATION OF PROPERTY IN KENSINGTON.

THE following is the result of the recent quinquennial valuation of property in the parish of St. Mary Abbotts, Kensington:—

	Gas, Water, and Railway Companies.		Houses, Land, and other Companies than in No. 1.	
	Gross. £	Rateable. £	Gross. £	Rateable. £
New Valuation List appproved 30th October, 1880	95,985	84,777	1,873,516	1,563,410
Valuation List in force to 5th April, 1881 ...	55,600	46,334	1,709,762	1,426,652
Increase ...	40,385	38,443	163,754	136,758

A YEAR'S BUILDING IN GREENOCK.

THE members of the Greenock Dean of Guild Court last week had a very pleasant meeting, when Dean Smith made his statement of the work passed through the court for the year ending with October. Altogether there had been 688 cases before the court, or 138 more than in the preceding year, showing that Greenock had not so seriously shared the great building depression as Glasgow and other towns in Scotland. Of the buildings erected during the year, there were twenty-two blocks or tenements, giving accommodation to 149 families; twenty villas for the better class population; nineteen workshops and stores; and fifty-one miscellaneous buildings, which included a wall, enclosing an extension of the public cemetery, of about a mile in length. In the way of public buildings, there were erected Free St. Andrew's Church, a Roman Catholic school, new Post-office buildings, the first section of the new Municipal buildings, and the West-end baths building. The estimated value of new buildings erected during the year was 181,900*l.*, an increase of 61,000*l.* as compared with the preceding twelve months; and with 12,000*l.* spent on the construction of sewers, the total sum is 193,900*l.* Greenock is extending, and its building trade appears to be healthy.

Criticism.—Mr. T. H. Hall Caine begins, November 15, at the Liverpool Free Library, a course of lectures on "Curiosities of Criticism: 1800—25." The lecturer's syllabus states that the lectures will deal with the critical anomalies on Wordsworth, Southey, Coleridge, Byron, Leigh Hunt, and Keats.

SOCIETY OF ARTS.

The first meeting of the 127th session of the Society will be held on Wednesday the 17th inst., when the opening address will be delivered by Mr. F. J. Bramwell, F.R.S., chairman of the Council.

The following arrangements for the Wednesday evenings before Christmas have been made:—

Nov. 17.—Opening meeting of the session. Address by Mr. F. J. Bramwell, F.R.S., chairman of the Council.
Nov. 24.—The Influence of Barry upon English Art. By J. Comyns Carr.
Dec. 1.—The Photophone. By W. H. Preece, Pres. Soc. Tel. Engineers.
Dec. 8.—London Fogs. By Dr. Alfred Carpenter.
Dec. 15.—The Use of Sound for Signals. By E. Price Edwards, secretary to the deputy-master of the Trinity House. On this evening Dr. Tyndall, F.R.S. will preside.

The first course of Cantor Lectures will be on "Some Points of Contact between the Scientific and Artistic Aspects of Pottery and Porcelain," by Prof. A. H. Church, F.C.S. Five lectures. The following is the syllabus of the course.

Nov. 22.—Bricks, Tiles, and unglazed Terra-cottas in general.
Nov. 29.—Vitreous, Plumbiferous, Boracic, and Felspathic Glazes and Enamels. Iridescent and Metallic Lustres, and Colouring Substances.
Dec. 6.—Stoneware and other Wares glazed with salt.
Dec. 13.—Soft Paste Porcelains,—European, and Oriental; and
Dec. 20.—Hard Paste Porcelains,—Chinese, Japanese, and European.

DISCOVERY OF ROMAN ANTIQUITIES IN YORK.

On the 16th of October the workmen engaged in excavating for the foundations of a new building attached to St. Mary's Convent, York (which is now being enlarged under the direction and from the designs of Messrs. Goldie & Child, architects), made a very remarkable discovery. At 6 ft. below the level of the ground several pieces of stone were found which, upon closer inspection, proved to be the remains of three small Roman altars, and near to them was a much larger mass which, upon being uncovered, proved to be a statue cut out of sandstone nearly life-size.

Of the altars, two are tolerably perfect. The largest measures 17 in. in height, and is 8 in. wide, measured at the shaft or body of the altar. The *mensa* or head is 9 in. in width, and shows the usual cavity for burning incense. It was evidently one of those small altars which the Romans set up in front of the statues in their private residences, and which, from their small size, could be removed from place to place with the rest of their household goods. It is carved out of hard polished stone, and is adorned with ornamental fluting. The remains of colour can be distinctly traced. The inscription is legible, and has been thus read:—

"C. JULIUS CRESCENTIUS
MATRIBUS DOMESTICIS
V. S. M. L.
ANNO URBIS CONDITÆ 1001" (or 1005).

The second altar is of sandstone, the same material as the figure, to which it was probably attached. It is 13½ in. in height, and the body of the altar is 7 in. wide. The only word that can be traced of the inscription is the word "MARTI," probably "Marti."

The third stone, which is also supposed to have formed the body of an altar, though both *mensa* and base have disappeared, bears an inscription, of which the following words alone have been made out:—

"DEO VETERI BIBLI—"

The termination of the last word is at present disputed.

The statue, which seems to be in a very perfect condition, except that the feet are wanting, represents a young man of muscular frame, clad in a military dress of the prætorian rank. The head, though perfect, was unfortunately broken off in the process of digging the statue up. It is presumed by one of the antiquaries who have seen these remains that the figure is intended to represent the god Mars, and that the altar bearing the word "Marti" was connected with it.

There can be no doubt that such a very remarkable discovery as this will lead to considerable comment, and that the inscriptions will lead to some discussion among the learned. Several readings and translations have been suggested to us, but we prefer to wait and see what others learned in such matters have to advance before expressing any opinion.

"SOME WORDS OF FAREWELL."

Mr. S. O. Hall, F.S.A., after editing for forty-two years the *Art Journal*, which he founded, has resigned the position, and has published some interesting and touching words of farewell to the public. Sketching the position of things at the time the journal was started, he shows that there was literally no "patronage" for British art. Collectors did, indeed, buy pictures as befitting household adornments, but they were "old masters" with familiar names, canvasses that had never been seen by the artists to whom they were attributed, copies or imitations by "'prentice hands;" and he showed, month after month, that a larger number of Titians, Raffaelles, and Rubenses paid duty in a year, than these masters had produced during their lives. On the other hand, he made manifest the policy of buying only such pictures as could be readily identified,—certified by the artists who were living; urging the probability that they would increase and not decrease in value, while it was almost certain that so-called "old masters" would ultimately be worth little more than the panels and frames. He has had his reward in living to see such old masters valued accordingly, and a thorough transfer of patronage to modern art.

In speaking of the circumstances which encouraged him in the task, Mr. Hall justly refers, as amongst them, to the operations of the Art-Union of London, but he does not say, as he might,—he has probably forgotten it in the lapse of years,—that it was the establishment of that society which led to the foundation of the journal, and provided for its first base of operations. Mr. Hall points with just pride to the part he has taken in bringing about the association of the Industrial Arts with the Fine Arts proper, and needs no excuse, though he asks it, for seeking to show that the art spirit and character of the age have been largely served and materially advanced by the journal he is about to consign to other hands,—to enjoy the repose earned by forty-two years of labour, and by sixty years of work as "a man of letters by profession." He does not look to be altogether idle, but hopes for ease and leisure to complete a work on which he has been some years engaged,—"Recollections of a Long Life."

Sincerely and heartily we wish him health and energy completely to carry out his wish.

ARTISANS' DWELLINGS IN LONDON.

On the 5th inst. a meeting of delegates from the Metropolitan Vestries was held at the St. Martin's Vestry-hall, Charing-cross, to adopt a memorial to the Home Secretary, based on a report agreed upon at a previous meeting, on the subject of the Artisans' Dwellings Act. Mr. E. J. Watherston presided. The following were among the conclusions arrived at in the report:—That no class of citizens had a right to dwellings or sites for dwellings at the public cost; that only imperative considerations of public health could justify the outlay of the public money for such purposes as those of the Artisans' Dwellings Act; and if these considerations could be adequately provided for under Torrens's Act, it was unjust to add to the heavy and constantly-increasing weight of local taxation by enforcing the provisions of Mr. Cross's Act. That owners of the class of property chiefly affected by these Acts should be placed under strong pecuniary inducements to keep it in proper and habitable condition; that, if property had been kept in such a state as to be unfit for human habitation, or so as to become a nuisance, the penalty of such a course should fall upon the owners, and that the provisions of the Act should be vigorously applied whenever premises were in the condition contemplated by Section 5, Act of 1868, whether that condition had resulted from overcrowding, defective construction, the absence of sufficient area for light and air, or general dilapidation and uncleanliness. That the working of the Artisans' and Labourers' Dwellings Improvement Act, 1875, was impolitic and ruinously extravagant, and that in the interests of the ratepayers the provisions of the Acts known as Torrens's Act, 1868-79, should be put in operation and fully exhausted by the local authorities throughout the metropolis before any further action was taken under the first-mentioned Act. That the cost of works under Torrens's Acts, whether executed by the owner or by the local authority, should be apportioned by the arbitrator between the parties holding the several freehold and leasehold interests, regard being had to their various responsibilities and the value of their interests.

On Monday afternoon, at a largely-attended meeting of the Council of the Charity Organisation Society, held under the presidency of General Cavenagh, the subject of artisans' dwellings in London was dealt with in a report from a special committee appointed by the society. This committee included the Duke of Westminster, the Earl of Shaftesbury, Lord Norton, Sir R. Cross, M.P., Sir C. P. Trevelyan, Sir U. Kay-Shuttleworth, Mr. Ernest Hart, Dr. Jabez Hogg, Dr. Hawksley, Dr. Greenhill, Miss Octavia Hill, and others. The report was now presented, and after entering fully into the great losses occasioned in purchasing and clearing the blocks of unhealthy houses and the re-sale of sites, the committee expressed the belief that "such losses might be very greatly reduced by an amended law and improved administration," and quoted the report of the Metropolitan Board of Works, which body laid stress upon "the slow and cumbrous method of procedure," and the "numerous and protracted formalities required by the statute." The committee recommended that a letter should be sent to the Home Secretary, asking that the Minister would appoint a departmental committee to make a searching and authoritative investigation into the causes of the delay, expense, and other evils that had attended the administration of the Artisans' Dwellings Acts, and the sections of the Metropolitan Streets Improvements Acts (of 1872 and 1877) providing for the re-housing of persons displaced under those Acts. This recommendation was adopted.

CONSECRATION OF A CHURCH AT GUNNISLAKE, CORNWALL.

The new church of St. Anne, Gunnislake, which takes the place of a little building, formerly a Baptist Chapel, was consecrated on Tuesday, November 2nd, by the Bishop of Truro. The new edifice, of which Mr. J. Piers St. Aubyn is the architect, is in the Early English style. The massive granite pillars of the arcade, the little clearstory, and the lancet lights, are very effective. The granite is the pure silver-grey stone of the district, and was supplied by Mr. E. Story, of the Gunnislake granite quarries and works. The church stands upon a very steep piece of ground, and the architect has resorted to a device to avoid the use of more building material than possible. He has arranged the seats of the nave in a series of steps, which have no bad effect, and have the advantage of enabling the congregation to see the preacher, and to have a full view of the communion-table.

The total cost of the building was 2,000*l.*, 500*l.* being given by the Duke of Bedford, and the Earl of Mount-Edgcumbe rendered liberal assistance.

The interior of the building is 83 ft. by 43 ft. wide, and will accommodate 300 people. The woodwork is chiefly pitch-pine. The iron communion-rails were wrought by Mr. W. Rose Kilby, son of the builder. The vestries are under the church, and are 20 ft. by 15 ft.

DISTRICT MARKETS.

Sir,—Of course, the realisation of such a project in London would meet with much opposition, but none the less would it be a benefit to the public. The extremely high price of food in some quarters of our great and increasing City drives people with limited incomes, however unwillingly, to co-operative stores, and this is on the increase, however much the provision-tradesmen may affect to ignore it. Every visitor to Paris must have seen what pleasing as well as useful features of that attractive centre of civilisation are the markets, gay with fruit and flowers, while, at the same time, affording also more substantial articles of supply. I should like to see such markets established in each of our suburbs. Also they would afford opportunities for very pleasing architectural structures. If two or three men of wealth would take up this idea, there seems but little doubt that it might be carried out to a financial success, and to the great advantage of the public. Perhaps the most striking anomaly in the food-supply of the metropolis of this sea-

girt isle is the high price of the fish that swarm round its shores. Scarcely a fourth of the price for this article of food paid in the western districts goes to the hardy mariner who wins it, with labour and peril, from the waves, and all the rest stops with the middlemen, who stand between the consumer and the toiler of the sea. This is one of the points in which the establishment of such district markets would be calculated to yield relief to the public. Many others exist, and I venture to write this for the chance of its insertion in the *Builder*,—not only because the cheapening of supply of the various articles of food to the consumer is a sanitary question, but that the structures for accommodating such markets would offer fertile opportunities for pleasing architectural display. C. S.

THE TOPOGRAPHICAL SOCIETY OF LONDON.

SIR,—In reference to the inaugural meeting of the above Society, held at the Mansion House, it may be of advantage to the profession to know that extensive collections of London topography are already in existence which are open to them for consultation. The Croll, and the recently-acquired Crace, collections are in the British Museum; the small Fauntleroy collection is in the Soane Museum; there are collections forming in the Guildhall Library, and illustrations of the utmost interest are contained in the Bodleian and Pepysian libraries. Besides these, my own collection, numbering upwards of 100,000 prints and drawings of London, can be seen by architects desirous of consulting it for any special purpose.

Without wishing to discourage the Society in any one of the objects they have set themselves, my own experience, extending over forty years, is that original illustrations of old London are rapidly becoming more and more difficult to obtain, and that, even with ample funds, many years must elapse before anything like a representative collection can be brought together. The Society has, however, planned out useful work in so many directions that its resources are sure in any case to find ample employment.

J. E. GARDNER.

453, *Strand*.

HOUSE-DRAINAGE AND SEWER WORKS AS A SPECIALTY.

SIR,—I beg to back up the remarks of a "Practical Sanitarian" at page 514, October 23rd, regarding the use of small-bore drain-pipes. Like him I deprecate the use of 4 in. drain-pipes for closets, &c., and especially if the distance is yards. I think, however, that needless expense is very often incurred by putting in 9 in. pipes where a less size would serve better. The ordinary sizes in use are 4 in., 6 in., and 9 in. diameter for houses and tenements. Now, I think, that 5 in., 6 in., and 7 in. would, for general use, be much better. Where the pipe has a fall of 1 in 30 it will take a very large flow of water to fill up a 7-in. pipe three-fifths. Bad workmanship has had a good deal to do with putting in large-sized pipes, *e. g.*, by leaving "shirt-collars" of cement sticking up at the joints. With leaking joints, again, the soil is left lying in the drain-pipe, owing to the water running into the ground through the joints, and so the larger the pipes the longer time is required to fill them up,—ergo, the old masons reasoned "large pipes are better than small ones!" How many thousands of lives have been lost by this stupid carelessness and ignorance none can tell: but the number must be great, and the evil is still going on. It is *legal*, however, and you cannot hang a man for *legal murder!* You poor betrayed woman is a wretch for killing her child, and may be sent to the gallows, but the speculative builder, who, often knowingly, executes his drainage so that wholesale disease and death are bound to be the result, gets off scot free! How admirable are our laws, and how honourable are our legislators!

I was lately examining the drains in a fine castle where the drain-pipes were partly laid through an expensive tunnel, and debouched into a stream less than 10 yards from the house. I turned on all the water-closets at once, but not a drop of water came out at the end of the 9-in. drain-pipe, it all soaked into the ground. In this case the joints were well cemented all round except a small piece at the bottom of each where the workman seems to have been unable to get his hand in easily between the bottom of the pipe and the stone floor of the tunnel. This incident caused me to get pipes made with attached rests about 1 in. high, so that in such cases, or where pipes were laid on a concrete bed, the workman could easily get his hand or tool in under the joint and so have no excuse for making a bad joint. The bottom of this rest is made flat, so as to prevent the pipe from rolling or moving after the joint is made. Rain or water in the trench is also prevented spoiling the joint, as would be the case with the holes dug at each joint, as shown by Mr. Waring in "Fig. 19," page 377, of your issue for the 25th of September. Of course, after these pipes have been laid, and the joints set and tested, the pipes required to be packed with the soil, or, better still, concreted either half-way up or wholly round. If outside the house the former is sufficient, which I have done where the drains were higher than the well supplying water to a mansion-house. These pipes were patented by me in December last, and the judges of the Philosophical Society's Exhibition at Glasgow just closed have awarded me: he "First-class Certificate—Highest Award" for them, in conjunction with my patent ventilating drain-trap, now largely used all over the kingdom. Even with the best materials, and no estimate, I find it difficult to get good work without close supervision; hence the necessity that exists for allowing no new houses to be occupied until the drainage and sanitary fittings have been passed by a competent inspector. Until such is carried out, I look upon the public as guilty of suicide, and our legislators of manslaughter, for all the deaths that have occurred, and which will occur, from the bad drainage of houses, say since January, 1880.

W. P. BUCHAN.

OLD PLASTER CEILINGS.

SIR,—Having had a large experience in reproducing old ceilings, especially of the date of George I., I can endorse Mr. Robins's statement as to the dangerous condition in which they often are.

I remember seeing the parts of the ceiling of the ball-room in old Northumberland House after the fire, and was astonished that the huge masses of plaster had not come down before; there were heads of boys in solid stucco (which I could scarcely lift) held up by a single spike.

There is, however, a remedy for this in the patent Fibrous Plaster. Any amount of relief can be produced, and the fibrous nature of the material prevents any portion of it being detached from the other part, besides being in itself exceedingly light. JOHN JACKSON.

BUILDERS' ACTIONS.

IN the Court of Exchequer, Dublin, on Monday, before Mr. Justice Barry and a special jury, a case, Ham noad *v.* Graham, was heard. The plaintiff, Mr. A. Hammond, a builder and contractor, sought to recover 276*l.* 12*s.* 5*d.*, balance alleged to be due by the defendant, Dr. John Graham, of Westmoreland-street, in this city, on foot of a building contract, and for 12*l.* for extra work in the construction of a drug-store and photograph-gallery at the rear of the defendant's premises, according to the plan of Mr. Briggs, architect. The defendant traversed the cause of the action, and pleaded various matters in the way of defence and set-off. He sued for 1,300*l.* as a counter-claim, on the ground that the work was badly done, which necessitated the taking down of the building and its reconstruction. The jury found for the defendant that there was nothing due to the plaintiff on the original contract, and they found that the plaintiff on the counter-claim was entitled to 13*l.* 1*s.*

COMPETITIONS.

Newtown Church, Exeter.—The Exeter Church Extension Society have selected Mr. R. Medley Fulford, of Exeter, as architect for the proposed church in Newtown. Seven sets of designs were sent in under motto by the Exeter architects to whom the competition was confined, and they were all submitted to Mr. Rohson, architect of London, who reported in favour of Mr. Fulford's design, bearing the motto of "Laus Deo," as worthy of the first place, and that of Mr. Webb, second. It is proposed to proceed with a portion of the work, if funds will not admit of the whole being carried out at present. The church is to be erected behind the Board Schools, at an estimated cost of about 6,000*l.*, and will accommodate 800 adults.

Books.

The Irrigation Works of India, and their Financial Results. By ROBERT B. BUCKLEY, Associate-Member of the Institution of Civil Engineers, Member of the Institute of Mechanical Engineers, Executive Engineer of the Public Works Department of India. London: W. H. Allen & Co. 1880.

GREAT difficulty exists in obtaining any reliable information as to the irrigation works of India. It is not easy even for the professional men who are engaged in these undertakings in one part of that vast continent to ascertain what is being done in other parts of India. Still less is it easy for the English student to do so. There is thus ample room for such a work as that of Mr. Buckley, which is a compilation from all accessible sources of information on the subject, consisting principally in Government reports and Parliamentary papers.

Down to the year 1854, all public works executed in India, except railways, were carried on by the Engineer department of the Army, under the superintendence of a military board. The expenditure was treated as a part of the ordinary current expenses of the year, and no distinction was made as to "capital," or productive and non-productive works. It is thus almost impossible to ascertain the financial outcome of these earlier works. Some of the most magnificent, and some of the most lucrative of the irrigation works of India were commenced under this system. Such were a part of the Ganges canal, commenced in 1847; the West Jumna canal, in 1817; the Cauvery Delta works, in 1834; those of the Godaveri, in 1844; and those of the Kistna in 1852.

In 1858, when the construction of railways, on the guarantee and under the supervision of the State, was in full activity, great pressure was brought to bear upon the Government of India, in order to induce it to promote irrigation by the same method of raising capital. The Madras Irrigation Company was then formed, with a Government guarantee of five per cent. upon a capital of one million pounds. A few years after a private company undertook, without any guarantee, the construction of a system of canals in Orissa. Both these attempts proved to be costly failures. The Orissa Company, formed under the title of the East India Irrigation Company, became practically bankrupt, and the works were purchased by the Government at a price far above their market-value. The Madras Company has only succeeded for one year in meeting its working expenses out of its revenue. It is still at work under the Government guarantee.

From 1867 to 1878, inclusive, while the sum of 18,600,000*l.* has been spent on State Railways, and 14,500,000*l.* on famine relief, less than 10,600,000*l.* has been spent on Irrigation works. The total outlay on works of this nature, up to the last return, was hard upon 17,000,000*l.*, including the outlay of the Madras Irrigation Company. The aggregate net gain, after paying not only working expenses, but 4½ per cent. interest on capital, was 85,500*l.* But the interest thus earned amounted to 700,000*l.*; and the working expenses distributed no less than 396,000*l.* per annum in the payment of labour and materials. Again, where the direct receipts of land revenue from irrigation works amounts to 680,000*l.*, the indirect increase of land revenue due to such works amounted to upwards of 700,000*l.* Taking good and bad together, therefore, India has been largely benefited by the expenditure on irrigation, while the benefit to the Government, in money, has been perceptibly larger than would have been the return of an equal sum of money if invested in English railways.

The irrigation works of India are divided into six groups, corresponding with the provinces in which they are situated. These are:—

1. The Madras irrigation works.
2. The Bombay irrigation works.
3. The Sind irrigation works.
4. The Bengal irrigation works.
5. The North-West Provinces irrigation works.
6. The Punjab irrigation works.

These comprise all the important works of India. There are others of less magnitude, chiefly tank works in Mysore, Rajpootana, and British Burmah, as to which available information is yet wanting.

The works thus locally distributed are divided as to their hydraulic character into five great classes. These are:—

1. Perennial canals, which draw their supplies from rivers that provide the requisite quantity of water throughout the year. These may almost be called derived rivers.

2. Intermittent canals, which draw their supplies from rivers of variable volume, which is stored, and rendered constantly available for the canals by means of reservoirs found in the basins of the rivers.

3. Chronic canals, which have a supply only during the rainy season.

4. Inundation canals, which draw the supplies from rivers having a constant discharge of more or less magnitude, but which are so constructed that the water only enters the canals when the rivers are in flood.

5. Tanks, or works which impound a supply from rivers with small catchment areas, or collect a supply by means of embankments thrown across valleys or gorges.

Of these works, all of the first class, the perennial canals, with but one or two exceptions, have been constructed by the British Government. Works of the last two classes, on the other hand, were largely constructed by the native princes of India before the English obtained possession of the country. They are to be found, on all scales, in almost all parts of India. The great Chembrambankum tank, in Madras, covers an area of nine square miles. In the Punjab and in the Sind are found inundation canals of from 200 ft. to 300 ft. in width. The account given by Mr. Buckley divides the works, in the first instance, according to the six provinces, and then shows to which of the above five classes each canal belongs.

A table is annexed to the first chapter, showing the rainfall in the twenty-two different tracts of country into which India is meteorologically divided. The annual fall ranges from 9 in., in Sind and Cutch, to 193 in. in Arakan.

This enormous variation is alone enough to show, not only the extreme importance of the subject of irrigation, but the wide difference of the methods which the engineer is at liberty to dispose, for that purpose, in different districts.

For any detailed description of the various groups of works, we must refer the reader to the volume itself. So large is the subject, that Mr. Buckley has been limited in the scale on which he treats it by the 200 pages of his volume. He refers to the special accounts which have been given of various works for the guidance of those who wish to enter into minute particulars. On one point it would have added to the value of the work if the author had been less reticent. Speaking of the Ganges Canal, into which water was admitted in April, 1851, he says, "During the next few years defects in the works gradually came to light which it is unnecessary here to recapitulate in detail. The chief defect was excessive declivity in the bed of the main channel, which caused a velocity of current greater than the sandy soil was calculated to withstand without erosion." As the original estimate, on the designs of Sir Proby Cautley, in 1841, for main canals and branches, amounted to 722,640*l.*, while the actual expenditure, up to the end of 1877-78, was 3,055,015*l.*, it is evident that this is a work into the plans and execution of which it would be highly instructive for the student of the subject of irrigation to enter fully and closely. It is only fair to the reputation of Sir Proby Cautley to cite, on this point, the evidence of the translator of Herr Kutter, who is now recognised as the first European authority on hydraulic formulæ. "Colonel Cautley," writes Mr. Jackson, in his preface to the translation of Kutter's formulæ, "relied upon Duhuat when he laid out the Ganges Canal, and found him but a rotten reed, for the water in every instance tore along at an unexpected velocity, and erosion of the bed and destruction of the works followed in its wake. Duhuat, then, must be put upon the top shelf of the book-case, and it will be just as well, when the steps are taken, to carry up every English work in which the names of Brunning, Girard, Bossut, Prony, Eytelwein, or D'Aubuisson are continually recurring as authorities against whom no action can be taken. In this general clearance Beardman, Downing, Box, and almost every other hydraulic text-book compiled by Englishmen, will, with more or less hesitation, have been shelved, and the young engineer will then be able to form a fair estimate of the contributions his countrymen have made to the common fund of knowledge concerning the laws which govern the flow of water."

Of the modern successful irrigation works of India, the most remarkable is that of the Cauvery Delta, designed by Sir Arthur Cotton, in 1834. This work consisted in a weir of 1,950 ft. in length across the Coleroon, a branch of the Cauvery, and in derived canals and subsidiary works. The sum of 134,000*l.* was expended on the works; and in 1875-6 the revenue, after paying working expenses, yielded a return of 85·8 per cent. on this sum. It will be difficult to find a parallel to this, as a financial operation. But the Godavery works, in the same year, yielded 16·94 per cent.; the West Jumna, 24·92; the East Jumna, 25·18; and the Scinde irrigation works, 24·16 per cent., on their respective capitals, after payment of working expenses. It must be remembered that the physical conditions which allow of such advantageous operations are very rare, and that even in some of these, advantage has been taken of works effected by some of the former rulers of India. But the irregularity of financial result is only a proof of the extreme importance of an accurate knowledge of the subject. It is as a first step towards this, and as a guide to the sources of more minute and detailed information, that we cordially recommend the modest and impartial work of Mr. Buckley to our readers.

Old French Plate; with Tables of the Paris Date-letters, and Fac-similes of other Marks. By Wilfred J. Cripps, M.A. London: John Murray. 1880.

Collectors of old French plate and students of the history of metal-working have reason to be grateful to Mr. Cripps. For the first time in any language, so far as we know, here are brought together fac-similes of so many of the marks used by makers and the official bodies who had control over the manufacture of plate in France, that the student may "fix the date of almost every specimen of old plate made in Paris," and ascertain the origin of a good deal of the old provincial French plate that he has an opportunity of examining. The historical chapter preceding the tables of marks is carefully compiled, and very interesting.

Miscellanea.

Association of Municipal and Sanitary Engineers.—The Lancashire and Cheshire District meeting of this Association was held on the 5th inst., when the members to the number of about forty visited the Salford new sewage works at Mode-wheel, Weaste, and the Manchester Corporation night soil works at Holt Town. The members of the Association were met at Weaste by Mr. Arthur Jacob, the borough engineer of Salford, who, before conducting the party over the works, entered into a brief description of the development of the sewerage system of Salford, the construction of the intercepting sewer from Broughton to Mode-wheel, and the nature of the works which are now being constructed at the latter place for dealing with the sewage of the borough before allowing it to pass into the river Irwell. The sewage, when the works are completed, will be delivered into pumping wells constructed near the outlet of the intercepting sewer, and from these it will be raised by a pair of powerful pumping engines into a mixing-house, where it will be thoroughly mixed with lime and other chemical ingredients; it will be conveyed by a couple of cast-iron mains into a series of concrete tanks where it will undergo a process of precipitation. These tanks are twelve in number in two parallel lines, and the sewage which is delivered into the tank, the furthest from the pumping station, in the process of precipitation, flows back towards the mixing-house, where the clarified effluent water, before passing into the river, will drive a pair of vortex-wheels which will actuate the machinery in the mixing-house. The precipitated material from the sewage is afterwards conveyed from the tanks into adjoining mud-pits, where it was allowed to dry. The works, which had been considerably delayed by the discovery of a peat-moss under the foundations of the tanks, have been in course of construction for about two years, and it is expected they will be completed in another twelve months. The precipitating tanks are 113 ft. long, with an average width of 78 ft., and a total area of 102,857 square feet. The works were originally designed by Mr. Fowler, the late borough engineer, but have undergone considerable modification, and are now being carried out under the supervision of Mr. Jacob.

Unsanitary Dwellings in Holborn.—Last week, at the Guildhall, before Alderman Sir Thos. Gabriel and Mr. Alderman Nottage, several adjourned summonses were heard concerning the unsanitary condition of certain houses in Elycourt, Holborn. The summonses were issued at the instance of Dr. W. Sedgwick Saunders, the medical officer of health for the City, on behalf of the Commissioners of Sewers, against the freeholders, leaseholders, and occupiers of eight houses in the court, to show cause why they should not be pulled down, as they were in such an unwholesome state as to be totally unfit for human habitation. Dr. Saunders, Dr. Sparks, and Inspectors Payne, Clark, and Saltmarsh gave evidence. Eventually Alderman Sir T. Gabriel said that he and Mr. Alderman Nottage were of opinion that the houses were permanently unwholesome, and that nothing short of pulling them down would meet the requirements of the case. Mr. Bartlett, on behalf of Messrs. Goathead, the trustees of the freeholders of Nos. 8, 9, 10, and 12, said that if Mr. Newby, the lessee, would give up the houses he would forgive him the rent he owed, and would pay the expenses in the action of ejectment which was now pending. Mr. Pontifex, on behalf of Captain Meeking, made a similar offer with regard to their interests in the property. Alderman Sir T. Gabriel, after a long discussion, adjourned the summonses relating to No. 7 *sine die*; that relating to No. 11 to January 7th; and with respect to Nos. 8, 9, 10, and 12, made an order that these should be pulled down within six weeks.

Handbook to the Builders' Supply Stores. The Builders' Supply Stores (145, Holborn-bars) have been established nearly a quarter of a century, so that their usefulness would seem to be proved. The handbook now issued gives particulars and trade prices of materials and fittings kept in stock, or supplied by associated firms.

Everton House.—Colonel Trevor Goff, late of the Highlanders, having acquired a considerable tract of land in the neighbourhood of Everton, near Lymington, resolved, some little time ago, to build himself a mansion there. Mr. George R. Crickmay, of Parliament-street, Westminster, and of Weymouth, was consulted, with the result that an edifice has been erected. The style of architecture is a free rendering of the Elizabethan style of domestic architecture. It is built of red brick, with Bath stone dressings. Red tiles are also utilised in the walls, whilst the gables are of half-timbered work. The roofs are of high pitch, and covered in with red tiles, and the chimneys are carried well up, breaking the sky-line picturesquely, and intermingling with the varied gable lines and general grouping. The cornices from which the roofs spring are deeply coved out in plaster, and bear upon their faces ornamental stucco-work of *sgraffito* character. The building rests upon a Portland stone plinth. On the front of the house towards the sea there is an open colonnade, supported by carved cantilever, and carried by an arcade of cut and moulded brick, which rest in their turn upon columns of polished red Aberdeen granite, with carved annulets, and carrying carved capitals. The whole of the ornamental carved work has been executed by Mr. Harry Hems. The contractor for the whole of the works is Mr. A. H. Preen, of Blandford.

Fittings for Trinidad Government Buildings.—The Crown Agents for the Colonies have recently directed some important decorations to be executed in the residence of the Governor, and amongst the new fittings which they have ordered to be supplied are some elegant chandeliers and brackets, also globe lights, especially prepared for the various rooms and corridors. The manufacture of these excellent specimens of modern art has been entrusted to Messrs. Henry Greene & Son, of Cannon-street, London Bridge, at whose establishment they have been displayed for a few days previously to their being shipped to their destination. The principal chandelier is very handsome, being a combination of ormolu with richly-cut crystal jewels set in the scrolls of the arms, the central body whence these scrolls spring being formed in massive metal work of very rich character, having ornamental crystal glass vases introduced into the stem of the chandelier, the whole being finished with pendent drops of the early Venetian style. There are smaller chandeliers *en suite* for the public and private drawing-rooms, dining-rooms, &c., the whole forming an exhibition very creditable to Messrs. Greene. Mr. Edmeston is the architect of the buildings.

Institution of Civil Engineers.—A list of subjects on which original communications are invited has been issued. It directs attention to the various trust funds, the interest on which provides the means of rewarding meritorious papers. The annual income derived from this source now reaches nearly 450*l.*, the whole of which is available for the purposes named, and with the exception of the Miller Fund and the Howard Bequest (which are restricted by the donors to particular objects) any person, whether connected with the Institution or not, native or foreigner, may compete. The students of the Institution are further eligible for the receipt of Miller scholarships and prizes for papers read at the supplemental meetings specially held for that class. The meetings were resumed on Tuesday, the 9th inst., when a paper by Mr. B. Walker, of Leeds, was read, treating of "Machinery for Steel-making by the Bessemer and the Siemens Processes." At the following meeting Mr. Seyrig, of Paris, will present a communication on "The Erection of Metallic Bridges."

Small Savings by Postage-Stamps.—From and after Monday, the 15th inst., at every Post-office in the United Kingdom, forms for the making of small deposits in Post-office Savings-Banks will be issued gratuitously. Each of these forms, which are about the size of an ordinary cheque, will have twelve divisions, in each of which a penny postage-stamp can be placed. When a form has thus been filled with twelve stamps, it will be received at any Post-office at which there is a savings-bank, as a deposit of a shilling. During the seven weeks that the experiment has been in operation in ten counties only, more than 14,000 of these forms have been received, and more than 7,000 new accounts have been opened through their agency. The arrangement promises to encourage thrift.

Improvements in the City, and Value of Property.—It has been some years in contemplation to form a new street leading from Monument-yard in a south-easterly direction into Lower Thames-street, coming ont opposite Billingsgate Market. The first instalment of this new road is now in course of formation, the purchase of a large warehouse situate at the corner of Monument-yard and Pudding-lane having been arranged between the Commissioners of Sewers and the Governors of Christ's Hospital, the freeholders of the property. The warehouse occupied about 3,480 superficial feet, and the price arranged between Mr. Haywood on behalf of the City and Mr. H. S. Legg on behalf of Christ's Hospital,—viz, 24,000*l.*,—has now been paid. A new roadway, therefore, is being formed on each side of the Monument, which joins at the back (eastwards), and then leads into Pudding-lane, occupying the site of the warehouse just mentioned, where, for the present, it will stop until funds are forthcoming to carry it on.

Accidents in Building.—On the 4th inst. Mr. St. Clare Bedford held an inquest at Charing-cross Hospital, as to the death of Henry Laurence Groom, aged 22. The deceased, a bricklayer's pointer, on the afternoon of the 1st inst. was standing on the end of a scaffold some 50 ft. high outside a building in course of repair in Old Compton-street, Soho, when he missed his footing and, falling to the ground, received injuries which resulted in his death soon afterwards. The foreman of the works, in reply to the Coroner, said that it was not usual to place pieces of timber to act as barriers at either end of the scaffold, although it could he done. The Coroner observed that the number of deaths from this cause was very great, and builders should take care to insure the lives of their workmen. The jury, in returning a verdict of "Accidental death," added that in future precautions should be adopted in order to prevent the lamentable loss of life so prevalent in building operations.

Albert Hall.—Arrangements have been made for the tenth season of the Royal Albert Hall Choral Society, under Mr. Barnby. The season was commenced on Thursday, the 11th of November, with a performance of Handel's "Judas Maccabæus," when the usual orchestra of 100 members was increased by the band of the Coldstream Guards. A grand performance of Mendelssohn's "Elijah" will be given on Thursday, the 2nd of December. Professor Macfarren's Oratorio, "St. John the Baptist," has been included in the programme, and arrangements are pending for a grand performance of Dr. Sullivan's new Cantata, "The Martyr of Antioch."

The Water Question.—At the Lamheth Vestry, Mr. W. T. Wiseman has given notice of a motion for discussion on the 18th inst., declaring further and immediate legislation is necessary respecting the supply of water to the metropolis and suburbs; that a special or royal commission should he forthwith appointed to inquire into and report upon the present and other available sources of supply; and that no legislation will he deemed satisfactory hy the ratepayers and water-consumers, unless it secures pure, full, and constant supply.

A Window for St. Alban's Abbey.—At a meeting of the Common Council last week, on the motion of Mr. Thomas Bedford, it was decided, "That this Court having resolved to restore the great east window in the lady-chapel of St. Alban's Abbey, and being desirous that the said window should he in every way worthy of the Corporation and of the magnificent building in which it is placed, agrees to fill the same with stained glass in the highest style of art, at an expense not exceeding 280*l.*"

Value of Land in the City.—The report of the special committee appointed by the members of Lloyd's to obtain the terms upon which the land situated at the north-west corner of the present site of Leadenhall-market might he purchased, states that the City Lands Committee declined the offer of 7*l.* 10s. per square foot for the area (about 33,000 ft.), equivalent to a total of about 247,000*l.* The City Lands Committee estimate the value of the land at about 350,000*l.*

London and Middlesex Archæological Society.—The Session for 1880-1 will commence on the 15th inst., when a paper will he read hy the Rev. F. C. Cass, M.A., "On the Battle of Barnet." The evening meetings will be continued from November to May, at 4, St. Martin's-place.

Builders' Benevolent Institution.—The thirty-third anniversary festival of this Institution was held at the Freemasons' Tavern on Thursday evening, Mr. Thomas F. Rider, president, in the chair. The gathering was a very successful one. Upwards of 250 of the friends of the charity sat down to dinner, and the subscriptions and donations announced reached the handsome total of 1,014*l.* 16s., of which sum the President's list (including 52*l.* 10s. from himself and 52*l.* 10s. from Mrs. Rider) accounted for 662*l.* 18s. We shall give a report of the proceedings next week.

Design for Battersea Bridge.—At a meeting of the Chelsea Vestry, on the 9th, it was moved hy Mr. Wheeler:—"That this Vestry is of opinion that the preparation of the design of the new Battersea Bridge should not he confined to the officers of the Metropolitan Board, but should he submitted to public competition, and that a copy of this resolution he forwarded to the Metropolitan Board of Works." The motion was, however, negatived.

Angle, Bulb, and Tee Iron.—Messrs. G. Bailey Toms & Co., of Laurence Pountney-hill, have issued an amended list of sizes of joist, channel, angle, tee, and fancy iron, which contains almost every section manufactured, comprising as it does between 1,200 and 1,300 sizes. It will he found of value to builders, engineers, and shipbuilders, when designing work, because it shows at a glance whether any section decided on is rolled or not.

Mr. Norton, of Old Bond-street, has been appointed Consulting Surveyor to the National Thrift Building Society, who have commenced business at 33, New Bridge-street, with a strong direction. The Society advertise a prize essay competition on "National Thrift," with prizes for the three best essays.

Royal Scottish Academy.—On Wednesday, at a meeting of the Royal Scottish Academy, held in Edinburgh, Mr. R. P. Bell and Mr. George Aikman were elected Associates of the Academy.

Balusters and Newels.—Messrs. Eberhard & Co., of Edward-street, Hampstead-road, have issued a new illustrated sheet of balusters, newels, and handrails, of superior design, and at prices that will compete with foreign manufactures.

Selwyn College.—It is stated that through the liberality of two donors, the building of the first block of Selwyn College, to accommodate sixty students, will soon he commenced.

TENDERS

For alterations and additions to West Hill Schools, Hednesford, for the Cannock School Board. Mr. B. Baker, architect, Willenhall. Quantities by the architect:—

Butler, Darlaston	£2,379	10	0
Tildesley, Willenhall	2,190	0	0
Punfield, Willenhall	2,173	0	0
Watton & Sons, Tamworth	2,163	18	8
Whittome, Stafford	2,149	0	0
Lovatt, Wolverhampton	2,109	0	0
Jones & Sons, Sedgley	2,095	0	0
Grosvenor, Stafford	2,070	0	0
Bedford, Wolverhampton	2,050	0	0
Bennett, Birmingham	2,033	0	0
Bradney & Co., Wolverhampton	1,993	0	0
Barton, Hednesford	1,994	0	0
Tesco, Darlaston	1,927	0	0
Guest, Stourbridge (accepted)	1,825	0	0
Tracey, Stafford	1,801	0	0

For additions to premises, Love-lane, City. Messrs. Ford & Hesketh, architects:—

Simpson & Son	£22,891	0	0
Colls & Sons	20,604	0	0

CONTENTS.

Architecture and Building in Cyprus.

THE use of *arconi*, or large pointed arches of stone, in place of ordinary beams or trusses, for the support of the floors of dwelling-houses, is a peculiar feature in the domestic architecture of the island of Cyprus. It affords a special motive for decoration, from the desire which is naturally felt to give relief to the large plain spandrels, undivided by panelling or framework, and uniformly painted white, which divide the arches. So universal is the adoption of this mode of structure that, even in cases where there is no abutment that can safely resist the thrust of a large arch, the form is imitated in wood, which is coloured to represent masonry. The arches balance one another, but tie-bars are never introduced. They are of pointed form, the span varying from 18 ft. to 30 ft., and the altitude varying from one-half to two-thirds of the width of the span. The mean depth of the voussoire, or rim of the arch, is from 12 in. to 16 in., and the thickness varies from 7 in. to 10 in.

The area to be covered by a building is divided into rectangles, of which the width is not more than from 9 ft. to 12 ft., by these *arconi*. Upon them are laid beams made of the wood which the island supplies, in the way of joists, about a foot apart, the ends being mortised together. On these joists is laid a parallel series of whole canes on a stratum of cane matting, covered with an inch or two of sand or fine gravel. On this a pavement of stone slabs is laid, set in mortar.

Another distinctive feature of the architecture of Cyprus is the rigid orientation of the buildings. In all cases where it is possible, the length of the building is drawn in a line from east to west, so as to offer one face to the north wind and another to the noon-day sun. On the southern exposure is generally placed a *loggia* looking out on a garden, and shaded by trees, chiefly the carnba or the lemon-tree. On the north are generally placed the various appendages to the main building. This rule is so rigidly observed, that where the streets do not run east and west, the ground-floor of the adjoining house is constructed parallel with the line of the street, but the remainder of the edifice is carried up at an angle, so as to secure the orientation of the walls; cantilevers or brackets being introduced where required, made of wood, and variously ornamented. Where the difference of line is very great, the change is effected by a series of steps. This curious method of building is also found to prevail in Alexandria in Egypt.

The use of these *arconi*, instead of the ordinary beams, is attributed by Signor Luigi (an engineer pupil, holding a travelling studentship, from whose report to the Italian Minister of Public Works we take the preceding details) to the absence of timber of a size sufficient to make large beams in Cyprus. In another part of the report this absence is attributed to the ravages of the Turks, who have cut down and devastated the magnificent forests which dotted the island before its conquest by those depredators. We need not say that the influence of the materials which a country yields on the art and architecture of that country (as to which a recent writer in an art periodical appears to consider himself to be the discoverer) is well known. If there be any want of just appreciation of the subject, it is mainly as to the very restricted local limits within which this influence often makes itself perceptible. Thus in that part of the Adriatic seaboard where a fine travertine is deposited by the streams, decorative sculpture blossoms on every house-front almost with the luxuriance of a growth of ivy. At a very short distance, in the hills, not a scrap of this rich decoration is to be seen. But the difficulty in the present case is to some extent that of date. We are not disposed to attribute the origin of the *arconi* to so late a time as the Turkish conquest. As far as we are in possession of data on which to form an opinion, it has usually been at a very early period in the art history of a people that their canons of structure were fixed, and no doubt fixed in accordance with the nature of their building materials. Thus we find wooden forms of structure made permanent in stone. Thus, even in the case of Cyprus, we are told of stone forms of structure being simulated in wood. The *arconi* of Cyprus might with far greater probability have been traced to the influence of Roman builders. Enormous structures at Rome, Verona, Capua, Posilippo, Pompeii, and elsewhere in Italy, yet display the lofty vaults on which the Romans of the Imperial times reared their theatres, their baths, and their palaces. But these Italian vaults and arches, so far as our present acquaintance with them extends, are semicircular. Nowhere in Italy, in buildings earlier than the Papal sway, do we remember to have found the *sesto acuto*, or pointed arch. Arabic or Moorish influence is rather indicated by the occurrence of this form in Cyprus. At all events, the assumption that the *arconi* are the natural outcome of the destruction of the forests by the Turks is one that we are not prepared to admit without direct and conclusive evidence.

The building materials of Cyprus, though marble has not been found in the island, are abundant and varied. There is a calcareous stone approaching the texture of chalk, which abounds in the chain of Cerigne, the northern of the two ranges which traverse the island in an easterly and westerly direction, of a grey colour; which is sufficiently compact, as well as being of fine grain, to be made a substitute for marble in work which is not subjected to the weather. It is, however, difficult to obtain in large blocks, and suffers much if exposed. A material in more common use is an eocene sandstone, of yellow colour and fine grain, which is said closely to resemble in its appearance the well-known eocene limestone of the Paris basin. This occurs in regular beds of from 16 in. to 18 in. thick, sometimes, though rarely, attaining the thickness of 3 ft. It alternates with strata of very friable stone, and is obtainable in any required dimensions by the use of wooden or iron wedges. Powder is not employed in quarrying it. When first extracted, it is very soft and very easily wrought. It is capable of receiving ornamental and very delicate work, and hardens as it dries on exposure to the air. Its chief defect is that it cannot resist frost.

The most abundant building material in the island is a shell-bearing conglomerate of the quarternary period, which occurs in very regular beds in the neighbourhood of the sea. It is formed of fine sand, small pebbles, and a large number of small shells and their *detritus*. It often contains fragments of coral. It is easy to work when first quarried, though not so much so as the previously-described stone. It is of a fine yellowish-brown tint, and its effect in structural harmony is very good. Most of the architectural monuments of Cyprus are built of this stone.

Amongst these buildings may be named the tower of Commenda, the cathedral, the Palace of the Knights, the wall of Nicosia, the abbey of Lapais, the castles of Kantara, Buffavento, and Saint Ilarion, which crown the three highest peaks of the Cerigne chain of mountains, and all the Gothic architecture of Famagosta. The latter, very delicately wrought, shows the admirable durability of the stone, which has been tested by the lapse of five or six centuries. A proof of the estimation in which this stone is held is afforded by the fact that the castle of Buffavento is constructed of this material, quarried on the shore below, although the peak on which the castle stands is formed of the Jurassic limestone. At present this stone is but little used in building, as the houses are generally constructed of sun-baked brick. It is used for voussoirs, mouldings, &c., and in the rough state costs from 7 to 8 francs per mètre cube, or from 2½d. per cubic foot upwards.

The lime of Cyprus is of indifferent quality. It is furnished principally from the chain of the Cerigne mountains. Lime was recently produced by burning pieces of marble found in the ruins of the ancient cities of the island, but that kind of vandalism is now forbidden. Kitrea is the district which now supplies the whole of the island with lime. It is irregularly burnt, and not good, though it is slightly hydraulic. It

costs from 10 to 12 paras the oca, which is equal to from 1s. 3d. to 1s. 6d. per hundredweight. Little use, however, is made of lime in domestic buildings.

Cyprus is famous for that form of sulphate of lime which the Italians know by the name of *gesso*. It is found in abundance in the white marl, which forms the soil of half of the island. It occurs in many varieties, and of a texture that is either compact, laminated, tabular, crystalline, or fibrous, the latter kind being the most pure. The tabular *gesso* readily divides into flags of large size, and is in use throughout the island for pavements, steps, window-cills, facings, &c. The pavements of this material are more durable than would at first appear to be the case, in consequence of the Oriental habits of the islanders, in the way of wearing slippers, and of covering the floors with carpets or mats. This tabular *gesso* is quarried in the open air by means of long wedges, dividing the block into prismatic masses, which are then split into layers. These are afterwards squared, and roughly dressed. Large quantities are produced at Pyla, Ipsos, Caclia, and Macrassica, and they are exported to Syria and to Malta. They are generally from 18 in. to 2 ft. wide, and cost from 7½d. to 8d. per square yard. Compact, granular, and laminated *gesso* abounds at Ipsos, Lessi, Aradippo, Athiena, Larnaca, and Nicosia, and is used for plaster. The "lance-head *gesso*" yields an excellent scagliola, and is found at Pyla and at Ipsos, but in small quantities.

The burning of the *gesso* is effected in the most primitive manner. The stone is placed in conical heaps of two yards in diameter, and a yard and a half high, a cavity being left in the midst, which is filled with roots or brushwood, that yield more smoke than heat. Thus the stone becomes blackened, and irregularly burnt. When burnt, it sells at from 3 to 4 paras the oca, or from 4½d. to 5½d. per cwt. The quality is excellent, and, with more careful preparation, it might be exported in large quantities.

Cyprus abounds in good clay; and excellent bricks are made at Nicosia, Larnaca, Mazoto, Arposa, and Limasol. The clay is mixed as is customary in Europe, and the bricks are burnt in clamps, the fuel being roots, cotton stalks, and brushwood. They have the same dimensions as Italian bricks, and cost from 16s. to 20s. per thousand. They are, however, but little used, the Cypriots preferring to use sun-dried bricks, which, owing to the dryness of the climate, the great heat of the summer, and the low height to which the houses are reared, answer very well. These bricks are made of sixteen or eighteen parts of brick earth, mixed with one part of straw. They are made in moulds measuring 16 in. by 20 in. by 25 in., and are laid to dry on a floor exposed to the sun for ten or fifteen days. They attain a respectable hardness and durability. Sometimes sea-weed (*alga marina*) is used in the composition instead of straw. A man and two boys will make as many as 1,000 of these bricks in a day. The cost is from 12s. to 14s. per thousand.

Finer clay, fit for pottery, is also found in the island. Larnaca, Limasol, Lapisthos, Varostra, and Como are the localities in which pottery for domestic use is made, as well as water-pots for irrigation, and pipes for the conduct of water. The utensils are well made and properly burnt; but they are wanting in elegance, and are but rarely glazed. Fine clay, fit for plates, tazze, and similar objects, is found near Carpazo, but in quantities so small as not to cover the cost of working.

The ordinary houses of the peasantry, consisting of one or two rooms, are built of these sun-dried bricks, and thatched with straw. But they are not ill-adapted to the habits of the people, and are especially calculated to resist the torrid heat of the insular summer.

The bettermost houses are built on foundations of stone set in the lime of Kitrea, which is slightly hydraulic, mixed with sand, and with Italian pozzolana. The lime is allowed to slake by exposure to the air; it is used in the state of powder. The depth of the foundations is small; from 18 in. to 4 ft. 6 in. below the surface of the soil. The thickness of the foundation varies from 2 ft. to 2 ft. 6 in. For houses of a single story the foundation is carried up for 18 in. or 20 in. above the ground. For houses in two stories, the walls of the lower plane are built in masonry, at least as high as the upper cill of the windows. Above this the wall is carried up with a thickness of from 18 in. to 21 in. of sun-dried bricks, set in clay and straw. The bricks are laid so as form the thickness of the wall by their length, and are rapidly set by eye. The joints are never more than 4-10th in. wide. It is rarely the case that either plumb-line or level is used by the builders. The work is roughly done, and it is much if the angles of the building are vertical.

A bricklayer, with two boys, will lay from 500 to 600 bricks in a day, making from 7½ to 9 cubic yards of work. The construction is carried on in layers of from 6 ft. to 9 ft. deep, each layer being left for some days to dry before a new one is added. The wall, when finished, is plastered over without with a wash of clay mixed with straw, or clay and tow, and within with lime-wash, or a thin layer of *gesso*. The outer coating has to be renewed every third year, as it suffers from the rain. The material for coating the walls is supplied to the workmen in the most primitive manner, being made into a ball, and thrown from hand till it reaches the man who has to spread it.

The doorways are from 3 ft. 3 in. to 6 ft. 3 in. wide, and the windows from 3 ft. to 5 ft. They are always provided with a wooden cill. Above they are covered with slabs of stone or of *gesso*, or with wood. In the latter case relieving arches are turned above the architrave. The cost of the *arconi*, of which we have already spoken as supporting the floors, is from 10d. to 1s. per foot of span. The material of which these arches are built is generally the yellow tertiary sandstone, before described, which is called *macigno*. The roofs are formed in the same way as the floors, but with a slope of from 7 to 1 to 10 to 1. It is rarely the case that ceilings are introduced. The framework of the doors and windows is of the rudest description, and is only endurable in consequence of the warmth and dryness of the climate. Glass is used in the windows, in the better class of houses, but it is not so fixed as to close the apertures against draughts. Sometimes the window-frames are painted; but they are generally merely rubbed with oil so as to show the graining of the wood.

The kitchens are unworthy of the name; the fireplace consists of a bench of masonry with two or three *fornelli* (little vertical holes), never provided with top or chimney. The smoke spreads freely in the air, and escapes through small holes left in the walls near the roof. Chimneys are unknown. Signor Luigi says that he did not see one in Cyprus. The ovens are very simple. They are of an internal diameter of about 30 inches, and are built of sun-dried bricks, set in clay and straw. They are extremely economical, both as to their first construction (costing from four shillings to five shillings each) and from the small quantity of fuel which they require.

All the houses are provided with wells, of from 32 in. to 40 in. in diameter, and from 10 ft. to 33 ft. in depth. Beneath an upper stratum of compact clay, or of soft conglomerate, occurs a water-bearing sand, more or less compact. The water is not always good, being often charged with salts of soda and of magnesia.

The wells are sunk by two men, one digging, and the other removing the material. In a day they will sink from 6 ft. to 9 ft. It is rarely the case that any lining is used, a dwarf wall round the aperture being the utmost finish that is usual. The cost of these wells varies from 10 francs for a depth of 3½ mètres in compact clay soil, to as much as 60 francs for a depth of 10 mètres in hard conglomerate.

In the principal towns, Nicosia, Famagosta, and Larnaca, in addition to private wells and public fountains, fed from connected wells, vertical shafts are sunk into the water-bearing stratum, from 5 to 10 mètres apart, and are connected by little tunnels, 3 ft. wide and 6 ft. or 7 ft. high, directed as nearly as possible according to the dip of the subterranean water surface. They are placed so close together, not for the sake of increasing the water yield, but for the guidance of the workmen, and the sake of ventilation in excavating the tunnels. The tunnel is commenced at the lowest point, and runs upwards. As little rise as possible is given to it, and masonry lining is very seldom used. The cost of this work, including shafts, tunnel, and what little masonry used, is from 50 to 80 francs per mètre run of tunnel. The canal is continued in the open, the sides being walled, and rendered with a mixture of lime and earth which forms a sort of hydraulic cement, and the conduit being supported by embankment or masonry where the ground requires. At Nicosia at the present time iron tubing is being substituted for the ancient conduits in masonry.

ART COMPANIES (LIMITED).

For some time past there has been an increasing tendency on the part of the public to take their artistic taste and opinions, as Mr. Justin M'Carthy says, in his "History of Modern England," "in platoons," in the same way that Charlemagne's converts got their Christianity. People have been impressed with a considerable desire to have furniture that is in good taste, coupled with an inability or disinclination to give any thought of their own to it, or to exercise any individual taste. Thus the purveyors of furniture of all kinds have had very much their own way of it: they have engaged artists, have had furniture and upholstery designed in what was recognised as the taste of the day, and some of the leading firms dealing in this class of work have become practically almost purveyors of taste for the public, and have been half-unconsciously accepted as such by the latter. This unsatisfactory and half-understood way of doing the business is, however, no longer to be tolerated. If a thing is right to be done at all, let it be done openly and thoroughly. If art can be furnished retail, why not wholesale? Accordingly we have before us the prospectuses of two Limited Companies, the object of which is to purvey artistic taste for the public at large.

The "Furnishers' Alliance Company," with a capital of 50,000*l.* in 10,000 shares of 5*l.* each, is under the artistic superintendence of Dr. Christopher Dresser, whose knowledge of decoration, theoretically and practically, is not to be questioned. The company undertakes to supply the general public with artistic house-furnishing requirements of the best description, including furniture, carpets, wall decorations, hangings, pottery, table glass, silversmith's wares, hardware, &c., to meet the "unprecedented demand for artistic objects" which "the advanced standard of public taste during the last few years" has created. The whole direction and the selection of goods is entrusted to the eminent authority above named, and we are assured that "no object, whether an important work or a mere adjunct of furnishing, will be displayed unless its art qualities have been duly tested; the public will thus have an absolute guarantee that every article sold, whether costly or cheap, will possess intrinsic art merit, as regards its originality, design, and execution." By what process the art qualities of any object are to be "tested" we are not informed; but no doubt we are behind the age. There is evidently some new process of what may be called æsthetic chemistry invented, to which each object will be subjected for quantitative analysis, and we may expect, when the new establishment is in working order, to see the objects that are offered ticketed with the result of the analysis, as thus:

Form	33·715
Colour	41·23
Æsthetic correctness and suitability	25·055
	100

Thus, it will be possible for the public, by a simple process of addition, and by due observance of the figures representing each quality in the article, to obtain by precise analysis the special art-quality they want; at least, so we conclude from the terms of the prospectus.

The other company, "The London Decorating Company (Limited)," issue a prospectus which, on the outside of it, is more obviously and ostensibly an art scheme, seeing that it has a "picture" on the back of three allegorical figures with a decorated wall behind. The art department in this company is under the directorship of Mr. Walter Crane, from whose pencil we may presume there came these three figures of young women typifying Science, Art, and Health, the latter, we observe, turning her back on the spectator, perhaps a delicate allusion to the difficulties in the way of our health caused by fog and smoke, of which we are having more than usual at present. On turning to the prospectus, however, we find that health takes a rather prominent part in the society's scheme, which seems to have arisen out of an idea of extending the business of a certain Stone Paint and Protective Liquid Company, which has been taken over, so as to make it include the provision of artistic decoration also. This way of putting it gives no doubt a sort of practical status to the company, though, in the end, we presume it is pretty much the same thing as the other, and that the object of both is to

turn to commercial account the now-prevalent fashionable turn in favour of what is called art-furniture and art-decoration. As far as the practical side of the matter is concerned, the company's prospectus is satisfactory and sensible. They observe that many processes and materials used in decoration are known to be injurious to health, that scientific men are constantly recommending important and valuable processes, which the trade would gladly adopt if the necessary materials were provided through the several channels; but that scarcely any one knows where they may be obtained, and that sometimes they cannot be obtained at all; that means, we suppose, that they cannot be obtained consistently with commercial conditions. The London Decorating Company undertakes to purvey for and supply all such materials and processes, in regard to which they will be advised by Mr. Crookes, F.R.S., who will supervise the chemical tests and processes employed to secure that the paints, paper-hangings, and other materials, shall be free from poisonous or injurious qualities. So far so good. That is a process which a company under the advice of scientific experts may very well and usefully perform, and the company show considerable generalship and perception of what is likely to "go down" in thus emphasising the health part of their scheme. And in regard to the art part of it, the company are at least wisely reticent in not offering to supply any "test" of artistic quality. They also state that other artists and designers of high standing will be associated with the company, "so that all styles of art may be readily available," and, so far as the wording of the circular goes, it would appear that the customer in special cases may even be allowed to select his artist, though the indications on this head are somewhat vague. In other cases, where the work is not of a highly important nature, and where the customer does not want to spend more than he can help, a schedule of questions will be sent, the answers to which "will enable the artist to select a suitable design from the standing designs of the company, which will be numerous and regularly increased."

Now what does all this really mean? Of course, in the first instance, it means that the promoters think they have evolved a good investment for money, and expect to make such company a paying concern. That is the way in which we have come to look upon art, then, as a thing to be "exploited" for the benefit of shareholders. This is certainly not a very high view to take of the matter, to begin with. But the essential fallacy of both schemes is contained in the preposterous idea that art can be produced wholesale by a company, in the same way as patent locks or any other article of household furniture. The last-named company, as we observed, have sense enough to be a little reticent on this point; but they hit, without knowing it, on the real objection to their scheme in their way of recommending their art-director, "whose pictures are so familiar to every cultivated household." Just so. The type of art which is represented, and well represented, by the work of Mr. Crane, is what it is the fashion to admire, and "cultivated households" are those which believe in this type of art, and fill their houses with it. Those who do not are, we presume, uncultivated households. This is a most delightful begging of the whole question. We know a good many cultivated people who do not think so much of this type of art, of mere lank conventional figures all with the same expression; but the company would be ready, of course, to answer any argument against the fashionable form of decorative art by the simple and, we admit, entirely unanswerable retort that those who do not care for it are not cultivated. But the fallacy of the whole scheme lies in the radically false idea that art, which is to be of any value, can be produced wholesale to order, and of any pattern. What makes artistic design of any value is the presence of individual thought and individual style and expression; and the influence of such companies as we have referred to will be, must be, to stifle still further the influence of individual taste, and to reduce decorative art to a mere dead fashion followed for fashion's sake. Such schemes, if they succeed and acquire large public patronage, will put the finishing touch to the absurd affectation which has recently possessed the public mind of having all their houses decorated in a certain prevalent fashion, all their furniture made according to what are supposed to be "art" patterns. Go into house after house, and you find the same style of furniture and wall-papers, selected, not as the result of individual preferences arising out of the taste and study of the owners, but as what "art-furniture" firms are now making, and in regard to which anything that can really be called art or design really enters about as much as it enters into the tailor's consideration of the cut of your coat,—as much, but not more. People are encouraged to think themselves artistic because they use this type of furniture, when in reality they are simply following a precedent; and it is well known that some of the most prominent decorating firms will not even allow a customer to have a taste of his own, and will tell him so broadly, or hint almost as plainly that he must take what combinations they think best. No really "cultivated" person would condescend to give up his own tastes in this way into the hands of an art-upholsterer for a moment. But now we are offered schemes which will reduce all this affectation and pedantry to a wholesale system. The work of the individual artist, which, even under the present retail system of art-furnishing, is usually quite lost under the name of the "firm," would now (should these schemes succeed) be yet more surely swamped, and what is called "art" would be regarded as a form of goods to be produced wholesale to order from a manufactory. To all people who have any wide "cultivation," any insight into what "art" really means, and what makes it worth having or caring about, the mere statement of the case would be sufficient to show its absurdity. To those who choose to embark capital in such a speculation, we have, of course, nothing to say; that is their concern, and if they believe that the public have arrived at that state of "gulliability," in regard to æsthetics, that will induce them to believe that they can buy art at an art-shop, let them go in and win by all means, only do not let them pretend to pose as promoters of art or of artistic education. They have just as much right to such a standing as a company would have who, if there should arise a great fashion for one particular school of painting, say the Dutch, should open an establishment for providing an unlimited number of pictures in the manner of Teniers or Ostade. Decorations are a less important, and in some sense less intellectual, form of art than pictures, but what holds good in respect of one branch of art holds good in all. "Parroting" is of no real value; individual genius and thought working in reference to nature and to natural principles is what makes art, and nothing produced by rule and on a system can be of any value; and our advice to those who are attracted by such schemes is to consider a little what art really means, "to beware of spurious imitations," and not to allow themselves to be gulled into imagining that art can be turned out to order from an art-mill, in any quantities, like so many bales of Manchester goods.

BEWICK'S WORKS.

The exhibition of a number of Bewick's original water-colour studies for his subjects, along with impressions of the engravings from them, at the Fine-Art Society's Galleries in New Bond-street, will probably bring a good many of the general public who visit it to a first idea of the nature of Bewick's genius and the character of his work. Familiar as his name is to all who are especially interested in art, we suspect that to the outside circle it has been often little more than a name, and in some cases not even that. The exhibition of some of his works collectively ought, therefore, to be very useful, and we trust it will receive the attention it deserves, though it is a great pity that works of so minute and delicate a nature should not be examined under a better light than is to be found in the small front room in which they are exhibited.

The exhibition has been rendered possible by the liberality of the Misses Bewick in lending a large number of their father's drawings and engravings. The catalogue *raisonnée* offered to visitors gives a sketch of the circumstances of the artist's life, with comments on the drawings, which last are much too wordy and pretentious, and in some cases utterly absurd. The rage for deluging people with reflections on the works of art which they go to see is becoming a positive nuisance and impertinence, and ought to be checked. Nearly three pages of "gush" are offered to the holder of the catalogue in regard to the one little tailpiece of men shooting in a snow-covered landscape, with the usual cant phrases about "wealth of conception," &c., and with discoveries as to the meaning of this and that detail in the landscape which would probably have very much astonished Bewick if he could have read them. In the middle distance of the landscape is a rail-fence half-seen above the snow, a very small incident in a very small work; but this is how the critic fastens on it:—"The upright posts of the fence have individuality; thus the inequalities in the distances between them tell that the carpenter who set them up considered as he went on, but not before, how the line was to be spaced out and his material economised; again, some of the posts have, more than others, yielded to the weather; some posts have sunk or gone away in bad foundations or soft ground, and, as the circumstances compelled, sloped to the right or left." Wonderful! One would suppose that a dilapidated post-and-rail fence were one of the most unusual and significant objects to be seen in the world. In regard to another drawing, representing an old decayed boat, we are called on to admire "the dexterity which so deftly foreshortened the broken planks and battered ribs," as if artists, as a rule, did not attempt to draw in perspective; and we are told that "each plank has a biography in these details." The drawings are both admirable specimens of Bewick's peculiar qualities, but to have this kind of rant about them put into one's hands is enough to disgust amateurs who have any remnants of common sense left in their composition.

No one can look over this collection of drawings without being sometimes reminded of Hollar, of whose works a large collection was exhibited in the same gallery not very long since. Like Hollar, Bewick delighted in finishing with the most minute realism small objects which gave occasion for the display of the highest technical qualities of execution; Bewick usually chooses feathers for this kind of study, Hollar liked nothing better than shells, but also expended his skill on such things as muffs and other small articles of dress. Like Hollar, also, Bewick's skill seems to have been occasionally employed in the production of work of a strictly business nature; for the exhibition includes two bank-notes of North-country banks, engraved by him. He does not appear to have got through, however, anything like the enormous amount of work achieved by Hollar; and, on the other hand, he possessed powers of imagination and invention of which Hollar has left no indication. His head and tail pieces, by some of which he is most widely known, sufficiently indicate this. Small as they are, they exhibit humour, pathos, and a very close study and perception of human character, and of the action both of men and animals. There could not be a better illustration of this last quality than in the cut in which a mastiff is about to fly at the throat of a man: the energy of the dog is quite alarming, and the action of the man holding his stick with both hands across his chest as a bar to protect his throat, is just as real and natural. Another remarkably good one is that of a pack of boys run away with in a cart, the horse of which has started off, reins on neck, while left alone by the carter, who is running after him; the helpless condition of the occupants of the cart, holding on to its front and sides (one having been already thrown out), is most amusing; and we can fancy that such sketches are merely the transfer to paper of incidents witnessed by the artist in his Northumbrian village.

The comparison of the water-colour studies with the engravings in nearly all of this class of pieces is very much in favour of the engravings. In fact, in these cases the drawings are almost obviously finished just sufficiently to afford a good copy to work from, and many details in the engravings are not in the originals. In most cases the sketches have been copied the direct way on the blocks, and the impressions are therefore the reverse way. There are certain things which Bewick is not very successful with in the drawings, and sometimes in the engravings also; for instance, his drawing of water is mannered and deficient in variety. In one subject, representing a man fishing in the middle of a stream, it is curious that in both the original sketch and the engraving occurs the same oversight; the reflection of the figure, which is swayed rather to one side in attitude, is continued in the same line in the water instead of being reversed. It may, perhaps, be said that in the matter of reflections in water it is more often possible to catch good artists tripping than in anything else in nature. In looking

over the collection one cannot but note the rather frequent recurrence of snow pieces. In one of these, which are all beautiful in their way, it is noticeable (in the one numbered 50) how delicately the effect of the shadow on one side of the furrows of a snow-covered field is given; you can see that it is shadow on snow. The serious moral element in many of these little pieces,—serious in intent even when half-comic in expression, is of course not to be overlooked; among the most noteworthy examples are the wooden-legged soldier shaking hands with his old friend the bricklayer, whom he finds still whole and hearty in his native village to which he has returned aged and maimed (Bewick was a strong anti-"Jingo"); and in a more satirical vein the sketch representing the devil swinging himself easily on a gallows and contemplating the church in the distance.

In the case of the bird subjects, the original drawings are much more elaborate and highly finished than those of the imaginary pieces, for obvious reasons. These were accurate realistic studies, made as guides to the engraving of subjects which could not be kept long enough to serve as direct models for the lengthy process of cutting the block. In some few cases the coloured drawings are superior to the engravings, but not often; when the engravings are inferior in one point they often show superiority in another. Bewick's power and finish in the use of colour are however remarkably exemplified in many of these water-colour drawings of birds, and as these, of course, are not familiarly or generally known, they add very largely indeed to the interest of the exhibition. In the engravings, as many of our readers know well, the most remarkable characteristic is the softness and delicacy with which the texture of feathers, and their manner of growth, are represented, sometimes in a manner which seems to an ordinary eye quite incompatible with the stubborn and mechanical process of wood engraving. And in fact these works do represent what is very exceptional in the art, and what it would be impossible to get now, the characteristic touch of a master who gave a meaning to every stroke, and did everything (in his best works, at all events) with his own hand and eye. Wood engraving has become so comparatively mechanical now, that this delicacy of touch and style is not to be had at any price; the artist who might have engraved in this style in Bewick's day would now give himself to etching, and in all probability Bewick himself would have been an etcher had he lived in our day. Wood-engraving has, owing to great demand, sunk into a kind of popular art supplying reproductions speedily for popular taste; and the result is, that the highest class of artists who deal in reproducing processes at all have come to think lightly of engraving, and to make it a point of honour to give the first place to the needle and the copper as the only reproducing process worth the attention of an artist of the higher class. This is in some sense a very undesirable conclusion. Wood-engraving is a type of work much more easily reproduced and multiplied than etching, and is, *pro tanto*, the more valuable, if it be thorough individual artist's work in the first instance. And Bewick's wood engraving is so. No one could pretend to place the value of these engravings lower, in an artistic point of view, than it could be if they were etchings, and their practical value is greater. The impressions from them have been more numerous and more perfect than etchings on copper could have furnished. The difference is, that artistic work on wood is more laborious, and claims more time and pains from the artist, than the freer method on copper. But Bewick's engravings prove that the artist's feeling and touch may show itself on wood as perfectly as on copper, granted that the artist is willing to bestow the labour. Let him be willing to do so, and wood-engraving takes its old place as one of the finest of the reproducing forms of artistic work. That is the lesson we read in Bewick's engravings.

A Testimonial consisting of a centre ornament in silver, two dessert stands and salver, was presented on the 16th inst. to Mr. Thomas Hawksley, C.E., F.R.S., by the directors of the Nottingham Waterworks Company, in acknowledgment of his services as their Engineer-in-Chief, from the commencement of the undertaking, A.D. 1830, to the dissolution of the company, A.D. 1880 (a period of fifty years). The testimonial was designed and executed by Messrs. Hunt & Roskell.

DEPUTATION TO THE ADMINISTRATION ON THE FLOODS.

THE FIRST PRACTICAL STEP TO BE TAKEN.

The large and influential deputation which, on the 12th current, had an interview with the Chairman of the Local Government Board on the subject of the recent floods, was an example of a non-political public movement of no small importance. It is needless to say how thoroughly we sympathise with the object of the deputation, and with the appropriate tone in which Mr. Dodson replied to their remarks. The subject of the interview, as our readers are aware, is one to which, from the very first installation of the Local Government Board, we have not ceased, as occasion arose, to call the attention of the Government and of the public. On the present occasion, men of the highest position, as territorial landowners, and as public men, spoke of the enormous damage which, with much other waste of public money, might have been altogether averted, if our representations as to the primary need of a hydrographic survey of England had received the attention which we venture to say they deserved.

The Duke of Bedford, whose very name suggests the honourable association of the former members of his house with the great work of reclaiming the fens, introduced the deputation. The Speaker of the House of Commons, as member for Cambridgeshire, said that the question "was not only one affecting Cambridgeshire and the Levels, but that the rivers of every watershed throughout the kingdom are interested in the matter." Mr. Magniac, M.P., speaking as representing the town of Bedford and the County of Bedfordshire, "knew of tens of thousands of acres that were practically under water. One farmer he knew had not seen a large portion of his farm for two years, though he had to pay rent for it." The removal of mills, Mr. Magniac thought, would be a great benefit to all around. Mr. Palmer, Q.C., M.P. for Lincoln, said that district had suffered more than almost any other place in the country. Mr. Cope, of Huntingdon, spoke of the ravages committed by the Ouse for the last three years. In this valley alone the keep of 30,000 cattle had been destroyed, and the fertility of the soil permanently deteriorated. The death-rate had nearly doubled in the town of Huntingdon, and in the surrounding villages many persons had been obliged to live all the summer in the upper rooms of their houses, to which they obtained access only by boats. The Marquis of Huntly suggested the vesting the control of the watershed of rivers in one managing body. The Earl of Jersey called attention to the floods of the Thames. Other gentlemen spoke of the inability of the inhabitants of any of the districts affected to protect themselves, unless provision was made by new legislation for the comprehensive treatment of each watershed taken as a whole. We cordially endorse every word above cited.

Mr. Dodson, in reply, expressed his entire agreement with the sentiments expressed by the deputation. He commented with satisfaction on the general accord in the view that the inhabitants of the various districts would be prepared locally to effect the regulation of the river courses, if they were authorised so to do, by a measure which would treat each river system as a unity, and spread the cost only over the whole area affected. He also collected from the deputation that the increase of land-drainage was one of the causes to which the more destructive nature of floods was to be attributed, and promised to lay the whole matter before his colleagues. The speech of the right honourable gentleman was manly, statesmanlike, and to the point.

There are three highly important matters bearing on this difficult subject which were not touched either by the speakers or the President of the Local Government Board. The first is that the recent increase of damage from floods is not peculiar to England. It has been felt, and that most disastrously, in France, in Italy, in Hungary, and elsewhere. The Rhone, the Po, the Tiber, the Seine, the Danube, and other great rivers, have spread desolation over their banks. But the Governments of France, of Italy, and of Austria, have seen the threatened extent of the evil, and the responsibility under which they lay to meet it. In every case they have called in the best services of the most eminent men. They have named technical commissions; they have obtained exact hydrographic surveys of the river courses; and they have adopted well-considered measures for the protection of the country. Great works have been executed, others are in progress, or under consideration. In each of these countries the engineer has been set to work by the Government to protect the country.

The second point (which compared to the others is almost a bye) is, that although the draining of land tends to bring down the floods more rapidly than heretofore, the volume of water that is carried down is more increased by the destruction of timber and cover of all kinds than by any other cause. When the hills have been stripped of trees, what were formerly beneficial rivulets, of constant flow, are converted into destructive torrents, dry as soon as they have ceased to do damage. It may be difficult to point, in this country, to wholesale destruction of cover such as is to be seen on the slopes of the Apennines, but the steady warfare which the farmer has been lately taught to wage against hedge-rows, coppices, standing timber, and wood of all kinds, is to a great extent a cause of destructive flood. In a properly-sheltered and partly-wooded district the effect of vegetation on the rain is threefold. It entangles it in its fall, absorbing a considerable portion, and converting it into vegetable tissue; it evaporates a much larger portion from the enormous evaporative surface of branches and leaves; and it retains yet another portion, until it sinks into the soil (instead of at once running off the surface), by the entanglement of roots, stems, and moss. By this compound action, every tree and every hedge is a storm regulator. By cutting these down, and exposing enormous areas of undivided arable land, to sun and wind, the hygrometric character of the climate is changed, the permanently productive character of the soil is injured, and the floods are doubled or trebled, not so much in velocity as in volume. Any one who doubts this should read the reports addressed on the subject to the various Ministers of Public Works of the Governments we have cited.

Thirdly and lastly, and quite independent of any legislation as to water-shed boards (desirable as such a measure is), the first, foremost, and *sine qua non* condition of any effective action in the matter is a HYDROGRAPHIC SURVEY. Have we any need, after citing the remarks of the deputation, to reproduce our former arguments on this score? Can there be a moment's doubt about it? Are we to remain the only people in civilised Europe among whom, if a question is asked as to the volume of any of our rivers, the only reply that can be given is, "It is unknown"? Such is now the case; and whether commenced by Government as a necessary part of the Ordnance Survey, or whether inaugurated in detail, water-shed by water-shed, such a Survey is necessarily the first step to be taken to prevent floods. The deputation do not seem to have been accompanied by an engineer; but we cannot doubt that men of their eminence,—peers, members of the House of Commons, and large proprietors,—can only need to have this fact called to their attention to see that the Survey must be the first step to dealing with the floods.

THE PLUMB-RULE AND LEVEL, AND THEIR LESSONS.

In a preceding issue we gave a brief description of an improved plumb-rule, the invention of a building workman, and we hope that the instrument will be found generally useful; for there has been for centuries a need for the introduction of a compact, correct, and more ready instrument than the one in use. The plumb-rule, in its true construction, application, and proof, has furnished more than once a theme for a technical lesson or lessons in technical education for workmen in the columns of the *Builder*. One or two instances, among others, may be worth recalling. In 1871 the present writer published a sketch in these pages, entitled "How do you Prove your Plumb-rule? A Technical Lesson," which elicited other articles and communications from artisans and others on the "Technical Education of Workmen," some of them bearing directly on the plumb-rule and geometrical lessons involved in the application of workmen's tools. One of the most interesting of these communications was from the pen of poor "Jack Plane" (the late Mr. Randall), who died shortly afterwards through an unfortunate accident met in pursuit of his trade. The *nom de plume*, "Jack Plane," often occurred in

these pages previously to the date of his decease, and it were to be wished that we had in our midst many such intelligent and practical-minded working-men as the carpenter contributor of the *Builder*. "Jack Plane" well knew that every stroke the carpenter and the joiner take at their work is either a line, a square, or a circle, and that their daily labour is with the rule, the square, and compasses. Consequently, every part of their work is a lesson in geometry demonstrated before their eyes, and yet many of them remain unconscious of the facts or incapable of properly understanding them.

Now, the plumb-rule is a very simple instrument, and any man that ever handled a saw or a plane without being a mechanic considers himself capable of making one. Indeed, building workmen themselves think little time or care is necessary to construct one, so they are often constructed accordingly, and proved in rule-of-thumb manner. They vary in length and breadth, and betimes in thickness of scantling, according to the work they are intended for, or the usage they may be or are likely to be subjected to. Some workmen take a little pains in making one, and finishing it with a little taste, and with certain adjuncts when they intend the plumb-rule to last more than for a temporary job. A plumb-rule as ordinarily made, say, is a piece of a deal or pine leaf from three to four or more feet long, and from five to six or more inches wide. It has a pencil or otherwise a cutting gauge-line down the centre of its width, and three saw kerfs or notches in its top end, the middle one being in a line with the string-line, and those on either side, which are cut mostly oblique, being intended for fastening purposes, when there is an overplus of bob-line, the overlength being pressed into these side notches once or twice, and should any small overlength remain after adjustment it is allowed to drop behind. On the face of the plumb-rule, near the bottom, and centrally, a hole is cut of an egg-oval shape, for the play of the leaden "bob," which latter is about the size of a hen's egg, but rather more pointed on its top side. In a proper plumb-rule the string is made to pass directly through the elongated thickness of the "bob," and knotted at the bottom. On the face of some plumb-rules, immediately above the "bob"-hole, a fence is placed of a segment or looped shape, intended to confine the string and bob within reasonable limits and render it the sooner adjustable when required; for what is technically known as "killing the bob," or bringing the bob to hang without swinging or swaying more than is needed, has to be resorted to by the adjusting hand of the operator. To the uninitiated our description of an ordinary plumb-rule may appear somewhat complex, and it may be thought that the surroundings of the instrument are not so very simple after all, but the sight of the instrument itself ready for use, or in use, will at once show that the instrument is simplicity itself, as far as its construction and application are concerned. The defects of the ordinary plumb-rule are chiefly those connected with the attaching string, which twists in wet weather and breaks in dry, though in dry and wet, when used in outside building work, there is a constant wear and tear through fraying and unravelling, which, independently of breaking, renders a new string often necessary. It might be thought that the ordinary defects of the plumb-rule would have long since prompted some building workman to invent a new form of instrument, but the immemorial one being so readily constructed, and costing so little, and being at the same time so approximately accurate for all the practical purposes of building, workmen have gone on contentedly using it, never dreaming of, or perhaps seldom or never wishing for, a better instrument. We ourselves suggested several years ago the construction of a somewhat similar plumb-rule to that now introduced by Mr. Ryan, a weighted metal rod, hung in pendulum fashion, fixed in a groove or slit centrally on the broad face of the plumb-rule. But it did not take practical form. Many other matters since have occurred, knocking states and buildings out of perpendicular, and we have been obliged to move on with the instruments to our hands.

In making a wooden level or levelling instrument, the building operative proceeds on similar lines to those adopted by him with the plumb-rule; for the level in form is in part a plain rule, with its string and bob, though it cannot, as made, be applied in a perpendicular direction. Bricklayers and stonemasons, and often carpenters and joiners, for levelling purposes, use the spirit-level made to varying sizes. This instrument, of the size that is generally used and carried by workmen in their tool-baskets, is useful for short lengths of work, but over a long range, a good-sized accurate wooden building level is a safer instrument. A certain stone tested by a short spirit instrument may appear level while a course of three or more, a whole course may dip or have a rise at either end. In plumbing, the face of a wall, brick or stone, a rather longer plumb-rule should be preferred than a short one, even though it should not be so handy for the workman. Hundreds of houses are yearly built which are not truly perpendicular or plumb in their fronts; and when a row of speculative houses is built, the front walls are the only part to which the hurry-scurry or scamping workmen pay any attention as regards an approach to fair plumbing. Let any one with a good pair of eyes accustomed to look at frames, door-joints, openings, or walls "out of winding," walk into the suburbs, and make a perambulation of some of our sundry new streets daily cropping up. Let him use his eyes, or even one of them, by standing close to the buildings, or at the gable-end of one commencing the row. Illustrations of bad plumbing, and consequently bad workmanship (and materials too) will be plentiful. Front walls bulging in their centre, overhanging some inches atop, or undulating several times in their height,—the result of plumbing with a vengeance, and scamping on even worse grounds. Fractures or settlements in the brickwork of the suburban houses will be found in abundance, and though not all the direct consequence of bad plumbing and levelling, yet both are contributories to the results. A wall built with bad materials, particularly bad mortar, if built perfectly plumb, will have the better chance of standing than one that overhangs or undulates; but scamping builders are partial to an inland batter in wall-building as well as in scaffolding, for very obvious and cogent reasons. If some of the scamping builders of the present or last generation had been hung plumb as an example of equitable State handiwork, their successors would be acting more uprightly to-day, and building more perpendicularly. The men that "run up" in this world find their level at last.

Reverting to the plumb-rule and level, it may be noticed that the spirit level has been applied before now, but the arrangement has not come into use.

We want thinking workmen as well as working machines. A machine may work ordinarily well, but it will never put thought and expression into the work it executes, though it is in itself the outcome of deep and prolonged thought and experiment. Long since we have shown in these pages how the workman can prove his ordinarily-made plumb-rule, and yet how few operatives have learned to do so by any other method than "rule of thumb," despite the advance of, or the agitation for, the technical education of the workman. The carpenter's or building workman's square and mitre jack are constantly-used instruments in our building workshops, and yet many of their users are ignorant of the angle they geometrically form. The three common angles of 45°, 60°, and 90° often occur or are always occurring in building operations, yet there are hundreds of workmen who would be unable at a moment's notice to tell what parts of a circle these angles represent. Worthy "Jack Plane," in the *Builder* nearly a decade since, confessed from his own wide experience at that time of his fellow workmen that, although the mitre was in common use, not one workman in twenty knew that the angle of 45° was a true mitre. A number of his fellow workmen were equally ignorant of striking a "bob" hole, and did not know there was a correct method for describing the egg oval that constituted it. How much have our building workmen, as a general body, advanced since then in technical knowledge and its application to the true performance of their work? If there has, as we fear, been little appreciable advance, is it not time for the credit of the country that the movement for the supply of this urgent want should be at once expedited?

Sanitary Science and Civil Architecture.—At the next meeting of the Royal Institute of British Architects, to be held on the 29th inst., a paper will be read on "Sanitary Science in its Relation to Civil Architecture," by Mr. E. C. Robins, F.S.A.

THE WASTE LANDS OF ITALY AND OF IRELAND.

There is one portion of the area of Europe that is more desolate than the bogs of Connaught. It is found in the midst of the garden of the West, and in the immediate vicinity of the seat of the ancient capital of the world. Few things are more striking to a stranger than the abrupt and dismal contrast which is presented by those portions of Italy which are afflicted by malaria, and the laughing cultivation of such districts as *Campania Felix*, or the vineyards and olive forests of the Adriatic seaboard.

The causes of this desolation, and the means to be adopted for the reclamation of such fever-smitten spots as the *Campagna di Roma*, have long been matters of anxious discussion among the statesmen of Italy. Without at once entering into the thorny questions of the spongy nature of the soil, which some persons declare to be incapable of drainage, of the influence of level, and of geological depression; or of the effect of mis-government in past time in robbing the land of its natural cultivators, it may be interesting to see what the Italian Government is now practically attempting in the matter. The parallelism between this "squalid desert," and some of that waste land in Ireland which the bishops of the Romish Church desire to see restored to cultivation, is so close as to be not a little instructive.

Under the provisions of a recent law, the Italian Minister of Public Works nominated a technical commission for the purpose of investigating the subject of the reclamation of the *Agro Romano*. The Commission has recently sent in its report. It was the unanimous opinion of the Commissioners that it was impossible to restore the squalid desert, as they term it, of the *Campagna* to a healthy condition, except under the influence of cultivation. As to the details of the mode of culture they declined to express any opinion, further than that it was necessary to encourage the stalling of oxen on the territory for the sake of the manure. But as to the aid which the Government, at no permanent cost to the State, could afford towards the reclamation of the waste, their recommendations were practical and business-like.

The Commission recommend the establishment of four village centres of population, at a distance of about six miles from Rome, and on the lines of the Civita Vecchia, the Naples, and the Orte railways, and the Tivoli tramway. In each of these localities they propose that the proprietors of the land should be asked to place about 1,500 acres at the disposal of the Government for purposes of cultivation. No inducement is mentioned in the report for this patriotic act, but it may be supposed that the improvement of the soil is intended to cover some rent to the owner. On this point it would be desirable, however, to have something more definite. In the centre of each of these districts the Government is recommended to buy enough land to give room for the building of a village that would hold from 4,000 to 5,000 inhabitants. Roads are to be made and drained by the Government, to the site of new villages, and the land surrounding them is also to be reclaimed and drained in the most efficient manner.

Starting with 200 families to one village, the Government is to advance to the new colonists the money necessary to build their habitations, and to break up the soil for cultivation. A low rent, paid in kind, as a fixed proportion of the annual produce, is looked to as the means of reimbursing the outlay of the State. For the houses, they are to be leased to the builders, the rent being enough to pay interest and sinking fund on the capital advanced, and on the share of the cost of roads and drainage due to each house. By this means, at a fixed time, the houses will become the absolute property of the builders, the State in this case acting somewhat the part of a building society in this country. In case of the refusal of the proprietors to allow their lands to be occupied, they are to be purchased by the Government, and gradually redeemed, in the same way as the houses, so as to become the property of the cultivators.

While it is thus proposed to extend cultivated zones of land step by step into the Campagna, it is proposed, by way of rendering the advance of cultivation more easy, that the present unrestricted right of freedom for semi-wild oxen should be restricted; and that those proprietors who now cultivate any part of the district should be compelled to build healthy abodes for their work-

people. For this purpose, as well as for that of building cattle-sheds, the Commission propose that the Government should advance the money on loans similar to those offered to the settler in the new agricultural villages.

The ruling idea of the plan is, the intervention of the Government as the provider of temporary assistance, at no ultimate cost to the State. How far the invited colonists are likely to be forthcoming, on these terms, it is not intimated. The question, indeed, is probably one only to be decided by experience. It is very well for the Commission to steer clear of details, and to mention in the most casual manner the preliminary making good of the land by the best methods. It is here that the shoe pinches. If preliminary drainage will so far exterminate the malaria as to make the sites of the new villages only moderately healthy, there can be little doubt that immigrants would be only too eager. As to that, the report is silent. Nor do we suppose that there is any professional man who knows the locality, who would be willing to peril his reputation by predicting the effects of the first process of "*bonificazione*."

ARTISANS' WAGES ON THE CONTINENT.

An inquiry has been recently set on foot by the Industrial Society of Mülhouse as to the condition of wages in Alsace and the neighbouring provinces, principally affecting, as is natural, the textile trades, but extending also to other collateral trades. The cotton wages are below those of England or America; but it is somewhat singular that they show little or no fluctuation; though, on the other hand, the tendency is to steadily increase. Wages in textiles seldom dance up and down during the year on the Continent as they do in England, but they also have the advantage (for the operative) of seldom or never retrograding. At the commencement of the present century, when cotton was still spun by hand, a woman earned about 40 centimes (4d.) a day; at the present time the Alsace spinner (male) earns 3 fr. 50 c. to 4 fr. 50 c. (2s. 6d. to 3s. 4d.) per day, while the woman makes 1 fr. 50 c. to 2 fr. 50 c. Old records, dating from 1606, state that at that period 12 deniers, equal to about 3½d., was the price for spinning a kilogramme (2 lb.) of cotton by hand; 100 years later the payment for spinning the same quantity of flax was 7d. The Strasburg weavers of 1646 used to get a haller and a half for an ell of cloth for a dress, which was at the rate of about 1½d. per yard. Some old documents in the Convent of Unterlinden, at Colmar, show that the price of manufacturing a yard of linen in 1710 was from 1½d. to 2½d.; while now the same quantity costs 9d. The following short *résumé* of daily wages in francs at the present time paid in the cotton trade of Alsace, the Vosges, and Normandy will be of some interest:—

	Alsace.	Vosges.	Normandy.
	fr. c. fr. c.	fr. c. fr. c.	fr. c. fr. c.
Carders	2 80 to 2 75	3 25 to 3 75	3 50 to 4 0
Combers	1 40 to 2 0		
Drawers	1 30 to 2 0	1 75 to 2 25	2 20 to 2 50
Rovers	1 20 to 1 25	1 80 to 2 50	2 0 to 4 0
Bobbin Winders and Piecers...	1 0 to 1 50	0 90 to 1 25	1 0 to 1 75
Spinners	3 50 to 4 50	3 75 to 4 20	4 0 to 5 0

It will be seen from this table that textile wages are by no means uniform even in the same country (considering, for the nonce, Alsace as still French), the scale being higher in Normandy than in either of the other two districts. The general rate of pay, both in Germany and Switzerland, is still less. It is stated that in Alsace the manufacturers complain very much of the difficulty of obtaining sufficient number of children to act as bobbin-winders and piecers, in consequence of the dislike of the country people to send their boys and girls into the factories. Generally speaking, it may be said that wages in the cotton-mills of Lancashire are nearly 50 per cent. higher than at Mülhouse, added to which there is a great difference in the duration of the hours of labour, the week's work in England being fifty-six hours, while at Colmar and Mülhouse it consists of eleven or twelve hours a day, and in certain districts of the Vosges, of thirteen to fourteen hours a day. In some of the better regulated mills, however, such as those of M. Dollfus at Dornach and M. Herzog at Logelbach, it has been recognised that the hands engaged in the production of fine cotton and muslin goods turn out as much work in eleven hours as they used to do in twelve, the attention being better concentrated,—and it is a regular arrangement for the women to leave the mill for half an hour or an hour in the morning so as to allow them to prepare the mid-day family meal. Throughout other branches of textile trades, there is not very much uniformity on the Continent, wages differing very much according to the place. The linen-weavers at Colmar earn about 2 fr. to 3 fr. 50 c. per day for men, and 1 fr. 25 c. to 2 fr. 50 c. for women. In the woollen (merino) factories at Buhl, the women get 2 fr. to 2 fr. 50 c., the men 3 fr. 50 c. In the cloth-mills at Biechwiller, wages are not so high, having, in point of fact, been declining ever since the annexation to Germany. This branch, however, is the only one in the textiles in which there has not been a steady advance. Bleachers can earn 2 fr. 50 c. for a day of eleven hours; women, 1 fr. 75 c.; boys, fifteen to eighteen years old, 1 fr. 80 c.; and girls 1 fr. 40 c.

Turning to other trades, we find varying degrees of earnings, according to the place or the skill of the workmen. The chemical workers and starch-makers at Thann, Strasburg, and Colmar make about 2·75 to 3 francs per day, while in the paper-mills at Rixheim and Turkheim (where wall-papers are made) the wages for machinists, printers, and engravers are 3·60 to 5 francs; ordinary workmen, 2·50; women, 1·50; children, from 1 to 1·25. The Strasburg tanners earn 3·25 francs a day, whereas in 1850 they could only make 2·25. The glass-workers at Wildenstein get from 2·50 to 4, and the boys have 1·25, being an increase of about 25 per cent. in the last fifty years. Strasburg brewers earn from 4 to 4·50 f. a day, together with an allowance of beer. In the tobacco warehouses, foremen and overlookers are paid 6 to 7·50 f. per day; workmen, 2·75 to 4; women 1·75 to 2·50. In the printing trade at Strasburg the wages for machine-men are 15 to 35 francs per week; compositors 20 to 34 (generally piece-work); layers on, 4 to 16; binders, 10 to 36; girls employed in folding, 4 to 12 francs. In fitting and engineering shops, wages are singularly low, averaging 3·70 per day at Mülhouse, and 3·80 at Grafenstadt, a decline from the wages of 1878, which then reached 5 to 8 francs. But in certain mechanical trades connected with the textiles, such as engraving on metal for patterned cloths, the skilled hands can earn 12 francs a day. Work is, however, somewhat unsteady in this trade, sometimes there being none, while at other times there is a considerable rush of orders. Fitters and machinists make about 29 francs in the fortnight, or 2·40 per day; adjusters, 42 to 60, or 4·15 per day; turners and smiths, 54 to 57, or 4·65 per day; strikers, 2·90; coppersmiths, 5·25; tinsmithe, 4·25; saddlers, 3·50; carpenters, 4; joiners, 3·10; masons, 3·50; masons' labourers, 2·40; foremen masons, 30 francs the week; foremen joiners, 43; foremen mechanics, 55. As a general rule, wages in country places are lower than those of the towns; but, on the other hand, the artisan has very often some counterbalance in the shape of a little bit of garden or land, which he himself knows how to turn to some profit. Wages often vary according to the cheapness or dearness of living in the neighbourhood, as for instance in Normandy, where provisions are dearer than they are in Alsace and the Vosges. One cause of this is probably the proximity of Normandy to England, and the readiness with which Normandy farmers can find a better market there for their agricultural produce than they can at home.

THE NORTHERN IRON TRADE.

Alike in respect of the extent of production and of price, the condition of the iron trade of the North is, in all its branches, very greatly improved from those it knew a year ago, though the full extent of the first force of the revival has not been maintained. But when it is known that in the crude iron branch of the trade there were in September, 1879, only 80 furnaces in blast in the Cleveland and Durham district, and there are now 117; that the output of the furnaces last year was at the rate of 4,800 tons daily for the whole of the district; and that it is now at the rate of 7,000 tons daily, and the change in the extent in the production is at once apparent,—a change which has called into use a very large amount of labour, for which a year ago extra-parochial assistance was needed; and a large amount of capital, the works representing which last year were unproductive and wasting. That enlarged production was in response to an increase of the demand, and though one branch of the demand has for the time collapsed, yet the effect of the general enlargement is seen in the fact that the stocks of pig iron in the hands of the makers is considerably less than it was a year ago. It is evident, therefore, that large as has been the production over that period, the sales of crude iron have been still larger. But whilst the increase in the production has been chiefly noticeable in the latter portion of the time, that increase in the demand which has stimulated it was shown most markedly at the earlier part of the period; and thus it is that though stocks are less now than they were a year or so ago, they are in excess of what they were at the middle part of the year. Without there should be an early increase in the demand, it must be concluded that the output is in excess of it,—in which case increased stocks, weaker markets, and falling prices would be early characteristics of the trade in the Cleveland and Durham district; for that district is largely dependent upon the demand for crude iron from other manufacturing centres, about one-half of the total production being sold in the shape of pig iron to other home and foreign manufacturing centres.

But what must be considered the decline in recent months in the demand for the cheap crude iron of Cleveland, has not yet been accompanied by any falling off in the demand for the local manufactures from that iron. The chief of these is now that for iron for shipbuilding purposes; and whilst a year ago the associated makers of Durham and the North of England sold on an average 20,000 tons of plates and angles monthly, they now sell about 34,000 tons monthly; and this increase of 14,000 tons in the monthly sales has been accompanied by an equally satisfactory increase in the average realised price,—in the case of plates, the chief part of the trade, from 5*l.* 10s. per ton to 6*l.* 13s.; and in the case of angles from 5*l.* per ton to 5*l.* 19s. per ton. The satisfactory enlargement of the volume of trade has called into operation a large number of the rolling-mills in Durham that have long been idle; and the increase of the average price has, under the sliding-scale regulation in force, given a slight but acceptable addition to the wages of the workmen employed in the manufactured iron trade of the North of England, so that there has been, and yet remains, a substantial and general increase in this branch of the metallurgical industries of the North of England. With the increased consumption of pig iron locally necessitated, there is a fuller employment in contributory industries; in the iron and coal mines, in the carrying industries, and in others which share in the results. The whole trade of the North of England is, indeed, changed in the course of the year, and though the cause of the primal stimulus has passed away for the present,—the demand for crude iron for the United States,—yet the effects in great part remain; and there is a partially counterbalancing growth in the enlarged demand for pig iron for the Continent. Partial progress has been made in the district, it may be added, with the erection of works in different parts capable of meeting the growing demand for steel for various constructive purposes, and these works, in at least one important centre, will be for the use of the native iron in that manufacture.

At the present time the tendency of the trade in the North of England is not so markedly progressive as it was. Although the number of furnaces in blast is sixteen less than it was in 1873, yet, owing to regular working, and to the use of large furnaces, the present production of iron is at its maximum. We have seen that it is at the present time above a demand which shows a declension, if a temporary one. Whether or not the demand will rise now that prices of pig iron are so very low, and that rates of freight are also low, cannot be foretold. There have been inquiries for crude iron for the United States, and one or two small lots have been shipped from South Durham to America, but there is as yet no sign of a demand to anything like the extent that was known a year ago. From the Continent and from other home consuming districts there is a steady demand, whilst that for the local malleable iron trade is about at its largest for some years, and has, with the briskness in the shipbuilding trade, the indication of continued and even increased demand. And the change in the steel manufactures,—the proved success of the Thomas-Gilchrist process

—will stimulate the demand for cheap crude iron,—such as that of Cleveland. For the past two or three years there have been immense importations of Spanish and other foreign iron ores into the northern district, chiefly for use in the steel manufacture. The use of Cleveland iron may now be expected not only to grow, but to become slowly substitutional for those rich ores of Spain; and from all these sources it may be concluded that there is a probability of greater demand being known for pig-iron. In the manufactured iron trade the greatest animation is in the branches for the production of shipbuilding, and from the number of vessels on the stocks of the shipyards, and on the order books of the builders, the animation must for some time continue. The question of price is rather different, for it must be concluded that the facilities of production have become operative, rather preceding than following an increased demand. As this is the case, prices have weakened of late for all classes of iron, and till the conditions of demand and supply are changed that weakness will continue. But though prices are low, there is a counterbalancing lowness of the prices of raw materials, and thus the iron trade of the north may be said to be profitable at the present time. That in favoured instances this is eminently the case is proved by the fact that the largest Durham ironmaking company, —the Consett Iron Company,—has paid for its past year the large dividend of 20 per cent., whilst others not quite so favourably circumstanced have paid smaller but still substantial dividends. With a profitable trade, and one that seems to have the elements of growth, the iron manufacture of the North needs only to keep its production regulated by the fluctuating demand, to be ready in every way to share in the renewed period of prosperity that seems likely to dawn on the iron trade when nations are recuperated by economy and by the blessing of abundant harvests.

BARRACKS: THEIR PLANNING AND CONSTRUCTION.

ROYAL INSTITUTE OF BRITISH ARCHITECTS.

At the second ordinary general meeting of this Institute for the present session, Professor T. Hayter Lewis, vice-president, in the chair, the secretary announced the decease, on the 30th ult., of Mr. E. M. J. Forster, Associate.

Mr. E. Ingress Bell (of the War Office), Associate, then read a paper on "The Modern Barrack, its Plan and Construction." The author commenced by a reference to the power conferred by the "Military Forces Localisation Act" of 1872, for building barracks and otherwise effecting the localisation of the home forces. It was desired to maintain the permanent identification of particular regiments with particular localities. Since the passing of the Act old barracks had been enlarged or new ones built at fifty-four different stations in the United Kingdom, accommodating a total force of 12,000 men, and costing no less than two and a half millions sterling, exclusive of the land upon which they stand. He then dealt with the great barrack-building movement which marked the close of the last century,—using the defects of the system then inaugurated as a scale by which to test the improvements exhibited by the barracks of the present day. He dwelt upon the unvarying ugliness of the typical barrack of the last century, and traced the causes of its defective plan to the circumstances under which it was built. After the establishment of the army on a legal footing, at the Restoration, no barracks were built with the exception of those at Whitehall for the Horse and Foot Guards, and a few in Scotland. The reason was the antipathy of the nation to a standing army, and the consequent repugnance of the Parliament to vote the required funds. Meanwhile the army increased in numbers, and suffered in health from exposure and privation. The mortality amongst the troops was so alarming that various expedients were adopted; but still barracks were refused. Even so late as 1766, Blackstone wrote:—"Nothing should be more guarded against in a free community than making the military form a body distinct from the people. The soldiers should be intermixed with the people. No barracks should be allowed." The crowning objection to their erection was the use to which they had been put in Ireland. At length it became essential that some recognised plan for housing the troops should be adopted, and in the latter part of the century Mr. Pitt proposed a measure for building the necessary barracks. An enormous number of barracks was commenced simultaneously all over the country; they were based on one defective and hastily-considered model, and to that period (1793-97) we owed the dreary pile whose very name had become a synonym for ugliness and which was seen in most of our more important towns. The first step to systematise the construction of barracks on a better plan was taken at the close of the Crimean war. Committees and Royal Commissions under the auspices of Lords Panmure and Herbert inquired into and reported upon the condition of every barrack in the United Kingdom; and long and sad was the list of their shortcomings. The architectural profession was invited to compete for the erection of an infantry and a cavalry barrack. Those at Chelsea and at Knightsbridge were the indirect result; but in both cases the competition plans were set aside and the actual plans of the buildings, though not the elevations, were designed by the authorities at the War Office. The defects of the old system were due to complicated planning; overcrowding on the ground; buildings interfering with the ventilation of one another, containing too many rooms and too great a number of stories, built round enclosed courts, or too near boundary-walls; and to defective sanitation in all its branches. It was found that the excessive mortality amongst the troops,—no less than twice that of the civil population,—was traceable to specific diseases directly induced by the unhealthiness of barrack-rooms, by want of ventilation, by defective water-supply and sewerage.* The result was the promulgation of a series of recommendations:—(1) Prescribing the superficial and cubical space to be allotted to each man; (2) abolishing the old offensive urine-tubs from the barrack-rooms; (3) providing separate quarters for married men, baths, washing establishments, workshops, reading and recreation rooms, skittle-alleys, &c.; (4) regulating the warming, ventilation, water-supply, and drainage. The regulations which followed were directed to an improvement of the general system of barrack plan, and to the proper remedy for each particular defect in construction, warming, ventilating, &c. Consequently, at the present day, there is no one of her Majesty's subjects who is more scientifically provided for in all that conduces to health and physical well-being than the common soldier. The type of barrack which was accepted in the eighteenth century was exhibited in the plans of a vast unexecuted project for Hyde Park, and the want of provision for the decencies and necessities of barrack life was shown therein. The difficulties of acquiring, at reasonable rates, sites for Government buildings having been touched upon, Mr. Bell adverted to the conditions necessary to be observed in the disposition of the barracks as a whole, namely:—The want of a clear space around the barrack wall; of an ample parade-ground; the proper placing of the officers' quarters; the keep and store accommodation; guard-house; hospital; canteens; and the other items in a barrack establishment. The separate accommodation of each, and their proper mutual relation, were discussed and described in particular. The means of lighting and proportion of window space; the arrangements for warming and ventilating; the admission of fresh air and the extraction of foul air; the proportion of inlets and exits; and the special provisions and precautions rendered necessary by the habits of the soldier, were described. It was necessary that the soldier's rooms should be provided with indestructible fittings. With him valves were simply things to be fastened down, and ventilation openings only things to be stopped up. Long experience of his idiosyncrasies and of the exigencies of barrack occupation went to prove that of all methods of warming barrack-rooms that of the open fireplace was the best, and the best open fireplace was one perfected upon suggestions furnished by earlier models by Captain Galton. Under the old system fresh-air inlets were undreamt of, and the rooms were warmed at the expense of the purity of the air within them; under the new system the contrary, in some instances, had proved the case; and the rooms had been over-ventilated. It was easy to warm a room, equally easy to ventilate it, but not easy to both warm and ventilate it at the same time. The problem was no other than that of applying a constant system to varying atmospheric conditions, and all that could be looked for was a reasonable compromise, which experiment alone would dictate. Mr. Bell stated that a site for an ordinary barrack must comprise ten acres, exclusive of a training-ground and an encamping-ground for the militia. Instances were given of departure from the typical plan caused by special conditions of site, &c., and the scope left for ingenuity of planning in individual cases, notwithstanding the necessity for conforming to settled rules and principles, details of cost per man, and per cubic foot divided for the separate classes of buildings were given. Each barrack-room was designed to hold one-eighth part of the rank and file composing a brigade depôt, viz., twenty-eight men. 720 ft. of cubical space were allotted to each man. The married men had each a living-room, a bedroom, and a kitchen. The non-commissioned officers' quarters constituted a little club, furnished with comforts, aids to study, and means of wholesome recreation, for the like of which the city clerk scarcely knew where to look. The officers' quarters called for no special remark. The average cost per head of a barrack, in the latter part of the last century, was 12*l.*; the cost of the new Chelsea Barracks* was about 225*l.* per head, and of the Brigade Depôts 200*l.* per head. The improvements effected by somewhat similar means in the arrangement of stable buildings, the system of ventilation, of drainage, and other matters relating thereto, were explained. Cavalry stables were now arranged in two rows of stalls, the heads of the horses in each case being against an outer side wall. Every horse was allowed 1,200 cubical feet of space. A window was placed over every stall, and 8 ft. above the floor, and all the stable windows were made to open. When rooms were built over stables, foul-air shafts were carried up to above the roofs. These shafts had a sectional area of 18 in. per horse. The stalls were drained by surface channels only; these were carried to a distance of 12 ft. outside the stable. The loose boxes were 17 ft. by 12 ft. and 12 ft. high, allowing 2,500 cubical feet per horse. The parallel movement towards ameliorating the barracks of France, in which the English lead has been followed, and with due acknowledgments, was then described,—elucidated by the reports of M. Emile Trélat, and some useful and interesting extracts from the report were given in substance. The "Système Tollet," tried experimentally at Bonrges, Macon, Autun, and elsewhere,—based mainly upon English experience, and found to be quite successful,—was referred to, and its main features were elucidated. In conclusion, an appeal as to the improved character of the exterior appearance of the modern barrack was made to new buildings at Inverness, Reading, and elsewhere. Some deductions from Government experience and investigation bearing upon the larger civil buildings, such as workhouses, model buildings, &c., were submitted to the members. The whole subject was fully illustrated by drawings of old barracks, and of barracks built, or building by the War Department,—drawings which were placed at the service of the author, together with other facilities, by the courtesy of the Secretary of State for War.

The following is a list of the various illustrations to which Mr. Bell referred, and which were exhibited during the evening:—Downpatrick New Brigade Depôt: hospital annexe; Inverness New Brigade Depôt: plans, &c.; Oxford New Brigade Depôt: officers' stables, perspective sketch of keep, &c.; Worcester New Brigade Depôt: block plan; Type for Keep of Brigade Depôts; detailed plan of a modern barrack-room; Knightsbridge New Barracks: plans and view;† The Horse Guards, Whitehall: historical chart;‡ Project for Barracks in Hyde Park (A.D. 1716): plans, &c.;§ The Old Palace in the Savoy as converted into Barracks (A.D. 1736): plans, &c.; Vienna New Barracks for

* More than twenty years ago we called attention to the manner in which our soldiers were being murdered by being "stowed away" without the slightest regard to sanitary considerations. In our volume for 1858, pp. 150, 170, we gave some illustrations of "interiors" in the Portman-street Barracks (now removed) and in the old cavalry barracks at Knightsbridge.—Ed.

* A plan of the quarters for one company of Infantry in these barracks (Mr. George Morgan, architect), was published in vol. xiv. (1856) of the *Builder*, p. 160.

† Views and block plan of the new Knightsbridge Barracks were published in the *Builder* for 1878 (vol. xxxvi.), pp. 112, 113.

‡ This chart was, through Mr. Ingress Bell, presented to the Institute by Mr. Tregellas, of the War Office.

§ This project consisted of a design for a very extensive range of buildings, intended to accommodate no fewer than 7,000 men. It was prepared by one Du Bois, described on the plan as "one of his Majesty's engineers."

the Imperial Guard; The Système Tollet: plans, &c.*

In the discussion which followed,

Mr. Charles Barry, in moving a vote of thanks to Mr. Ingress Bell, said the paper in its earlier portion had given some interesting historical and other information as to early barrack construction, and in its latter part had given a great deal of what might fairly be styled authoritative information deduced under the best possible circumstances from expensively conducted experiments made by the War Office,—information which architects, who were not permitted to enter the arcana of military architecture, might yet turn to good account in the humbler sphere of civil architecture. The action of the War Office in regard to barrack construction seemed to have been tolerably consistent from the first, and except in one single instance, it did not seem to have sought outside aid. The result, as Mr. Bell had shown, was that the earlier barracks were very unsatisfactory. Mr. Bell had recounted how, in the case of the cavalry barracks at Knightsbridge, the plans submitted by Mr. Wyatt were set aside in favour of those furnished by the War-office officials, Mr. Wyatt's elevations alone being used. That was a very unsatisfactory method of working, because all architects recognised it as an essential condition that the outside and inside of a building should be interdependent. The result of the various sanitary inquiries made by the War-office authorities could not fail to be of much use to architects, and might be studied with profit. He ventured to suggest that similar *data* to that which had been collected by the Government with regard to the health of troops in barracks was very much wanted with regard to the health of occupants of other buildings, and particularly with regard to the health of people of the working-class housed during recent years in the large blocks of buildings which had been erected for them in London and elsewhere. One piece of information in Mr. Bell's paper which must have surprised many who heard it read was as to the cost of carrying out these barrack buildings. Mr. Bell spoke of their cubing out, on an average, at 5½d. per foot, in these present days of expensive labour, while 6¾d. per foot cube was mentioned as that of the cost of what were practically dwelling-houses, viz., the married quarters; and 8d. was given as the price for the gentlemen's residences known as officers' quarters. These prices struck him as being very low. He supposed the works were carried out by competition amongst builders in the usual way? Mr. Bell had spoken of the new barracks at Inverness in such terms that ought to induce every architect to see them, for he had said that every part of the buildings was consistent in character, satisfactory in aspect, and bespeaking its object. If those buildings really did conform to that very high standard of excellence, they constituted one of the most remarkable successes that could possibly be achieved in building. As to the cost per head given by Mr. Bell (225*l.* in one instance cited), it seemed to him (Mr. Barry) to be very high [A voice: "Enormous"] as compared with the cost of other public buildings, such as large schools in which the scholars were resident.

Dr. Balfour (who was introduced to the meeting as having been secretary of the commission instituted by Lord Panmure and Mr. Sidney Herbert to inquire into the sanitary condition of the soldier) observed that Mr. Bell might have brought the period in which barracks were generally unhealthy down to a much later date than the end of the last century; indeed, very nearly to the middle of this century. In 1836 he was appointed, with two military officers, to make a report on the health of the troops, and they found that in the barracks at Tobago the space allotted to each man was only 220 cubic feet. It was, therefore, not surprising to find that the mortality amongst the troops stationed there was very great. He had had the honour to serve for eight years in the Guards, and in his time there was in Hyde Park a building which he could not call a barrack, and adjoining it, a storehouse. The lower part of the building made to serve as a barrack was occupied as a guard-house for the troops who had the watching of the powder-magazine, and the upper floor was occupied as a dormitory and day-room for the company of soldiers engaged on that duty. So small was it, however, that the paillasses had to be arranged in tiers, one above another, on each side of the room, and besides that, there was an additional line of beds made up on the floor in the gangway between the double tier of beds on each side. The place was crowded to four times its healthy capacity, and it was therefore not to be wondered at that phthisis had largely prevailed amongst the men. As showing the light appreciation in which the health of the soldier was held by even high officials in the army at one time, Dr. Balfour mentioned that when, after the fire at the Tower of London, new barracks had been built, the authorities ordered that the men were to occupy some old buildings, as they wanted the new buildings for a store-house for blankets, for the old buildings were much too damp for blankets! The Duke of Wellington, when the matter was brought to his notice, ordered the troops to occupy the new barracks, and directed the storekeeper to put his blankets,—where he liked. On the matter of ventilation, Dr. Balfour mentioned, as having been successful in the old barracks at Winchester, the use of false or hollow beams running across the ceiling from outer wall to outer wall, the bottoms of such beams being of perforated zinc. He agreed with all that had been said in favour of Captain Galton's stoves, but when used it should be seen that they were properly fitted, as he found, when he was in charge of Netley Hospital, that though the Galton stoves had been fitted in the corridors, they had been provided neither with air-chambers behind the grates nor with louvre openings into the rooms.

Mr. Thomas Porter agreed with Mr. Barry in thinking that 200*l.* and upwards per head for buildings of the class described in the paper was an excessive price to pay, unless it included the cost of the ground, which he understood was not the case; but he could not agree with Mr. Barry in thinking that 5½d. per foot cube was a low price for such buildings, which were mainly composed of large rooms. Nor did he understand how, in the buildings described, the cost per foot cube could be reconciled with the cost per head.

Mr. E. C. Robins, in the course of a few remarks, spoke of the value of the statistics and data furnished by Mr. Bell in the paper, and referred to the works of Parkes and De Chaumont as being especially worthy of study by architects.

Mr. William White and Mr. Henry Dawson both expressed their inability to understand the cost of the buildings treated of in Mr. Bell's paper, Mr. White pointing out the vast difference between their cost and that of the older barracks.

The Chairman, in summing up the discussion, spoke of the paper as a valuable contribution to the Transactions of the Institute. The only thing with which he could compare it at the moment was the able article "Barracks" in the new edition of the *Encyclopædia Britannica*, which bore the initials of a well-known officer of the Royal Engineers. With regard to the cost of some of the buildings mentioned in the paper, he was able to say of his own knowledge that in the case of the new Chelsea Barracks a very large sum had to be expended in foundations on a portion of the site which had formerly been a part of the bed of the river. In putting the vote of thanks to the meeting, the Chairman included the name of Mr. Tregellas, for his kindness in presenting to the Institute the very interesting historical chart showing the Horse Guards buildings in Whitehall.

Mr. Ingress Bell, in replying on the discussions, said that in all cases the erection of the buildings he had described had been submitted to competition in the building trade in the usual way. The apparent discrepancy of cost per foot cube of the different portions of a modern barrack, as compared with the cost per head, would be explained by the fact that besides the barrack buildings proper there were numerous accessory buildings, such as canteens, cook-houses, bath-rooms, &c. As to Mr. Barry's *badinage* about the Inverness barracks, he (Mr. Bell) had been somewhat misunderstood with respect to the character of their design. All he wished to bring out was that they would compare favourably with most other buildings of their class.

* Of other illustrations of buildings for soldiers which we have published in past volumes, we may name the following:—Victoria Military Hospital, Netley (Mr. Mennie, architect), vol. xiv. (1856), pp. 458, 469; the Officers' new Barracks, Dover Castle (elevation by Mr. Salvin), vol. xvi. (1858), p. 679; and Plan for a Regimental Hospital (by Dr. Combe, Royal Artillery), vol. xviii. (1860), p. 608.

HINTS ON HOUSE DECORATION.

This was the subject of a long address given by Mr. William Morris, under the auspices of "The Trades Guild of Learning," on Saturday evening last, in the Hall of the Society of Arts, which was crowded to its utmost limits. Professor Hales, of King's College, presided, in the unavoidable absence, through domestic affliction, of Mr. Arthur Cohen, Q.C., M.P., who had been announced to preside.

Mr. Morris said that perhaps it would detract from the value of the instruction that his audience might get from him when he told them that he had no claim to represent any one craft in particular. Division of labour, which had played so great a part in furthering competitive commerce, which few dared to resist, and of which none, as it seemed to him, could foresee the result, had dealt especially hard upon that field of human culture in which he was born to labour. Division of labour, which was once the servant, was now the master of competitive commerce, which latter itself was once the servant, though now the master, of civilisation. It had resulted in some men becoming acquainted with many crafts, though masters of none. He would hold his peace on these matters unless he hoped by speaking to stir up others than himself to discontent with and rebellion against things as they were,—rebellion not against the laws of Nature, but against the customs of folly. Let them, however, proceed to consider by what forethought they could make the actual dwellings which almost all of them were of necessity compelled to live in, brighter, better, and more wholesome. In dealing with the subject he should perforce be speaking of those middle-class dwellings of which he knew most. There was no dignity or unity of plan about an ordinary modern house, big or little, and it was devoid of a centre. In brief, it was a mere congeries of rooms, with no special relation to each other. A few lucky people had the good fortune to live in the grand old houses their forefathers built. To such persons all he could say would be to remind them not to forget their duty to those buildings, not to alter or torment them, but to treat them as if their builders could still be wounded by their griefs and rejoiced by their well-being. There were some others who lived in houses that could scarcely be called noble,—nay, they might be called ignoble, but they were yet built solidly and conscientiously; and though they had little beauty, or none at all, they were characterised by fitness and common sense. The earliest buildings of this class dated from the time of Queen Anne, but many of them were later, and of the Georgian period. But these classes of buildings were very difficult to decorate properly, especially by those who had any leaning towards romance, because they still had some traces of style left in them. It should not be forgotten that the rebellion which they had met that night to further had been begun, for of late years houses had risen which were neither the cut-and-dried stock designs of the builder, nor academical imitations of by-gone styles. Especially deserving of their thanks was the School Board for London, who had shown that they recognised that art might go for something in education by refusing to allow shabbiness and scamped work to be characteristic of their school buildings. It was most inspiriting to see their fine buildings rising over the sordid level of the surrounding streets, and to be reminded of the well-founded hope in which they were built. Holland House, Kensington, was almost the only building left in London of the first-class of dwellings which he had mentioned. There were, until within the last few years, one or two houses in Lime-street of about the same period, but unfortunately they belonged to a society too poor to keep them standing,—viz., the honourable Company of Fishmongers. Besides these two classes of old houses, there were a few modern ones inhabited by the ringleaders of the rebellion against sordid ugliness. But the houses of those three classes taken together were utterly insignificant in number compared with the great mass of the houses of the people, —houses which he hoped it would one day be difficult to believe could ever have been built for a people not lacking in honesty and independence. The truth was that the people who lived in them had long since ceased to think about them, being content to live in them so long as they were warm and dry. He and those who thought with him wanted to make

the dwellings of the people fit for their occupants in appearance as well as in comfort. The first step towards the attainment of that end was to get people to interest themselves in the question as to what was best to be done with the makeshift houses which (however desirous of obtaining dwellings more satisfactory in an art point of view) the great majority of people would have to continue to live in for some years to come. Such makeshift buildings could not be got rid of all at once. For his own part, however had the house he lived in might be, he would not despair of improving it, in some degree, at any rate. He felt that he should have little claim upon the attention of his audience if the question involved nothing more than gaining a little more content and pleasure for those who already did not lack their fair share of them. The question included much more than that. His hope was that those who began to consider how to make the best of the chambers in which they ate, slept, and sat, would soon begin to feel an earnest discontent with the sordidness by which they were surrounded. His extravagant hope was that people might some day learn something of art, and form a longing for more, and that they would realise that there was no way of getting it except that of giving a man work to do congenial to him, without fear of intimidation by fellow-workmen and without anxiety as to the means of livelihood for himself and family. Before proceeding to speak of the interior of the house, the lecturer referred to the garden, which, he said, suburban gardeners generally made the worst of, aping, in the little patches of ground which the elastic conscience of the speculating builder left for them, all the windings and other features appropriate only to landscape gardening on a large scale. The abomination called "carpet-gardening" carried in its name the best proof of its own absurdity. As to the outside of the house itself, it was generally too ugly to render it possible to do much with it. In ordinary houses the paint used externally should be chiefly white or whitish, for when a building was ugly in form it would bear no ornamentation in the way of colour. The sash-bars of the windows should always be painted white, so as to break up the dreariness of the outside of the house. The lecturer cautioned people against using the dull brownish reds now apparently becoming fashionable for external painted work. This colour was sometimes called "chocolate," but a better name for it would be "cockroach" colour. He then proceeded to dwell on the details of interior house-decoration, referring, among other matters, to ceiling decoration, and urging the avoidance (where it was not possible to expose the timbers of the roof or floor above an apartment) of what he called those ghastly caricatures of art which made up the sum of modern cast plaster-work. Perhaps, he said, there were few of the crafts accessory to building which had fallen so low as that of the plasterer. He deprecated the filling to repletion with furniture of some rooms, and recommended people to let their furniture be simple though artistic, but only what was necessary for use,—none to satisfy the claims of fashion. All rooms should look as though intended to live in. Why should a dining-room generally look like nothing so much as a dentist's parlour, only to be occupied during an operation, and to be left when the operation was over,—the tooth out or the dinner in? While all rooms of well-to-do people should be artistic and comfortable in their decoration and furniture, their *ensemble* should not be such as to make a poor man ill at ease in them, nor should their luxuriousness be such as to make a thoughtful man ashamed. As things were at present, rich people would not have art, and poor people could not. A great deal had been heard of late about "cheap art." What was meant by it? Was there to be one art for the rich and another for the poor? Art was art, and people who talked about cheapening it forgot that it was not so accommodating as Law and Religion. And how was this cheap art proposed to be got? A great deal of it by that universal panacea, division of labour. A Pecksniff was to squint and scrawl for a time on a sheet of paper, and that sheet of paper was afterwards to set a lot of men to turn cranks all day for hire. From this were to accrue three-fold blessings,—food and clothing and very little leisure to the operatives, enormous riches to the capitalist, and moderate riches to the squinter on the paper. The result was to be an abundance of cheap art for the operatives or crank-turners. There had been many schemes suggested for such operations as skinning a flint or boiling down a flea for the sake of its tallow, and this scheme for the production of cheap art was on a par with them. The only way in which it was possible for art to live in the industrial crafts was to make each workman a master of his trade from beginning to end, and to abolish the pernicious system of keeping a man perpetually doing only one thing,—working at only one "branch" of his trade. Only the workman who was master of his craft from beginning to end could produce works of artistic merit, but under the present system of division of labour such a man was likely to be regarded as a very troublesome fellow, and as mere grit and friction in the gold-grinding machine.

A SUBSIDING TOWN.

We were recently at Northwich, where the chief trade is pumping brine out of the ground in order to produce common salt, and were much astonished by the appearance presented by part of it. The effect of continued pumping causes the surface of the ground to sink, and this subsidence results in serious damage to building property. A project is on foot, we believe, to obtain, by legislation, means of compensating owners of property injured by the subsidence, and not before it was needed. It would be difficult by words to convey an idea of the sad condition of many parts of the town. All new buildings are now constructed of timber framing, the lower part of which is formed of massive pieces of timber or oills, and as the ground subsides, and the house becomes 2 ft. or 3 ft. lower than the street, instead of perhaps 6 in. or 1 ft. above it, as originally constructed, screw-jacks are introduced under the timber oills or plates, and the whole is raised up to its original position. We saw one house and shop that had been twice raised, though it has been built only a very few years. The old County Court-room has come forward lately, as if to enlist legal assistance. We were at Northwich during the recent floods, and the lower streets with the basements of the houses, and the ground-floor too, were entirely under water. Northwich evidently needs looking after.

INDUSTRIAL ART-TRAINING AT GENEVA.

A favourable report reaches us concerning the Geneva special school founded two years ago by the State for the study of decorative arts. This establishment is situated in the capital itself, and the building cost the canton of Geneva no less than 40,000*l*. It suffices, however, to visit one of the apartments of the ground-floor to meet at once a clear proof of the success of the enterprise. This portion of the building is set aside for the exposition of the works of art achieved by the pupils; but the show-cases which were to hold these objects will be found nearly empty. The fact is, that nearly every article exhibited has at once found a purchaser, and thus this room remains in a denuded condition. Close at hand there are the offices for the administration of the school, and the workshop for the ceramic arts. The ovens and the foundry are, however, in an outer building. On the first and second floor of the school will be found the workshops for the moulding, chasing, and sculpture on wood and stone.

The school of 250 pupils and its annual budget amounts to 3,200*l*. There are two categories of pupils,—the first, known as the regular pupils, must, to be admitted, possess a diploma from the Municipal School of Arts applied to Industry, or else pass an examination. When they have thus established their competency and natural aptitude, they are admitted as regular pupils, and follow either a complete course of artistic training, or devote themselves to one special branch. These pupils alone are allowed to participate in the competitions and prizes offered by the State. The second class of pupils are the outdoor pupils, for the most part artisans, apprentices, and tradesmen; they are allowed to follow the course of training gratuitously when they can prove that they possess sufficient natural aptitude to benefit from this opportunity. There are three classes: the first for modelling and sculpture of ornament and the figure; the second, small and large *repoussé* work; the third, the ceramic arts.

The teaching is of an essentially practical description, and the professors keep a keen watch to prevent the pupils losing any time. In fact, all students who are not earnest in their work, or who are not sufficiently gifted to work with success, are carefully eliminated. Any absence during class hours is reported, and repeated offence in this respect may entail expulsion from the school. Altogether the work is carried forward in real earnest, and does credit to the small but well-administered canton of Geneva. The Swiss have so often distinguished themselves in schools of art in France and elsewhere that we are pleased to note the increased facilities now afforded by which they will be able to work in their own country, surrounded by the noble scenery that cannot fail to inspire all true artists.

COLOGNE CATHEDRAL.

A PORTION OF THE WEST FRONT.

As most of our readers are aware, the west front of Cologne Cathedral was one of the portions of that great church left in a very incomplete state by its Mediæval builders. In fact, what had been executed amounted to little more than a third of the southern tower and the basement of the northern one. Attached to the southern tower was a part of the jamb of the great west window. Nearly the whole of this was fourteenth-century work, though there were indications that a small portion of the north tower was of an earlier date. Our illustration represents the lower part of the southern tower, and shows one of the windows and the remarkably elegant doorway. This doorway, for more than four centuries, formed the principal entrance to the cathedral, and its tympanum is decorated with sculptures representing scenes from the lives of St. Peter and St. Paul. The canopy above it was a very beautiful example of German Geometrical tracery, but was in such a decayed state as to render its removal, some months back, absolutely necessary. The whole of this tower is covered with scaffolding, and is now in course of restoration. Our drawing represents it as it appeared before this operation was commenced, and before the canopy over the doorway was removed. We trust that the restoration in progress will not obliterate the appearance of antiquity of this part of the building, because it is very interesting to those who are now living, and will be still more to those who come after us, to be able to trace exactly where the Mediæval work ended and the modern work began. We hope, also, that even if the present pump is destroyed, it will be replaced by some kind of fountain or ornamental well, as these wells attached to German churches date from very early times, and are interesting features. The examples of them are very numerous; the best known, and those which recur most readily to our memory, are in Ratisbon cathedral, the Minster at Freiburg, and the cathedrals of Paderborn, Augsburg, and Prague. We have no doubt that the present not very ornamental pump at Cologne occupies the position of an ancient structure similar to those to which we have alluded.

While speaking about Cologne Cathedral, we should like to know whether any of our readers can explain the very singular view of Cologne Cathedral represented in p. xoi. of the "Nuremberg Chronicle"? Here a very lofty tower, of more than four stories in height, is shown to the north-east, and the apse, in a very unfinished condition, with a great crane on the top of it, is shown to the west. What makes the matter somewhat singular is that in this view the other churches of the town, especially St. Cunibert's and St. Martin's, are tolerably correctly drawn. We confess that we are quite at a loss to account for this very peculiar representation,—or shall we say misrepresentation?—of the cathedral. It is quite impossible that it could have looked at all like this in the year 1493, which is the date of the publishing of the "Nuremberg Chronicle." Is it possible that the engraving can be taken from a drawing made some centuries earlier, and that the tower shown belonged to the former cathedral? If what we surmise is the case, the drawing must have been made some time previously to the year 1322, as it shows the apse in a very unfinished state, and without a roof; whereas we know that the choir was completed and consecrated in that year.

It has been asserted that Conrad von Höchsteten did not really begin the present cathedral in 1248, but that he only patched up the older church, and that the present cathedral was not commenced until 1270 or 1275. This statement we find repeated in Murray's Handbook for Northern Germany. We cannot find what authority there

ie for thi« statement, ae it is quite at variance with that of Kugler; hat, judging from the style of the building, we should not he at all enrprised to find that it wae true. We have come acrose another statement, that Cologne Cathedral wae designed by Archbishop Englebert, whose shrine ie now to be seen in the cathedral. There appear, however, to have been two archbishope of the name of Englebert, Archbiehop Englebert II., whose name was von Rile, erected the beautiful "Bergen Tower" in 1261. The name von Rile is singular, as being that of the man to whom the design for the choir of the cathedral ie attributed, "Gerhard von Rile."

Now, if Archbishop Englebert von Rile designed the cathedral, it could not possibly have been commenced in 1248. Victor Hugo eays, in his charming work upon the Rhine, that the architect of Cologne Cathedral was named "Englebert de Berg." This is, however, probably the eame person as Englebert von Rile, and hie bearing the name *de* (or rather *von*) Berg may account for the tower which he erected at the eouth end of the town being called the "Bergen Thurm."

A letter in the *Athenæum*, by Mr. Edward Scott, gives a copy of a deed of contract entered into between a certain Rudenger, director of the works at Cologne Cathedral, and the Burgrave of Drachenfels, to the effect that the latter shall eupply stone from his quarry, "*ad opus structure Coloniensis*," and the date 1280 is attached to the contract. Now there is a eingular thing about this document, and that ie the fact that it nowhere mentions the cathedral aehaving heen then commenced! On the contrary, any person reading it would naturally suppose that it wae a contract to supply stone for a church about to he hnilt. Of this man called Rudenger we know as little as we do of Gerhard von Rile [why does Mr. Scott spell the name "*Riehl*"?] All the German anthorities we have seen spell it in the way we have adopted]. Whether they were master-maeons or contractors; whether they were eimply men employed by the chapter to arrange for the purchase of materials, or whether they were the absolute architects of the building, there is nothing to show. We have, however, the following namee associated with the building of Cologne Cathedral:—

Gerhard von Rile	c. 1248
Archbishop Englebert von Rile	c. 1261
Rndenger	1280
Meieter Johan von Köln	1322

The tradition that Albertus Magnus designed Cologne Cathedral seems to be devoid of foundation, and if, ae is also stated, that prelate designed his own cathedral church at Ratisbon, he is not likely to have designed the cathedral at Cologne, as the buildings show the influence of two different schools of architecture. Perhaps the fact that Albertus Magnus died at Cologne about the year 1300, and was, as the "Nuremberg Chronicle" relates, buried in the Church of the Holy Croee in that city,* may have given rise to a supposition that he had eomething to do with the erection of the cathedral.

Whether we have yet found the name of the architect of the magnificent Cathedral of Cologne is a matter of donht; and until eome more positive evidence is forthcoming, we must follow the example of the buildere of the Walhalla at Ratisbon, who have erected a tablet to his memory, without venturing to suggest his name.

NEW PREMISES FOR THE MANCHESTER AND COUNTY BANK, KING-STREET, MANCHESTER.

These premiece have been erected on the site of one of the oldeet houses in Manchester, Dr. White'e house, afterwarde converted into the York Hotel, and then used for a long period as offices until its purchase by the hank.

The building has a frontage to King-street of 53 ft., and to Chapel-walke at the eide, of 127 ft.; ahout half-way back from the front the site widene out to 64 ft. 6 in.

The whole block ie appropriated to the use of the hank; the towor on the left of the principal front containe an entrance porch, 19 ft. by 13 ft., with stone groined roof; above thie are waiting-room and directors' lavatory, the whole crowned by a slated spire rieing to a height of about 120 ft. Immediately to the right of the tower are windows lighting the staircase leading to the board-room, which ie on the first floor, and occupies the remainder of the frontage on this story; below it is the general committee-room, and above eome spare rooms. The upper windows to the eide street are those of the directors' dining-room, kitchen porter's residence, &c.

As the rooms to the front and side occupy only some 25 ft. in depth, there ie a large internal epace forming the hanking-room proper, lighted from ahove, which, however, extends to the side street and ie lighted on that eide by the lower range of windows. The banking-room thus formed ie ahont 100 ft. by 60 ft., and consiste of a central nave, 26 ft. wide, divided by granite columne from two eide aisles, 10 ft. 6 in. and 20 ft. 6 in. wide respectively.

Parallel to the side street, and leaving a space for the customers of 11 ft. in width hetween it and the wall, is the counter, 61 ft. long; hehind the counter and the epace for the cashiers is a dwarf ecreen, 5 ft. 3 in. high, heyond which all the clerke are accommodated; the managers' desks are at one end of the nave, on a raised daie surrounded hy a dwarf ecreen, and giving them complete supervision of the room. In the hasement are clerks' lavatoriee and cloak-rooms, book and etationery etores, and three strong-rooms situated in the centre of the cellars. Theso etrong-rooms, measuring ahout 19 ft. by 12 ft. each, are hnilt of iron plates enclosed on all sidee and above and helow hy hrickwork of great strength, hnilt of blue Staffordshire hricks in cement, and entered by magnificent fire-and-fraud-proof doors made hy Chatwood, of Bolton. The rest of the cellars are all lined with glazed white and grey hricks, arranged in eimple patterne, and the ceilinge are of etrong hrick arching.

The banking-room itself has oak panelled ceilings, that of the nave being arched, and the panels glazed; above this, again, ie the outer roof, glazed on Rendle's system. The walls are lined with panelled oak dados, 6 ft. high, above which they are covered with creamy coloured Belgian marble, the object being to have this part of the establishment finished in each a manner that painting and whitewashing might never be required. The floors of all passagee, &c., traversed by the customers, are laid in vitrified mosaic by Oppenheimer, and have a very artistic and business-like appearance. The strong-rooms are approached by hydranlic lifte, by meane of which the books, cash, &c., can he lowered and raiced. The board, committee, &c., roome, are all finished in pitch-pine, with high dadoee and panelled ceilings of that material.

The exterior of the building is faced with Spinkwell etone, the plinth, however, heing in polished red granite. The general contractors were Messrs. R. Neill & Sons, of Manchester, with whom worked Hamilton, bricksetter; Graham, maeon; Woolstenhulmee, ironfoundere; Jaffrey, plumher; Messrs. Pattison provided the marhle wall lining; Mr. Wilson, gratee and gas standards; Messrs. Lavers & Barrand, and Messrs. Edmundson & Son, the stained glass; Messre. Wren & Hopkinson, the hydraulic lifte; Messre. Milner & Co., the locks. Meesre. Mills & Murgatroyd were the architecte.

* See p. cclxiii.

THE SUBMARINE TELEGRAPH COMPANY'S NEW OFFICES.

The Submarine Telegraph Company was established in the year 1850, to work submarine telegraph cables, under concessions granted by the French and Belgian Governments, and was the pioneer of submarine telegraphy. The company hegan operations hy laying down a cable, containing four conductors, hetween Dover and Calais, and another cable, containing six conductors, hetween Dover and Ostend. There are at the present time twenty-four conductors laid down hetwoen England and France, contained in six cables; ten conductore between England and Belgium, contained in two cables; and one conductor hetween Jereey and France. By the Telegraph Act of 1868 the Government acquired, hy purchase from the Electric Telegraph Company and Reuter's Telegram Company respectively, two cables to Holland, containing eight conductors, and one cable to Cermany, containing four conductors. These three cables to Holland and Cermany are worked by the Submarine Telegraph Company, in addition to the before-mentioned cablee to France and Belgium. Beeidee the cable to Germany, purchaeed of Reuter'e Telegram Company, there ie another cable laid down between England and Borkum, helonging to the Cerman Union Telegraph Company, worked by the Submarine Company, affording three more conductors for the general European correepondence, *viâ* Germany, and one conductor, worked by the Anglo-American Company, for American telegrame. The cost of a telegram between England and the coaet of France in the year 1850, when the first cahle was laid, wae 6d. a word. Thie rate has heen gradnally reduced, until, in the year 1867, the price of a twenty-word meesage from London to any part of France wae 4 france, or 3s. 4d.

At the Telegraph Conference held in London laet year the rate for messages to and from any part of the United Kingdom, and any part of France, was fixed at 2½d. per word, and for Belgium, 2d. per word. If this were widely known the submarine wiree would be even more used than they now are.

Two pneumatic tuhes are laid down between the Post-office in St. Martin's-le-Grand and the Company's new building for the conveyance and distribution of telegrame tranemitted to and from the Continent and provincial statione in the United Kingdom; and a third pneumatic tube is connected with the original office of the company in Threadneedle-street, which will for the future be occupied exclusively hy the Post-office as a Postal Telegraph Station. There will aleo he placed two pneumatic tuhee in connexion with the Stock Exchange, to he used exclusively for the membere of that institution. All these tuhes are made of lead, and are about 2½ in. in diameter. They are enclosed in cast-iron pipes for protection, and are laid nnderground. At present there are transmitted by the Submarine Telegraph Company about 8,500 messagee a day on an average. The office is open day and night, and on every day, without exception, throughout the year.

The new officee are eituate at the angle of Throgmorton-avenne and London-wall, upon ground leased from the Carpenters' Company for a period of eighty yeare, at an annual rental of 1,200*l.*, being at the rate of 6s. per foot super. The eite occupiee a enperficial area of 4,000 ft., having a frontage of 50 ft. to London-wall, and 80 ft. to the Avenue. The total area of floor-space on the eight floore amounte to 21,000 square feet.

The mezzanine and lower baeement contain the rooms for the batteriee, Otto gae-engines, etoree, &c.

On the ground-floor are the public office, messengers' room, &c., towards the Avenue, and two spacious shops towarde London-wall.

On the firet floor are the board, retiring, secretary'e, and clerks' rooms; on the second floor the accountant'e rooms and Morse-hand storee; the third and fourth floors are appropriated entirely to working the instrnmente; and the fifth floor ie reserved for fnture extension.

The two elevations rise to a height of 62 ft. from the pavement to the parapet, and are faced with Portland etone.

The carving is eomewhat elaborate, and eymbolises the four quarters of the globe, the monogram of the company, and other emblematic designs.

The works have been done at a cost of ahout 20,000*l.*, hy the following contractore:—Messrs. Peto Brothers, general contractors; Messrs. Edmundson & Co., gae engineere; Messrs. H. Greene & Son, gas-fittings; Mr. Banner, ventilation of drains, closets, &c., and M. Papier, of the instrument-rooms; Shand, Mason, & Co., for fire appliances; Pearson for trapless twin hasine; J. W. Falkner for fittings; R. Adams for casement fittings; and Daymond for carving.

Mr. Grant was clerk of works; Mr. Caird, hnilder's foreman.

The architect to the company is Mr. Norton, of Old Bond-street, under whose superintendence the works have heen executed.

Stained Glass.—The large west window of St. Jude'e Church, Gray'e Inn-road, has just been filled with etained-glass repreeentations of the Four Evangeliets. The centre-piece of tracery above these containe the figure of "Our Lord Bleesing the World." In the base of the window are the emblematical hearings of the figures. The window was designed and executed by Mr. Geo. Reee, of Lamb's Conduit-etreet.

NEW SNEINTON CHURCH INSTITUTE.

This new building is situated at the corner of Beaumont-street and Notintone-street, opposite to St. Stephen's Church and adjacent to the Board Schools. The style of the architecture is Venetian Gothic, freely treated. The jambs and arches of the windows and doors, and the cornices, are of moulded brickwork supplied by the Hathern Brick Company from designs of the architects. The doorway to the large hall is constructed of Darley Dale stone with red Mansfield for the columns, the caps of which are carved in natural foliage, and upon the tympanum the name of the institution is cut in raised letters. The entrance to the coffee-tavern is built with moulded brickwork, and upon the tympanum of the door is placed a shield bearing the arms of the diocese. The caretaker's house is in Beaumont-street, from which side also the coffee-tavern is entered.

This part of the building consists of a well-proportioned room, 41 ft. in length, 20 ft. in width, and 22 ft. high. In the rear is the kitchen, conveniently situated, furnished with efficient appliances and hoist as a means of service to the hall above. Communicating with the coffee-tavern is the men's club-room, an apartment 20 ft. long and 16 ft. wide, and another room intended to be let for Oddfellows' lodges and other purposes on week-days, and used as a mission-room on Sundays. To render it available for this latter purpose there is an entrance from Notintone-street.

From this side of the building the Young Men's Institute rooms are approached, and these consist of a reading-room, 24 ft. in length by 16 ft. wide, and a room for games, &c., 41 ft. long by 17 ft. wide. Throughout the whole of the ground-floor there is a communication by means of which the caretaker can have access to all rooms without going out of the building. The approach to the large hall is by a stone staircase 6 ft. wide, entered from the northern end of the Notintone-street front. A small committee-room is here provided on the ground floor. From the corridor at the head of the staircase the doors of the large hall open to this room together with the platform. The retiring-rooms behind occupy the whole of the upper part of the building. The hall is 66 ft. in length, and 41 ft. in width, 30 ft. from floor to ceiling, and is capable of seating 500 people; a balcony runs round three sides. Underneath one side there is a passage by which the platform and retiring-rooms are reached, the latter being provided with lavatories. The roof of the hall is open timber, match boarded. The platform will accommodate a large number of persons, and is designed with especial regard to the requirements of concerted and chorus music. The hot-water apparatus by which the rooms are warmed has been supplied by Messrs. H. S. Cropper & Company, of Nottingham. The lighting is by sunlights, and the fresh air is admitted by casements in the windows, also by perforated boarding above the plate running round the room, communicating with the dormer ventilators in the roof. The exit of vitiated air is provided for by perforated zinc plates placed in the ceiling, and in direct connexion with the ventilating turret through which the sunlights discharge their heated vapours into the open air. The building has been erected in a satisfactory manner by Messrs. Wheatley & Maule. Messrs. Truman & Pratt, Long-row, Nottingham, are the architects.

THE BANK OF SCOTLAND, DUNDEE.

This building has recently undergone extensive alterations and additions. The floors and internal walls of the basement and ground stories were entirely removed, and the plan was rearranged on a more symmetrical basis. The original area was considerably extended by absorbing an open court, and the lighting much improved by glazing the roof of the extended portion. The building, which stands at the corner of two chief thoroughfares, has had the ground story rebuilt. Mr. G. S. Aitken, Dundee, was the architect.

Dusseldorf Exhibition.—The materials used in the construction of the Düsseldorf Exhibition are being in most part sent to Breslau, where an exhibition of Silesian industry is to take place next year. There is a surplus at Düsseldorf of 15,000*l.*, being nearly 15 per cent. of the gross receipts.

MR. EDMUND SHARPE'S WORKS.

For the List of Books, see page 595 of last week's *Builder*.

LIST OF PAPERS IN TRANSACTIONS OF DIFFERENT SOCIETIES, &c.

Transactions] of the Royal Institute of British Architects:—

I. On the Subordination and Distinctive Peculiarities of the Mouldings of the Seven Periods of English Architecture. Read at the Ordinary General Meeting, May 19th, 1851. Eight pages.

II. Letter to Professor Donaldson from Naples, dated Jan. 7th, 1865.

Two pages, printed with "Occasional Papers." In this paper Mr. Sharpe states that "the true history of Italian Mediæval Architecture has yet to be written." He was making preparations for writing and illustrating part of such a history when he died at Milan, in 1877.

III. The Architecture of the Cistercians. Read June 19th, 1871.

In Transactions 1870-71, pages 189 to 210. One plate (Cistercian Abbey, model plan).

Report of Proceedings,—General Conference of Architects, 1871:—

Perspective Views in Architectural Competitions. Opening of Discussion, May 24th, 1871. Pages 63 to 67.

The *Journal* of the British Archæological Association:—

On the Ruins of the Cistercian Monastery of St. Mary-in-Furness. Vol. VI. (1851), pages 309 to 317; 359 to 374. Ground-plan, and 24 woodcuts.

The *Archæological Journal*, published under the direction of the Council of the Royal Archæological Institute of Great Britain and Ireland:—

I. On the Geometrical Period of Gothic Architecture. Read at the Lincoln meeting, in June, 1848. Vol. IX. (1852). Pages 170 to 179.

"This formed the basis of a work, subsequently published, in which I proposed a new division and nomenclature of the styles of English Architecture." (Allusion to "Seven Periods,"—in Paper read at Lincoln in 1868. See below.)

II. Report as to Byland Abbey Exploration. Dated Nov. 14, 1875.

Vol. XXXIII. (1876), pages 2 to 5.

III. Description of Byland Abbey.

Vol. XXXIII. (1876), pages 5 to 8.

Separate card (8¾ in. by 5½ in.).

Guide to the description of Ely Cathedral delivered July 10th, 1854. (Cambridge printed).

Reports and Papers read at the Meetings of the Architectural Societies of the Diocese of Lincoln, county of York, &c., during the year 1868. Lincoln: Williamson. 8vo.:

On Lincoln Cathedral.—A paper read at the Lincoln meeting [of the Lincoln Diocesan Architectural Society], June 17th, 1868. Pages 179 to 190.

This paper was also published as a pamphlet. Pages 1 to 12.

Separate card (8¾ in. by 5¾ in.)

Guide to the Architectural History of Lincoln Cathedral, as described June 17th, 1868. (Lancaster printed).

PAMPHLETS.

I. A Letter on Branch Railways, addressed to the Right Honourable Lord Stanley of Alderley, President of the Board of Trade, &c., containing suggestions for the erection of a system of secondary railways for the agricultural districts. With an Appendix and Map. London: Simpkin, Marshall, & Co. (Lancaster printed), 1857.

8vo. Thirty-six pages. Map of Vale of Llanrwst. 1s. 6d.

II. A Letter to the Right Honourable the Chancellor of the Exchequer on the Disfranchisement of the Borough of Lancaster. Lancaster, 1867.

8vo. Objecting to the Disfranchisement by Mr. Disraeli's 1867 Bill.

III. Four Letters on Colour in Churches, on Walls, and in Windows. (Reprinted from the *Builder*).

a. First edition. London: Spon. (Lancaster printed), 1870. 8vo., Twenty-seven pages.

b. Second edition. London: Spon. 1871. 8vo., Twenty-four pages.

QUERIES.

1. It is intended to compile as an appendix to these lists references to the critical notices of Mr. Sharpe's works. A general reference to the publications in which such notices may be found will be valued by the compilers, if the exact reference cannot be furnished to them.

2. The compilers have also in hand a list of papers printed in the professional journals, and will be glad to receive notes as to them, or as to any of Mr. Sharpe's contributions or communications to journals, magazines, reviews, &c.

3. In September, 1845, a paper was read by Mr. Sharpe at the Winchester meeting of the Royal Archæological Institute, "On the Pointed Arch, illustrated by Drawings and by Models of Vaulting and Groining." The origin of the pointed arch was always a favourite subject with Mr. Sharpe, and was brought forward many times in his published works. Was this, apparently the earliest of his papers, published?

4. In July, 1853, it was stated at the Chichester meeting of the Royal Archæological Institute that "examination had been made of the great portion of the churches of Sussex [by Mr. Sharpe] for the express purpose of bringing the results of the careful survey before the Institute." This was alluded to by Mr. Sharpe at a meeting [when?] of the Royal Institute of British Architects in consequence of something said there by Professor Willis; but were the notes completed and printed after all?

5. At the Kingston-upon-Hull meeting of the Royal Archæological Institute in 1867, Mr. Sharpe gave a paper on Selby Abbey (where he acted as *cicerone*); notices of other churches in the East Riding; also, remarks on Thornton Abbey Chapter-house, and the offices of the Abbey. These were not published in the *Archæological Journal*; are they in print anywhere?

6. There are probably occasional papers in the publications of other societies, English and foreign, as yet unknown to the compilers, who therefore ask for information; as also with respect to plates, &c., contributed to works by other authors.

Communications to be addressed to Mr. J. S. Quilter, 10, Brunswick-square, W.C.

LANDSCAPE BUILDING.

A town ought not, even when stretched on the most level plain, to be laid out too stiffly. The plan of it ought not to be a simple device of streets lying along, with others lying across at right angles to these, like the checks of a tartan plaid. No doubt there should be order in the plan, but there should be variety also. In one quarter the streets might be arranged like the spokes in a cart-wheel, which all diverge from one particular notable central body. In another quarter they might be arranged like the principal streets of Carlsruhe, in the Duchy of Baden, are, which radiate from the grand ducal palace, like the rays of a fan. A town is not properly built, with respect to landscape, where the streets are so narrow, and the buildings so close together, that to apply a common expression you cannot see the town for the houses. The passengers along the street should not be enclosed by monotonous ranges of houses, as by prison walls; but through gaps and openings frequently occurring he should be afforded glimpses of the composition of the town, and down avenues and vistas get occasional views of ornate and remarkable buildings—of monuments and statues, and even of parks and trees, as he moves along. In the spacious parts of the town the blocks of buildings might be set down in open order, like battalions of soldiers ranged in preparation for the combat on the battle-field.

In old times, after town walls of stone had given place to flat earthen fortifications, ramparts gave breadth and definition to town landscape—now we have to look to terracing and esplanades to fulfil this purpose. There is great scope for a discriminating imagination to work in laying out these properly. Large solitary buildings, superb crescents and circuses, have little effect, and lose much of their grandeur when they are not surrounded by a border of ground marked out as their own policy by a parapet, retaining wall, or green slope, and to make this border of sufficient size, and yet not too large, to make it appear wide and not waste, requires a just and discriminating eye.

It contributes to the variety and elegance of a street to have ins and outs. It adds to its amenity, more especially if it be long, when some of the buildings are withdrawn behind the line of the others, and placed in recess. In one division of a chief street the blocks of houses on each side might be placed at one end at a considerable distance apart, and the open space between them kept wide, and the other blocks might be made gradually to converge, to draw closer to the centre of the street and to each other,—step by step,—thus making the plan of the open street similar to the sections of a telescope, till they approached at the other end within easy hail of each other.

A very long street should not be laid out in a perfectly straight line, if it is possible to avoid it, but should either be laid out on a very flat curve, or should bend gracefully away from the straight at either end If a street sweeps towards the sun at the extremities of its curve, the effect of the line is bold; if, on the contrary, the extremities sweep from the sun, the effect is fine. Where the line takes the form of the letter S, there is always indication of caprice. In landscape building, as in landscape gardening, the device of making smaller objects cluster round a larger one, and that other device of leading up from a number of insignificant figures, past guarded and chequered intermediate objects to one grand culminating figure, should not be neglected.

There are always a sufficient number of large buildings in every town to form culminating figures. Cathedrals, halls of justice, town-halls, exchanges, hospitals, barracks, theatres, and, for it is principally great size that is wanted, even prisons are all appropriate for this purpose; they all form heads and peaks rising out of the broken sea of buildings of which the town is composed, and they are all sufficiently large and important to concentrate lines and avenues of approach upon to a greater or lesser extent.

I would even advocate the keeping down the size and restraining the ornamentation, in the houses forming the sides of the streets leading up to the most magnificent fanes, making their architecture tidy and clean, and neat to be sure, but comparatively plain and homely, making them to a certain regulated size and measure of ornament, although still handsome and well-appointed, but of that simple elegance which, like the modest flower, is passed by with little notice in order that the full efflorescence of sculpture might burst forth more luxuriously and voluptuously and conspicuously in the shafts, and mullions, and arches, and cornices, in the flutings and scrolls, in the supports and buttresses, in the domes and minarets and turrets, in the gilded balls and rosy trellises and flaming pinnacles,—cutting against the blue and white sky,—of the mighty fane itself.

There is a large space opened up in the side of a principal street or chief thoroughfare; through this opening, the angles and corners of other buildings are seen to stand projected, like the wings of the scenery of the stage; there are angles and corners of other buildings beyond these again, so that the eye dodges from projection to recess, from recess to projection one after another in unequal steps successively, and as the opening grows narrower and narrower, as it cuts deeper and further back, the sight is at last either lost in a pillar of darkness or rests on the clear, perceived through an upright slashing between the walls. These large openings in the side of streets, which afford such town vistas, are generally temporary, and are soon built up, we would propose making them (or something of the same kind, but perhaps more ornamental) permanent.

We build too much on the simple system of adding house to house and street to street, and designing single buildings alone. Our architects are too moderate in their ambition; they are content with getting a church, a hall, or a hospital to design, when they should aspire to the whole quarter of a city. One mind is confined to the planning of a block of houses which should have scope given it in plotting for the erection of a suburb. Genius is cramped and shut in; there is no outlet for a happy thought,—no room for a long shot ahead,—no chance of bringing out a harmonious symphony of buildings in a cordon.

The architect should work out his finest effects of chiaroscuro, not on a solitary building, but on a whole street or square of houses. It is the privilege of ruins to present large sheets of light amidst the black recesses of the angles of their walls. Should the architect attempt to produce a similar effect in his design, he would find it quite impossible to do so with a single house. In a slated and glazed building no large sheets of perfectly pure light and blue sky can be introduced; but if he has a square of houses or a street to work upon, he can introduce large sheets of light where he pleases, by leaving open spaces between the houses; and he can make these spaces wide or narrow, as may suit, or seem best. If he has a whole quarter of a town to design, he can work with light and shadow on a grand scale.

We should be glad to see an attempt made to work out some of the quarters of our cities as one design, and as one harmonious whole. There is rhythm in architecture as well as rhythm in poetry, and some attempt should be made to maintain it in the one as in the other. As it is to-day there is no absolute certainty even that a *single block* of building will be presented to view in a balanced form, even when it is designed by a single architect, and the whole of it erected at one time. When the one-half is built after the other, and the design of each half is by a separate architect, it is almost certain, such is the neglect of rhythm in architecture at the present day, that the one-half will not balance the other. A very common thing to see is one half of a block of buildings in the Gothic and the other half in the Italian style of ornamentation. When a professional architect is called upon to prepare a design for a building to be put down by the side of the design of another professional architect, instead of trying to make his design harmonise with that of his professional brother, and, exerting a legitimate rivalry, he frequently tries to prepare one which will drown his brother's design altogether. But by setting the elevation of the one house at variance with the other, the effect produced is generally like placing a blue and green light side by side,—the eye is set blinking, and can settle on neither. Thus the architect defeats his own object in such a case.

Where there is a city architect, he should be invested with a certain power of control over the styles of architecture to be introduced into particular localities. It would add to the character of a city if some of its quarters were carried out architectnrally, as harmonious wholes; and I could even name spots where the genius of one designer has dominated and produced a balanced and harmonious set of elevations. The effect is at once striking and satisfactory.

The view of the great street of a great city when it is empty of carts and carriages, and heavy traffic,—on a Sunday or holiday, or in the early morning,—the view of the great street of a great city is imposing, and gives expansion to the mind. It stretches away in a long vista, the sides of which are composed of countless buildings, with innumerable doors and windows, and posts and pilasters on either hand. In the principal part of the street there is a grand building, it may be the Town-hall or the Exchange, with a row of great steps stretched across its base, and above that a colonnade of tall, graceful, commanding pillars, upon the top of which rests a noble architrave. On the pavement in front of this grand edifice stand statues of the mighty men of old, and in some quiet nook, represented in the finest whitest marble, the graceful figure of a damsel or two,—

> "High in the air, 'over that very porch,'
> Four steeds divine,
> That strike the orb resounding with their feet,
> Forth from their nostrils snort ethereal flame."

But, alas! we can scarcely obtain the view of the great street of a great city now,—without a shadow coming between us and the end of the view. The gloomy girder railway-bridge interrupts the line, and breaks the continuity of our principal street and leading thoroughfares. It also disfigures the river view of the city, and displays its unseemliness and deformity by the very side of our handsomest over-river bridges,—the masterpieces of Rennie and Telford.

Another difficulty the landscape builder has to contend with is the passion for economising space, and the confirmed habit of filling up every available inch of building-ground in the heart of the town. No sooner is one building pulled down by city improvers to give light and air to one closely-packed portion of the town than another open place is covered and built up in another portion of it. And unless the law for providing light and air to all tenements be made stricter than it is, this kind of work is sure to go on to the deterioration of all amenity, and the closing up of the view of all architectural beauty.

City improvement, however, is a subject on which I do not propose to enter. W. Y. B.

NEW BUILDINGS IN VICTORIA-STREET, WESTMINSTER.

QUEEN'S MANSIONS.—ARMY AND NAVY HOTEL.

THE vacant land on the north side of Victoria-street, Westminster, has for the most part been now covered with spacious buildings, consisting largely of residential blocks in flats for the upper classes. A very extensive block, designated Queen's Mansions, is at present in course of erection, and almost completed externally. It is situated immediately opposite to the Army and Navy Co-operative Stores, having a frontage to Victoria-street of upwards of 150 ft., and is very lofty, containing five floors, the elevation being carried to a height of between 75 ft. and 80 ft. The materials are red brick, with a profusion of Portland stone dressings and window ornamentation. Massive bay windows, projecting considerably beyond the main face of the frontage, are carried up in succession from the ground-floor to the upper floors of the building, and at the foot of each floor window there is a prominent stone balcony. The building internally is intended to be artistically decorated, and to comprise spacious suites of family apartments on each floor, which will have the advantage of a lift in addition to the staircase approaches.

On the same side of the street eastward, a site has been secured on which the new Army and Navy Hotel is about to be erected. For the purposes of this new building the greater portion of the site of Palmer's old almshouses has been purchased. These almshouses, which were first established and built in 1650, but rebuilt in 1817, are now in course of demolition. The site of the buildings and gardens extends in depth from Victoria-street, Chapel-street, Broadway, northwards, the Victoria-street frontage being about 60 ft. in length. The new hotel will cover a large portion of the site until recently occupied as the almshouses. It is stated that in place of the old dwellings now being taken down, the trustees are about to erect new almshouses in Rochester-row. The new hotel, for the special use of the two services, is intended to be of large dimensions, and its erection is to be commenced as soon as the ground is cleared.

Although, as above stated, the vacant land in this important West-end thoroughfare is being occupied by new buildings, it should be added that there are at present two huge and dismal-looking blocks, which are best described as unfinished carcasses, the works at which are for the present, at least, suspended. One of these, at the western end of the thoroughfare, not far from the Victoria Railway Station, is a massive and substantial building entirely in Portland stone, upon which, it is said, upwards of 15,000*l.* have been already expended. Externally the building has been completed, with the exception of the carving and sculpture on the main frontages, but the interior work remains to be done. It is intended as residential chambers, similar to the "Members' Mansions" a little further eastward. The other unfinished building, the works at which have also been stopped, is a large red-brick structure of about 140 ft. in length, and five stories in height, showing nothing more than the shell. It is stated to have been originally intended for a co-operative store.

VALUE OF FREEHOLD PROPERTY IN HATTON GARDEN AND CHARTERHOUSE LANE.

ON Tuesday, Messrs. Debenham, Tewson, & Co., offered for sale, at the Auction Mart, two freehold properties, situated in the neighbourhood of Hatton-garden and Charterhouse-lane, respectively. The property in the locality of Hatton-garden comprised a building of five floors in Charles-street, at the corner of Great Saffron-hill, close to Hatton-garden, and the recent improvements in that neighbourhood. The property, which covers an area of 1,965 superficial feet, was said to be very substantially constructed of stone. The premises are let on lease to Messrs. Wyman & Westwood, wholesale druggists, for the residue of a term of twenty-one years from June, 1879, at a rental of 400*l.* per annum, the lessees undertaking to repair, pay insurance premiums, and all usual outgoings. There was a close competition for the property by several bidders, and it was ultimately sold for 7,300*l.*

The property in the neighbourhood of Charterhouse-street comprised the premises Nos. 24 and 25, Charterhouse-lane, situated immediately opposite the Metropolitan Meat Market, having a frontage of 22 ft., and occupying an area of 770 superficial feet. They were said to be let on lease for a term of fourteen years from June, 1872, at a rent of 60*l.* per annum. It was stated that the property was of greater value as a site for a more important building. The first bid was 2,000*l.*, the offer being rapidly brought up to 3,250*l.*, at which it was sold.

The Hanover Gallery, Bond-street.—The winter exhibition in this bright and commodious little gallery includes 144 pictures, two small pieces of sculpture, and 333 drawings and sketches made for *Punch* by Tenniel (5), Sambourne (10), Keene (105), and Du Maurier (213). The largest work amongst the pictures is a painting by R. B. Browning, "The Delivery to the Secular Arm" (No. 5), which displays a higher aim and more technical ability than the painter has before shown. Pictures by Messrs. Millais, Watts, Val. Prinsep, Boughton, Alma Tadema, Marks, Sir F. Leighton, and some other eminent artists, are in the collection.

ENGINEERING EXHIBITION AT ISLINGTON.

The Engineering Exhibition at the Agricultural Hall, Islington, opened on Monday last, is perhaps the least successful of the trade exhibitions which have been held there of late. It is certainly by no means so large and so fairly representative a collection of materials and appliances as were the Building Trade and Printing Exhibitions. There is very little machinery in motion, and the area of the hall is only partially occupied, although what we heard characterised as "peepshow business" is more largely represented than in the previous exhibitions of the same series. Besides peepshows pure and simple, there are exhibited such things as the *Little Western* dory-boat (in which cockle-shell of a craft two men were foolhardy enough to cross the Atlantic from America not long ago), spring mattresses, cooking-stoves, stove-polish, toilet-soap, cement for mending broken glass and china, Indian hearthrugs, gas-burners, "non-alcoholic champagne," bronghame, and a number of other materials or products that have little or no relation to the asserted object of the exhibition. The two largest and best displays are made by Messrs. S. & E. Ransome & Co. and Messrs. Moser & Son. The former firm have a good display of hoisting crabs for builders' use, screw-jacks, sack-hoists, saw-benches, emery-wheels, "free-grit" and "annular" grindstones (made of Ransome's well-known artificial stone), and a good collection of engineering tools of every description, including their new "crucible cast-steel" spanners, which possess the merits of strength, lightness, and cheapness. The stand occupied by Messrs. Moser & Son is interesting not only by reason of the extent and variety of the machinery and appliances exhibited, but because it forms almost a small museum of specimens illustrating the fracture and behaviour under various tests and modes of treatment of "S. C. Crown" and "H.P." iron. The specimens of the former brand exhibit in their fracture a strong fibrous texture; while examples of the latter brand of iron (which is manufactured by Messrs. Moser themselves) are put forward as evidence in support of their statement that the material combines in itself the characteristics of both steel and copper. Mr. E. S. Hindley, of Bourton, Dorset, exhibits some portable combined vertical engines and boilers, together with horizontal engines and a circular saw-bench. Messrs. Smith & Coventry exhibit their patent "open-spindle capstan-rest chasing lathe," which makes screws, studs, pins, &c., from the bar with once chucking. The same firm also show drilling, milling, and drill-grinding machines. Messrs. Thomas B. Jordan & Son exhibit their patent pulverising-machine, for crushing and pulverising emery, granite, limestone, flints, cements, &c., to any degree of fineness without the use of sieves. The degree of fineness of the material leaving the machine is regulated pneumatically. Messrs. A. Lusty & Co. exhibit band-saws and band-sawing machinery. The Rustless and General Iron Company (Messrs. James E. & Samuel Spencer) exhibit "Anti-corrodo" tubes and fittings of all kinds, treated by Barff's "anti-corrodo" rustless process. Mr. James Hardinge exhibits the "Swifteure" wood-working machine, together with "Hurricane" portable forges and other workshop and portable plant. Among other exhibits more or less directly of interest to the building trade are the paints of the Indestructible Paint Company; Jeyes's "Concentrated Creosote" (used in tanks of boiling water with the view of preserving timber); Messrs. Ewart & Son's "Empress" ventilator, their "Crown" boiler for baths, &c., and their "Amethysta" gas-stove for warming and ventilating by introducing a continuous current of fresh warm air into apartments; Messrs. Robert Boyle & Son's self-acting "Air-Pump Ventilators"; Messrs. Maryon & Co.'s self-acting lattice shutters and grills for shop-fronts and private houses; Balmain's luminous paint; Messrs. W. Sneaton & Sons' patent "Eddystone" water-closets, and their machine-made cast-lead "Eclipse" traps; McHaffie's, Sharp's, Kite's, and other ventilators; the "Otto" and Bisschop's gas-engines; Hodson's patent rotary steam-engines; Hamilton's patent prismoidal lights, stall-boards, &c.; and, to bring this list to a close, Spence's metal, exhibited by Messrs. J. Berger Spence & Co. The capabilities of this material, practical as well as artistic, were fully described in a paper read before the Society of Arts early this year by Dr. Granville Cole, and reported by us at the time.* Its practical uses include its employment, in lieu of lead, for jointing gas and water mains, and for fixing ironwork in stone, &c. Its artistic value is sufficiently attested by the display made by Messrs. Spence in the Agricultural Hall, which includes some bas-reliefs, medallions, and a bust of Sir Henry Cole. The "Crown Jewel" stove is as peculiar in appearance as the problem which it seeks to partially solve is important. It is an American invention, and it claims to be absolutely smokeless; it only burns anthracite coal or coke. It somewhat resembles in form an ornate but gigantic lantern, resting on a stand, the fire being enclosed in a basin-shaped grate, and visible all round through the talc windows which constitute the bulbous or lantern-like portion of the stove. It is charged with fuel by means of a vertical cylinder easily got at by the removal of the top cap. This fuel cylinder being fully charged, the stove burns for a long time without attention; for as fast as the fuel is consumed by combustion, the grate is automatically replenished from the cylinder. There are many other things which we have not space to mention. The exhibition, which closes this (Saturday) evening, has not been very numerously attended.

THE GLASS TRADE IN ENGLAND.

At the suggestion of Mr. C. R. Crickmay, architect, of Weymouth, who had grieved over the knowledge that a large and increasing quantity of glass for building purposes is imported into this country, and was naturally anxious that our own country should not only supply itself, but stand first in the estimation of the consumers in every country, the Worshipful Company of Glass Sellers have offered substantial prizes for an essay on "The Past and Present Position of the Glass Trade in all its Branches, and Suggestions for Improvement in the English Trade," and propose to give a gentleman of authority 25*l.* for adjudicating on the respective merits of the several essays.

It seems to us that instead of referring the essays to one person they should refer them to a committee of three, or at any rate two, representing the technical aspect of the question, the art aspect, and the commercial aspect. The Company would probably find competent persons who would undertake this without a fee. One other suggestion we would make, which is, that instead of offering three premiums, as is proposed, the whole sum at their disposal should be offered for the best essay. This course would be more likely to bring the right man into the field.

VALUE OF OLD SION COLLEGE SITE.

According to the sums realised for a number of building sites on the Sion College Estate in Aldermanbury, which were let on lease last week for a term of eighty years, at the Auction Mart, by Messrs. Fox & Bousfield, the governors of the college are likely to be put into possession of a very large annual income, representing a capital sum which will be comparatively little affected by the cost of the intended new college buildings on the Thames Embankment. The sites let last week were seven in number, containing altogether an area of 7,500 ft., and consisted of the land upon which the president's house and a number of shops and other ancient structures fronting London-wall and Aldermanbury until recently stood. Four of the sites immediately adjoin St. Alphage's Church, and a question of ancient lights as affecting this edifice arose in connexion with the intended new warehouse or other buildings, but this has been arranged.

There was a very numerous attendance at the letting of the sites last week, and in order to show the restrictions under which the new buildings are to be erected, a model, pointing out the same, was exhibited in the room, and explained by the auctioneer. The sites were all quickly let; the four sites in Aldermanbury-avenue, extending in depth to the church, realising 310*l.*, 150*l.*, 125*l.*, and 130*l.* each, or 715*l.* per annum altogether; and the three sites facing London-wall being let for 230*l.*, 230*l.*, and 300*l.* per annum each, together 760*l.* per annum, or an aggregate sum for the seven sites, containing 7,500 superficial feet, of 1,475*l.* per annum. The entire site of the college and grounds, which will now shortly be covered with buildings of a mercantile character, is about an acre in extent, and supposing the remaining sites to be let at the same rate as those which were disposed of last week, the Governors of the college will ultimately derive an annual income from the site of about 7,400*l.* per annum, the whole of the site, according to the history of the college, having originally been purchased, in the seventeenth century, for 2,450*l.*

Capitalising the above annual sum at twenty years' purchase gives about 150,000*l.* as the present value of the freehold of the site, but it was observed at the letting last week that a fairer estimate would be twenty-five years' purchase, which would represent as its present value, 185,000*l.*

* *Builder*, vol. xxxviii., p. 213.

LIVERPOOL ARCHITECTURAL SOCIETY.

The annual dinner of this Society was held on Tuesday, the 5th of October, at the Alexandra Hotel, Dale-street, forty-four members and guests being present, among the latter Mr. J. Murgatroyd, president of the Manchester Architectural Association; Mr. J. Holden, hon. secretary of the Manchester Society of Architects; Mr. Alexander Ross, president of the Liverpool Engineering Society; and Mr. J. C. White, president of the Liverpool Master Builders' Association.

The first ordinary meeting of the society was held on the following day, October the 6th, the president, Mr. Charles Aldridge, F.R.I.B.A., in the chair.

After the election of members, and other business, the report of the visitors on last session's work by members of the class of construction and design was read, the first prize being awarded to Leonard J. Pilkington, and the second to Constantine Phillips. The President then read his opening address, of which the following are the preliminary remarks:—

"We commence to-day the thirty-third session of this society, which I need scarcely remind you has the privilege of seniority amongst all the provincial architectural societies, a fact of which I think we should be proud. During the thirty-three years since the society was founded it has had no doubt its ups and downs,—periods of success and depression,—but I think I may venture to say that at no time has it been more prosperous or better supported by the profession in Liverpool than at the present. We now number 138 members, composed of forty-seven Fellows, twenty Professional Associates, thirty-five Associates, thirty-two Students, and four Honorary and Corresponding Members.

Prosperity, however, is often as trying as adversity: at the one time we are apt to despond, and give up endeavouring to improve matters when they seem so hopeless, and at the other time we run into the danger of following a similar course, by the very reason of our success, thinking we have gained the summit of our ambition; but should we not seize the present opportunity to look around us and see what we can do to enlarge the sphere of our society, and attract others to join us? We must not rest content until we have induced every architect and architectural student to become a member, and surely there is no reason why this should not be. There is another way by which we can add very much to our usefulness, and that is by increasing the work done by the educational branch. The class of design and construction, which was commenced three years ago, has now, I am glad to say, become sufficiently strong in numbers to warrant us undertaking a course that I have contemplated for some time, and which will, I hope, be carried out this session if I can get the necessary support from the Fellows and students. It is proposed the class should meet fortnightly instead of monthly, and that at each alternate meeting a short course of instruction be given on construction. These lectures might be arranged in the same way as a specification, so that the course during the present session might comprise all the trades, commencing at excavator and bricklayer. I have drawn up a syllabus of these lectures, together with a list of subjects for the class of design, and I hope on this day fortnight the first lecture will be given."

Free Lectures: Parkes Museum.—In response to a suggestion made to the Executive Committee by the Nineteenth Century Building Society, the following course of lectures on "Dwelling Houses," largely descriptive of articles and apparatus in the Museum, will be delivered in the Museum, University College, Gower-street. The admission to the lectures will be by free tickets, which will be distributed through the agency of the metropolitan building societies. December 11th, "Situation and Construction," by Edwd. C. Robins, F.S.A.; January 8th, 1881, "Ventilation, Lighting, and Warming," by Edwd. C. Robins; January 22nd, "Water Supply and Filtration," by Prof. W. H. Corfield; February 5th, "Drainage," by Rogers Field, C.E.; and February 19th, "Water-closets, Sinks, and Baths," by Prof. W. H. Corfield. Each lecture will commence at half-past three in the afternoon.

BUILDERS' BENEVOLENT INSTITUTION.

ANNUAL DINNER.

THE thirty-third anniversary festival in aid of the funds of this deserving Institution was celebrated on Thursday, the 11th inst., at the Freemasons' Tavern, Mr. Thomas F. Rider (of the firm of Rider & Son, Union-street, Borough) in the chair, supported by Mr. Edward I'Anson, F.R.I.B.A., Mr. George Plucknett (Cubitt & Co.), Mr. John Hebb (Assistant Architect, Metropolitan Board of Works), Mr. ex-Sheriff Burt, Mr. E. B. I'Anson, M.A., Mr. F. J. Dove (Dove Brothers), and about 250 other supporters and friends of the Institution.

The usual loyal and patriotic toasts were duly honoured, the Chairman, in proposing that of "Prince and Princess of Wales and the rest of the Members of the Royal Family," remarking that their Royal Highnesses the Prince of Wales, the Duke of Connaught, and Prince Leopold, might almost be claimed by the builders as belonging to their trade; for were they not all three most excellent Masons? and was not masonry one of the most important departments of building work? In proposing the toast of "The Army, Navy, and Reserve Forces," he observed that the Navy, like the building trade, had been somewhat interfered with by the introduction of iron in place of wood.

Major Bratton, in responding for the Army and Navy, referred to the ill-fated *Atalanta*, and paid a warm tribute of praise to her commander, Captain Francis Stirling, with whom he (the gallant Major) had served for three years. The foundering of that vessel was, he was quite sure, due to no want of skill in seamanship on the part of her captain.

Captain Bird responded for "The Reserve Forces."

The Chairman, in proposing the toast of the evening, "The Builders' Benevolent Institution," said: "At a preliminary meeting of the various branches of the building trades, called together by Mr. Thomas Cozens, of 17, Lissongrove, North-street, Marylebone, on Wednesday evening, January 27, 1847, at the 'King Alfred' Tavern, Lisson-grove, — present, Mr. Cozens, stonemason," and nineteen others, consisting of three builders, three carpenters, two bricklayers, two plumbers, two ironmongers, one grainer, one paperhanger, two timber merchants, one lead merchant, and two whose occupation is not stated,—"for the purpose of forming an association for the relief of decayed masters connected with the building trades, Mr. Cozens having been unanimously elected to the chair, the objects of the meeting were taken into serious consideration, and various discussions took place, when it was proposed by Mr. George Chamberlain, lead merchant, seconded by Mr. Ferguson, paperhanger, and unanimously resolved, 'That the gentlemen present should form a committee, provisionally, for the purpose of carrying out the objects of the Institution,' and Mr. William Grubb was appointed secretary *pro tem.*'" Such, gentlemen, is the entry in the old minute-book with regard to the formation of this Institution. Various committee meetings were then held, and on the 22nd of February the title of "Builders' Benevolent Institution" was settled upon. On the 29th of March the first committee was appointed, amongst whom were Mr. Cozens, the founder; three of the Messrs. Bird (two of whom for so many years did excellent service to the Institution),—and, by the bye, other birds have also been great friends to the Institution, including the Condor and the Dove; Mr. Ebbs (whose widow has been since 1877 a pensioner of the charity); and Mr. Richardson, who, as many of us will remember, has often told us that he was at the formation of the society. Mr. Biers, who was president of the Master Carpenters' Society, seems to have been the first president, for I find that on the 19th of July they did what all new institutions must do, had a great public meeting, which was held at the old Freemasons' Tavern,—present, Mr. Biers in the chair, supported by Lord Robert Grosvenor, M.P., Lord Dudley Stuart, M.P., Col. Thomas Wood, M.P., Sir Benjamin Hall, M.P., Mr. David Salomons, Mr. Geo. Cochrane, and a large number of influential representatives of building interests. The chairman made a capital speech, beginning, of course, by expressing the usual wish that some one more able had been found to preside. That is my own wish to-night. He pointed out the many risks and difficulties attending the building trade, and after going into a most glowing description of the likeness between the builder's trade and the calling of a sailor, concluded by proposing that as soon as 4,000*l.* had been subscribed, operations should be commenced, and also that when 5,000*l.* more had been separately collected for the "Builders' Almshouses," they should be commenced. This and other resolutions were carried, and I notice amongst the names of those supporting them George Spencer Smith (grandfather of Mr. H. G. Smith, known to us all), and Joshua Higgs (the father of Mr. W. Higgs, our president a few years ago). On the 30th of July the first application for a pension came from one Robert Wright, but he was informed "the funds did not admit of it." An appeal was issued to the trade on behalf of the Institution, attached to a copy of the rules. Mr. George Bird was elected treasurer,—an office which he continued to fill until 1861,—a period of twenty-four years,—when our excellent friend Mr. Plucknett succeeded him. In August of the same year (1847), nineteen applications were made for pensions, and of the applicants, fifteen were approved as candidates. On the 30th of that month it was decided that the pensions should be from 10*l.* to 30*l.* per annum,—a sufficiently wide margin; that, at the discretion of the committee, on the death of a pensioner, his pension might be continued to his widow; and that temporary relief might be granted to orphans. In November, 1847, 200*l.* Stock was bought. The next matter of importance was the determination, in 1848, to have an annual dinner, and on the 19th of July was celebrated the first anniversary of the foundation of the Institution, and it may perhaps interest you to know what the arrangements of the committee were for the entertainment of the guests. I find that it was finally arranged,—"That the dinner should consist of soups, fish, meat, poultry, and vegetables in season, two 'firsts' of champagne, port and sherry *ad libitum*, coffee or tea, soda-water, ginger-beer, &c.; that the ladies in the gallery should be provided with 'a *déjeûner* of cold viands, wine, ginger-beer, soda-water, coffee, or tea," that vocalists were engaged, and "Mr. Day asked to furnish an instrument for the night." Lord Robert Grosvenor, M.P., was in the chair, and the whole of the proceedings seem to have passed off most amicably, for there is no entry of them in the minute-book.* In October it was resolved, on the suggestion of Mr. Joseph Bird, that a series of balls should be given, the profits to be appropriated to the funds of the Institution, and the first one did take place on the 19th of January, 1849, resulting in a profit to the Institution of 20*l.* 12*s.* 6*d.*, and from that time for twenty-four years an annual ball took place under the supervision of Mr. Joseph Bird. They have continued to be given. The next one will be held at Willis's Rooms, St. James's, on the 27th of January, 1881, and Mr. Keeble will be very glad to receive the names of any gentlemen willing to become stewards. On the 4th of December, 1849, it was decided that the pension should be 24*l.* per annum, and that as soon as the subscriptions reached the sum of 250*l.*, half that amount should be spent in pensions, and the rest funded. In May, 1849, Mr. Grubb, the secretary, resigned, and the late Mr. A. G. Harris (whose invaluable services to the Institution many of us remember) was elected to that position. On the 30th of July the second annual meeting was held, when Mr. Biers was re-elected president; an election for five pensioners fixed to take place at the end of October in the same year, and the amounts of the pensions settled to be 24*l.* per annum for males and 20*l.* per annum for females. On the 29th of November the election was held, when four men and one woman were placed on the funds of the Institution. From that time the progress of the Institution has been steady. Year by year men well known in the building trade have occupied the position of president,—Mr. William Cubitt, afterwards Lord Mayor of London, being the first, followed by Sir Samuel Morton Peto, Messrs. Charles and Thomas Lucas, Messrs. Lawrence, Mr. Trollope, Mr. Plucknett, and others. The money collected for the purpose of building almshouses, after many discussions was at last, with the approval of the subscribers and the consent of the Charity Commissioners, added to the Relief Fund, which now reaches the sum of 21,400*l.* The pensions, through the indomitable perseverance of my predecessor (Mr. F. J. Dove), have been raised to 39*l.* for men and 30*l.* for women, necessitating, of course, a much-increased outlay. One hundred and eighteen persons have enjoyed the benefit of the pensions, and there are now more than fifty on the books. For the next election, which will take place on the 25th inst., there are nine candidates,—five men and four women. Gentlemen, I have roughly sketched for you the rise and progress of the Institution on whose behalf I now appeal to you, and I am afraid I have somewhat trespassed on your time, but I have been told that from its formation no account of its origin has ever been given on such an occasion as this. The building trade, as those who are in it well know, is one exposed to enormous risks. Strikes and lock-outs,—those barbarous expedients with which it is attempted to settle disputes between masters and men; unhealthy competition, that bane of commerce in all times; accidents through the carelessness of workmen; bad weather, and many other things, combine to render the building trade one of the most precarious in existence. In proof of this I may mention that one of the present applicants for a pension is the widow of a builder formerly on the committee of this Institution, and a liberal donor to the charity, and we soon expect to receive a similar application from the widow of a late partner in one of the largest building firms in London, who was ruined in carrying out a large contract at the West End. I appeal, then, to the master builders of London to support this Institution, on the ground, partly, that they may, some of them, some day or other require the assistance which it is able to give. I appeal to them on the ground that those who are engaged in the same business as themselves have a prior claim on their charity. I appeal to the merchants connected with the building trade to do what they can for us; and lastly, I appeal to all to help us to make the Institution one of the largest and best charities of the charitable metropolis of the world. I beg to propose "The Builders' Benevolent Institution," coupled with the name of Mr. George Plucknett, its respected treasurer.

Mr. Plucknett, in responding, said he could only hope that the very enthusiastic manner in which the toast had been received was an augury that the company intended to enable him, as treasurer, to meet the Institution's liabilities for the coming year with ease. When their late president, Mr. Dove, expressed his desire to see the amount of the pensions increased, the proposal met with his (Mr. Plucknett's) cordial concurrence, and at the annual general meeting held in July, the question was fully discussed, and the increased pensions decided upon. At that meeting they had the satisfaction of receiving a communication from Mr. George Godwin,—a gentleman well known to almost everybody in the building trade,—saying that he entirely approved of the proposed increase in the pensions, and offering to subscribe ten pounds a year for ten years towards that object if nineteen other gentlemen would do the same, and so guarantee an increased income to the Institution of 200*l.* per annum. He hoped that Mr. Godwin's offer would not be lost sight of. Considering the vast interests of the trade which it represented, the Builders' Benevolent Institution ought to be one of the best-supported charities of the metropolis. When he stated that there were about 700 charitable institutions of a similar kind in the metropolis, with a yearly income of more than 3,000,000*l.* sterling, he thought it was not too much to hope that the builders of London would see to it that their charity continued to maintain its position. In conclusion, Mr. Plucknett said that the Institution had never had a president who had taken greater interest in it than Mr. Rider had done.

The Secretary (Major Bratton) then read a list of subscriptions and donations amounting, as we stated last week, to 1,014*l.* 16*s.*,—a larger sum than has been obtained for many years past.

Mr. Edward I'Anson, in proposing the toast of "The Chairman and President," said he had the greatest pleasure in proposing Mr. Rider's health. He had for fifty years or more known Mr. Rider's firm,—Mr. Rider and his excellent and respected father. The name of Rider in

* A full report of the proceedings at this dinner will be found in our volume for 1848, p. 356, and a report of the foundation-meeting, previously referred to by the chairman, in the volume for 1847, p. 352. In fact, the early history of the Institution can best be read in the *Builder*, without the advocacy of which at one particular moment the endeavour to found it would have collapsed. In the notice of the foundation meeting it will be seen the chairman, Mr. Biers, proposed a special vote of thanks "to the editor of the *Builder* for bringing this Institution before the notice of the public."

his (Mr. I'Anson's) office had always been a household word. There had never been a year for fifty years past in which Messrs. Rider had not been carrying out works for Messrs. I'Anson. He had not only known the Messrs. Rider for the long period mentioned, but he had learned to respect them. All that they had done had been done with the utmost ability and honesty, and he had therefore reason to speak in the most complimentary way of them.

The toast was very heartily received, and the chairman having briefly responded,

Mr. Glanvill proposed "The Vice-Presidents and Trustees," coupled with the name of Mr. F. J. Dove, who briefly replied, expressing his thanks to the President for the efforts which he had made on behalf of the Institution. It was satisfactory to know, from the amount of the subscriptions and donations announced, that those efforts had been crowned with a success which would not only make it easy for the committee to pay the increased amounts of the pensions, but would possibly allow of the election of more pensioners.

Mr. Ex-Sheriff Burt, in proposing "The Architects and Surveyors," said he was delighted to see so many architects present and taking an interest in the Institution. The architects and surveyors of the metropolis played a most important part in the life of the great city. They frequently were beset by apparently insuperable difficulties, but they generally succeeded in satisfactorily surmounting them, and, as a rule, builders and contractors had very little fault to find with the way in which they were treated by the members of those professions. With the toast were associated the names of Mr. Edward I'Anson and Mr. Franklin.

Mr. I'Anson, in responding, said it gave him very great pleasure indeed to meet so large a gathering of so important a community as the builders of London. The builders on the one hand, and the architects and surveyors on the other, were engaged in setting in motion a large mass of people, who were all, it was to be hoped, honestly and diligently seeking to promote the best interests of the great commonwealth to which they belonged by producing good and perfect buildings. He had been now labouring nearly fifty years as an architect, and he had never had any disagreement with any builder who had carried out works for him. Indeed, he had always found that his works had been excellently carried out by his friends, the builders.

Mr. Franklin also responded, observing that he was very pleased to hear Mr. I'Anson express himself with so much satisfaction as to the way in which the builders of London did their work. He (Mr. Franklin) would fain look forward, as many others did, to a very good time coming for the building trade; but it was his decided conviction that that good time would only arrive when builders would refuse to make tenders upon quantities that they could not possibly rely upon or understand. When that time arrived the trade would become so prosperous that it would think nothing of subscribing even a much larger sum than 1,000*l.* to the funds of the Institution.

The only remaining toast was that of "The Committee and Stewards," coupled with the names of Mr. T. G. Smith and Mr. Randall, who briefly replied.*

NEW CHURCH AT DUDDO, NORTH-NORTHUMBERLAND.

On Tuesday, the 9th inst., the new church that has been in course of erection since the autumn of the past year, when Louisa, Lady Waterford, laid the foundation-stone, was consecrated by the Bishop of Durham. About twenty clergymen, including the Archdeacon of Lindisfarne, the Hon. F. R. Grey, and the Vicar of Duddo, the Rev. Beverley S. Wilson, assisted in the ceremony, which was performed in the presence of a large congregation which completely filled the edifice. The church is placed on a slope by the roadside, near the vicarage-house, in a wide wild tract of country surrounded by hills, and is built of the excellent stone of the district which has in it many of the beautiful tints of Sandown. The church consists of a nave, 46 ft. by 25 ft., and chancel, 25 ft. by 20 ft. At the west end of the nave is a tower, capped by a hell-turret; and on the north side of the chancel is a chamber for the organ and a vestry. To this plain and simple outline satisfactory architectural effect is given by the details of the windows, which are enriched with tracery, and filled with lead patterned glazing. The niched doorways help the effect. In the interior the open-timbered roofs, each compartment of which gets richer as it approaches the east end, the columniated chancel-arch, the pulpit of open-panelled work, and the communion-table of similar perforated woodwork, add to the general air of unity. The chancel is furnished with stalls to seat twenty, and the nave is seated with rush-bottomed chairs for the accommodation of 158.

Owing to the low prices which obtained at the date of the competitive tendering, in consequence of the existing depression in the building trades, a church of some architectural effect has been produced at a very small cost.

Mr. F. R. Wilson, Alnwick, is the architect. The contractors were:—Mr. H. Elliot, mason, Hornclife; Mr. A. E. Burn, joiner, Spital; Mr. J. Turner, slater, Hornclife; Mr. R. Sidey, plumber, glazier, and smith, Tweedmouth; Mr. A. Robertson, painter, Alnwick. A bell, 2 ft. in diameter, wheel, and gear, were supplied by Messrs. H. Watson & Son, Newcastle-on-Tyne.

* We are pleased to be able to add that (as will be seen by an advertisement in another column), in consequence of the generous support accorded to the Institution at this dinner, four pensioners (two men and two women) will be elected on Thursday next, the 25th inst., instead of one man and one woman, as formerly arranged.

PALÆOGRAPHY.

There are in the British Museum Library, to which institution I referred in the *Builder*, No. 1,952, various collections of MSS. accessible and well preserved. Many of these, however, and MSS. in other collections, are difficult to decipher. Probably most of them can be deciphered only by experienced experts. Occasionally a rare MS. is construed and issued by the Camden Society, &c., or extracts are contained in some volume. The comparison of a printed translation with an original document clearly denotes the truth of this statement. See, for instance, the coronation speech of Henry VIII.,—MS., in vol. i. of Ellis's "Historical Letters," s. 2. It is a subject for regret that such should be the case, because these MSS. are interesting, rare, and valuable, probably. Some of them at least might be printed or copied fairly for public use, selected specially for the purpose, according to the plan adopted in the publication of the Harleian MSS. in 12 vols., 4to. As they are now, many MSS. in the British Museum Library are useless except to experts and the few persons who may be initiated in the art of palæography. Even when a document has been deciphered, it requires a special knowledge to understand the various abbreviations. A glossary generally is appended for this purpose, of which there are specimens in Cole's "Historical Documents," folio, 1844, and in Wright's "Court Hand Restored," &c. The ordinary reader would find it difficult to decipher even John Milton's "Common-Place Book," of which there is an autotype copy with a translation in the British Museum Library, and yet that is comparatively easy to unravel. The Hargrave MSS. in this collection contain various specimens of orthography, ancient and modern. Some of these are easy to decipher, while many of them are only to be unravelled by experts if at all. Hence many of these volumes are sealed books as to the public, and are likely to remain so, although bought at a high price. An intended work upon palæography some years since was expected from Mr. R. Sims, of the British Museum MS. department, but it has not yet appeared. I believe that the works extant upon this subject are (1) Astle's "Origin and Progress of Writing," reprinted recently by Chatto & Windus; (2) Madox's "Formulare Anglicanum"; (3) Casley's Collection of MSS. in the King's Library, British Museum Library; (4) Wright's "Court Hand Restored," ninth edition, 1878, by Martin, of the London Record Office, with additions; (5) Chassan's thin octavo volume in French; (6) specimens of inscriptions in churches, &c., are contained in "Bibliotheca Topographica Britannica," vol. vi, and in "A New Boke of Handwriting," 1590, press-mark 1268*a*, British Museum Library. The Palæographical Society of London have issued rare specimens in folio. In Wright's original preface it is stated that "few persons are to be found capable of reading or explaining old deeds and charters with satisfaction to themselves or others." So it was in A.D. 1773, and probably it is so now. Also, "the Reading of the old law hands is (1773) very nearly, if not altogether, obsolete, though useful." This author then showed the utility of jurists having this knowledge for several reasons, and he mentions several cases in which copies of records produced in Courts of Justice as evidence were rejected as evidence, the originals being extant. The fifth edition of this volume ("Court Hand Restored"), contains extracts from the Returns of Astle and Cayley. Wright's volume includes the old law hands. Some of the specimens are taken from Astle, and in the appendix are ancient names of places in the United Kingdom, and a table of ancient surnames, with an exposition of Latin words, &c. There are many MSS. of the Middle Ages and of more recent date which require additional aid for satisfactory interpretation by the inexperienced reader certainly.

Mr. Astle stated that "the characters introduced by William I. were called Lombardic; but soon afterwards acquired the appellation of Norman characters, generally used in grants, charters, public instruments, and law proceedings, with little alteration until the reign of Edward III. In that of Richard II. variations took place in handwritings of records and law proceedings; the characters used from that time to the reign of Henry VIII. are composed partly of characters called Set Chancery and Common Chancery, and of some of the letters called Court-hand. The Chancery letters were used for all records which passed the great seal; the court-hand in the Courts of King's Bench and of Common Pleas, for fines, placita, &c. These latter came into use about the middle of the sixteenth century, and were continued until about the middle of the late reign, when they were disused. (See 4 G. II., c. 26, and 6 G. II., c. 14, requiring all law-pleadings, deeds, &c. to be thereafter written in English.) They were originally the Lombardic or Norman, but corrupted and deformed so that they bore little resemblance to their prototypes. In the sixteenth century the English lawyers engrossed their conveyances and legal instruments in characters called Secretary, which are still in use."

"Many grants and charters, especially those written by the monks, were in letters called Modern Gothic, which took place in England in the twelfth century. From the latter end of the thirteenth to the seventeenth century, lawyers, when they wrote in the English language, made use of characters derived from Modern Gothic for conveyances, wills, &c., about the middle of the seventeenth century. I think the Set Chancery most durable and proper to be used for patents, charters, &c."

"The character of handwriting of ancient records," according to Mr. J. Caley, "has gradually degenerated from age to age. Thus, the records of the Saxon era, written in Saxon or Latin, are more plain and legible than those of subsequent eras, little obscured with abbreviations which have created doubt and ambiguity in after ages, particularly in that valuable record, Domesday Book."

From the Norman Conquest until the reign of Henry III. the character is plain and perspicuous. Of this reign (Henry III.) many records cannot be read with facility on account of the intricacy of the character and the number of abbreviations. "The same observations may be applied to records from this reign until that of Edward III. inclusive. From this period downwards, I have experimentally found that less difficulty occurs in reading and translating records; and that the hands used from the reign of Richard II., to that of Philip and Mary, may be read without much trouble. Hitherto each reign appears to have had a set or uniform character. In the reign of Elizabeth and her successors the clerical mode seems to have been in a great measure abandoned, and each transcriber to have written according to his own fancy; and the English records of the sixteenth and seventeenth centuries are in general more difficult to be read than the Latin records of preceding ages." Every word of these statements I believe to be correct; and it is according to my experience.

The remedy for the deficiency is to make palæography a science, like that of book-keeping and stenography: to encourage persons to study it, under advice, and to make it a remunerative profession. No doubt some persons would excel more than others; but that is the case in all employments. Where funds are at hand a selection of documents should be transcribed or printed for public use, and bound up from time to time with an index and a table of contents, in the British Museum, &c., the originals being preserved carefully. C. C.

cost of 30,000*l.*, in opposition to the strongly-expressed opinion of the ratepayers; yet they grudge the poor a decent lodging. Of course, the owner of the highly-rented slum, and the speculating builder with houses on hand he can neither sell nor let, will both oppose the Act, and these classes are well represented on the vestries; but I hope the Government, considering the urgent necessities of the poor, will turn a deaf ear to vestries and vested interests.

JAS. YOUNG.

STRENGTHENING EMBANKMENTS.

SIR,—In a foreign paper of the 7th instant I notice it is stated that, from actual experience on extensive railways in Prussia, the embankments are very much strengthened by planting in them a species of willow tree (*salix*), white *alba* being, it would seem, preferable.

It is stated that the roots of these trees form a thick trellis or lattice enveloping the whole surface, and thus imprisoning the earth. The nature of these trees permits them to grow very readily, requiring little or no care. As a kind of creeper for protecting embankments it is, by the same authority, said to merit the attention of architects.

E.

*** The use of vegetable growths to strengthen dykes in Holland is a practice of great antiquity.

MEASURING TAPES.

SIR,—In despair I write to ask you, as editors are supposed to know everything appertaining to the speciality of their papers, where can I get measuring tapes that are of any service after they have been used a few times? I have tried all sorts. There can be no doubt that the steel tapes would be the best if manufacturers would make them of more substance, and would link them say every 5 ft. and put two swivels in a 66 ft. tape. As they are made, all, or at least all I have been able to get, are warranted to kink and break the first or second time they are used, as the metal is so thin, and consequently so sharp, that you stand a good chance of having a finger or two cleanly cut through before you know where you are, which is not quite pleasant.

INQUIRER.

"DISTRICT MARKETS."

SIR,—A company is already in active working order, carrying out the various objects referred to in last week's *Builder*.

The name is "The Local Meat Markets" (Limited); the first one, called the "Dowgate Market," is in Upper Thames-street, and occupies the space under the Cannon-street Station, City; others will be erected in due course. I enclose full particulars, and as architect to the company, I should feel obliged if you could further the important problem of supplying good food at reasonable prices.

PHILIP B. LEE.

CHURCH-BUILDING NEWS.

Walkern.—The rood-screen in the ancient parish church here has, at the cost of the vicar (the Rev. J. C. Wright), been restored. The chancel was restored some little time ago. The ancient rood-screen had fallen into a deplorable and dangerous state of decay. Mr. Hugh Roumien Gough, architect, of Westminster, was consulted by Mr. Wright, and under Mr. Gough's immediate direction the screen was taken down, and having been thoroughly overhauled, is now once again *in situ*. It is an excellent example of Perpendicular Gothic woodwork, some 12 ft. or 13 ft. high, and reaching right across the chancel. The lower panels are filled with traceried and carved work of a vigorous kind. Above, a wealth of pierced open-work bursts out from the supporting standards, and exhibits much delicate and refined detail thereon. The main cornice above is deeply moulded, and has its hollows enriched by detached patera. A new moulded cill has been put in as a footing, and the main uprights, which were in a bad state of decay, have been scarfed and mortised. On either side of the central doorway are buttresses surmounted by carved pinnacles, and similar buttresses are in like positions upon the other uprights. The screen had been bedaubed with a variety of coats of paint, whitewash, varnish, graining, &c., by successive generations of churchwardens. These have all been removed by a chemical preparation. The work of restoring the screen was entrusted to Mr. Harry Hems, of Exeter.

Ealing.—The church of St. Stephen, Castlehill, Ealing, has just been enlarged by a new south aisle, south transept, organ-chamber (with choir-vestry under), and south porch, giving an addition of 224 sittings to the church. The work has been carried out from the designs and under the superintendence of Mr. Rovedino, architect, the builder being Mr. Nye, of Ealing.

VARIORUM.

DR. HENRY SCHLIEMANN'S expected new volume, "Ilios: the City and Country of the Trojans," has been published by Mr. Murray. It gives the result of researches and discoveries throughout the Troad in the years 1871, 1872, 1873, 1878, and 1879, and includes appendices and notes by Professors Virchow, Max Müller, A. H. Sayce, J. P. Mahaffy, Brugsch-Bey, and several others, illustrating, amplifying, and confirming the brilliant and astounding researches and discoveries made by Dr. Schliemann. The book has an interest and value beyond ordinary commendation, and will receive at our hands in due course the same amount of consideration that we felt ourselves bound to give to the previous works of its author.——"Japanese Pottery," being a native report, with an introduction and catalogue by Augustus W. Franks, M.A. (Chapman & Hall). This is one of the South Kensington hand-books, but differs somewhat from the others, in consequence of the circumstances under which it was prepared. The pith of it is translated from a report by a Japanese expert, and Mr. Augustine Franks has contributed much from his remarkable stores of knowledge to increase its value. The illustrations include a large number of marks.——Hardwicke's *Science Gossip* for November 1st includes an interesting and instructive paper, entitled, "A Wood-Carver's Experience of the Death-watch Beetle."——"The Arithmesis" (Dunton, 352, Clapham-road) is a superior kind of Ready Reckoner. It refers to marketings, wages, savings, interest, and victualling, and will be found useful by many persons.——The *American Architect* devotes a whole number (253, October 30th) to an illustrated account of the Museum of Fine Arts, Boston, and a very interesting number it is.

Miscellanea.

The "Inner Circle" Railway Completion.—A letter has been addressed to the City Commission of Sewers by the Joint Committee of the Metropolitan and District Railways relative to the Inner Circle Railway completion, offering 500,000*l.* in consideration of the Commission providing the railways with 60 ft. of clear space, partly under the surface and partly open, for the construction of stations and works between certain points marked in the plans, and a sufficient space, 37 ft. wide, for the construction of a double line and works under the property to be acquired between those points. In regard to any additional property required for station approaches, the Joint Committee were willing to purchase it and to re-sell to the Commission any surplus needed for street improvements at a price to be agreed on by arbitration. The letter was referred for consideration to the Improvement Committee, with power to confer with the Metropolitan Board of Works.

A Local Government Inquiry was held at West Bromwich on the 9th inst. before Mr. J. Thornhill Harrison, C.E., respecting an application made by the Improvement Commissioners for sanction to borrow the sum of 97,500*l.* for the following purposes:—60,000*l.* for the purchase of land, and carrying out the 1st section of the Main Drainage Scheme prepared by Mr. John T. Eayrs, C.E.; 25,000*l.* for the completion of the gas-works; 10,000*l.* for paving footpaths with blue bricks; 1,500*l.* for fire-hydrants; and 1,000*l.* for refreshment-room and shelter for public park. Evidence was given in detail respecting the various amounts to which there was no opposition. The inspector afterwards visited the site of the proposed sewage-farm.

Gateshead School Board.—At a meeting on the 10th inst. the plans of Messrs. Oliver & Leeson, architects, Newcastle-on-Tyne, for proposed group of schools at Durham-road, were approved. The same architects were instructed to prepare designs for another group of schools at Askew-road.

Dr. Siemens's New Fire-Grate.—Dr. C. W. Siemens describes in *Nature* a new modification of the ordinary fire-grate, by which all smoke is done away with, and all the heat is thrown out to the room, at a cost considerably less than the ordinary coal-consuming grate. Instead of the bars at the bottom, an iron dead-plate is substituted, and, instead of coal, coke or anthracite is used. To this dead-plate is riveted a stout copper-plate facing the back of the fire-grate, and extending 5 in. both upwards and downwards from the point of junction. The dead-plate stops short about 1 in. behind the bottom bar of the grate to make room for ¾-in. gas-pipe, which is perforated with holes of about 1-20th in. in diameter, placed zig-zag at distances of ¾ in. along its upper surface. This pipe rests upon a lower plate, which is bent downwards towards the back, so as to provide a vertical and horizontal channel of about 1 in. in breadth between the two plates. A trap-door, held up by a spring, is provided for the discharge of ashes falling into this channel. The vertical portion of this channel is occupied by a strip of sheet copper, about 4 in. deep, bent in and out like a lady's frill, and riveted to the copper back-piece. Copper being an excellent conductor of heat, this piece, presenting (if not less than ¼ in. thick) a considerable sectional conductive area, transfers the heat from the back of the grate to the frill-work in the vertical channel. An air current is set up by this heat, which in passing along the horizontal channel impinges on the line of gas-flames and greatly increases their brilliancy. So great is the heat imparted to the air by this simple arrangement that a piece of lead of about half a pound in weight introduced through the trap-door into this channel melted in five minutes, proving a temperature to exist exceeding 619 deg. F. or 326 deg. C. The abstraction of heat from the back has, moreover, the advantage of retarding the combustion of the coke there while promoting it at the front of the grate. In a large fireplace in a room of 7,200 cubic feet, facing the north, the temperature was easily maintained at 60 deg., and the result of one day's campaign of nine hours was a consumption of 62 cubic feet of gas and 22 lb. of coke, the total cost being 4·725d., or at the rate of about one half-penny per hour.

The Re-building of Whitechapel Church. On the 11th inst. a meeting was held in the church-room of Whitechapel Church, where the trustees of the parish and the committee for the building of the old church had been invited to attend. The rector, the Rev. J. F. Kitto, presided, and presented a report on behalf of the rector and churchwardens, who, with Mr. Gadesden, had been appointed to communicate with Mr. Coope, M.P., with a view to his undertaking the rebuilding of the church. The report stated that Mr. Coope had undertaken to make himself responsible for the rebuilding of the church, subject to certain conditions as to means being taken with the view to obtain better acoustical properties in the church when rebuilt than were found to be possessed by the church burnt down, as to the approval by the parishioners of the designs for the new building, and as to certain sums being set apart from the insurance-money in order to reinstate the font, lectern, pulpit, stained-glass, and other special features. The report was adopted, and Mr. Coope's offer accepted with gratitude.

American Institute of Architects.—A meeting of the Convention of the American Institute of Architects was to take place on November 17th, in Philadelphia. Several matters of great general interest were to be decided at the session. Several different schemes were to be offered for the remodelling of the constitution, which will, whatever plan is adopted, be a momentous event. Besides this business, special reports were to be presented upon colonial architecture and on the construction of tenement-houses, by committees appointed for the purpose at the last convention, and it was hoped that a number of interesting papers would be read and discussed.

Removal of a Church.—The church of St. Stephen, Edge-hill, Liverpool, is being removed from one side of the street to another for a railway improvement. It was built from designs by the late Sir Gilbert Scott.

North Woolwich Gardens.—The *City Press* says it is proposed to convert into a recreation-ground the well-known gardens at North Woolwich; and the Metropolitan Board of Works is to be asked to purchase them.

Electric Lighting for the City.—On Tuesday, at the meeting of the City Commissioners of Sewers, a report was brought up by Mr. Innes, from the Streets Committee, on the subject of electric lighting in the City. They stated that they had received a variety of tenders, in considering which they had been guided not only by the prices mentioned but by the effect produced by the different systems in actual operation, all of which they had seen. They had decided, for the purposes of the experiment, to divide the streets into three districts, each of them including one of the City bridges. The first district would comprise Blackfriars-bridge, New Bridge-steeet, Ludgate-circus, Ludgate-hill, St. Paul's-churchyard (north side), and Cheapside, as far as King-street. They recommended that the tender for this district of the Anglo-American Electric Light Company (Brush system) should be accepted, at a cost of 1,410*l.* for the twelve months. The number of electric lamps would be thirty-two, replacing about 150 gas-lamps. The second district would comprise Southwark Bridge, Queen Victoria-street, lower part of Queen-street, and Queen-street-place. They suggested the acceptance of the tender of the Electric and Magnetic Company (Jablochkoff system), at a cost of 2,930*l.* for the twelve months. The number of electric lamps would be fifty-two, replacing about 161 gas-lamps. The third district would comprise London Bridge, upper part of Queen-street, Cheapside (between King-street and the Poultry), King-street, Guildhall-yard, Poultry, Mansion House-street, the Royal Exchange, King William-street, and Adelaide-place. For this district they advised the acceptance of the tender of Messrs. Siemens Brothers, at a cost of 3,720*l.* for the year. The number of electric lamps would be 32, replacing 138 gas-lamps. On a rough calculation the cost, including the plant, &c., would be about four times the price now paid for gas-lighting, but, eliminating the expenses which would not recur, the cost would be only twice that of gas. The Commission unanimously adopted the report of the committee, and the experiment is to commence on the 1st of February next.

St. Mark's, Venice.—Under the auspices of the Society for the Preservation of Ancient Buildings, a committee has been appointed to endeavour to get some heed paid to its protest against the proposed works at St. Mark's, Venice. They say that, "the more the recent restorations of St. Mark's are examined, the more clearly does it appear that those who are responsible for their execution had quite determined to carry them further in the same spirit. It is impossible to doubt, for instance, from the evidence of the portion already executed at the south-west angle, that the architect who has just rebuilt the southern front of the nave contemplated rebuilding the western front also, and on new lines; whilst the mosaicists would undoubtedly be ready to carry on their works on pavement, and ceiling, and walls, with precisely the same justification as before. This being the case, and recognising the wide-spread and extraordinary love for this great church among educated men of all countries, specially among students of art, and the real and profoundly sad sensation which has been produced among them by these restorations, it is felt that the only course open to those who wish to prevent such a calamity as the completion of such works would certainly be, is to join themselves together in a committee, with the sole object of using all possible means for the preservation of the genuine character of St. Mark's. The exceptional nature of the danger seems to justify what is no doubt an exceptional proceeding. The object will be to use every means for promoting a sympathetic co-operation with those numerous and influential Italians who hold the same views. The committee, individually and as a body, being actuated by the most cordial and friendly feelings towards the Italian nation, extreme care will be taken to act as delicately as possible, by friendly representations, and with every determination not to wound any national susceptibilities, or to take exception to what are plainly necessary repairs." The honorary secretary, Mr. Henry Wallis (9, Buckingham-street, Strand) will be glad to receive the names of those who may be disposed to help them.

Institution of Surveyors.—At the next meeting, to be held on Monday evening, November 22nd, a paper will be read by Mr. Francis Turner (Associate), entitled, "The Law as affecting Quantity Surveyors."

The Roman Villa at Brading.—Sir: With reference to this subject, which has excited so much public interest, I am directed to acquaint you that, by the co-operation of the Society of Antiquaries and the Royal Institute of British Architects, an influential committee has been formed to continue the researches, protect and exhibit on the spot the discoveries, and suitably record them. The small preliminary committee which has hitherto acted, of which Mr. C. Nicholson, of Ventnor, was treasurer, has dissolved itself, to facilitate the new organisation, and the owners of the estate on which the discoveries have been made are represented on the new committee, which will not in any way supersede or interfere with the labours so satisfactorily performed by Messrs. John E. Price and F. G. Hilton Price, but will strengthen their hands and leave the executive with them. The committee hopes to be able to prepare its report in the early part of next month. Meanwhile, I shall be glad to furnish further particulars to any persons who may be desirous to promote the objects of the committee by contributing to the Roman Villa Fund. The committee consists of Major A. F. Leeds, chairman; H. C. Coote, John Evans, A. W. Franks, W. A. Glynn, George Godwin, Professor T. Hayter Lewis, Sir John Lubbock, H. S. Milman, W. Munns, F. C. Penrose, Major-General Pitt Rivers, F. G. Hilton Price, J. E. Price, Professor Rolleston, C. Roach Smith, Captain Thorp, J. Whichcord, and Alfred White. The treasurer is Lieutenant-Colonel Malone, Capital and Counties Bank (Limited), Ryde Branch, but subscriptions may also be paid to Mr. F. G. H. Price, at Messrs. Childs' Bank, London.—E. W. Brabrook, Hon. Sec.

The Steam Navvy.—The usual fortnightly meeting of the Liverpool Engineering Society was held at the Royal Institution, Colquitt-street, on the 10th inst., Mr. Alexander Ross, president, in the chair, when a paper entitled "Earthworks and the Steam Navvy," was read by Mr. H. O. Baldry. The paper chiefly consisted of a description of the steam navvy as constructed by Messrs. Ruston & Dunbar, and the method of its employment in earthwork excavations, followed by an estimate of the saving to be effected by its use in place of hand labour. The most effective mode of working is that in which the machine stands on a central line of rails, with a wagon-road on each side; but this is only available in excavations 40 ft. wide or more. So that in ordinary railway-cuttings, a single wagon-road has to be used. The machine requires about twelve men for its operation, and can excavate about 500 cubic yards per day of light clay or moderately-soft chalk, one cubic yard being lifted by the excavating bucket at each stroke. At this rate of working the cost would be at the rate of about 3d. per yard, as compared with 4½d. by hand labour.

Windsor Castle.—At Windsor Castle, preparations are being made for the return of her Majesty from Scotland, and in anticipation of the arrival of the Court from the North. During the absence of the Queen at Osborne and in the Highlands various necessary repairs and renovations have been effected by the Office of Works Department in the buildings used by the Royal Family on the east side of the Castle. At St. George's Chapel the upper portion of the extensive scaffolding, erected for the repairing of the west end, has been struck, and the work of refacing with Oxford stone, which is being carried out under the supervision of Mr. Nutt, clerk of the works to the Dean and Chapter, is nearly completed. The stones used have been dressed with a composition designed to preserve the masonry from the weather, the west front, owing to its lofty elevation, being greatly exposed to the elements.

Erith.—The Church of St. John the Baptist at Erith has recently received an addition in the form of two stained-glass windows. The first, situated in the west aisle (a three-light window), contains a representation of "Christ healing the Sick." In the north window are full-length figures of the Apostles Peter, James, and John. The windows were designed and executed by Mr. Geo. Rees, of Lamb's Conduit-street.

Presentation.—The workmen employed at Churchers College, Petersfield, met together at the Swan Hotel, on the evening of the 13th inst., and presented to Mr. B. K. Webber, the late manager, on his leaving, a token of their esteem and regard in the shape of a silver goblet. The chairman, Mr. G. Isaacs, spoke in warm terms of their late manager.

St. Etheldreda, Ely-Place.—Two large-size statues of St. Peter and St. Paul have recently been placed in position in this ancient chapel, on the carved stone corbels of the wall arcading under the arched gabling between the windows. It is intended to reinstate the whole series of the twelve Apostles and four Evangelists. The sculptor, Mr. Doherty, of Blackfriars, has followed, to a certain extent, the figures in the interesting Shrine of St. Sibald at Nuremburg, a casting of which is at the South Kensington Museum. It was at the suggestion of the late Sir George Gilbert Scott that the projecting corbels were restored by the architects from one which had escaped destruction.

TENDERS

For new stables at Smitham Bottom, near Caterham Junction, for Mr. James Watney, M.P. Mr. C. W. Bovis, architect:—

		Extra if built in Cement.
Rowland	£935 0 0	£50 0 0
Grant (accepted)	978 0 0	52 0 0

For building two houses and shops adjoining the New Cock Tavern, Holloway-road, for Mr. J. W. Jennings. Quantities by Mr. H. Worthington and Mr. L. Canning. Mr. W. J. Worthington, architect:—

Cowland, Bros.	£2,194 0 0
Phillips	2,165 0 0
Cocks	2,139 0 0
Morter	2,082 0 0
Beale	2,019 0 0
Lamble (accepted)	1,989 0 0

For erection of two shops, with dwelling-houses attached, in Front-street, Arnold, Notts. Mr. Fredk. Jackson, architect:—

Marriott & Wartnaby, Nottingham	£635 0 0
Bell & Son, Nottingham	628 0 0
Jew & Hickling, Arnold	525 0 0
Smith & Greaves, Arnold	518 0 0
Wayte, Arnold (accepted)	447 10 0

For alteration and enlargement of Upton House, Upton, Essex, for Mr. J. S. Curwen. Mr. George McDonell, architect:—

Becroft (accepted)	£350 0 0

For erecting new mission-hall in Villier-road, Willesden, for the Rev. J. Arthur Rawlins. Mr. W. Graves, architect. Quantities by Mr. W. Barnett:—

Tennant	£1,435 0 0
Marks	1,389 0 0
Hunt	1,381 0 0
Stimpson & Co.	1,362 0 0
Vears & Co.	1,344 0 0
Toms	1,339 0 0
Ward	1,325 0 0
Spencer & Co.	1,229 0 0

For pulling down and rebuilding the Crown and Anchor public-house, Brixton-road, for Mr. R. May. Mr. W. T. Farthing, architect:—

Kirk & Randall	£4,340 0 0
Sly	4,201 0 0
Patman & Fotheringham	4,185 0 0
Jackson & Todd	3,887 0 0
Spencer & Co.	3,880 0 0
Gill	3,767 0 0
Burge & Moore	3,731 0 0
Burman	3,677 0 0
Francis	3,670 0 0

For superstructure of warehouses, Farringdon-street Mr. George Vickery, architect:—

Hall, Beddall, & Co.	£15,970 0 0
J. & J. Greenwood	15,649 0 0
Colls & Sons	15,510 0 0
Crabb	15,320 0 0
Hart	15,244 0 0

Ashby, Bros.	14,900 0 0
Ashby & Horner	14,769 0 0
Conder	14,778 0 0
Brass	14,733 0 0

For mission premises, with shops, High-street, Hoxton. Mr. M. M. Glover, architect:—

Jarvis & Son	£5,939 0 0
Staines & Son	5,684 0 0
Williams & Son	5,530 0 0

For proposed alterations at Carpenters' Arms, Carpenters-road, Stratford, for Mr. Symes. Mr. H. J. Newton, architect:—

Strong, Bros.	£400 0 0
Brown	368 0 0
Cross	292 0 0
Hawkins	285 0 0
Walker (accepted)	205 0 0
New Counter.	
Warne	£118 0 0
Heath	109 0 0
Matthews	93 10 0
Mott (accepted)	92 10 0

For proposed alterations at the George and Dragon, for Mr. Bower, at York-road, Battersea. Mr. H. J. Newton, architect:—

Beale	£317 0 0
Taylor	312 0 0
Lamble	310 0 0
Godden (accepted)	283 0 0
New Counter.	
Heath	£157 0 0
Warne	151 0 0
Hellings	149 10 0
Moody (accepted)	127 10 0

For repairs, &c., to shops, City-road, for Mr. Mace:—

Taylor & Parfitt (accepted)	£472 0 0

For the erection of two shops and dwelling-houses in Mnch Park-street, Coventry, for Mr. E. Ralphs. Mr. Herbert W. Chattaway, architect:—

Brown, Coventry	£1,175	0	0
Worwood, Coventry	993	0	0
Storer, Coventry	980	0	0
Joyce & Harrison, Leicester	975	0	0
Frith, Coventry	965	0	0
Haywood, Coventry	950	0	0
Mayo, Coventry (accepted)	875	0	0

For alterations and additions to the Cancer Hospital, Brompton. Mr. A. Graham, architect:—

Maton	£30,894	0	0
Bull & Son	27,900	0	0
Higgs & Hill	27,840	0	0
Nightingale	27,781	0	0
Bywaters	27,555	0	0
Chappell	27,530	0	0
Shaw	27,500	0	0
Patrick & Son	27,318	0	0
Smith & Co.	27,285	0	0
Braid & Co.	27,200	0	0
Hall, Beddall, & Co.	26,850	0	0
Holland & Hannen	26,821	0	0
Brass	26,635	0	0
Lawrance	26,223	0	0

For shop front and alterations at Leighton Buzzard, for Mr. W. S. Page. Mr. Gotto, architect:—

Dawson	£290	0	0
Webb	277	17	0
Mead	270	0	0
Groom	249	10	0
Edwards	240	0	0
Garside	240	0	0
Cook	244	10	0
Gibbs (accepted)	193	0	0

For a new house in the Finchley-road, London, for Mr. Samuel Palmer. Messrs. Morris & Stallwood, architects. Quantities by Messrs. Henry Cooper & Sons:—

Hall, Beddall, & Co.	£13,674	0	0
Clarke & Bracey	12,667	0	0
Shaw	12,637	0	0
Braid & Co.	12,300	0	0
Lucas, Bros.	12,144	0	0
Brass (accepted)	11,769	0	0

For additions and alterations at No. 5, Forest-place, Leytonstone. Mr. G. E. Pritchett, architect:—

				Credit for old materials.		
Eaton	£568	0	0	£10	0	0
Day	537	0	0	5	0	0
Cains	534	5	0	10	0	0
Wood	480	0	0	10	0	0
Hosking	487	0	0	20	0	0
Body & Co.	476	17	0	15	0	0
Arber	467	0	0	5	0	0

For the erection of villa residence at Beulah-hill, Upper Norwood, for Mr. W. S. Black. Mr. Charles Bell, architect. Quantities supplied by Mr. H. Lovegrove:—

Jenkins	£2,485	0	0
Eldridge & Gee	2,400	0	0
Wright	2,332	0	0
Hobson	2,237	0	0
Woodward	2,250	0	0
J. & C. Bowyer	2,239	0	0
Castle, Bros.	2,200	0	0
J. & S. Bowyer	2,077	0	0
Smith & Sons	2,069	0	0
Ta rant & Sons	1,998	0	0
Goad	1,845	0	0

For alterations to Nos. 108, 110, and 112, Belvedere-road, Lambeth, for conversion into offices for the Anglo-American Electric Light Company. Mr. George Edwards, architect. Quantities supplied by Mr. H. Lovegrove:—

Green	£820	0	0
Goad	741	0	0
Richardson	710	0	0
Stimpson & Co.	706	0	0
White	630	0	0
Cullum (accepted)	580	0	0

For house and conservatory, South-hill Park Estate, Bromley, for Mr. J. H. Lepper. Quantities supplied. Mr. J. Sulman, architect:—

	House.			Conservatory.		
Higgs & Hill	£1,631	0	0	£89	0	0
Bolding	1,600	0	0	100	0	0
Bowyer	1,568	0	0	108	0	0
Stephens & Bastow	1,499	0	0	91	0	0
Arnold	1,443	0	0	85	0	0
Douglas & Payne	1,436	0	0	92	0	0
Smith & Sons	1,426	0	0	83	0	0
Crossley	1,376	0	0	83	0	0

For a Wesleyan Chapel, Addiscombe, Croydon. Mr. H. P. Bonner, architect. Quantities by Mr. R. W. Griffiths:—

Clark & Bracey	£7,266	0	0
Staines & Sons	7,184	0	0
Crossley	7,120	0	0
Marrinage	7,070	0	0
Perry & Co.	6,981	0	0
Smith & Sons	6,875	0	0
Higgs	5,993	0	0

For alterations to Beech House, Park-lane, Croydon, for Mr. J. Brown. Messrs. Podmore & Martin architects:—

Marriage	£326	0	0
Smith & Sons	291	0	0
Pearson & Myles	249	0	0

For shops, and alterations at the Pelicans, Peckham-road, for Mr. Hndson. Mr. Millard, architect:—

Macey & Sons	£2,995	0	0
Taylor & Parfitt	2,835	0	0
North, Bros.	2,585	0	0

For repairs at Copenhagen-place, Limehouse, for Mr. Gilling. Messrs. Gordon & Lowther, architects:—

Dye	£293	0	0
Taylor & Parfitt	285	0	0
Starkey	282	0	0

Richmond Baths.—Mr. Lucas writes to say that, in hurry, two important "hills" were omitted, and that he withdrew his tender on discovering the error.

ILLUSTRATIONS.

CONTENTS.

A Cultivated Traveller on Art Abroad.

BELGIAN man of letters, known on the Continent by his works on the rural economy of Belgium and of Holland, on the instruction of the people, and on the primitive forms of property, made a tour in Italy at the close of 1878 and during the early part of 1879. His object was, not to see the country and the works of art, with which he was already acquainted, but to study on the spot the changes produced by the recent political transformation of Italy. Notes of his journey were published at the time, and have been recently collected in a volume. The clearness of his views, and the beauty of his language, give a value to a work which in its form is essentially fugitive. Some of his pen-and-ink vignettes illustrative of Italian art will be welcome to many readers. Some of the remarks, especially those on the motives of architectural details, if not altogether novel, are well put, and admirable in their truth.

"The monument of Maximilian at Innspruck," says the letter-writer, "with which I was not previously acquainted, made a great impression on me. The bas-reliefs of the Mansoleum, in white marble, form a base too fragile to support the statue of the Emperor which surmounts it. But all around, and between the columns, are ranged twenty-eight colossal statues in bronze, which have an overpowering effect. They are those of the ancestors of Maximilian, the Dukes of Burgundy, Philip the Good, Charles the Bold, and the Archdukes of Austria; then Philip le Bel and his Queen, Clovis in the costume of a Hungarian magnate, and King Arthur as a knight sheathed in iron,—a true *chef-d'œuvre*. Elegance, force, grace, nobleness in pose, all are here united. It is equal to the 'Penseroso' of Michelangelo."

Let us now cross the Alps. The date is in the month of November, just two years ago. "Even," says the author, "at this season Venice is a wonder. It is the only town which no other town is like. The sea, raised by the wind, which drives it landwards, struggles with a strong current in the canals, breaking over the Place of Saint Mark, and penetrates even to the cathedral. It is transparent, pure, and of the most beautiful green, instead of being yellow and stagnant as in the summer. The water, clear, living, joyous, bathes and reflects the ancient and sombre palaces. It is a breath of youth in the old city.

St. Mark's is the only church in Italy which produces a complete and unmixed impression. The interior of the Duomo at Milan is very fine, but the exterior is overloaded and not in pure taste; one might call it a cathedral in alabaster or in sugar. At Rome, St. Peter's is overwhelming in its grandeur, but spoiled by the profusion of ornaments. The façade is a failure. The churches of Orvieto and of Sienna are jewels, but they do not awaken the religious sentiment. The Pantheon is a perfect monument; but it is a Pagan temple, not a church."

A month later the writer is at Rome. He visited anew, he says, St. Peter's throughout, from the peristyle at the entrance to the summit of the ball. "It is a prodigious, astonishing, monument, but in bad taste. Michelangelo has wrought a miracle; he has reared the Pantheon in the air, but with what result? I love far more the Pantheon solidly planted on the earth, with its low cupola, allowing the light to fall through its circular aperture, opening directly under the vault of heaven; a simple and beautiful idea. The side windows at St. Peter's resemble those of a palace, and are out of place in a temple. Architecture is an art over which Reason and Taste should preside. Every detail should have its object. The Greeks have admirably comprehended this; thus in the Parthenon there is nothing without a motive. Therefore their works are perfect. Michelangelo, in spite of his stupendous genius, was the great corrupter of taste. Everywhere he sought effort, the extraordinary, the violent. See his Sibyls and his prophets on the Sistine Chapel. Our architects too often follow his example. Their edifices do not correspond to the object for which they were built.

Look at the Palais de Justice at Brussels. It has great qualities; beauty of outline, force and harmony in its lines; but where is its symbolism? Where is the justification of the disposition? Nothing indicates for what purpose it was built. Why that dome or superstructure, whatever it be, that crowns the edifice? It is without use, and it impairs the general effect. The interior arrangements are detestable. The very aim of the building is sacrificed to the façade. It is unreason, that is to say, the antithesis of architecture, when, on the contrary, everything ought to have its reason. St. Peter's, opening above our heads at a giddy height its gigantic cupola, has at least the merit of giving an impression of the infinite which suits a church. The Gothic cathedrals are full of ideas, of symbols. They are books of stone, which set forth the doctrines of Catholicism to those who do not know how to read. It is the same with the temples of India and of Egypt. There, again, although in a form less perfect than that of Greece, the architect has understood his mission. The Roman monuments, the circus, the thermæ, the theatres, the amphitheatres, the forums, the aqueducts, correspond admirably to their destination. They display reason incarnate in marble. Both in exterior aspect and in interior decoration, the Pantheon is incomparably superior to St. Peter's."

We give these extracts, not as authoritative canons, nor as expressing altogether our own opinions, but as the original criticisms of a travelled and thoughtful scholar, which cannot be read without giving food for reflection. Here is another sketch.

"They talk to me much of an art-critic, well-known in Italy and in Germany, the Senator Giovanni Morelli. His special study is the art of verifying the authenticity of pictures. To arrive at the criterion, he studies with the most minute care, magnifying-glass in hand, the work of a master as to whom there is no doubt. If this painter has several styles, he takes a specimen of each. He examines the colours employed by preference,—each artist has his own, the touch of the brush, the particulars of design, the character of the figures, the drawing of the hands, the feet, the draperies, the landscape, the architectural traits. It is certain that each painter had, and still has, his own mode of seeing and of rendering objects. It is only necessary to understand this. Thoré, writing under the pseudonym of Bürger, has applied this mode of criticism to the pictures of the Dutch school with the most instructive delicacy of perception. The critiosims of M. Morelli have produced sensation and gained authority in Rome. Applying his process to the Borghese Gallery, he has demonstrated that the famous portrait of Cæsar Borgia, by Raffaelle, is not by Raffaelle, and does not represent Cæsar Borgia. A new road, in my judgment, is thus opened for the criticism of art. But to succeed in it demands long study, and a scrupulous patience, unwearied in the examination of details."

We reproduce with the more pleasure this account of the criticism of Signor Morelli, from the circumstance of having recently turned attention to the very subject. To become past master in such an art demands the study of a life. But even the time which can be spared from a busy life will accumulate much that is of value, if systematically employed. We are happy to be able to offer one original contribution to this mode of criticism, to which we shall be glad to call the attention of our readers and of Signor Morelli. Photography may be used to detect restoration or tampering with an old picture. We made the discovery by accident. Another Signor Morelli, a very admirable draughtsman, was some time since engaged in taking photographs of the pictures in our own National Gallery. Looking at the first proof of one of them, a well-known Madonna,—there was a disfiguring blur over the forehead. "Oh," said the photographer, "that is a first proof,—I will set that to rights in the negative." So, no doubt, he did. But it was the first proof that was of value. Visiting the Gallery to refresh remembrance of the picture, no such blur was to be seen,—to be seen at the first glance. But the magnifying glass showed, on careful inspection, that the restorer had been at work. He

had repaired some casual damage, and done it with a skill that reproduced the colour, the touch, and the texture of the painter. But he had not used the same pigments, and this was instantly detected by the subtle chemistry of light.

At a time when every study has a tendency to become so strictly special that anything like a knowledge of *ensemble* is regarded almost with suspicion, it is of unusual interest to collect the views taken by a man of general culture, a scholar and a traveller, on such points as those which we have cited. There can be little doubt that such opinions as those above quoted on architectural motives both represent the views of a certain and important public, and lead, in their turn, to extend and enforce these views. Unless the architect keeps in electric contact with such a current of thought, he will fall behind the age. The most lasting impression produced by such a work as we have been citing is the cardinal importance of general culture in the development of artistic excellence.

EARLY GREEK SCULPTURE.

The book which Mr. A. S. Murray, of the British Museum, publishes under the title "History of Greek Sculpture"* would perhaps be better described under the heading we have given; at least, most readers would not be likely to gather from the present title that they were taking up a book in which the works which make the great glory and fame of Greek sculpture are hardly mentioned. It may be questioned even whether the word "history" can quite correctly be applied to the treatment of a subject in regard to which hardly any basis for historical accuracy as to facts can be said to exist. A review of the known remains of Greek sculpture, the probable dates of the various examples that are preserved, and the conclusions to be drawn, from the varieties of style observed in them, as to the progress of the art and the culture of the artists and their method of working, is fully possible, and this is really the nature of the work put forth by our author. But it seems a misnomer to speak of history where almost everything which is advanced as such is more or less conjectural; where the character of the work of this or that artist, whose date even perhaps is only approximately attainable, has to be conjectured from what is said of his work, in vague and ambiguous terms, by some ancient writer, who himself is often only repeating a tradition from some one else; and when the nearest that can be got to illustrating his work is to endeavour to connect with his name some isolated example which seems to answer sufficiently to the description of one of his statues. This can hardly be called history at the best; and our impression is that of all the conjectures on these points nothing more than possibility is proved as to any definite fact; even probability is questionable. The book is a study of the remains of Greek sculpture, not a history; and as such is of much value and interest, especially for general readers. It brings together within convenient compass much of what is known and conjectured on the subject, combined with theories and suggestions of the author's which are calculated at least to set the reader thinking, and with a considerable number of well-executed illustrations of objects of art bearing on the subject.

The introductory chapter on the theory and general principles which limit the art of sculpture is pretty much what has been often said before, sometimes a good deal better said,—for perspicuity of literary style and logical progression of the argument are not very conspicuous in the author's writing, and the reader has at times to take a good deal of trouble to find out the relation of one statement with another, and the point towards which the author is progressing. There is, however, a good and practically useful generalisation in the opening paragraph, in the remark that in the earlier stage of Greek art, progress was chiefly in the way of acquiring facility in the use of the material, while in the later stage the effort was to obtain fulness of knowledge of the original from which the artist worked. This, though susceptible of question in some points of view, is a good working generalisation; perhaps impressing one the more as such from its appearing at the close of a somewhat clumsily-expressed exordium. "In language a thought, and the form in which it is expressed, must be conveyed through a new medium; while in art the essential character of the object is reproduced in a new material. For both there must be freedom, but not without these limits." What limits? We can guess, of course, what must be the meaning intended, but the sentence in itself conveys no meaning to any one who has not the idea in his mind already. In this and other parts of the book we seem to meet with repetitions of what are now almost commonplaces of artistic criticism, but expressed in a very unintelligible, or, at least, awkward form. The sentence on page 12, as to "physical and moral turpitude being so closely allied in the judgment of the Greeks, and both equally detestable," is rather surprising. It is the great charge against the Greeks that moral turpitude was not nearly as hateful to them as it ought to have been; and the fact was not that physical and moral turpitude were closely allied in their eyes, but that physical imperfection was regarded as so serious an evil that a man was liable to be as much depreciated on account of it as if he were morally base, or even more so; which is a different thing from regarding the two qualities as closely allied.

The second chapter touches on the evidences as to the degree of power in various handicrafts and in the working of various materials which had been reached at the epoch represented by Homer; *i.e.*, of course, the epoch when the author or authors of these poems lived, not those which they profess historically to describe. In the next chapter a curious attempt is made to reconstruct the shield of Achilles from antique remnants of art, the process having been to copy from the most ancient authentic source a representation of each of the incidents said to have been represented on the shield, and then combine the whole, we presume with some modifications in detail, into the arrangement of the shield-subjects as described by Homer. But, in order to afford a more natural suggestion, in the shape of the shield, for the grouping and separation of the subjects, the author adopts a form of shield not circular, but with deep indentations on two opposite points of its margin, which cut into and divide the subjects, so as to necessitate a grouping of them, and interrupt their progression round the whole circle. For authority for this shape the author quotes two vases, one in the British Museum and one at Berlin. We do not in the least question the validity of the authorities, but they are absurdly inadequate against the overwhelming number of representations of circular shields in existence, and against the positive impression of a circular shield which the Homeric narrative conveys to us. One point alone seems to us conclusive, the placing of the conventional representation of ocean round the rim of the shield. This is a most natural idea in regard to a circular shield, not only decoratively, but also physically, as the Homeric age believed that the sea encompassed and surrounded the earth: on the shield of the form conjectured by Mr. Murray, this decoration loses all its effectiveness and meaning. The designs on the shield form a curious piece of patchwork, but, no doubt, they are something more like what really was in the mind of the Homeric narrator than is Flaxman's beautiful reproduction; and it is well for readers to be practically reminded in this way that the art contemplated by the poets and people of the Homeric age was not the art of the complete Greek period. General readers are so apt to apply to anything with the name of "Greek" the ideas and forms most popularly connected with Greek art, that they do not recognise the fact that what passed for sculptural art in the Homeric time was something very different from the Parthenon frieze. Mr. Murray makes some good suggestions in favour of the idea of an Assyrian origin of the legend of the shield and its description. He observes that the incident which rendered the making of the shield necessary, the loss of his first shield by Achilles owing to his having lent his armour to Patroclus, seems not unlike an excuse for bringing in a familiar legend, and that the description was a traditional one. That would account, as he says, for the omission of any mention by Homer of ships as objects on the shield, if the description were originally invented by an inland people. The description of the Achillean shield has been an object of so much interest to all students of the history of art and art-workmanship, that no attempt to throw new light on the meaning of it can be considered as superfluous.

Among some remarks on what most of us regard as the more questionable elements in Greek sculptural practice,—questionable either historically or artistically,—we find it suggested that the use of gold and ivory for early statues of deities appears to have superseded an early custom of clothing them in actual drapery, doubtless richly embroidered with gold. "For these figures various kinds of wood were employed, such as ebony, cypress, cedar, oak, yew, lotos, olive, fig, and others, and from the pillar-like form of these figures it would seem that the trunk of the tree had been left unadorned, with nothing more than a head carved on it." We presume the author means to imply that the terminal figures so common in later Greek and in Roman art were merely the old trunk and head forms, as he supposes them, assuming a more definite sculptural shape, and without the actual drapery. The supposition appears not improbable, certainly, and gives an explanation of the origin of the terminal figure; though it is reducing the dignity of ancient sculptural art sadly to imagine any department of it, and that, too, the important department which consisted in the representation of the deities, as little better in principle than a modern milliner's lay figure. "Nor is it unlikely," he adds, "that the images often standing in country places to represent patron divinities consisted of trunks of trees left with their roots in the ground, and with a slightly fashioned human head and arms. As such appears the Dionysos Dendrites occasionally figured on painted vases." There may have been one excuse for treating the representations of the deities thus, one which often has influence over early ritualistic art,—namely, that as the mere representation or symbol of the god, the work gained an importance and sanctity which placed it beyond the necessity of attracting respect by a more elaborate attempt at artistic realism or effect. The use of ivory to supersede these draped statues might not unnaturally have also have been accompanied by realistic colouring, which would keep up the habit of expecting colour in statuary, and thus explain what seems to many of us the incongruous taste of colouring marble statues. Sculpture in marble, when it succeeded sculpture in wood and ivory, "was encumbered with this traditional use of natural colours. But sculpture in marble had no true opening till temples came to be built with splendour, calling for the same plastic enrichment on a colossal scale which previously had been developed, so to speak, on thrones and chests": and this is a very probable sequence.

In regard to the sculpture on the temple at Selinus, attention is drawn to the contrast between these sculptures,—archaic and almost grotesque as many of them are,—and the Egyptian type; to the rigid immobility of Egyptian sculpture, compared with the exaggerated forms and straining attitude of the limbs in the Selinus metopes, as in the well-known one of Perseus cutting off the head of a hideous Medusa. This exaggeration of forms and action the author regards as the effort of these early sculptors of the Greek school to realise life and movement in the figure. A remark which is made in the same chapter is worth bearing in mind; that Greek sculpture grew up chiefly under the practice of working in relief, and that consequently no difficulty would be experienced in representing violent action in such a medium, compared with what would be experienced by sculptors struggling with the imperfectly understood mechanism of the human form in the representation of figures in the round, which must necessarily be subject to conditions of mechanical balance that would not affect figures in relief. This serves, as he truly observes, to explain the contrast which may be noticed between the violent, if not very free or natural, action in figures in relief, compared with the stiffness and the cautious and tentative reserve of figures in the round belonging probably to the same period, and of which some examples are given.

We must refer the reader to the volume for the attempt to characterise the various schools down to the period of Phidias, as our author recognises them, and the characteristics of individual sculptors. Much of this is, as we have already hinted, little more than conjecture, and the balancing of one probability or possibility against another. The book can hardly fail to be useful to most of those who read it, by

* "A History of Greek Sculpture from the Earliest Times down to the Age of Phidias." By A. S. Murray, of the department of Greek and Roman Antiquities, British Museum. With illustrations. London: John Murray. 1880.

suggesting new ideas to them, bringing together a considerable number of old ones, affording a kind of summary of what has been said and suggested in reference to the subjects treated of, and also giving in the foot-notes useful references to standard works which may be consulted. But we must regard the work as a *résumé* of the thoughts and fancies of an archæologist, rather than as proving anything material in relation to the subject of which it treats.

ART AND ARCHITECTURE IN GERMANY AND AUSTRIA.

THE above is the title of a paper from the pen of M. A. Turnei, engineer and architect, published in Germany. It reviews the architectural activity and the art efforts during the last few decades in Germany and Austria, and we on that account translate such portions of it as are likely to interest and possibly benefit students of Continental art and architecture in this country.

The author says that the efforts made in respect of art throughout Germany bear witness to a zeal which manifests itself not only in the establishment and development of collections, but extends its operations also to the localities in which they have been placed. Thus Frankfurt-on-the-Main has recently completed the almost monumental edifice holding the Städel Gallery, in Sachsenhausen; Hamburg, Stuttgart, Leipzig, Cassel, &c., have erected new buildings for their collections, which, it is true (as, for instance, the gallery at Cassel), do not always answer to the requirements which might be made with regard to arrangement and light. Those who have had occasion to inspect the old picture-gallery at the Belvedere at Cassel, and observed the inadequacy of space and light, will be agreeably surprised by the judicious arrangement and suitable lighting effect in the new gallery building.

The picture-gallery in the Neckarstrasse at Stuttgart suffers also from defective light, especially in the side cabinets. In the Museum at Berlin, and more particularly in the National Gallery, it is at certain times of the day simply impossible to examine the pictures hung in the smaller rooms, on account of the great reflection. The rooms in the Dresden Gallery which are lighted from above suffer likewise greatly from disturbing reflection, although otherwise this gallery, independent of its intrinsic value, must be classed among the most judiciously arranged collections. All these defects show how difficult it is to come up to all the requirements respecting lighting which must be insisted on in the case of a picture-gallery if its effect as a whole is not to be permanently injured. In Berlin a remedy has been supplied in the skylighted rooms of the Old Museum by screens, which are suspended free under the lantern, and which aid in neutralising the differences of light during the various parts of the day.

It is the same principle as that applied by King Ludwig I. of Bavaria in the case of the Rottmann landscapes in the New Pinakothek, Munich,—of course, here in a more complicated, more luxurious form, as an inserted porch; but the effect produced by this projecting roof in the lighting is extraordinary, as it is not easy to obtain by the direct operation of light. But the steady endeavour to take the practical requirements in this respect more into account than was formerly the case is becoming general, so that in a very short time Germans will possess a number of art institutions which may not only be described as excellent as regards their contents, but will be striking with respect to their interior arrangements.

There has been great architectural activity during the last ten years in the various capitals and smaller towns of Germany. Dresden has obtained in the Nicolai School (see *Builder*, March 8, 1879) a very healthy basis for a better development of architecture, and a series of new buildings in the English Quarter of the Old and New Town are excellent specimens. We need not especially refer to the Picture Gallery, nor the new Theatre, by Semper; they are specimens of architecture which, like his other works at Zürich, and the two Imperial Museums and the Hoftheäter at Vienna, will continue to be monuments of the first order.

Dresden has an advantage over other towns in possessing in the Elbe sandstone a cheap and excellent building material, but it is the custom to use it more for the walls themselves than for the facing of buildings. Notwithstanding the abundance of sandstone, the practice of cementing prevails largely in Saxony; visible brickwork is also very little represented.

Compared with Munich, the architecture of Dresden is in a more advanced state; the beautiful situation of the Saxon capital, the large influx of strangers, and also the great number of wealthy inhabitants, admit of the employment of larger means for secular architecture than on the average is the case at Munich.

The modern architecture of Dresden, compared with that of Munich, is more uniform,—nearly throughout in the Italian Renaissance style; while in Munich it is of the most motley description. Upon the Classic period of Ludwig I. followed the endeavour to produce a new style in the Maximilianstrasse, and upon this the period of Italian Renaissance of the Neuerather school; and at present there is an attempt at making German Renaissance the dominant style.

With respect to the latter experiment, Munich is not alone. At Vienna, such experiments have been more or less successfully made in the Reissnerstrasse, and at the new Justizpalast (see *Builder* of September 14, 1878), and by Domhaumeister Schmidt at various private buildings; but a more general introduction or supplanting of the prevailing Italian Renaissance has not been effected; the attempts have been isolated.

Such buildings have been more extensively erected in Berlin, where the undertakings in the Beuthstrasse, the Passage, and more recently in the Leipziger and Friedrichstrasse (see *Builder, passim*) have called into existence very excellent structures, which can no longer be classed among mere experiments. This cannot be asserted of Munich architecture, the works in the domain of German Renaissance, so far as they can be really included in that style, being merely experimental.

A very happy result has been effected in the façade of the Kunstgewerbehaus, Munich, and the endeavours to bring the interior into stylistic harmony with the outside deserves recognition, even if we do not agree with the mode of architecture which constructs vaulting and pointed arches of wood, and lines them with boards, as has been done in the large hall. But for the remaining undertakings in the province of German Renaissance at Munich, this could be generally admitted; they are far behind the Berlin works, and are devoid of a uniform character, which ought to be especially pronounced in this style of architecture. The *motifs* have not always been very well selected and carried out, and as far as the high-gabled façades (which seem to be greatly preferred) are concerned, they cannot be recommended for imitation; they are inferior to similar Middle-age gabled houses, as they may still be seen in Cassel, Cologne, and the Rhine towns, as well as in many other cities of Germany. Those fretwork gables are not praiseworthy specimens of German Renaissance, and, if they were more fully developed, would lead us back necessarily to the Rococo period; while, again, there are a whole series of really beautiful Renaissance buildings of the older period in Germany, which, like the Castle of Heidelberg, may be recommended. We need only look round among the older towns; the Castle of Offenbach, Aschaffenburg, a number of beautiful objects in the Rhenish cities, part of the Rathhaus of Lübeck, buildings in Berlin, and even in Eastern Prussia, for instance, in Görlitz and Breslau, deserve notice in this respect.

As far as the development of the German Renaissance is considered in its general typical features, it would, if truly and intelligently understood, be capable of fertile changes, and it would thus have a future; but as matters stand at present, and especially with regard to Munich undertakings in this department, much would have to take a turn for the better before it could compete successfully with the Italian Renaissance.

At present, and for a long time to come, the latter will retain the upper hand, and has found a home, in all small and large towns,—not, it must be admitted, to the disadvantage of art and its development.

In any case, it is desirable that in Munich architecture should emerge from the stage of mere experiment which has become chronic; that in that city not only builders and contractors, but also architects, should receive commissions from its citizens, a matter difficult to carry out in practice. At any rate, buildings such as we see in the Hessstrasse, which are devoid of the alpha and omega of architectonic ideas, would become scarcer, and thus a state of matters avoided which cannot recommend Munich, the first art-home of Germany, very much in the domains of art and architecture. If Munich did not possess the beautiful structures from the times of Ludwig I., the works of Neurenther, the Rathhaus of Haubrieser, and some of the better works of Schmidt, the city would be especially poor in striking specimens of architecture.

How different is the impression made by Stuttgart with regard to secular architecture. True, it has no imposing residential barracks, but the private residences are throughout of a pleasant and tasteful exterior, and their characteristics show that their owners think more of a better class of house than is the case in Munich.

In the same manner, if we walk through the villa-suburbs of Frankfurt-on-the-Main, Wiesbaden, Hamburg, &c., we gain the conviction that in those cities secular architecture assumes more and more a monumental and pleasing character, that the citizen is growing more select in his taste. Frankfort especially makes an agreeable impression in this respect (see *Builder, passim*); its villas of the outer periphery, and the buildings in the Kaiserstrasse, the new Exchange, the Opera-house, the Städelsche Institut in Sachsenhausen, represent to a large extent striking architectural objects. They are less structures run up by speculators than buildings demanded by modern requirements. They are the villas of rich merchants, such as we find them at Bremen, but especially in Hamburg. The latter city, which after the great fire of 1842 had such a splendid chance of carrying out the regulation and suitable reconstruction of the town, let this opportunity pass by, although there were present all the conditions required for a magnificent reconstruction, a desire expressed by Semper fifty years ago.

Notwithstanding, the rebuilding took place in the old angular fashion, narrow and rarely straight streets cross each other, and these are again enclosed as in a frame by residences of the ordinary type of older cities. As a contrast, the immediate neighbourhood outside the Public Grounds is of a more agreeable character. The whole series of villas along the Alster-Basin as far as Uhlenhorst and the immediate neighbourhood cause an excellent impression; they are mostly in the Italian Renaissance; the features of the city and neighbourhood would be much more imposing if changes had been effected in its interior and on the ramparts, and the Grounds of the Alster had been run round the whole town, as has been done in such excellent manner in Frankfurt-on-the-Main and at Leipzig. In this respect, Frankfurt has outstripped Hamburg; it does not possess such beautiful and riverine surroundings as the latter city, but it has spent more upon the town and its neighbourhood.

The greatest architectural stagnation prevails in Lübeck; everywhere else, in Wiesbaden, Coblenz, Cologne, Düsseldorf, Brunswick, Hanover, Cassel, &c., a greater or less activity has set in, and even smaller towns are not behindhand in proportion. Lübeck, on the contrary, has remained the town of the Middle Ages; all that is wanted to make the picture perfect is to replace the old inclosing walls, and to join them to the still existing gates. The number of modern buildings in Lübeck is limited, and even its surroundings show less of the suburbs of our time than we find them in all older cities, even at Nürnberg. In proportion to its sister towns, Frankfurt, Bremen, and Hamburg, this city, formerly one of the principal ones, has remained far behind in the race; but as a town proper, with its historical monuments and sign-posts, it is more interesting than those less modern, yet retaining the old healthy core and character.

There is a far greater number of towns which have preserved their architecture of the Middle Ages in Northern Germany than in the south. South Germany still possesses in Rothenburg on the Tauber, Markbreit, Ansbach, Nürnberg, especially in the latter, interesting types of old towns; but vandalism in modern garb is making sad havoc among the rare examples of Middle-age architecture,—pulling them down one after another; and tedious and uninteresting streets and houses take the place of romantic "Gassen" and buildings of a bygone age and departed art.

In North Germany also, though at present in a less degree, modern barracks push aside the best buildings of olden times. In Danzig, Königsberg, Breslau,—everywhere this ten-

dency shows itself in a dominating manner. Frankfurt-on-the-Oder and Görlitz have become quite modern towns, and although in the latter a great number of more ancient and highly interesting buildings have been preserved, the new town predominates.

On the whole, there exists in Germany a tendency to modernise, not always accompanied, however, by a happy result. The fact by itself would have incontestably to be declared a success if at the same time something better with regard to artistic progress were to more generally take the place of the old buildings; but in all the towns, large and small, with few exceptions, the work of building is in the hands of speculators and builders who have never, or very rarely, received a competent technical training, and whose talents are insufficient, in most cases, to replace by natural abilities what they are deficient in by study. It would be an idle attempt to try to teach the general public a better understanding. They do not possess the required judgment, and the freedom of trading in its most extensive application is nothing less than a preventive against relative excesses, and of the decadence in the art-domain of architecture,—and, as a further consequence, of the mechanic arts and art-industry.

In Vienna more caution has been used in this respect. The trade of the builder in that city, which has achieved most striking results in architecture and art industry, has never enjoyed such liberty as that any speculator without the necessary training and ability would be permitted to undertake building on his own accord. A special concession is necessary, which depends upon the capacity of individuals, and even builders by trade are compelled to employ an architect. These licences are withdrawn as soon as the builder offends in the matter of construction and safety of the buildings he erects, or when accidents happen through such neglect or incapacity; and it may be asserted that this system works wonderfully well, and deserves imitation elsewhere. What is wanted is not theoretical examination, which has sometimes very little practical value, but proof of capability, by showing that proper schools have been frequented and independent work executed in the special branch which has been selected.

It is only upon these lines that the right way for improvement in architecture and art-industry can be pursued. But this mode of progress may be aided very much by the assistance rendered on the part of governments, and especially of representative bodies. The latter more particularly often retard their development by withholding, from motives of false economy, the necessary funds required for the promotion of art and science, for the erection of public buildings, &c. These bodies, as a rule, do not consider that the means thus granted benefit the whole community, and that the state is bound to provide ways and means for future development, to remove obstacles, and to erect such landmarks as will direct a nation in the right way of progress. A rational and productive political economy, an increase of general prosperity, and the advancement of art and science, are practicable only on the basis of such principles.

VALUE OF BUILDING LAND AT MUSWELL HILL.

A BUILDING estate at Muswell Hill, consisting of about twelve acres, was sold at the Auction Mart, last week, by Messrs. Driver & Co. It is situated close to the Muswell Hill entrance to the Alexandra Palace, and within a short distance of the Hornsey and Crouch End Stations on the Great Northern Railway. It was described as well adapted for the erection of villa residences and shops, for which there is a great demand in the neighbourhood. After some active bidding, the estate was sold for 10,000*l.*, representing nearly 900*l.* an acre. This is said to be a larger sum than the average price which similar land in the locality has hitherto fetched. It was stated in the room that one of the metropolitan companies was the purchaser.

Sion College and St. Alphage's Church.—Mr. Charles Smith, vestry-clerk to the parish of St. Alphage, denies that the question of light as affecting the church has been arranged, and the parish is determined to maintain its rights. We simply reported what was stated at the auction. A model was, we believe, exhibited showing the way in which the difficulty would be surmounted.

NOISES.

RECENT revelations of science have shown that noise is a more comparative term than was previously supposed. So far as the special business of the builder is concerned, the word has been applied to what must now be looked upon as a very mediocre kind of vibration, when contrasted with the efforts of science to produce a really great noise. The consecutive system of architecture, which must necessarily prevail in large and densely-populated areas, has many disadvantages, and not the least of these is the conveyance of irrelevant sounds through the thin partitions that divide one building from another. The strains of a piano or the murmurs of conversation are seldom an acquisition when they come from a neighbour's house filtered through an ill-"deafened" wall. But the devices that are employed to avoid annoyance from causes of this sort are often sufficient if they are properly applied. The dirty mixtures of soot and other abominations are perhaps not very consistent with the highest conceptions of sanitation, but they are nevertheless sufficient in many cases to serve the purpose aimed at. The life of the tenant, however, would be a burden to him if his neighbour were given to making experiments with a steam-syren. We mention this instrument because it is constructed for the special purpose of making a "big" noise. It would be sufficient, under ordinary circumstances to keep a whole street from enjoying the blessings of sleep; and those of our readers who have heard it booming loud above the uproar of a storm, to warn ships from a dangerous headland in foggy weather, would probably be inclined to admit that its capacity for wakefulness would extend over the whole area of an average London parish. But if we take this as the maximum of noise which science has been able to produce, our wonder is exceeded by revelations as to what is going on around us that the ear unaided is not able to detect. The world of sound has just had its boundaries marvellously enlarged, with regard to vibrations that require special appliances in order to be heard. The microphone has been, in many respects, eclipsed by an instrument recently invented by Professor Graham Bell, to which he has given the name of the photophone. The general result of both instruments has been to show a mobility among the component particles of so-called solids that had never been more than suspected previously. The most teuable theories on the subject of heat seemed to demand as their foundation a certain kind and amount of atomic motion which appeared to be the only rational way of accounting for the phenomenon. Now it not only has transpired that such molecular movement does occur, but the vibrations even of light acting upon, or rather, to speak more correctly, among the particles of solid metals, have become audible to the human ear. It seems, in fact, that electricity, by reproducing the most delicate vibrations on an enlarged scale, is capable of doing for the human ear what the microscope has already accomplished for our organs of sight.

It can hardly be said that the vibrations are exactly reproduced. What reaches the ear is not an intensified continuation of the air vibrations originally set up by the movements of the molecules, but all the same we have, if not an exact copy, at least an audible proof of their existence. For several years the effect of light upon the metal seleuium has been the subject of investigation among men of science, who have severally and separately contributed a number of facts with regard to its behaviour under the influence of various kinds of vibrations. These experiments have been conducted principally in relation to the effect of light upon the metal as a conductor of electricity. It appears that rays of a particular kind, falling upon seleuium, increase its electrical resistance. This fact suggested to the mind of Professor Graham Bell that alterations in the intensity of light falling upon a sensitive surface of this kind might be reproduced as sound through the medium of another substance vibrating in accordance with the rapid alterations going on in the electrical conductivity of the seleniun. This has been accomplished, and it now transpires that only a simple set of apparatus is required in order to convert the rays of the heliograph, which has already done such good service in the late campaign in Afghanistan, into the channel of actual speech.

This is, indeed, a startling announcement, and means that when the apparatus is perfected two persons, separated, it may be, by many miles, will be able to hear each other speak with nothing but a beam of light passing between them as the medium for reproducing the sound of their voices. Not contented with this marvellous application of known facts to practical purposes, the Professor has generalised the scope of his experiments, and shown that noise in the microphonic sense of the term is going on among solid bodies in a way that the microphone in its original form could have scarcely led one to expect. Light falling on selenium leads to a commotion among the particles of the metal which is alleged to be audible. There is no reason to suppose that other solid substances are proof against similar disturbances.

Such discoveries open up an almost new conception of what the world is made of. Truly there are "more things in heaven and earth than are dreamt of in our philosophy." No sooner has man removed the imaginative charm of the unknown from his every-day life by the exploration of every nook and cranny of the world he lives in than a new world is revealed to him that can only be groped into by the aid of scientific instruments. But what shall we say of organisms infinitely below ourselves in the scale of creation to whom, for all we know, this world of sound is as familiar as the vibrations of every-day life to the ears of ordinary humanity? Who knows but that the hearing organs of insects may be sufficiently delicate to detect the sounds which are quite beyond our power of perception?

In this view of their capabilities, perhaps the rising sun is to them the herald of an uproar among the particles of the surfaces upon which they move. The walls of a house or the panes of glass in a window may, during the continuance of daylight, be in a constant condition of audible vibration which only ceases with the advent of darkness. The effect of moonlight upon the electrical resistance of selenium has already been proved to have a character peculiar to itself. Who knows, then, but that the rising moon brings about a new order of sounds for the delicate organisms that are capable of detecting them? So long as we are startled by discoveries that call upon us to recognise the mystery of the infinitely little, we need not complain about the want of great additions to our knowledge of the infinitely great. Nevertheless, our acquaintance with the wonders of both seem to move on together. The revelations of the spectroscope informing us of the composition of distant planets is not less wonderful than the revelations about sound which are now engrossing the attention of the scientific community.

SOME CANADIAN INDUSTRIES.

To allay the anxiety of political economists, who know not how to dispose of surplus populations, retaining intact the body social, Emigration springs to the front and challenges attention. To this sharp remedy for the "frettings, aches, and cares" which beset the worker in old countries, statesmen and speculative people in general are growing resigned; statistics show that, spite of the enormous increase in emigration latterly, populations advance. As regards a large number of emigrants, their choice sways between the United States and Canada, peculiarly, just now, falling upon the latter country. Ten years, spent in numerous vocations in Canada, have naturally afforded the writer of this sketch opportunities for observation above the average.

Although timber and grain are the chief products of Canada, mining interests now assert themselves; material is there in plenty; capital and labour are needed to develop it.

It is no question, now, of royal alliances or delicate political adjustment. Fine feeling and cultured prowess in the field soon grow imbued with the common tarnish of smoke. Nations that have coal and iron, with sinew to the good, rule the world. In all these Canada is rich. Iron ore of high quality is, under various forms, found in almost all the provinces, though mining is yet in its infancy. Nova Scotia, perhaps, takes the lead, her furnaces having produced 20,000 tons of iron for a year recently elapsed. This old colony has long shared with New Brunswick the prestige that may accrue from being the greatest ship-building countries in the world, in proportion to their populations; so that the impetus which must be given to the iron maritime industries of the New Dominion's eastern sea-board by the development of mines

can scarcely he over-rated. Twenty years ago, ths writer served an engineer's apprenticesship at the enormous establishment of Messrs. Charlss Mare & Co., at Millwall. Day and night there arose the din of steam-hammers and the glare of furnaces, rendering visible dark hulls upon the stocks hy the river's sids. The "hands" were counted hy the thousand. Mors yet; the entire hend of the Thames engirdling that dreary marsh known as the "Isls of Dogs" was aglow and at work. Most of those yards are closed now, their work "gone to the Clyde." Ths fierce spirit of competition presses Northern shiphnilders not a little. It nsds hut a less doubtful Colonial policy than now holds, when, Canada heing formally confirmed in the advantages of imperial union, recognised as forming an inalienahle part of the empirs, men of the Clydo will establish hranch industriss in Nova Scotia.

In the province of Quehec, iron is sven mors plantiful, but mining has scarcely hegun. The French natives have little energy and less wealth, so that an immigration of both capital and labour must aid the fusion of existing social elements which confedsration must hring about.

Canadian iron-ors is, in the older districts, fonnd together with markstahle yellow-ochre, of dark-red colour when hnrnsd; somstimss as red hrematite imbsdded in crystallins limsstone of Silurian formation. The joint produce of the three oldor provincss for a recent ysar was 40,000 tons, of which two-thirds were charcoal-iron, owing to ths absence of coal from Ontario. It was not that railway communication was bad, bnt rather that timber for fuel purposes was so plentiful; year hy year, however, wood grows more dear and coal more cheap. The "Steel Company of Canada" produced, according to official accounts, in the year 1876, 15,274 tons of iron, employing nearly 200 men. Charcoal was used as fuel, hut is giving way to coke made on the premises. Charcoal pig-iron was shipped to England at the low freightage of $0 50 per ton.

British North America, Canada now, was first settled upon the coasts and along the margins of the lakes. It was long known that British Colnmhia had iron, hut the strata containing it have only recently hesn localised to the "Cascade" regiou, heyond which it is not found. It is in contiguity to extensive coal deposits.

Coming from the Pacific coast across the Rocky Mountains, we find iron and lignite ahundant hetween the Lakes Superior and Huron, as also in the district lying hetween the Georgian Bay and the Ottawa River. Further inland, altogether removed from the lakes, are coal-heds larger than any which are known elsewhere; there is at present, however, no communication with them either hy land or hy water. The completion of the Canadian Pacific Railway will open up the prairie-lands of the north-west, both to plough and pick-axe, rendering profitable the tracts of iron-stone reaching from the U.S. houndary-line to the Arctic Ocean itself.

Having glanced at the mines of Canada, and realised their undoubted importance in the future, some account of cnrrent iron-industries may interest. Vast in size as is Canada, the circle of actual manufactnro falls necessarily within the limits of settled occupation. There, next to the mason, the hlacksmith reigns supreme over the host of toilers, commanding steadiest wages; his harvest is gleaned from the peaceful cavalry of the country, the farmers and their teams of well-shod horses. In addition to this, ploughshares aro hreaking against stump and stone, reaper knife-guards becoming unriveted, while the maker of agricultural implements is not always within reach, so that Vulcan's sturdy son is "in clover" during harvest-season. Winter, again, sees him employed upon sleigh-runners, so that at no season is he idle.

Canadian hlacksmiths evince ingenuity and quickness rather than mnsonlar power, hut there is many the wayside forge, in very remote districts, from beneath whose pent-house shed heams the honest, ruddy face of the English smith. Always glad to greet a conntryman is he, and has stories to tell, leaning upon his sledge-hammer, of his distant hamlet in "Merrie England." Smiths' pay (jonrneymen's wages) ranges from $1·50 to $2 00 a day. "No very high rate, after all!" some one may cavil. No, hnt helives cheaply and well; his children are well edncated, and are worth money to him; and he has bought his house and "building lot." He may yet become Reeve or Mayor, or even expand into a rohust, if not hrilliant, member of Parliament.

No man, hlacksmith or else, works for others, in Canada, longer than he nsed; independencs is at once ths charm and monsy-winning secret of that free life. The hlacksmith is a pioneer rather than a followsr; so much have times changsd from the romantic cast of olden times, that hs precedes the missionary, running a neck-and-nsck race with even the zealous French Jesuit in the vangnard of civilisation. He hnilds his shanty, sets his forge agoing in charge of his hoy, and bimself, axe in hand, makes intermittant war upon the Titans of pine and oak.

Scarcely second to ths hlacksmith is ths maksr of agricultural implements: an important functionary in both civil and social circles. His profits are large, his work not particularly delicate, and he gives employmsnt to many raw hands, who, thrown idle by the inclsmsncy of ths ssasons, are ready to turn themselves to anything. In the smallest shop, howsver, one good mschanic, in the ssveral branches of wood and iron, is retained at high wages. He fesls himself at least as useful to ths world as his master,—a bearing which, far from aronsing bad fesling, wins esteem. If ths "hoss" havs marriagoahle daughtsrs, prospects of partnership improve.

Towering above the herd of lesser ones are some half-dozsn notahle makers, whose goods would, for lightnsss and finish, do credit to any country. Exigencies of Canadian farming, such as the shortnsss of harvest seasons and high price of labonr, have borne colonial makers of agricultural machinery to a height in their profession, whence they look down with compassion upon "Old Country" rivals, with their cnmhrous appliances. This is presumptuons; for the heavy clays of England demand different treatment from the light cleared soils of Canada; while, there, the extents of land only partially cleared of stumps snggest important modifications in ploughs and harrows. In Manitoha and mnch of the vast North-west territory, the soil is heavy and adhesive, so that steel ploughs can alone be used; parts, indeed, are made of glass, exceptionally. There are, as yet, no resident mannfactnrers thero, although iron is plentiful, and some enterprising Englishman with a few hundreds of pounds is much wanted. Wire fencing would be sure to pay, for timher is expensive.

Reverting to "Old Canada," the inference, from what has been said, that machinery nsurps hand-lahour, is enconraged. Steam and horse-power play a far more active part than here. The scythe is used in places where machines cannot penetrate, it is trne, and there are yet to be found settlers whose pride is their "cradling" prowess. Harvesting is disociated from the rnral and poetic surroundings that invest it at home. A sickle is viewed as a ouriosity, and maidens are too busy making cheese to find time for weaving wreaths of corn-flowers, which, indeed, are less common than the terrible Canadian thistle. Another of those old implements that have, by association of ideas, hecome the subject of chaste apotheosis, is the flail. The horse-power thrashing-machine has dethroned it. Go where you will, during the months of Jnly and August, you hear its humming. This, as well as the "root-cutter" and "reaper," is a dangerous machine, swelling the annual list of farm accidents. Smartly got up, they are christened by fanoy names, snch as the "Acme," the "Forest Queen," and the "Climax." Bright paint, however, does not always cover the hest work. At the yearly provincial exhibitions, held in rotation at the various towns, makers are well represented; nor are their reputations merely local. Many have taken medals at European exhibitions. Giving work to hoth wood and iron workers, the opening of a factory is an event to a hamlet. Clustering around it are houses, library, town-hall, chapel, school, and surgery; the yonthful town soon aspires to civic rights, this heing the dearest hope of the Canadian corporate mind.

If machineries used to gather in the harvest he elaborate, those for the opening of new territory are simple. Most characteristic of Canadian implements are axe and "buck-saw." With the former, the pioneer fells trees, squares timbers, splits fencing: his axe is his capital. The other, disdained by hackwoodsmen as a tool of effeminate luxury, is invalnahle in the preparing of wood for the stove. There are professional travelling huck-sawers, often negroes, and the saw proves a source of livelihood for those who are, in the griping rigours of winter, so unfortnnats as to lack work. Anyhody in whom the consciousness of having enjoysd an academic sducation does not outweigh mors solid considerations, may make tolerahle wages hy contracting with families to cut thsir "cord-wood."

The manufacture of saws and axss is naturally largely prossc utsd, the Canadian axs heing a modsl of elegance, and superior to English ones. Axe factories are somstimes vsry extensively built, arranged with small steam-hammers and shearing-machines, work heing found for the clevsr blacksmith in wslding the iron hody of the hlade with its steel-cutting edge. The "Galt Axe Factory" has a more than Amsrican celebrity, Australia heing a heavy customsr.

Among the necessaries of modern life, and high in the list of Canadian iron industries, is the sewing-machine. Though the largest factories are in the United Statss, Canada has many lasser onss: some of famous make. The "Osborn" and "Raymond" are at Guelph, Province of Ontario, forty-five miles from Toronto. The "Little Wanzer" is at Hamilton. Some ysars of piecework upon the "Osborn" enahle the writer to sstimate hoth the advantages and the defects of that system. Piecework to commence with, without any previous standard of day-lahour, snrsly leads to exorbitant prices for work done. This was the case there. By the vigilance of smployers, a "cutting-down" process was inaugurated by-and-by, which carried matters to the other extreme. There might, it is trne, bo worse luck than that of being obliged to work hard in order to make $10 per week, were it not that we had often to "lie off" a fortnight at a stretch, there being more stock on hand than could be at once sold. The work upon sewing-machines is of no great delicacy from the engineer's point of view, although a tact in adaptation is needed, only to ho attained by practice.

Tool-making is the choicest mechanical department in the iron hranches, nor can any hut good blacksmiths hold their own, hecause of the precision demanded in tempering the many little cutting-tools employed.

Most money is made, however, not hy the skilled mechanic, hut hy those for whom interest has secured a drilling or planing machine, or lathe. Either a pattern-shop is upon the premises, or woodworkers are employed at a distance, to make the boxes and tables. Machines are japanned also, so that an oven is needed, and the neighhouring fonndry placed nnder contribution for "castings." Sales are chiefly effected through travellers and agents resident in the varions towns of hoth continents; speculative canvassers frequently buy machines at redneed prices on their own account, finding their markets themselves. Capital being often scarce in the firm, this latter plan finds favonr. Business heing prosperous, ready money is coming in, while, the reverse happening, production is slackened, or the works even temporarily closed. The factories are modern, tastefully hnilt, and well furnished with plant. Proprietors are mostly men from the United States, who, leaving their country to evade the excessive taxation consequent upon the Civil War, settled in Canada, where they grow attached to her, and make good citizens.

Canada has several high-class engine-shops. Messrs. Goldie & McCulloch, of Galt, Ontario, make engines quite equal to any of the English makes. The men are in hulk Scotch, for party-feeling runs high, and factories acquire the national *bouquet* of their owners. Famed throughout the Dominion, this firm has constant and reliable employment to give; the huildings are upon as large a scale as most engine-shops at home. Wood is used as fuel, yet signs are rife throughout the land of speedy change in the direction of coal. Upon such extensive railway lines as the Canadian, there are, of course, well-ordered locomotive shops. There is not so much "hright work" about Canadian as about English locomotive engines; still, essential parts are as carefully looked after as here. In Toronto and Montreal there are rolling-mills, with puddling-furnace and tilt-hammers, bnt nothing heavier than rails can he made. Boiler-plate is imported. "Pont-y-pool" is largely used. Good tool-making factories exist,—a recent direction taken by native enterprise; but, both pig and malleahlo iron being fetched into the country, prices of material and lahour are high.

It must be long ere Canada exports finished material, hut ores have been profitably exported already, if upon a small scale. Nova Scotia, Quehec, and Ontario sent out, in 1876,

60,000 tons. Canadian independence does not threaten at the moment; thoughtful Colonial minds desire closer alliance with the mother country. It is, however, a possible episode in the future, nor to be feared, except on broad Imperial grounds. England would not cease to be the market for raw mine produce. British capital is invested far deeper in the secondary applications of metals than in the primary one of ore extraction. The former will increase, the latter decrease, as the colonies unearth their treasures.

What may prove to be the character of those vast coal-beds underlying the prairie regions of the North-west must determine the future of Canadian manufactured iron. To cover small orders at special prices, charcoal-iron is unrivalled, but, to enter the stream of foreign competition upon equal terms, Canada must use coal. This is no place for the discussion of Transatlantic fuels. Suffice it, that the coals of Canada differ much in quality, and one extensive tract at least, — the "Smoky River," — is contaminated by the presence of sulphur, the ruin of reducing operations and forge-work.

The axe and saw excepted, cutlery is brought from England, together with the various articles of farm and home use falling under the generic heading of hardware,—all but a long list of small matters, at once useful and ingenious, such as locks, window-fastenings, apple-parers, in which line the astute Yankee is supreme. The foundry is an institution of deserved standing in Canada. It generally stands alone, unattached to an engine-shop. Few towns,—and Canadian towns would be villages in England,—but have such an industry, where rough castings are turned out to suit prices and occasions. Here resorts the shrewd patentee to put his pet scheme into shape, for the cost is not great, and the proprietors are sure to be interested in a "new wrinkle." At such a little foundry, the writer, having ordered a weekly relay of window-fasteners from his own pattern, fixed his base of operations for an extended canvassing tour. Partly on foot, partly by land and water conveyance, he traversed the greater part of a province, penetrating into the forest fastnesses of Muskoka, whose depths had never echoed to the pioneer's axe, nor a window existed to fasten. Lake upon lake, river upon river met his gaze, all connected and navigable, while a prescience whispered of a day when many factories and men shall be at work there making engines for the fleets of steam craft destined to plough those waters. The business of fastening windows growing unlucrative, he retraced his steps, making up for lost time in the hamlets fringing that new district.

Iron ship-building is practically confined to the maritime province of Nova Scotia, where coal is accessible; yet upon the chain of fresh-water seas stretching inland from the Upper St. Lawrence to the foot of the Rocky Mountains is "verge and room enough" for a large iron mercantile marine.

Docks will one day be found upon these prairie-reaches, and forests of chimney-stalks rise from the flowery sward, as nature yields her desolate sovereignty. But, at present, the feverish anxiety to "better themselves" that animates Canadians strikes at the roots of mechanical efficiency. Everybody covets the possession of land, and most attain their ends in time. There is not in all the Dominion a trained body of shipwrights able to build fleets; and if there were, the labour would be too costly. New Brunswick is, perhaps, foremost in engine-building: she burns wood-fuel, and therein is the secret.

A word now at the close. A small iron capitalist must do well in Canada, if only he can adapt himself to the exigencies of the country, beginning with repairs. Wire-fencing, corrugated iron buildings, mill-machinery, are needed. The intelligent mechanic with some means can also succeed, if he can unlearn his home-lesson and place expedition before excellence; let him join the two qualities, and it will be so much the better for him. Inability to raise himself out of the accustomed rut is what keeps back very many mechanics abroad. No man should resign good prospects at home in the vague hope of bettering his lot; for, as the world goes, he who gets good wages for a fair day's labour has cause to be thankful: as views widen responsibilities accumulate. If independence be easier gained, toil is far more severe than at home; perseverance and integrity make their marks in England.

A CHRISTMAS REVERIE.

TIRED and weary during a long journey, I sat ruminating in the corner of a railway carriage, when gradually a change seemed to creep over everything; my travelling companions had altered their attire; fashions strange and queer supplanted the homely garments of a few moments ago; the carriage seemed much loftier, the window had stopped its rattling, the draft from the ill-fitting door had ceased, a fresh pleasant atmosphere pervaded the place, although the windows were closed. A narrow table which occupied the space between the travellers was filled with books and papers all stamped with the seal of the railway company, and a Morocco-bound time-table, with the date 1900 in gold letters, lay amongst them.

I turned to my companion, with whom I had been in conversation a few moments before, and asked the meaning of all this. "Surely," said he, "you have not travelled much of late, or you would have known what improvements have been made." I suppose I looked somewhat puzzled, so he proceeded to enlighten me.

"You must know," said he, "that about Christmas time some fifteen years ago things had become so bad that a week of abstention from railway travelling was appointed, and offerings of fuel and water were made to King Steam, with prayers to relieve us from the difficulty. A strange thing then occurred. In the new year all the boards of directors, on assembling as usual, found their places occupied by shadowy forms. The bravest tried to take their usual seats, but were thrown with some violence on the floor and against the wall. One chairman, a gentleman of immense energy, fetched the police, but when the bâtons of those officials were wrenched from their hands, and recoiled with force on their own heads, the inspector said it was a private matter, with which he declined to interfere, and withdrew his men. Each of the directors went post-haste to his solicitor to consult him as to what had best be done, and the shadows remained masters of the situation. Writs were issued, but have not yet been served, although years have elapsed, and even now the energetic officers of the law may be seen entering every house where 'spirits' is written over the door in hopes of doing their duty.

Next morning the travelling world were sorely puzzled. On applying at the ticket-offices, the little iron grilles were closed. Travellers knocked and listened for the customary civil response. Silence reigned within. Outside the stations, in the windows of tobacconists, stationers, everywhere, placards met their gaze with 'Coupons 1900' legibly inscribed. Entering a shop our traveller asked for a ticket. 'We don't sell tickets,' said the shopman. 'We sell coupons.' 'I want a first-class return available for a week,' said our traveller. 'We have no classes,' said the shopman, 'and no returns, and all our coupons are available for a year.' 'Tell us all about it,' said the traveller. 'I will,' said the shopman. 'This little morocco case contains a book of coupons. Each leaf is perforated, and contains ten coupons, and each coupon enables you to travel ten miles, first-class. Each coupon is also divided into ten parts, and each part is equal to one mile, so that each leaf enables you to travel by any railway 100 miles, or any part of the distance, first-class. If you prefer to travel second-class, each coupon is available for twice that distance; and if third-class, three times the distance; so that only one kind of coupon is issued, available for any class. No season tickets are now issued, and excursion trains, which caused many accidents, are done away with. These coupons are available for a year. At the end of the year they must be exchanged for others of a similar value, dated for the year following. This is necessary for book-keeping purposes. A traveller, in presenting his book at the gate, has it stamped with the mark of the station he starts from, and the class he intends to travel, and the collector at the other end tears out the requisite number of tickets, and they go back to the clearing-house, where they are exchanged for cash.'—'How,' said the traveller, 'do you get your profit?'—'I will easily show you,' answered the shopman. 'Formerly a great discrepancy occurred in the cost of tickets. The first-class season-ticket holders often travelled at a rate below the third-class ordinary traveller. This was unfair. The cost of the booking-offices is now saved; the company get their money in advance. They do not sell less than 100*l.* worth of tickets, from which they allow us a discount. That discount is our profit; and the companies also reckon on a certain per-centage on coupons lost or accidentally destroyed, which they do not replace. People travel when, how, and as far as they like, and all pay the same rates. Large employers of labour keep tickets by them, and give them to their workmen when they send them to country jobs, and, in fact, the advantages are so great that no one will now propose to return to the old system.'"

I thanked my companion for his interesting communication, and we stopped at a station. The name was legibly written in twenty places on a level with the eye, and the whole length of the train. Every one, without looking out of the window and inquiring what station it was, could easily see. Porters came and civilly asked if we wanted to get out, or had any packages for them. They were a most intelligent-looking body of men; and on my remarking it to my informant, he explained that no paid porters were now employed. "It was found," he said, "not to work well to pay all men alike. The idle and disagreeable men did least work; the civil and industrious men did most; so that it became a premium on idleness, which was unfair. The present men are paid according to the work they do,—so much a package, if put on a cab, so much more if taken to your house. The signalmen and drivers are put in at twenty-five, and pensioned off at forty. They are very well paid during their fifteen years of active service, so that if they have been careful they can live very comfortably on what they have saved and the amount of their pension. If they desire further work, they have always the preference for light-porter's work, and are a very happy and respected body of men, and the companies have found the freedom from accidents this has brought about more than compensate for the extra cost."

I noticed a box with the word "complaints" written on it, affixed to the wall, provided with a lock. "That box," my informant said, "is for dropping your card with any complaint you may wish to make at the back. The travelling inspector has the key, and the advantage is the complaint is investigated on the spot, and often within a few hours after it is made. Your name is not divulged, and as complaints, as a rule, are not made without some cause, it has a most wholesome effect on all concerned,—so much so, that the knowledge of the facility it gives the public to bring their complaints before the proper authorities, prevents cause being given for them."

The floor of the carriage, I was pleased to see, was level with the platform, and no space was left between the platform and carriage. This had been urged so often, that I was glad to notice those appeals had at last been effective.

The carriages were also much loftier than any I had before seen, and my informant explained this great advantage was obtained at a small additional cost.

My companion also explained to me the use of a pipe about 3 in. in diameter, that passed under the carriage, and was connected with another upright pipe in each compartment, terminating near the roof, and provided with a valve just over the head of the passengers; an india-rubber junction between each carriage made it continuous. "This," he said, "is for the admission of air without draught into each compartment, and can be used at night, or in wet weather, when the windows are closed." At the back of the tender I saw a carriage, the front compartment of which was fitted with several bright copper vessels, of which I could not understand the use. "You will see by and by," said my friend, "but the box in the corner is an ice-box. In warm weather the air is carried round a coil of pipes inside the box, and is thereby cooled before it enters the carriages, and in the winter the box, which is made of strong riveted iron, is filled with steam from the engine, when the air is warmed, so that by this simple means, and at a nominal cost, the carriages are kept at a comfortable temperature, and the air sweet at all times." The insides of the carriages looked in good taste, and the cushions were covered with a pretty washing material. I noticed an absence of the bits of looking-glass and cheap gilt mouldings I had always associated with first-class carriages, and when I sat down the cloud of dust one is usually enveloped in was not to be seen.

The cause of the first improvement he explained was that the railway companies no longer trusted to their own efforts in decoration, but had instituted a yearly exhibition at which prizes were awarded for improvements in railway matters, and as those prizes were large, they were enabled to avail themselves of the best talent obtainable. The cleanness of the cushions was owing to the system of summer and winter fittings having been adopted; in the autumn all the carriages are cleaned out and washed, the cushions with their gay covers are taken out, and others with more sombre coverings substituted. The horsehair with which the cushions are filled is turned out and washed, as well as the cases containing it; by this means the stuffy mangy effect of the old carriages was removed, and the carriages always looked clean and inviting. I noticed there was no refreshment room at the station we had just left, and inquired the reason. "The directors," my friend explained, "became at last ashamed to sell their customers refreshments they would neither eat themselves nor offer to their friends." "And what have they substituted?" said I. "I will show you," said my friend; and, touching an electric bell I had not before noticed, the window was almost directly opened by a man dressed as a cook. After a few whispered sentences he withdrew, and returned in about fifteen minutes with a dish of cutlets and fried potatoes, most appetising and nice, which he handed in at the window with a bottle of claret and a decantor of water. I thought I had observed for some minutes a smell of cooking, but fancied I must be mistaken, although now I at once divined the cause, and I at once saw the meaning of the copper vessels which had so puzzled me. "Don't you think a little cooking-apparatus carried with each train is better than the old refreshment-room"? said my friend. "There can be no doubt about it," said I; "and I wonder it was not adopted before."

"Why," said I, "are the papers and periodicals all stamped with the railway stamp?" "They belong," said my friend, "to the railway company, and are provided for the use of travellers without charge; when done with they are sent to the hospitals. Why," he continued, "should hotel-proprietors provide their customers with reading free, and not railway companies?" "I cannot tell," said I. "Why is the time-table bound in morocco, and printed on such good paper? It is very nice, but to purchase it monthly must be very expensive." "It is not published monthly, but yearly," said my friend, "the monthly time-tables, owing to the constant changes and the difficulty of making arrangements in advance, became such a plague that they were abolished, to the loss of no one but the publisher, and to the gain of the whole travelling public. It is as easy for a company to make its arrangements twelve months in advance as one month, and we have now a well-bound well-printed book instead of the flimsy old time-table, always out of date, of years ago."

"Why are the carriages different colours?" I inquired. "To distinguish the class," said my friend. "When a train draws into a station it is annoying to travel all along the train looking for the class of carriage you require. It is better to be able to tell from where you stand where your carriage is. The smoking-carriages are all placed behind, so that the smoke cannot annoy any one whose window may be open."

"The carriages with lace curtains and upholstered so prettily are for ladies; you will see 'Ladies only' on the doors and windows, on the Continental system. You will notice they are first, second, and third class, to suit all wants, and are much appreciated."

"Where are the arms that used to divide the seats?" I asked. "They are done away with," said my friend; "they took up a certain amount of room, and when a compartment contains only four passengers, which is often the case, they can make themselves much more comfortable when there are no arms than when there are."

"You will notice," said my friend, "the windows do not rattle; the little crank at the side of the sash works up and down with a vertical motion like a French bolt, which is much better than the slovenly old strap and the loose sash. The door fits air-tight, like a jeweller's case. You will notice the keen draught that cut your knees in winter is done away with."

"Why," said I, "is the back cushion hung at top and the lower edge fixed to the seat, and why does the cushion draw out with a frame?" "This," said my friend, "is for long journeys and night travelling. By this simple contrivance, which only costs a trifle, each seat is converted into a couch, and by putting one-half the passengers it will hold into a carriage, which is quite as many as we usually have of a night, each traveller gets as much comfort as if he were lying on his couch. It is most gratifying after riding some hours to alter the position. This can now be done, and it is, I assure you, much appreciated."

"How pleasant it is to read by this electric light," said I. "Yes," said my friend, "it is generated by the engine, and costs little. How people put up with those dirty, miserable, old oil-lamps so long I cannot think."

"But where are the papers?" I asked. "Oh," was the response, "they are all journals now; news is condensed, sensation articles don't pay; advertisements are much dearer, so advertisers condense their matter; the public like it better, and the journals pay better than the papers, and they are handier and much better for keeping and reference."

"But how do all these improvements affect the dividends? I fear they must reduce them." "Not at all," said my fellow traveller. "People have not the objection they once had to travelling; you are as comfortable now in a railway carriage as in your own room. The number of travellers has very much increased, and the dividends are higher than ever in spite of the extra expenses. You will find," he added, "that whether a man directs a railway or keeps a shop, it is all the same, he never loses any thing by studying the comforts of his customers."

At this point the word "Tickets" was shouted in my ear, and starting up I found myself, with all my bones aching, put back twenty years into the old musty carriage, with its low ceiling, its rattling windows, its draughty doors, its stifling atmosphere, its wretched lights; and when the train stopped, and I was begging a stolid porter to have the kindness to put my luggage in a cab, I found to my cost, as the girls sing,—

"It was a dream, it was a dream."

W. H. Lascelles.

THE ORIGIN OF THE POINTED ARCH DISCOVERED.

More theories to explain the origin of pointed architecture! and this time so profound, so philosophical and unassailable, as to remind us of the immense advances in knowledge that we moderns have made, and the great elevation at which the nineteenth century stands as above all other centuries.

A book has been recently published in London, illustrative of some Arabian matters, and the author, in speaking of the camel, confers on that very venerable and useful beast a distinction which we are not aware it has hitherto enjoyed. In fact, he traces the origin of the pointed arch to the hump on the camel's back. The common camel, as every one knows, has two humps, but the Arabian camel, or dromedary, the chosen animal, only one. Architects should look up this, if only for "the fun of the thing." The volume in question is published under a *nom de plume*, but the real name of the author is understood to be Falkenhergh. If the conclusions of this gentleman are sound, the whole of our Gothic class-books, manuals, and glossaries will have to undergo a thorough revision, to make room for the "camel-back theory." About the antiquity of the "ship of the desert" there can be no mistake; for if the animal has not existed through all geological time, it is sufficient for all reasonable people to know that it was contemporary with Adam and Moses. Notices of the camel will be found in the Book of Genesis, and we know camels formed a considerable portion of the property of Job, who is said to have possessed 3,000 of these animals. Surely a domestication extending even over 4,000 or 5,000 years will satisfy reasonable folk that the hump on the camel's back must have well impressed itself on the minds of the early builders. Euclid, Thales, and others, who worked out such forms geometrically, were, doubtless, inspired by the hump. Echo says "Humph!" But *place aux dames*. Here we have a delicate *brochure* in lilac and gold which settles the matter entirely,—"Architecture and how it arose. With a Model for the Gothic,"* by Charlotte A. Pound. The illustration on the cover tells the whole story. Put the tips of three fingers on each hand together, separate the lower part of the hands as far as this will allow of, hold the two first fingers erect, to take the shape of pinnacles, and there you have it! What can be simpler or more conclusive? Not only the ground-plan, but the whole structure (says the writer) may be tested by the human figure as to its principles of symmetry and proportion; the Hand which forms the Arch is itself the perfect model for that Arch." And then the fair enthusiast goes on to teach how the proportions are to be obtained, in that sweet dogmatic tone which belongs to the sex when they happen to be talking of what they have no knowledge of. The braceletted arms of a lady upraised with the bent fingers touching, form an arch "which gives the altitude of the Chancel Arch and Roof, and distinctly defines the form." The hands are to suggest arches of every size, and will give the proportion for the window. The thickness of the wrist will determine the space between the windows for buttresses; and "the knee upraised to the height of the elbow, gives both altitude and form for the Entrance Porch." This last piece of information is too subtle for us, we are bound to confess, but it is evidently quite as true and useful as the rest, or as the statement immediately following that the feet side by side turned up show the relative size for the Great Door. Strange to say, all this is written as if with a conviction of its entire truth, and with a good sprinkling of Biblical quotations; the kind intention of the lady being, after "study of the laws of symmetry and proportion," to supply to modern architects the deficiency caused by the loss of the laws of Gothic architecture!

* London: Marlborough & Co. 1880.

THE JORDAN BAROMETER.

It is impossible to foresee the result of the perfecting of any scientific instrument. It is rarely the case that such an instrument is,—like the spiders among *insecta* and their allies,—born in the form which it will maintain through life. Such, however, was the case with the weather-glass of Pascal. The best mercurial barometers of the present day are in principle, and almost in detail, identical with the tube which that great genius carried up the Puy de Dôme for his memorable experiment. The great defect of the mercurial barometer is the narrow limit of its movement. A difference of ten per cent. in the atmospheric pressure, which is about the maximum to be obtained at any fixed point on the surface of the earth, only causes a difference of 3 in. in the height of the column of mercury, and it is difficult to read the barometer more closely than to the tenth of an inch. The ball-like, or cup-like, form of the top of the mercury gives some indication as to the actually upward or downward tendency of the barometric movement,—but the desirability of a more visible display of the force of atmospheric pressure is undeniable.

Extreme delicacy, no doubt, is obtained by the use of an aneroid, furnished with vernier and magnifying glass. But the aneroid is better suited for observations involving change of place than for those made successively on the same spot. Like the old-fashioned wheel barometer, the aneroid usually requires a tap, to see that the needle is freely moving; and this is but a clumsy means of making a delicate observation. Years ago we remember, in the window of an optician in Liverpool, an inclined barometer. The upper 3 in. or 4 in. of vertical tube were replaced by 5 ft. or 6 ft. of inclined tube, so that by placing the graduation at right angles to the latter, the intervals of change were magnified from twelve to fifteen times. We are not aware how the ingenious modification acted. Those of our readers who were at the meeting of the British Association in Birmingham some fourteen years ago may remember that one of the lions of the place was a water barometer, erected in the house of an amateur, which seemed almost to breathe like a living being. A water barometer was made by Professor Daniell for the Royal Society in 1830. The indications given by this instrument (the movement being about twelve times as great as that of the mercurial column) are very distinct. But the variation of temperature exerts such an influence on the vapour rising from the water within the tube as to interfere with the accuracy of the instrument. In fact, it is not a barometer, pure and simple, but a combination of barometer and thermometer.

Mr. Jordan, of the Museum of Practical Geology in Jermyn-street, has met, and it seems safe to say has overcome, this defect in the water barometer. He has substituted for water, pure glycerine, the specific gravity of which is 1·26, —or only one-fourth more than that of water. And glycerine possesses the unusual advantage of combining perfect fluidity with a boiling point of 44° Fahr., and a correspondingly low freezing point. Thus, it raises no vapour to be affected by heat in the top of the tube, nor will it be injuriously affected by frost. The only defect of the substance is the readiness with which it absorbs water from the atmosphere. This has been met by Mr. Jordan by the ingenious device of giving the glycerine a waterproof coat, or, in other words, floating a layer of petroleum on the surface of the glycerine in the cistern. Thus, a barometer of extreme delicacy, and as little liable to get out of order as the mercurial barometer itself, has been placed at the service of science.

One of these barometers has been constructed at Kew Observatory; a second at the Museum of Practical Geology in Jermyn-street; a third at the South Kensington Museum; and a fourth at the office of the *Times* newspaper. This journal has commenced the publication of two hours' readings of the instrument, plotted on the natural scale. The unusual weather which has prevailed during the first week of these graphic indications has been illustrated by the very visible movement of the surface of the glycerine. What is now most to be desired is the erection of an adequate number of these instruments at certain well-selected points in the island, and the publication of the contemporaneous movements of the column. The strong accentuation of the variations already published is such as to raise the hope that much valuable information may be secured by the proper multiplication of these delicate observations.

ON SOME POINTS ARISING IN BUILDING CONTRACTS.

The case of Goodman *v.* Layhorn, which we reported in our last number, p. 628, raised a question of some importance to those engaged in building contracts, as regards the extent of the clause relating to the power of the arbitrator over disputes as to extras or the plan or specification of the work. The clause, or rather part of it, there ran, "In case and as often as any dispute shall arise touching the plan or specification or the work mentioned in the second stipulation of this contract, it shall be determined by the architect, and his certificate thereon, and any and every other certificate given by him, shall be final and conclusive between all parties concerned, except only by his final certificate he may correct any error in any former certificate." It was argued before Mr. Justice Lopes, in chambers, unsuccessfully by the counsel for the employer, that this was a submission to arbitration within the 11th Section of the Common Law Procedure Act, 1854, and that that being so, all proceedings in the action could be stayed by the Court, and the dispute referred to the employer's architect. But the late Lord Chief Justice Cockburn, and Mr. Justice Bowen, before whom the appeal came, adopted the view taken by Mr. Justice Lopes, or rather, they decided the case on one of the grounds presented by Mr. Roscoe, the counsel for the plaintiff (the builder), that the architect was not an impartial person, and that, therefore, even assuming this clause to be a submission to arbitration, the Court would not exercise its discretion and stay the proceedings so as to refer it to him; and there can be little doubt that the Court took the proper and most desirable view of the question. When once a writ has been issued, and the parties have become antagonistic, it is obviously undesirable that the architect, who is the agent in many respects of the employer, should settle the disputes. It is perfectly certain that if he were invested with this power, the builder would not be satisfied if he did not recover all he asked for. If questions as to certificates arise, which are matters closely touching the manner in which the architect has discharged his professional duties, it is obviously unseemly that this very architect should have to settle questions in regard to certificates given, or not given, made properly or improperly, by himself. In the case of Goodman *v.* Layborn also, the application was made after the pleadings had closed, whilst the section of the Common Law Procedure Act states that the application is to be made before plea or answer. As the Lord Chief Justice pointed out, it is obvious that the party who desires to avail himself of a clause by which disputes are to be submitted to arbitration, and of the statute, should do so with expedition, and not let the case drag its slow length along through various stages of pleading.

Apart, however, from these what may be called preliminary though conclusive points, it seems pretty clear that the clause which we have quoted, and others of a like nature, are not submissions to arbitration which can induce the Court to stop legal proceedings, or which can be made a rule of Court under the seventeenth section of the Common Law Procedure Act, 1854. In the case of Wadsworth *v.* Smith (40 *Law Journal* Reports, Queen's Bench, p. 118, and "Roscoe's Digest of Building Cases," p. 8) it was decided that a very similar clause was not a submission to arbitration. The late Chief Justice of England, who was a party to the decision in question, said that the statute had only reference "to submissions by consent of the parties, and where it is intended that the matter shall be judicially inquired into and shall not be left to the uncontrolled decision of some third person." The essence of a submission to arbitration seems indeed to be as the Lord Chief Justice put it, that "the matter shall be *judicially* inquired into." Now it can hardly be that the decision of an architect as to whether 20*l.* or 30*l.* is to be paid for extras is a decision arrived at after a judicial inquiry. A judicial inquiry obviously means one in which both sides are to be heard, and which, though not necessarily very formal in character, yet should partake somewhat of the nature of a legal trial. Again, Mr. Justice Hannen remarked, "I think the clause in question is not a submission to arbitration, but only an expansion of the usual provision in building contracts that on the question of extras, &c., the certificate of the architect shall be conclusive." No doubt, the words in Goodman *v.* Layborn, "as often as any dispute shall arise," may give some countenance to the view that the architect was to be invested with the functions of an arbitrator, especially having regard to Lord Blackburn's words in Wadsworth *v.* Smith,—"Where it is intended that the referee shall determine some dispute, there his decision amounts to an award." But having regard to the general tenor of building contracts, no disputes in fact can arise about extras, nor could they, properly speaking, have arisen in Goodman *v.* Layhorn, as the employer, when extras were charged for, had only to refer them for computation to the architect.

Another point in regard to building contracts arises upon a clause somewhat unusual in character, it is true, but which is found in some agreements. It is something to this effect, "that the payment of the balance does not free the contractor from any liability which he may justly be subject to." Suppose the building completed and payment made, some real or supposed defect is discovered several years after, and the employer thereupon commences an action for damages against the builder. We understand that, in the opinion of some contractors and builders, such a claim is an inequitable one. But there can be no doubt that if such a clause is placed in a building contract the house-owner may, with perfect legality, avail himself of it. As a matter of fact, as the case of Davis *v.* Hedges shows (L. R. 8 Q. B. 687, Roscoe's "Digest of Building Cases," p. 10), an employer may pay the full price for a building, may then find out that the work has not been efficiently done, and may then bring an action for damages without there being any such clause in the agreement, as we have mentioned above. So that, in fact, the introduction of such a clause is only to formulate and put into so many words a legal right which, in any case, exists. But it is perfectly clear that an employer who commences an action for damages against a builder for bad work or bad materials, some considerable time after the building is completed, would have to show, with great clearness and certainty, that what he complains of really and proximately arises from these causes, and not from others which do not concern the builder at all. Clearly, therefore, builders have nothing to be alarmed at in such a clause as the one now under discussion, and it is most desirable that they should not be under the impression that by receiving payment they are quit of all responsibility in connexion with the building which they have erected. Some short explanatory observations, and the essence of the case we have mentioned, will be found in Roscoe's "Digest of Building Cases" (p. 10), where a portion of the French Code Civil is also given, showing that in France architects and contractors are liable for ten years from the completion of the work for any faults in plan or construction. If there is any false impression as to the effect of payment, the sooner all builders and contractors learn by heart the case of Davis *v.* Hedges the better. If they are dissatisfied with their present legal position, the only course open to them is to insert in contracts some kind of statute of limitation, such as is the law of the land in France, though for a shorter period. But, considering the keenness of modern competition, it is more than doubtful if the public would employ builders who insisted on such a clause.

ST. LEONARD'S TOWER, WEST MALLING.

Sir,—Mr. Parker's remarks upon St. Leonard's Tower at Malling, printed in the *Times*, and more recently in the *Builder*, induce me to send you the following notes taken eight or ten years ago during a visit to Malling, and which may interest some of your readers.

This tower, apparently the earliest built and the latest part remaining of the residence of Bishop Gundulf, is probably one of the first Norman keeps, perhaps one of the earliest military towers in masons' work, after the departure of the Romans, constructed in England. With these pretensions, it deserves more attention than it has hitherto met with.

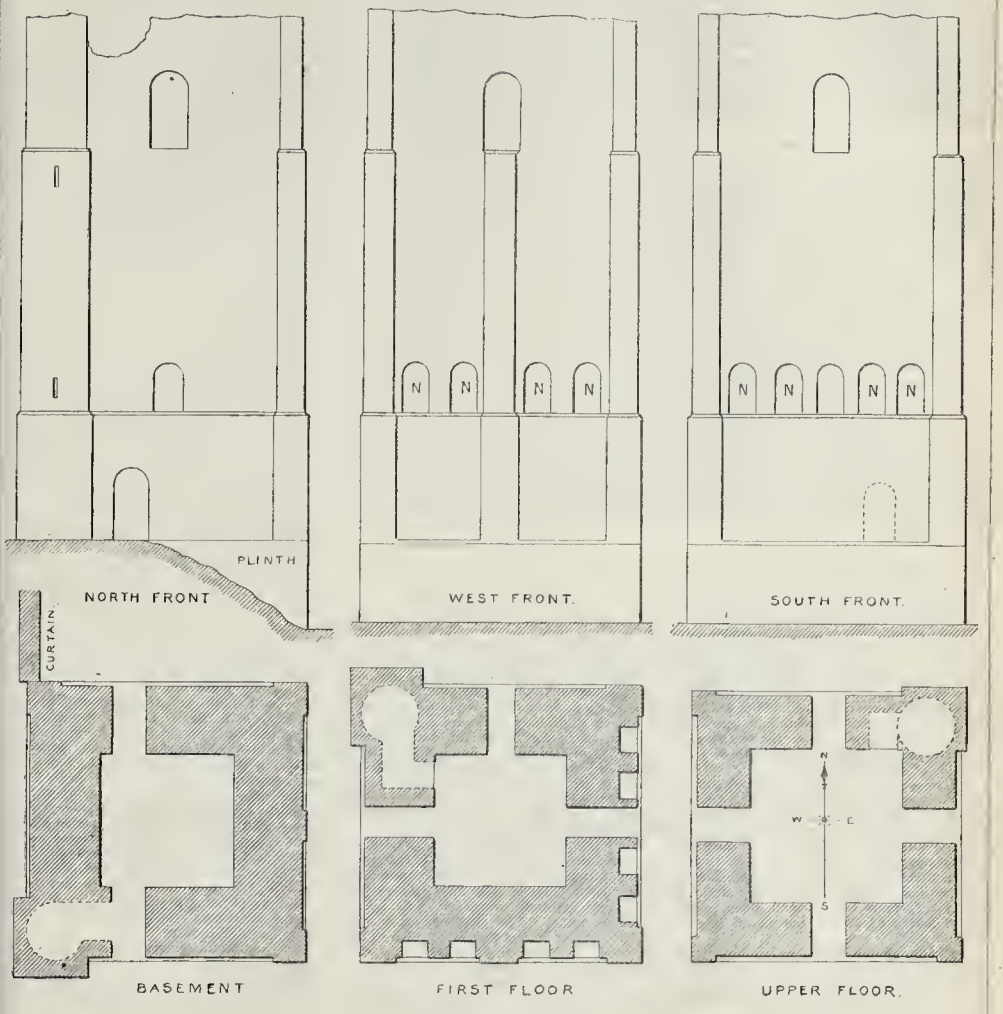
It stands about a quarter of a mile south-west of the parish church of Town, or West, Malling, in Kent, the plain heavy tower of which is also attributed to the bishop; and a little further from the remains of the religious house founded by the same skilful and magnificent prelate, and a remaining part of which seems also to have been his actual work.

The tower stands upon a ledge of horizontally-bedded sandstone rock, of a friable character, which juts out from and forms the east side of a short narrow combe, the defence of the castle on its western front, and which opens upon a stream tributary to the Medway, which stream receives a further addition from a spring which rises from beneath the rock about 100 yards south of the tower, and has been employed to strengthen the defences of the place on that side.

The tower is a very plain rectangular structure of the Early Norman type, about 32 ft. square at its base, and about 60 ft. high on its northern and eastern, and about 70 ft. on the two other faces, the difference being produced by the greater depth of the rocky shelf. The walls rise from a plain plinth, the top of which is at the ground level on the east face and north-east angle, and 10 ft. above the level on the south and west, so that the plinth is on these sides 10 ft. high. The tower is flanked at the end of each face by a pilaster strip, which rises from the plinth, and each adjacent pair meet and cover the contained angle. At three of the angles these strips have 6 in. projection, and are 3 ft. 6 in. wide, reduced by two sets off to 2 ft. 6 in. at the base of the parapet, into which they probably died. The pilasters covering the fourth, or north-east angle, are 7 ft. broad, and of 18 in. projection. These also have two sets-off. This increased breadth and projection is to accommodate a turnpike-stair, which rises from the base to the roof, and was evidently crowned by a square turret, but whether there were turrets at the other angles is doubtful, though, if present, they must have been of rather smaller dimensions. In the centre of the west face is another pilaster, 3 ft. broad, and of 6 in. projection. This also rises from the plinth; but stops at the level of the uppermost floor, at the base of a window, of which it forms the cill. Of the sets-off, that at the level of the first floor is carried round the tower; the upper one is confined to the pilasters. The parapet is gone, and the wall at the head of the staircase, being weakened by it, is somewhat broken down. The tower wall is described as battering, or inclining inwards; if so, the degree must be very slight, for its appearance is vertical, the set-off reducing it by about 6 in. or 8 in., so that at the summit the dimensions cannot be less than 30 ft. square, and the wall appears, from below, to be about 6 ft. thick.

The basement is without windows, but in the south face, near the east end, was a round-headed doorway, quite plain, without a portcullis or any moulding, and of about 3 ft. 6 in.

ST. LEONARD'S TOWER, WEST MALLING.



Scale, 16 *ft. to an Inch.*

opening. This is now, and evidently has long been, walled up, so that any rebate it may contain for the door is concealed. It opened on the top of the rock, and probably was approached by a wooden exterior stair, which must have been 10 ft. high. The present entrance is opposite to it at the same level, which there is that of the ground. This seems to have been a later opening, broken where the wall was reduced in thickness by a sort of lobby at the foot of the staircase. This is a very common treatment with Norman keeps, the ordinary doorway becoming inconvenient, and the times ceasing to demand extraordinary precaution.

The first floor has a plain round-headed flat-sided opening, that is, without splay or what in the North is called flanning, placed in the centre of the north, south, and east faces. On the south face this window is in the centre of a plain arcade, having on each side of it two similar arches, about 3 ft. broad and 2 ft. deep. The singular thing is that these niches are in the outer face of the wall, not, as would seem natural, and as occurs at Chepstow, in the inner face. In the west wall are four similar niches, but the central space is solid, occupied by the pilaster. There are two narrow round-headed loops on the north face, lighting the staircase at two levels.

The second and upper floor has four windows, one in each face. These are round-headed, quite plain, flat-sided, of about 4 ft. opening and 8 ft. high to the springing. The three floors seem to be,—the basement, 15 ft. high; the first or main floor, 30 ft.; and the upper floor, 15 ft. The floors were all of timber. There is no visible fireplace, nor do there seem to be any mural chambers or galleries. The walls at the base are 8 ft. thick. The staircase communicated with each floor, and with the roof. The line of the lower floor cut off the head of the original entrance doorway, as at Chepstow.

The masonry throughout is of a very sound and solid, though of a rude description. It is evidently original, and does not appear ever to have been repaired or even pointed. It is of rubble, the stones being pretty much as they came from the quarry, of all shapes, but rarely containing more than a foot cube. The work is roughly but decidedly coursed, with a slight tendency to the herring-bone pattern. The joints are very open, and the mortar has been very freely used. The quoins and window-dressings are of ashlar, apparently of some local ragstone, with wide joints.

It is difficult to form any safe conclusion as to the plan or area of the castle, of which this tower was certainly the keep. No doubt it lay to the north-east and east, where the ground forms a table-land a little above the keep level, and where there are traces of some rather extensive earthworks. There is a short piece of curtain-wall projecting a few yards from the south-east angle of the keep, and pointing eastwards. It looks of early masonry, but of rather later date than the keep, against which it is built without bond. It is about 25 ft. high. According to this evidence the south and west faces, at the least, must have been exterior, which, considering the arcades on their faces, and the position of the entrance-door, is curious. Probably the other end of the curtain abutted upon the north-east angle, but if so it did not bond, and has been destroyed, leaving no trace of its presence. This keep stands in three separate premises, two of which are, or rather were when these notes were taken, jealously closed. The only entrance is by the modern

door, which was fastened and the key judiciously mislaid; nor, at that time, was there a ladder to be found within reach of the tower. The garden, containing the earthworks, and within which probably stood the ball and lodgings, was attached to a private lunatic asylum. It is much to be desired that the Kent Archæological Society should take this tower in hand, and obtain proper plans and elevations of so very remarkable a building, with a good photograph of its masonry.

THE CHURCH TOWER.

A furlong or so from the castle is the parish church, the western tower of which is also attributed to Bishop Gundulf. This is a square, solid, heavy structure, about one diameter in height, very plain and simple, and without any ornament or set-off. The two western angles are capped with pilaster strips, which rise, not as usual from a plinth, but direct from the ground. There is a third pilaster, of much bolder projection, at the south-east angle. This stops short of the summit, and is mixed up with a buttress, apparently of Decorated date, and connected with an early south aisle, now removed. There is a west door, of late insertion, and above it a window, probably representing an original opening. The walls are thick, and there is an opening into the church. The tower stairs are of timber, as are the floors. In the south wall of the basement chamber is a small round-headed window, the exterior loop of which has been altered and made square-headed. The wall is rubble work, coursed and very open jointed. Though rough, it is rather superior to that of the castle, probably from respect to the character of the structure.

THE ABBEY.

The Abbey, or Nunnery, a Benedictine House, also founded by Gundulf, is about a quarter of a mile from the parish church, and just on the verge of the town. The remains are not considerable, and include a good and rather large Perpendicular gatehouse, with an earlier chapel attached. The west part of the church is standing, and the south wall, and a building connected with the south transept, probably the refectory. There are also some domestic buildings of Early English and Perpendicular date, now converted into a dwelling-house. These, the south wall of the nave, and the refectory, form three sides, probably of the cloister court.

The west front is mainly Norman, and the lowest stage is of very early work. On each side of the door are two round-headed recesses like those on the keep, and the character and material both of the rubble wall and the ashlar dressings correspond sufficiently closely to those of that tower. Of a similar character are the south wall of the nave and the walls of the refectory. There is also a small, plain, round-headed door that led from the church into the cloister.

The keep, church tower, and abbey church afford, within a narrow compass, an excellent study of Early Norman masonry, unaltered, or altered only by the effects of time and weather. All are to be attributed to Gundulf.

Gundulf was a native of the Vexin, and educated at Rouen. While there he visited the Holy Land, and must have had ample opportunity during his absence of studying Roman military works. On his return he became a monk of Bec, and was thence transferred to Duke William's newly-founded abbey of St. Stephen, at Caen. He was well known to Lanfranc, and, no doubt, to the Duke, for he was sent for to England, and in 1077 consecrated Bishop of Rochester. His first architectural work in England was, no less than the keep, known from the first as the "Tower," of London, and built probably in 1077–8. His next care would probably be his own cathedral, which he rebuilt, and of which a part of the west front is considered to be his work. He founded Malling Abbey about 1090, and it seems to have been completed or consecrated about 1106, and no doubt during these sixteen years he also built his castle. In the reign of William Rufus that king consented to his building a castle at Rochester, "*quia in opere cæmentarii plurimum sciens et efficax erat castrum sibi Hrofense lapideum de suo construeret.*" It cost him 60*l*. Where this keep stood is not known. It could scarcely have been the tower bearing Gundulf's name, and no doubt his work, attached to the north transept of the cathedral, for a tower so strong and so placed would, in the hands of the king, be more than inconvenient to the church, and it certainly was not the great and noble keep, of late Norman work, which rises so majestically between the cathedral and the Medway. Possibly this was the successor to the Gundulf tower, which, however, could scarcely have been in decay, though it might have been inconveniently small for so important a position. Gundulf died in 1108.

Mr. Parker is justified in regarding St. Leonard's Tower as one of the earliest Norman keeps in England, though I incline to think it probable that it was built when the Tower of London was completed. So narrow a question cannot be decided by the internal evidence of the work. I incline also to the belief that no keeps in Normandy are of earlier date than the reign of Duke William, though whether there are not one or two there earlier than his conquest of England has not, I think, been made clear. Arques, one of the earliest known, is a magnificent structure, for a beginning, and so, for that matter, is the London keep. Grand earthworks, lofty mounds, and deep and repeated ditches exist in abundance in both countries, of far earlier date than the eleventh century; but these were intended to be supplemented, and were, for at least two centuries, supplemented, not by works in masonry, but in timber, and certainly the shell keeps which are found in connexion with these features are never earlier than the close of the eleventh century, if so early; but the rectangular keeps were of somewhat earlier introduction, and the problem as to their first appearance can only be solved by a very close examination of those that remain both in England and Normandy, and of the square Roman towers in the south of France, by some person possessing the knowledge of detail, and the vast English experience of Mr. Parker.

G. T. C.

DECORATIVE SUGGESTIONS FROM NATURAL FORMS.—No. 7.

The natural specimen sketched here, *Masdevallia Lindenii*, is a flower remarkable for grace and elegance, in the symmetrical form of its long narrow leaves, which have a great resemblance to some common forms in Greek ornament, and the manner in which the flower rises up from among them on its tall stalk, which usually displays a slight bend backward in its rise, as if to compensate for the weight of the flowers in the opposite direction. The peculiar design of the flower, with the long tendril curving upwards from it, or, in a less developed state of the flower, overlying it in a sinuous bend, will be noticed. The flower is of a very delicate purplish tint, with a bright yellow tip.

Many things might be done in decoration with so suggestive a type. One point in the growth of the plant is, that the leaves seem remarkably independent of the flower-stem; they grow up separately around it, and it rises from the midst. The character of the two designs derived from it here is intended to keep this point in view: in each case long stems spring from between groups of leaf-forms. In the paters, which is intended as painted porcelain, the three portions of the design are grouped in relation to the three portions of the surface: the leaves cover the flat centre, the stems run round the curve or hollow leading up to the rim, and the flowers decorate the rim. The other design is intended for very light and delicate wrought-iron work arranged between standards—such work as might be used for a chancel-screen, or in some similar position. The tendril springing from the base of the flower is in this case twisted into small spirals, the treatment most suited to the character of the material.

LIVERPOOL ARCHITECTURAL SOCIETY.

The second ordinary meeting of the thirty-third session was held at the Royal Institution, Colquitt-street, on the evening of November 3, the president, Mr. C. Aldridge, F.R.I.B.A., being in the chair. There was a good attendance, and the paper of the evening, entitled "Two Faces under a Hood; or, Hypocriticism in Art," was read by Mr. Joseph Boult. A discussion ensued upon the merits and demerits of the Queen Anne style of architecture, in which Messrs. J. F. Doyle, Wm. Parslow, Joseph Boult, and the President took part.

Previously to the ordinary meeting, a meeting of the Class of Design and Construction was held in the small library, under the guidance of Mr. C. E. Deacon and Mr. J. F. Doyle, when thirteen sets of designs for a sideboard were handed in. The second meeting of this class was held on November 17th, when Mr. C. Aldridge, F.R.I.B.A., delivered the first of a series of lectures on Construction, the subjects being, the Local Building Acts; choice of site, soil, aspect, and levels; excavation and concrete.

MESSRS. CHILD'S NEW BANKING PREMISES, TEMPLE BAR.

We give a view in our present number of the front of these new buildings, recently completed. The work was executed in three divisions, to provide for the banking business being carried on during the rebuilding; the first division comprising the rear buildings, and containing a portion of the strong rooms and the servants' accommodation, thus leaving the old banking department and residence standing for use until the new was completed. A temporary banking-room constructed in Child's-place, of quarter-ing, covered with corrugated iron, the whole lined and specially framed to meet its intended purpose, was provided for occupation during the erection of the main front and the new banking-room. The latter has now been occupied about three months, the upper stories of the front main building having since been nearly finished.

The arrangement of the entire buildings necessitated great care to avoid infringements of the ancient lights with which the site is surrounded, and schemes for the improvement of the property adjoining, to the south and east, have been considered, and definite agreements negotiated. The plans have also been considerably modified as the work progressed, the original intention being to light the whole building (except in front) from two large internal courts, (faced with white glazed bricks) and to enter in front from a central doorway, the eastern portion of the main front building not then being proposed to be used for bank purposes; but the whole extent of the site is now devoted to the buildings of the bank.

The frontage of the building is about 73 ft., 50 ft. of which is within the City boundary, now defined by the western face of Temple Bar Memorial. A portion of the old City wall was removed in the course of the excavations, when other objects of interest were discovered, as have been from time to time noted in our pages, as were also particulars of the widening of the street at this point.

The entire front is of Portland stone, and the building is 57 ft. high from the pavement to the top of the main cornice. The carving to the front includes the bank's arms and emblems, combining the marigold and rising sun. The roofs generally are slated.

The front and only entrance is through a mahogany folding and swing-fitted doorway into a stone-built lobby, and through another similar set of swing doors into the banking-room, which is the whole width of the front, and 48 ft. from front to back, divided into bays by columns and pilasters; the large central square bay being formed by columns supporting beams to carry the superincumbent weight of the brick-arched ceiling and stories over.

The front and side windows are fitted with mahogany sashes protected by iron balance-weight shutters externally. The heating is effected by two open fireplaces, supplemented by a thorough system of hot-water piping and coils, and a sunburner partly supplies the artificial light and necessary ventilation, for which latter purpose extracting-flues are also provided.

At the back of the banking-room are fanlights, and a specially constructed ceiling light, amply lighting this spacious and lofty room, the fittings of which are specially designed and framed of picked mahogany. The gas-lighting is further provided for by standards, in some cases specially adapted to suit the desk arrangements. In the rear of the bank are the partners' three rooms, accessible from each other, and the principal staircase adjoins; these and the other principal rooms throughout are fitted entirely in wainscot oak. The ledger, chest, lift, and other strong rooms are very large, lofty, and spacious, solidly constructed and groined, in fireproof materials, rising from central columns, which latter were found in the excavations, and fitted with iron doors, gates, and other appliances by the best makers. The iron shelving is also constructed to design. A special feature in these rooms is that they are lighted through glazed grilles of wrought iron, and protected internally by massive iron shutters. Dining-rooms for the partners and clerks are also provided, on the ground-floor, with the requisite service arrangements, the building from front to back extending a distance of about 150 ft.

The basement is further devoted to very extensive groined strong-rooms and voucher-

CHANCEL OF S. SWITHIN'S CHURCH, LINCOLN. Jas. Fowler F.R.I.B.A. ARCHITECT LOUTH, LINC.

rooms, clerks' lavatory accommodation, kitchen service, and cellarage, the latter extending under the whole of Child's-place.

The large central front room on the first floor is furnished with dado and book-cases, &c., to design, and this and the other front rooms on this floor will be occupied as sitting-rooms by the residents, for whose accommodation, on the first, second, and third floors, a large number of bedrooms, with other rooms, are provided. An electric bell service is fitted throughout, also appliances in case of fire.

The works have been principally carried out by Messrs. George Smith & Co., contractors, from the designs and directions of Mr. John Gibson, architect, of Westminster. The proportions of the front are very agreeable, and the work throughout displays the same knowledge of detail that distingnishes other works by the same architect. Some account of the banking firm, which is the oldest in London, has been given in another volume of the *Builder*.

MONUMENT IN COMMEMORATION OF THE FRENCH REPUBLIC, PARIS.

Among the new monuments about to be erected in Paris is one intended for the adornment of the "Place de la République" in place of the fountain Château d'Eau, which has been cleared away. On the occasion of the late July *fêtes* a model of the new design in plaster was set up on the selected site, and of this we give an engraving. The sculpture is the work of M. Leopold Morice; the architecture, of M. Charles Morice.

ST. SWITHIN'S, LINCOLN.

The first stone of the new church of St. Swithin, Lincoln, was laid on Easter Monday, March 29, 1869, by the Bishop of the diocese. The nave and aisle only were built at that time, and the building remained in that condition until a little more than a year ago, when the first stone of the chancel was laid by Mr. N. Clayton. That addition to the edifice being completed, on Easter Monday last it was consecrated.

The Bishop on that occasion pointed out that the following churches have been built, rebuilt, restored, or enlarged between the two dates named, namely,—the Training School Chapel, new; St. Peter's-in-Eastgate, rebuilt; St. Paul's-in-the-Bail, rebuilt; St. Michael-on-Mount, beautified; St. Martin's, rebuilt; St. Peter's-at-Arches, restored and beautified; St. Mary's-le-Wigford, restored and enlarged; St. Swithin's, new church; St. Mark's, rebuilt; St. Andrew's church, new; and St. Botolph's, enlarged; while the church of St. Mary Magdalene is about to be restored. The sum of 9,000*l.* has already been expended on St. Swithin's Church, and about 5,000*l.* more is required to complete the design.

The new chancel is about 40 ft. long, 24 ft. wide, and two bays in length, each bay containing a three-light window, with wheel-tracery in the head. The east window is a very fine one, with five lights. Externally the bays are divided by buttresses, the double buttresses at the angles being surmounted by lofty pinnacles, and with the crocketed gables form a handsome termination to the church.

On the north of the chancel is a large organ-chamber, with a commodious vestry attached. The roof is polygonal-shaped, turreted and panelled, with a timber arch marking out the eastern bay. A stone sedilia, handsomely carved, occupies the south side of the sanctuary, while the northern side has an arch opening to the organ-chamber, with a doorway to the vestry. The chancel is raised above the nave by three steps, and has a panelled wall surmounted by light iron railing, with gates in the central opening. The stalls and prayer-desks are of carved oak. The cost of the alterations just completed is about 2,500*l.* The architect is Mr. James Fowler, of Lonth; and the buildor is Mr. C. Baines, of Newark. The east window is the gift of Mr. J. Shuttleworth, in memory of his late wife. The interior of this church has an air of quiet dignity which elicits many expressions of satisfaction.

The Photophone.—Professor Graham Bell has promised to read a paper before the Society of Arts upon his "Photophone," at the ordinary meeting on Wednesday, December 1.

THE USE OF CEMENTS.*

There is probably no more deeply-rooted conviction prevalent among architects than the belief we cherish in the excellence of Roman mortar. The Romans distinguished themselves among all the conquering nations of antiquity as mighty builders, and throughout every country which they snbdued we find the remains of public works and buildings, more or less perfect, as evidences of their occupation and monuments of the skill and enterprise of their architects. The builders of Rome undoubtedly made use of the limestones of the countries in which they worked, and sometimes they came across good limes of a cementitious character, and at others they found only fat or rich limes. In the former case we find the structures which have escaped destruction at the hands of man still extant; in the latter, where the mortar was made of bad or unsuitable lime, the buildings have crumbled away and have become obliterated by natural causes. The secret of the excellence of Roman mortar, so often and so laboriously sought after, is to a great extent a delusion, and we praise the mortar of the ancients only because all the bad mortar has long since perished. It is nevertheless a fact that we owe indirectly to the Romans the discovery of all our modern cements, for it was in consequence of researches made respecting the dnrability of ancient mortars that the reasen for what has been termed the hydraulicity of limes was explained early in the present century. To our own countryman, Smeaton, the builder of the Eddystone Lighthonse, and to Vicat and others on the Continent, must be assigned their due share of credit for these discoveries; and tbeir labours have since been ably supplemented hy the investigation of Pasley, John, Fuchs, and Pettenköfer. I will not occnpy yonr time with more than a brief record of the gradual growth of [our knowledge concerning cements, and I propose only to glance at the history of these materials, which is one of much interest. I wisb rather to treat of the employment of cements for practical prrposes, and to invite your attention to a brief consideration of the manner in which we have availed ourselves of the knowledge we have acquired concerning cements and cement action. I must first dwell for a few moments, however, upon the use of mortar in London in times past, hecause my argument will involve a clear appreciation of this part of the subject. After the Great Fire in 1666, Londou, as we all know, sprang up, by royal enactment, as a brick city, and the quaint wooden buildings which bad been the characteristics of the London of the past, were no longer recognised hy the new Building Act, and were condemned, as they still are, by the district surveyors. There must at once have been a great demand for lime, and the quarries adjacent to the metropolis were placed, no donbt, under heavy contributions for the necessary materials. The chalk nearest to Loudon, on the hanks of the estuary of the Thames, and north and south,—at Watford and Croydon,—is the white, flint-hearing, or, as geologists term it, "the upper chalk,"—one which yields a fat, pure lime, having little or no cementitious properties, and furnishing, therefore, a mortar of the worst possible kind. Further away,—on the hanks of the Medway, and on the chalk ranges of Dorking and Gnildford, or northwards, in various parts of Buckinghamshire,—we find the grey chalk, a totally differont substance, and one capable of yielding a lime of good quality. But it is impossible to examine the mortar of two hundred years ago without being convinced that it was white lime whioh onr ancestors prized, and mixed with the smallest possible quantity of sand. Tbe mortar of those days speedily dried, or obtained a false set, owing te the absorption of the water by the porous bricks, but it never became truly indurated, and, after all these years, it is found in the joints of many an old house in the City as a mere orumbling cake, which can be orushed into dust between the fingor and thnmb, and has no cohesive strength whatever. Just listen to what General Trenssart says concerning this kind of lime: "Thus chalk-lime mortar, when wet, is a pulp or paste, and when dry it is little better than dust." No wonder at the clonds of fine powder which half-blind us when any work of demolition is in progress in the older parts of London; the only strange thing is that the brickwork holds together so long as it does.

It seems somewhat astonishing in these days of rapid building to read the specifications of even one hnndred years ago only, and to learn the amount of labour then bestowed npon the preparation of even such mortar as this. Let me read you a passage from the "Builders' Price-book" of Batty Langley for the year of grace 1748. Speaking of what he terms "terrice mortar," probably trass, as he says terrice is a kind of sand brought from Holland, he tells us "the heat terrice mortar is made with two hushels, &c., of hot lime, and one bushel, &c., of terrice, well incorporated by beating, and which quantity to heat well is a good day's work for a labonrer." Think of this, poor overworked larryman, three hushels of mortar per diem "a good day's work"!

It was, I think, ont of no diarespect for the white chalk lime, hut rather from some strange belief in the colonr of the grey lime, that about the middle of the last century a fondness arose in London for what was called stone lime, such as that of Dorking or Merstham,—that is, a lime of stone-colonr,—for I can see no other reason for calling this chalk lime a stone lime, which it certainly is not. It was a fallacy dating hack to the time of Vitruvins, that the harder or denser the stone from which the lime was hurned, the harder the mortar made from it would eventually hecome. Smeaton was, perhaps, the first engineer to demonstrate this to be a mistake. So strongly was the truth of this fact believed in, however, that some have thought that an opportnnity was taken of this error, to introdude the Surrey and Medway limes, under false plumes, by terming them stone-limes, to convey the impression that they had heen hurned from limestone rock; indeed, Smeaton tells us such was the case. My own opinion is that certain grey limes had gained the reputation of being strong limes, that is, capable of uniting large volumes of sand, and that it was the colonr which gave the name, in this instance, of stono lime.

Pasley says, respecting this commonly-received opinion of the strength of grey lime, "We found by repeated experiments at Chatham that one cubic foot of Halling lime (very similar to that of Dorking) weighed nearly the same when fresh from the kiln; and by the gradual addition of water, that it dilated to the same increased bulk in the state of quicklime powder; but, when worked up into mortar not too short for use, that it would not bear qnite so large a proportion of sand as the common chalk lime had done: this experiment leading to a result in opposition to the common opinion amongst the builders in the motropolis, which is that the Dorking and Halling limes, as being stronger (limes), will, when made into mortar, bear more sand than common chalk lime."

We may assume that this rise of the grey lime in puhlic favour was partly due also to the increased facilities of oarriage, hy means of which the better limes were ahle to compete with the fat limes, which had been hitherto more readily obtained around London. Whatever may have been the reason for this preference, practical huilders doubtless soon found that the grey chalk lime yielded a far better mortar and would set harder with more sand than that made from the white ohalk and pure lime; but "Dorking stone lime" continues to this day a favourite piece of specification idiom.

The natural cement stones of the neigbbourhood of London were discovered by Dr. Parker, and specified for cement-making hy Messrs. Wyatt & Parker, in 1796. They patented the mode of making what was called Roman cement, by means of calcining the septaria or masses of nodular limestone found in the London clay. In course of time it became known that very similar results could be obtained by combining mixtures of olay and lime or chalk mechanically, and artificial cements, such as those of Vioat and Pasley, became largely employed. This mannfacture paved the way for Aspdin, with his Portland cement, patented in 1824, but it was not until 1847, or thereahonts, that tbe manufacture of Portland cement was perfected, and that what we now regard as Portland cement was made nse of upon any scale.

I bave said thus much on the history in order that I may prepare the way for my inquiry into our mode of using these cements, and glance at the extent to which they have supplanted lime. This may enable us perhaps to ascertain the causes of our failure, and properly to appreciate

* A Paper read before the Architectural Association on the 19th inst. by Mr. Gilbert R. Redgrave, as elsewhere mentioned.

the advantages we should gain from the more extended use of cements.

I am going to maintain that in good Portland cement we possess the best building material of the day, infinitely better than half the rubbish we make our houses of or pave our streets with, and a hundred-fold better when used as mortar than the compound we still go on specifying, as if we knew no more than our grandfathers of the properties of limes and cement. I trust I am not heretical in these matters, but I am so firmly convinced that lime, as now employed, will shortly become obsolete, or nearly so, as a building material, that I am able to speak out boldly in favour of cements. This brings me to my subject,—the use, or, rather, the uses, of cements; for we are almost daily adding to our store of knowledge concerning the numerous constructive purposes for which cements may be made available.

Before going further, I wish to be clearly understood in respect to the meaning of the term "cement." By the word "cement," as it is now used in building, a substance is implied which, when treated with water, will set or indurate without change of form. Limes of every variety show more or less energy to change their physical condition when water is ponred over them. Pure limes, such as those made from Carrara marble or white chalk, instantly unite with the water or become hydrated, expand to two or three times their bulk, develop intense heat, and fall to a powder. Very hydraulic limes, under the influence of water, show at first hardly any sign of action. They are termed by builders very "dead," and only after the lapse of hours, or even days, crumble into coarse, gritty fragments. Such limes, if ground or mechanically reduced to an impalpable powder, may solidify without heat or apparent expansion, and acquire a set of the same nature as Portland cement. These limes are true natural cements. Between the active pure limes and the natural cements are an infinity of hydraulic or partially hydraulic limes, some of which, namely, those of a dangerous type, will at first set under water, which is what the term "hydraulic" really implies, or in air, and gradually fall to pieces; while others, on the contrary, will at first crumble to a fine powder, which powder, however, on being worked up with more water, will set, after the manner of cement. Limes of this kind are termed by Vicat "intermediate limes," as they partake of the character both of limes and cements, and are intermediate in their action between the two. The eminently hydraulic limes of the lias formation, which are ground and sold as "lias cements," are natural cements of the former class; while all argillaceous limes, which will go abroad when treated with water, and subsequently set when made up with sand, belong to the latter class.

It may be useful here to point out that Portland cement (which is one of the very highest quality when properly made) sometimes, owing to defects in its manufacture, presents more the characteristics of an intermediate lime than those of a true cement. Thus it may, from imperfect calcination, faulty proportions, or undue admixture of the ingredients, blow and fall to pieces, after having become set, or it may crumble and fail to acquire cohesion when mixed with water; or, lastly, it may set so slowly as to be scarcely capable of being used for cementitious purposes at all. Portland cement, in fact, although the manufacture has now been brought to great perfection, is not wholly free from fluctuations in composition, which, in former times, brought great discredit upon the material, and which during the early days of its employment, caused it to suffer by contrast even with Roman cement.

The next consideration is the cause of cement action, that is, the explanation of the facts I have just been describing. Why do some limes swell up and fall to pieces when treated with water, while others remain wholly inert? The cause of hydraulicity was, to a certain extent, explained by Smeaton, who found by exposing the Aberthaw lime to the action of acid, that he obtained a residue of clay, and that all good "water-limes" examined by him left this sort of residue, while the pure limes, which were devoid of hydraulic properties, were entirely dissolved. He therefore rightly attributed this peculiar action to the presence of the clay. In his own words, he says, "In burning and falling down into a powder of a buff-coloured tinge, and in containing a considerable quantity of clay, I have found all water-limes to agree." Smeaton, who owned that he was no chemist, does not appear to have known the true reason for this action. It remained to Saussure to announce that this property depended solely upon the presence of the clay, while Descotils, in the year 1813, pointed out that the cause of the phenomenon was due to the presence of a large quantity of silicious matter, disseminated in very fine particles throughout the texture of the mineral. The chemistry of the action of cements and the formation of silicates in the kiln, which silicates become hydrated and rearrange themselves in consequence of the difference of their affinities, in the presence of the water, was first thoroughly explained by John, and the theory was perfected by Fuchs, of Munich. The study of this branch of the subject is one of great interest, and those who wish to pursue it further may do so by consulting the essay on lime in Knapp's "Technology."

It is strange that, although this action is in the main a chemical one, it can be greatly influenced by purely physical causes. To illustrate this, I will quote a recent and curious experiment of Dr. Knapp's in the laboratory at Brunswick. The avidity of quick-lime for water is one of the strongest we know of, and the rapidity of the combination of the lime causes so much warmth to be evolved that the particles are immediately raised to a red heat. Conflagrations, we know, often occur from what is termed the slaking of lime. Now, if quick-lime be reduced to powder in a pestle and mortar, and this powder be tightly rammed into a hollow cylinder perforated with minute holes, and fitted with screw caps to close the ends; on placing this lime cylinder in water, the moisture can only reach the enclosed quicklime very gradually and in very small quantities; the result is, that instead of slaking to a powder, the lime becomes converted by its hydration into a very hard and solid mass, as different as can well be imagined from ordinary slaked lime. Here a well-known chemical action is changed by purely physical means. Some chemists have thought that in the case of mixtures of lime and silicates, that is, in those limes which are more or less hydraulic, the particles of quicklime being coated over with an envelope of silicious matter, the water is only permitted to approach the lime very gradually, as was the case in the cylinder experiment I have described, and this theory has also been put forward by a German chemist to explain the reason for the peculiar action of General Scott's cement, or selenitic cement, as it is termed. I am afraid I am devoting more time than you will care for to these chemical questions, but I think they will enable us to appreciate better the action of cements. To sum up briefly the foregoing facts,—Pure limes, which after falling into a powder are made up into a paste and mixed with sand, yield mortars which have no inherent setting power, and can only become indurated by the slow and gradual recombination with carbonic acid. This re-formation of the carbonate can only proceed where atmospheric air, or water charged with carbonic acid gas, can penetrate, and the centres of thick walls, even after centuries, are often found with the mortar still in the state of putty, as when first used. Cements, on the contrary, owe but little to the atmosphere; indeed, true cements indurate better beneath the water than in the air. They possess in themselves the power of solidifying or becoming indurated, and attain their greatest strength in a few years at the most. It is a question which can scarcely be said to have been finally settled how long cements continue to harden; indeed, cements vary so much in this respect that the time differs in almost every sample, according to the composition and the degree of firing. Cements of the Roman type stand at one end of this scale, for many of them attain their full degree of hardness or tensile strength in from twenty to thirty days; while dense, well-made Portland cement of the highest quality would seem, from Mr. Grant's experiments, to continue to improve for seven years, and constitutes the other extreme of the scale.

In speaking of cements, I have purposely avoided all mention of that class of substances which, when added to rich or fat limes, impart to them hydraulic properties. These materials are puzzuolana, trass, arenes or volcanic sand, and many kinds of calcined argillaceous earth. There can be little doubt that all these substances owe their influence on mortars to the soluble silica contained in them. By soluble silica, I mean that variety of silicic acid which when treated with acids will gelatinise. Silica when heated to bright redness in the presence of bases acquires this soluble form, and most calcined clays, and volcanic minerals, which have been exposed to high temperatures, are more or less rich in gelatinous silica. Mortars compounded with pure lime and a sufficient quantity of substances capable of converting them into cements become, for the purpose of the arguments I am anxious to place before you, equivalent to cement mortars. Unfortunately, however, these mortars are rarely employed, except by engineers for docks, foundations, and other similar purposes, where the solvent action of water is dreaded. Occasionally, when, owing to the difficulty of obtaining good sand, the builder employs with fat limes burnt ballast or broken bricks, which are artificial puzzuolana, a mortar which sets surprisingly hard is obtained. Such good mortars are, however, exceptional, and their excellence is due only to the action of the "aggregate," and not in any way to the quality of the lime.

I now return to my subject, and propose to place before you the arguments in favour of employing cements instead of limes for mortar-making. First, cements will unite much larger quantities of sand and building materials into a homogeneous mass than limes, and they are therefore more economical to use than limes. I am sure that the plea of economy is one of the very strongest arguments of the present day, and therefore, though this is not my best plea, I introduce it first. Rather than take the price-book values of lime, cement, and sand, and with them construct an imaginary set of tables to show how the prices would work out, I will avail myself on the present occasion of the admirable series of experiments recorded by Mr. Colson in a paper presented to the Institution of Civil Engineers in 1878, in which this subject is most fully and ably dealt with. I am the more tempted to place before you Mr. Colson's figures, because he has with the painstaking care and accuracy which mark all his observations, not only given us the cost of different mortars, but also the actual strength of each of the various mixtures. His experiments will be all the more interesting, I think too, because the paper containing them was not read and discussed at a meeting, but formed one of the selected papers, published in Vol. 54 of the Proceedings of the Institution of Civil Engineers. It has, therefore, hitherto, not attracted that share of attention from architects and engineers which the importance of the subject demands. I will convey to you Mr. Colson's observations as far as possible in his own words.

"The object of these experiments," he tells us, "was to ascertain what proportion of Portland cement and sand would produce a mortar equal in strength to, and as convenient to work as, grey lime mortar, mixed in the proportions ordinarily adopted for constructive purposes." I may here observe that the difficulty in the use of cement mortars with large quantities of sand is their want of plasticity, and it is necessary to contrive means to overcome this, or the workman will not employ them, except in a very liquid, and therefore very objectionable condition. This tendency to shortness can be obviated by introducing chalk, lime-dust, loam, or other substances which produce a fat unctuous paste when treated with water, but all these materials tend to weaken the mortar. Still, it has been found, from careful experiments, that within certain limits it is possible to introduce even clay (which is, perhaps, the cheapest diluent which can be obtained) without reducing to any very serious extent the tensile strength of the mortar. The following series of experiments is very interesting, bearing as it does directly upon this point. The mortar was, we are told, in each case mixed to a workable consistency, equal, in fact, to the condition in which it could be used in the work. Mr. Colson's testing was carried out by means of briquettes, similar to those used in ascertaining the strength of Portland cement, having a neck of 1½ in. square, equal to a sectional area of 2¼ square inches. The mortars remained in the moulds until sufficiently hard to admit of removal. At the expiration of six months the blocks were tested for tensile strength, the results being shown in the first table. Mr. Colson says, respecting the samples of common lime mortar, that "the induration or chemical set had penetrated only to the extent of ⅛ in. to $\frac{1}{16}$ in.; but, in the majority of instances, only ¼ in. The remainder of the area of the fracture had only dried, and could be

crushed in the hand without any great exertion of force." The cement mortar with six, eight, and ten parts of sand, was, we are told, of "such a raw, harsh character, that it would be practically impossible to use it in a satisfactory manner. In order, therefore, to render it somewhat more convenient for working, a small quantity of lime or yellow loam was added, thus rendering the mortar more plastic and tenacious."

"The result of further experiments shows that the addition of lime and loam reduces the initial strength of cement-mortar considerably, the reduction due to the addition of loam being more marked than by the addition of lime. The quantity of unslaked lime or loam, viz., one-twelfth the bulk of the sand, was found to be as small a proportion as could be used to give the necessary tenacity."

Mr. Colson tells us that the experiments made with these mortars in brick joints "were not altogether satisfactory, inasmuch as the appliances at hand were not sufficiently accurate and delicate to justify a ratio of comparison. It may, however, be stated that the general result went to prove that the adhesive power of mortar mixed in the proportions of eight of sand to one of cement, with the addition of loam, was superior to grey lime mortar mixed in the proportion of two of sand to one of lime."

The second table shows the comparative cost of these different descriptions of mortar. As Mr. Colson points out, "such estimates must be received with caution, because difference of locality would exert a great influence upon the cost of production. The following statement is a close approximation of the cost of the several descriptions of mortar, the charge for labour and water, and also the bulk of mortar produced, being in each case the mean result of experiments."

The second argument in favour of using cement in lieu of lime is that cement possesses an inherent chemical set, or power of induration, whereas fat limes can only become indurated either by the slow and gradual influence of the carbonic acid contained in the atmosphere, or in consequence of the materials mixed with it to make the mortar. I have already, in the earlier part of this paper, dealt with the setting power of cements and the re-carbonation of limes. But it may be as well to glance at the facts again, to see what they imply. Cement mortar has everything necessary in itself, in whatever position it may be placed, to become hard: all that it requires is a reasonable amount of moisture. In the centre of walls, in trenches and foundations, and even under water, the induration of cement compounds proceeds steadily, until in due time the mass acquires the hardness of stone. Lime mortar, when fat limes are used, soon gets a thin skin of carbonate formed at the surface and joints, and the very formation of this exterior skin or coating at once presents a formidable obstacle to the induration of the lower or interior layers of the mortar. These merely dry into a crumbling porous powder, with little or no strength, and which, if the air cannot reach them, are no harder in 100 years than in a twelvemonth. Alberti states that he had seen lime in an old ditch that had been abandoned about 200 years "which was still so moist, well-tempered, and ripe, that not honey, or the marrow of animals, could be more so." What a contrast to this is presented by the fact that a week or two back, while a barge at some works upon which I am engaged in Staffordshire was being unloaded, a sack of Portland cement fell into the water: it could not be fished up for a day or two, but when recovered it had become converted into a stone-like mass moulded to the exact form of the sack.

Perhaps I shall be reminded that mortar joints are not by any means generally such worthless affairs as cement advocates are wont to describe them, and that even when white chalk lime or mountain limestone is used, the crystallisation of the hydrate of lime round the particles of sand presents the appearance of some slight induration. I will grant that such is to a certain extent the case, but I believe it will more often be found that this trifling amount of induration is due to the sand employed in forming the mortar. Lime has the power of slowly attacking silica, even in the form of quartz, and most sands present other bases favourable to the formation of compound silicates. We thus get in very old mortars a small percentage of silicate of lime, which can only be accounted for by some such action as this. Of course, when the lime is presented with a sufficient quantity of a substance of the nature of pozzuolana to enable it to form silicates in the work, we obtain a cement action differing but little from what would result from the use of true cements. Some writers seem to have thought that it might be cheaper, and more generally convenient, to form the cement in the work by compounding a mortar of a fat lime with the requisite quantity of calcined silicious clay; but this plan, after having been tried on the Continent, has been abandoned in favour of the mode patented by Vicat and St. Leger of making an artificial hydraulic lime from a mixture of chalk and clay. This manufacture is still carried on upon a considerable scale round Paris, at Issy and Meudon, and the use of pure lime, so vigorously denounced by Vicat, has since his time been to a great extent abandoned (at any rate, upon public works) in France. It cannot be said that here in England we have taken to heart the lessons we have learned, and the unscientific use of lime burned from the hard limestones of the North of England, and from the white chalk in our southern and eastern counties, still continues unchecked.

A third reason for employing cements in preference to limes is that a method has been discovered by General Scott by which limes can be converted into cements by a very simple process, and at a very moderate cost. Perhaps you will allow me to glance briefly at this invention, as it is one imperfectly understood. About twenty-five years ago General (then Captain) Scott, of the Royal Engineers, found that a sample of grey lime, burnt in a common fireplace, with a smothered fire, had acquired properties very different from those of the same lime if prepared in a clear bright fire. He at first thought that this peculiar result was due to the formation of a sub-carbonate of lime, owing to the imperfect combustion of the fuel, but subsequent experiments caused him to abandon this view, and to adopt the theory, which he ultimately found to be the correct one, that the change in the character of the lime was due to the presence of sulphur which had been absorbed from the ashes of the coal. This fact led to the invention of what was called Scott's cement, a material which was prepared as follows:—Tender-burnt grey chalk lime, made from a lower chalk, containing from 10 to 15 per cent. of silica and alumina (as, for instance, that of Lewes, in Sussex, or Burham, on the Medway), was re-heated to bright redness in shallow kilns or ovens, having perforated floors or hearths. When the lime was sufficiently hot, pots of sulphur were placed beneath the floors, and this sulphur was at once set fire to by the heat of the kilns. The fumes of the burning sulphur thus rose around the lime, and a coating of sulphate of lime was formed over each of the lumps. The lime was then ground between mill-stones, and Scott's cement ready for use was obtained. As it appeared that this cement owed its peculiar properties to very minute quantities of sulphate of lime, intimately mixed with it, General Scott thought it might be possible to prepare it in a cheaper way, as, for instance, by sprinkling lump lime with sulphuric acid, or mixing ground lime with plaster of Paris; but though each of these plans was tried most carefully, it was found to be impossible to secure uniformity by any other than the gaseous method before described. Many years later, during the building of the 1871 Exhibition, General Scott found that if the selenitic lime, however prepared, were first ground in a mortar-mill to a creamy paste, and the sand then added, a very good cement action was secured, and he made a selenitic cement, as he has termed it, from a careful mixture of ground hydraulic lime and sulphate of lime. This cement, if used as

directed by General Scott, will bind together six parts of sand into an extremely hard mortar, and will make a good concrete with nine parts of ballast. My argument in favour of the use of cement is therefore greatly strengthened by my being able to point to such a material as selenitic cement.

The question of the kind of sand to be employed hardly enters into my present subject. I may mention, however, that in using cements, in order to secure their utmost strength, clean sand is eminently necessary. Sharp large-grained sand makes better work than fine sand, and there seems scarcely any objection to clean sea-sand, except that for internal plastering it is liable to become damp on changes in the weather, as the salt absorbs moisture. Salt sand makes stronger cement-mortar than pit or river sand, provided all are equally clean.

I wish, in conclusion, to say a few words about the use of cement in concrete. In this direction I am convinced that hitherto very little has been accomplished, and we plod on here in London with bad bricks and bad mortar, as if there was no escape from a thoroughly vicious system of building, which ought to have been abandoned with the building of the Tower of Babel. Concrete-making and the numerous uses of cement concrete is a subject in itself for a long paper, and I can only point to a few directions in which the applications of concrete appear to deserve attention. I am disposed to affirm,—at any rate, I will do so for the purposes of argument,—that as London, from its peculiar position, is and must continue a brick city, we ought, with our present knowledge of the properties of cements, to make our bricks much smaller, to serve as mere "aggregates," or, what would be better still, we should calcine our brick-earth in heaps, as ballast is made, and unite this burnt clay into monolithic structures with Portland cement. I cannot perceive any legitimate argument in favour of selling under-burned, mis-shapen, discoloured lumps of calcined clay at so much per thousand, in order to enable builders to charge 1*d.* and upwards per rod for sticking them together into walls. Far better would it be to burn the bricks into clinkers, and then incorporate the fragments of them into solid homogeneous structures with good cement, at less than two-thirds the cost of brickwork. I sincerely hope I may live to see the day when bricks will be discarded, and I trust that the New Zealanders, when they explore the ruins of London, may find it necessary to dig very deep down into the *débris* before they find any "genuine, sound, square, hard-burned stock-bricks" for the ceramic museums of the future. The days are past when the colour of cements must ever be thrown in our teeth as a reproach. Mr. Lascelles has shown the possibility of so colouring Portland cement as to render it scarcely distinguishable from red brick or terra cotta, and the house he sent to the Paris Exhibition, designed by Mr. Norman Shaw, formed a new departure in concrete building. Mr. Lascelles is able to prepare mouldings and dressings in this material at a less cost than the same work in cut bricks or terra-cotta. In point of natural colour, selenitic cement, which is a warm buff, leaves little to be desired. Another direction in which cement concrete may be used with advantage is evidenced by the manufactures of Messrs. H. Sharp, Jones, & Co., of Poole. This firm has succeeded in making excellent drain-pipes of Portland cement concrete. The manufacture is a very interesting one, and as I have recently been permitted to examine the works, you will perhaps allow me briefly to describe the process. Cement of high quality is mixed with crushed pottery in the proportion of 1 of cement to about 3 of pottery. The concrete is made in small quantities in a special mixing-machine, the materials being first turned over dry, then sprinkled with water from a fine rose and made into a very dry concrete. The mixture is next lifted into a hopper, which feeds it automatically and very gradually into the moulds. These are made as cylinders of sheet-iron, the proper distance apart to form the thickness of the pipe, from 1 in. to 3 in., according to its diameter. This mould rotates slowly on a turn-table, while an iron rammer, worked up and down like a beetle, compresses the concrete into the mould as it falls from the hopper. When the pipe is full, it is wheeled away on a truck, mould and all, and stands for from 24 to 48 hours to set. When taken from the mould, the newly-made pipe is steeped for a week in a bath of silica, to indurate it more effectually, by the ingenious process invented by Mr. Highton, and used by the Patent Victoria Stone Company. The pipe may remain in the bath for about a week, when it is removed and stacked in the open air for some months before it is sent out for use. The Victoria Stone Company, just mentioned, make excellent paving slabs of granite chips and Portland cement. These slabs appear to be very durable, and they are not so costly as common York paving. Mr. Drake has recently shown me some interesting specimens of the marble and granite mosaic work and concrete his company are now producing. I have only now, in conclusion, to express the hope that I may have succeeded in showing that "the use of cement" is a subject well worthy of the careful attention of the architect.

In the discussion which followed, the President (Mr. Ernest C. Lee), while expressing his sense of the great practical importance of the subject treated of by Mr. Redgrave, said he was no great admirer of the homogeneous monolithic bonese the erection of which had been advocated.

Mr. W. H. Lascelles (of Bunhill-row) exhibited a number of specimens of bis moulded and coloured concrete work, and in response to an invitation from the chair, made a few remarks about them. One moulded or coffered slab which he produced was, he said, designed by a well-known architect, as part of a new method of getting ornamental though fireproof ceilings in rooms. Iron joists were embedded in concrete, and upon these concrete-covered joists the slabs were laid direct, leaving the joists and the under surfaces of the slabs to form the ceiling of the room below, the upper surfaces of the slabs forming the floor of the apartment above. This simple mode of fireproof flooring had received the approval of several architects of distinction. The objection that such floors would be too resonant or noisy when walked upon to allow of their coming into practical use had been falsified by facts. He had built some small houses with floors of that construction, and the tenants made no complaint of noise. Such upper rooms, it should be remembered, being bedrooms, would mostly be carpeted over on the portions walked on. He was now engaged (in connexion with one of the companies who made it their business to erect dwellings for artisans) in seeing whether he could not devise a floor of that kind for such buildings which should be cheaper as well as better than floors of the ordinary kind. The fireproof qualities of the floor had been tested at the Croydon Exhibition of the Sanitary Congress, with conclusive results in their favour. A remarkable property of the concrete material of which these floors were made was that it would bear the driving of nails into it not only without cracking, but would hold them most tenaciously. So well recognised was this quality of the material becoming, that bricks or blocks of it were now used for building into interior walls, instead of wood blocks, for fixing the joiners' work to. The first discoverer of this kind of concrete was the late Mr. Matthew Allen, but it had been much improved upon from time to time, and it had now been found possible to impart to it a good and durable red colour. It could be moulded to any form, and was hardly distinguishable from, though much cheaper than, the best cut brickwork.

Mr. Drake thought that the difficulty of giving concrete work a good aspect externally was now being solved. It had been very difficult to obtain reliable colouring matter for concrete work, and of late he had turned his attention to making the natural surface of the material sightly and even beautiful in itself. Many of the aggregates used, such as marble and granite chippings, were beautiful in themselves, and he had succeeded in making a concrete with a smooth and semi-polished surface in which the pieces of marble and granite forming the aggregates were shown in their own colours, forming a sort of natural mosaic work. (A door in this material, made for the Theatre Royal, Manchester, was exhibited.) The same material was also capable of large and effective use in the shape of small slabs or tiles for flooring purposes.

Mr. J. S. Quilter, in proposing a vote of thanks to Mr. Redgrave for his paper, said the more experience he had of the use of Portland cement, the more reason did he see to use it more largely than ever, and he was glad to see that its use was becoming common on the better class of building estates in the neighbourhood of London. On an estate at Streatham (entirely a clay district) houses were being carried up of concrete made of Portland cement and of burnt-clay ballast in the manner suggested by Mr. Redgrave.

The motion was duly seconded and carried, and Mr. Redgrave having briefly replied, the meeting terminated.

ARCHITECTURAL ASSOCIATION.

At the ordinary general meeting held on the 19th inst., Mr. Ernest C. Lee, president, in the chair, the following gentlemen were elected members, viz.,—Messrs. F. H. Tullock, A. Richards, C. Hunt, W. Cooper, W. M. Mitchell, F. H. Goddard, W. Bennett, W. Mills, J. R. Smith, G. G. Woodward, R. Astley, J. Adkins, A. Clapton, A. Crow, W. P. English, F. P. Pulham, G. H. Sale, G. W. Ward, A. T. Walmisley, H. H. Kemp, E. H. Selby, R. H. Tebb, H. F. A. Chidgey, F. R. Oglesby, T. A. Andrews, R. Barker, E. J. Ram, B. A. Colley, A. B. Few, A. K. Stephens, F. W. Mincey, A. W. Tribe, A. C. Houston, G. F. Byron, A. Huntley, W. Gilruth, E. H. Pritchett, P. Vernon, F. S. Capon, B. F. Simpson, F. Rowntree, F. Wilcox, T. M. Roberts, J. R. Younger, R. M. Kearns, H. Ling, F. L. Lee, W. Parker, and E. E. Carpenter.

Mr. Quilter, honorary secretary of the "Sharpe Memorial" committee, announced that the "Sharpe Memorial Volume" was now nearly ready. The whole of the plates (sixty in number) had been lithographed, and the letter-press was nearly ready. The number of subscribers up to the present time was 134, but it was desired to raise that number to at least 250 before the work was printed. The amount of the subscription was a guinea and a half.

The Chairman announced that in consequence of a domestic affliction Mr. C. G. Vinall would not be able to read the paper on "Furniture" promised by him for the 3rd prox. In its stead, a paper on the "Architecture and Architects of the Sixteenth Century" would be read by Mr. W. Hilton Nash.

Mr. Gilbert R. Redgrave then read a paper on "The Use of Cements," which we print under its own heading.

SCIENTIFIC AND ARTISTIC ASPECTS OF POTTERY AND PORCELAIN.

The first of a series of five Cantor Lectures on "Some Points of Contrast between the Scientific and Artistic Aspects of Pottery and Porcelain" was delivered on Monday evening last in the hall of the Society of Arts, by Professor A. H. Church, F.C.S., who commenced by observing that there were several opinions current as to the effect of scientific knowledge upon the artistic value of the products of manufacture. Some persons argued that the evidence afforded by the consummate beauty of certain Greek vases of what was known as "the period of perfection" would suffice to prove, not only that a rational and intimate and exhaustive knowledge of the chemistry and physics of ceramic materials and processes was not needed, but also that it was almost certain to end in what might be termed artistic disease, if not in the death of true beauty. The idea of such persons was that knowledge,—full, exact, and unbending, fettered the imagination and crushed all the poetry out of the handiwork of man. Quite on the other side were ranged the devotees of science. Science, they said, must be master. Nothing satisfactory, they would urge, could be obtained without mathematical precision. Not content with explaining, by means of all kinds of analytical processes, the causes of the beauty of any product of human skill, these rigid disciplinarians permitted no departure from established rule. But happily there was a third, and, it was to be hoped, an increasing class of persons concerned in ceramic and other manufactures, who took a broader view, and who were prepared to welcome any kind of aid from whatever quarter it might come. They called in the chemist to analyse old materials, and to analyse by synthesis for new ones; but, on the other hand, they would be always on their guard against the dull uniformity, the complete stagnation, consequent upon a mere mechanical routine. They would endeavour to find a scope for individual originality, remembering that a man could not be expected to be always producing the same pot any more than a great painter could be expected to endure the weary labour of continually painting *replicas* of even his best pictures. The energetic director of ceramic works would en-

deavour to learn from the best productions of other countries and other times. He would endeavour to introduce every improvement in grinding and washing the materials used, and in all kinds of glazes or finishes; and with excellence of materials he would do his best to combine good proportion and beauty of outline. It was abundantly clear that if the pottery of to-day was to stand the test of time, not only must it be good in material, but the highest art-knowledge and the highest art-power must be affiliated to the management of our potteries. The continual experimenting of Wedgwood, untrained as it was to a very great extent, would have led to no very great results had not the sweet neo-Classic art of Flaxman been available. In suggestion more fertile, in taste more eclectic, the spirit of to-day, if more exacting than the spirit of yesterday, should endeavour to obtain that quality of all-round perfection which inspired the efforts of the modern potters, though it but too often condemned them. The potters of the present day enjoyed greater and far better opportunities of education and execution than Wedgwood had, and they would certainly fail if they did not take full advantage of them. These were points which had been before urged on various occasions by many minds. In an address which he delivered eleven years ago before a local school of art, he conveyed very nearly the same ideas in very similar words. In the address he pointed out that when Bernard Palissy was at work, no knowledge, or very little indeed, as to the chemical and physical properties of the materials with which he worked was to be had. But during the last hundred years every problem which puzzled Palissy in glazing his ware had been solved by science. Mr. Soden Smith, in his report on the ceramic wares in the Philadelphia Exhibition, speaking of the English productions, contrasted their want of variety in new methods and descriptions of pottery as compared with the inventiveness of Wedgwood, and insisted upon the need of increased art-efforts in connexion with English pottery. To return to his own mode of treating the subject, the lecturer said that the title of the course indicated its scope, but not the limits which many causes combined to place upon his treatment of it. He purposed noting the relations subsisting between the chemical and physical qualities of some kinds of the material used for earthenware, china, pottery, and porcelain, and their artistic qualities as apprehended by the trade. He had then to discuss the physical or mechanical structure of materials used by the potter in connexion with their chemical composition. These were inseparable the one from the other. In other words, the chemical composition and special physical structure went together, and they affected the form, surface, and, of course, the colour of the articles produced,—and by colour he meant not only the ordinary prismatic and tertiary colours, but something more, viz., the transparency or translucency of the material itself. Form was, of course, a matter of primary interest in all good wares. Having, by means of various specimens of Japanese and other ware exhibited, pointed out how the materials used by the potter could be made to lend themselves to diversities in surface, form, and colour, the lecturer proceeded to refer to an interesting point in connexion with hard-burnt terra cotta. He observed that Messrs. Doulton lately noticed that upon all prominent points on any portion of a piece of terra-cotta work that had received special treatment in the way of modelling, or that had been subjected to considerable pressure, there would be found a sort of fine white bloom, at first sight efflorescent, but really not so. Now he had found that by well washing the terra-cotta clay with distilled water, the bloom did not appear in the articles made of clay so prepared. On analysing the bloom he had found it to contain sulphate of lime, which was ultimately turned into a complex silicate of lime, and being in the liquid, as it were, of the clay, it came up to the surfaces most subjected to pressure or to the manipulation of the modelling tools, and, combining with other materials on the surface, formed when burnt a highly vitrified substance, very hard. In his opinion this bloom was very detrimental to the ware. He did not want to see a perfect uniformity of colour, but the bloom to which he was referring did not come in the right places, and was therefore, he considered, injurious to the ware, although he knew that some artists and modellers were rather partial to it. At any rate, it was a matter worth further attention. Having briefly referred to the manner in which the chemical nature of a clay affected not only the wearing powers, but the capacity to receive and retain colour, of such articles as bricks and tiles, the lecturer spoke, in conclusion, of the varied and beautiful effects to be obtained by carefully mixing small quantities of mica, tourmaline, hornblende, asbestos, and other minerals of a like character with the clay used for some kinds of ceramic productions.

The following are the heads of the succeeding lectures of the course, viz.:—II. (Nov. 29), Vitreous, Plumbiferous, Boracic, and Felspathic Glazes and Enamels. Iridescent and Metallic Lustres, and Colouring Substances. III. (Dec. 9). Stoneware and other Wares glazed with Salt. IV. (Dec. 13). Soft-paste Porcelains, European and Oriental. V. (Dec. 20). Hard-paste Porcelains, Chinese, Japanese, and European.

INFLUENCE OF JAMES BARRY UPON ENGLISH ART.

This was the subject of a very interesting paper read by Mr. J. Comyns Carr at the Society of Arts on Wednesday evening last, Sir Henry Cole in the chair. After treating of the life and character of Barry, Mr. Carr said,—I shall not attempt to-night with any fulness of detail either to expound the merits or to mark the defects of Barry's painting. His most important work hangs before your eyes, and I scarcely think it likely that there is in our time room for much dispute as to the intrinsic value of the result. Whatever praise may now be accorded to his talent would go but a little way towards satisfying the claims that were at one time put forward on his behalf. His indulgent biographer contrasts his genius with that of Raffaelle, not altogether to Raffaello's advantage, and Barry himself, I think, believed that he had established a style combining the noblest qualities of the antique with the chosen excellence of the greatest of the Italians. Looking back with that cruel clearness of vision which comes with lapse of time, we can perceive the absolute insecurity of these pretensions. We are able to recognise that such art as this could not, in its nature, be a full or satisfying expression of the mind of its epoch. The failure, as we have already observed, was, in this sense, not Barry's alone; as he was among the first, so also he was in the same respect the greatest of those who laboured in vain. But the classical sentiment which dominated his style, and which pervaded all the art of the eighteenth century, which strove for the embodiment of imaginative ideas, was in two ways absolutely fatal to the production of any work of real and full vitality. For in the first place, he it remembered, that the conception of the antique world which then governed men's minds was in its essence a dead and paralysing conception. The formula which pedantic criticism and the fashion of the time had combined to force upon the world was such as by no ingenuity could he made to express the movement, the passion, and the variety of human life. Men who swore obedience to such a straitened ideal were compelled, even against their will, to falter in their devotion to nature, and to rigidly exclude from their sympathies the feelings and sentiments of their age. Even a genius so true and so refined as Flaxman's could not wholly escape from the mark of this fashion. He was so far restrained by the prevailing spirit, that he could only reconstruct the classic ideal within the limits of a domestic existence. So often as he ventured into a wider realm, so often do his works bear the impress of reverent learning rather than of individual power. He could not express, through classic forms, the presence of the modern spirit; he had not the strength which could forge the link to bind the old with the new, and if we compare his transcript of Greek art with that which had been made by the masters of the Renaissance, we shall have to confess that, although it bears externally the marks of a greater fidelity to the past, it has not an equal sympathy to attach itself to the realities of a present world.

If we can recognise this limitation in the noblest sculpture of the time, how much more strongly must it impress itself upon the products of an art whose resources imperatively demand vividness of realisation, and whose effects are therefore forced into closer comparison with the facts of nature? Painting of all the many forms of artistic expressions can the least afford to accept a convention which seeks to exclude from its views the energy and passion of actual life; and, in yielding to such an influence, it must inevitably take refuge in the nerveless grandeur of Barry's colossal style, or sink into the pretty insipidities of a Cipriani or a Kauffman. But this devotion to a false and limited idea of antique grace was not merely a source of weakness in itself; it served no less to deprive the painters of the eighteenth century of the full benefit they might have derived from the teaching and example of the great masters of the past. Few artists of his age could boast of a wider and more generous appreciation of Italian art than was possessed by Barry. His letters from Rome, and his notes upon the paintings and sculpture in Venice and Florence, prove that he understood, with a justice and discrimination that were rare in his day, the several stages in the advancement of the art, from Giotto to Michelangelo. He never assuredly made a better use of his fiery and impetuous temper than when he boldly lectured the monks at Milan upon their folly in painting the "Last Supper" of Leonardo; and the energy of his discourse on that occasion would, I think, almost suffice to strike terror into the heart of a modern restorer. But, in spite of Barry's real enthusiasm for the painters of the Renaissance, it is easy to perceive that he was constantly testing their work by reference to the standard of the antique. He did not study or accept them in the sense in which they have since been studied and accepted, as the instruments of a great imaginative impulse, whose individuality was stamped not less upon the method than upon the essence of their art; he chose rather to measure his praise of their genius according as he found they approached in their work to the correctness and proportion of ancient sculpture. Such a process of investigation could not be expected to reach the real spirit of Italian art. It was conducted by men who were intellectually already pledged to an impoverished ideal, which a pedantic criticism had chosen to graft upon antiquity, and who, therefore, discovered that Raffaelle and Michelangelo had little to teach which could not be better acquired from the surviving records of the art of Greece and Rome. There was, indeed, one man in England who possessed a keener insight into the great imaginative design of Florence, and better understood the uses of its example. The genius of Blake shot a momentary radiance across the dull sky, which others could not penetrate at all, and then sank earthward with no sure footing to tread the earth. He had the vision which showed him how great a thing painting had been when it stood as the mirror of men's highest imaginings, and he was quick to perceive the extent of the change that was needed before English painting could hope to undertake this difficult duty. But he must be judged as a seer rather than as an artist, for he had no strength sufficient to effect the revolution he so ardently desired, and while he failed through lack of practical power, others who were, like Barry, more perfectly equipped, failed no less from the lack of that intensity of imagination which, in Blake, was developed to the point of disease.

The defects that might be anticipated from this superstitious devotion to Classic style, with its consequent misapprehension of the greatness of Italian design, are easily traceable in the works of Barry. We are struck at once in looking at his pictures with the want of individuality, not merely in the features, but in forms, with the lack of passion and character in the faces, with the absence of expressive energy in the movement of the limbs. The action is either tame or exaggerated; the figures, even where the scale is colossal, are wanting in grandeur and dignity, and, at first sight, these things are more surprising, seeing that there existed at this time another kind of art which would specially tend to the development of the very qualities we miss. It is a remarkable phenomenon that the efforts of men like Barry, and West, and Haydon were contemporary with a series of the most brilliant triumphs in the practice of portraiture, and nothing shows more conclusively the insecure basis of the so-called ideal art of the period than its rigid and determined exclusion of all those qualities which make portraiture interesting. The comparison of two men like Barry and Reynolds must now be fatal to the pretensions of the former. Nor is this dependent merely upon difference of individual genius. If Reynolds had undertaken the task that

Barry attempted, he, too, would have failed in a greater or less degree, and it remains for us to consider, as one of the most interesting problems connected with art-history, in what manner the gradual progress of painting in England and in Europe has led to the decay of imaginative design, and to the assured supremacy of the departments of portrait, landscape, and the realistic illustration of contemporary manners. Looking first to England, we may see that the force of the Reformation, whatever may have been the gains in a spiritual sense, had unquestionably the effect of suddenly snapping the artistic tradition. It is not to be said that, even under more fortunate conditions, our early English painters could ever, by their independent effort, have enlarged the capabilities of their art as to render it fit to compete with that of other nations, but it is nevertheless true that, up to the time of the Reformation, English painting had a real existence; and if we go back to a still earlier date, we shall discover a period when the illuminated works of English MSS. were the most perfect in Europe. If, then, the Reformation, with the Puritan movement by which it was followed, had not entirely depressed the artistic spirit, the successive revolutions of style, which were deferred till the next century, might have more rapidly completed themselves, and the English school, as we now know it, would have had an earlier birth. But, when the Reformation came, the imaginative impulse was turned into a different channel. The force of the Protestant feeling expended itself in denunciation of the ornate luxury by which the earlier ritual had been surrounded, and, in the condemnation of Romish doctrine and practice, it was inevitable that all the outward graces of life, and the arts by which they were sustained, should be temporarily discouraged. Imagination, escaping from the control of the Church, and seeking for itself a free realm, became, by a strange irony of fate, one of the strongest elements of opposition to the art which, of all others, most imperatively needs imagination; and the artist, thus deprived of the sympathies of those who led the new movement of ideas, made scarcely any effort to keep pace with the intellectual development of the time. All the strength of our Renaissance found expression in our literature, and we are left to guess who, among the earlier poets of our school, might, under different conditions of national life, have become great imaginative painters. I know not if it is only a fancy, but I have sometimes thought that, in the author of the "Fairy Queen," there dwelt the soul of a painter; and in the precise and ordered pattern of his verse, so richly and so lovingly adorned with the description of all that might give delight to the eye, we have enshrined a series of visions that might, under other conditions, have found their way on to fresco or canvas. But it is only in the earlier stages of our literature that we are permitted to indulge such fancies, for soon the poet became also the dramatist; and the drama, while it is the highest expression of the literary spirit, serves also most clearly to assert the distinctions between the modes of literature and art.

Seeing, then, how completely literature had absorbed the national energies, it is not surprising to find that the after-growth of art in England is due to a foreign source. In the minds and in the homes of the cultivated classes the taste for art survived, and we had great collectors and connoisseurs before we could boast of great artists. Even before the Reformation had left its mark upon the English spirit, Holbein had found a home at the English Court, and when the work of the Reformation was complete, or nearly complete, Rubens and his great pupil, Vandyck, were invited to our shores. At first sight, indeed, it may seem strange that the residence among us of these great masters of the craft did not avail at once to establish the tradition of imaginative design, but the solution of this riddle is to be sought as well in the nature of the art of which these men were the professors as in that determined impulse towards literature of which we have already taken account.

House Property.—The freehold house, No. 49, Long-lane, Smithfield, adjoining the Barley Mow Tavern, one of the oldest houses in the City of London, having a ground floor area of only 190 ft., was sold last week by Mr. Robins, of Waterloo-place, for the sum of 860*l.*

DUDLEY GALLERY.

The present Winter Exhibition of Cabinet Pictures in oil is the fourteenth held here (so flies time), and comprises 453 paintings, and a dozen little pieces of sculpture. Of these latter Mr. Mullins sends "A Little Maid," in terra-cotta, Mr. Lawson a "Jeannie Deans," in the same material; and clever Mrs. R. J. Fennessy "Donatello, a Sketch for Bronze," which would pair very well with her "Cimabue," already issued in that metal. The collection of pictures shows much sound, honest work, but very few productions to excite great admiration. Looking even to the best known names, it is regrettable to find Mr. G. D. Leslie, R.A., wasting his skill on "Apple Dumplings" (150), and Mr. Stacy Marks, R.A., sending such an utterly uninteresting affair as "Studying Impromptus" (111). Mr. McWhirter's "Thunder Storm on the Grand Prairie" (107) is too like some very special occurrence to be accepted as representing the general. Nevertheless, there are plenty of pleasant pictures to justify a visit, as for example the "Pannier de Fleurs" (53), by H. Fantin; the charming "Spanish Lady" (61), by J. B. Burgess, A.R.A.; "Luring a Conger" (75), H. Macallum; "Première Communion, Dieppe" (95), a sketch by P. R. Morris, A.R.A., "The King's Highway" (173), S. E. Waller; "Le Déjeûner" (200), by Leon Lhermitte; "Souvenir of Algiers" (273), by A. Armitage, R.A.; "Rondinella" (295), by Alfred Ward; No. 324, by C. J. Lewis, marked,—"Now came still evening on and twilight grey"; and many others.

A SEWAGE FARM AT DARLINGTON.

Situated near to the border of the great coal-field of the North, and served early by railways, the ancient town of Darlington has in the past few decades risen in importance, in extent, and in population greatly. And whilst its wealth and that of its merchant princes have been multiplied, there have been some of the difficulties attendant upon large populations. For long the sewage of the town was dealt with after the primitive fashion, the river Skerne running near; but latterly a system of sewerage was introduced, and the outfall placed some miles below the town, and close to the junction of the rivers Skerne and Tees. But ultimately this disposal of the sewage of so vast a population was greatly objected to, and an injunction was obtained, forcing the Town Council of the borough to cease polluting the river. They resolved ultimately to dispose of the sewage by the establishment of a farm, to which it is conveyed. Thence, pumped up by an engine, the sewage is disposed of by irrigation; and whatever may be said of the cost of the sewage farm,—and on this head something is often said by the Town Council and the ratepayers,—it must be acknowledged that the river is purer, and that the complaints of its pollution are never heard of below the town. It is to be regretted that river pollution is allowed above the town of Darlington, and this the more because below that pollution the water supply of the chief towns on Teesside is abstracted from the river. Though the water may be purified in its course, yet there is an old adage that "prevention is better than cure," and it is regrettable that this has not been applied to the towns and villages above the water intake, as it has been to the one below that intake.

The sewage-farm of the Darlington Corporation has been in operation a few years, and it has cost close upon 100,000*l.*; the exact cost up to the date last reported,—March last,—being 97,165*l.*, this being the cost of land, of drainage formation, main effluent sewer, pumping station, reservoir, &c. The land obtained was in 1876-7, about 225 acres, and there has been a further addition since. In the first of these years the work in connexion with the needful reservoir was commenced, the engine-house being completed in the following year. Cottages for engine-men and farm-labourers were built in that year, and to these there have been added buildings for about fifty head of cattle and ten horses. Of these works, the cost was:—Preliminary Act of Parliament, 898*l.*; land and expenses, 53,323*l.*; outfall drain, 1,139*l.*; formation of main carriers, receiving-chambers, under drainage, &c., 6,834*l.*; reservoir, 4,516*l.*; gravitation sewer, 585*l.*; pumping-station and main, 5,454*l.*; and cottages, 487*l.* Up to March, 1879, the total cost was 73,339*l.* Since then additional land to the value of 20,623*l.* has been bought, and other items of cost have brought the total up, as before stated, to nearly 100,000*l.*

For the most recent period for which the official facts have been issued, it may be said that there were 203 acres of the farm under crop. Of these, 85 acres were permanent grass, 22 acres rye grass, 8 acres potatoes, 13 acres turnips, and 23 acres barley. Including the stock on hand, the amount spent on the farm in the last financial year was 10,521*l.*; and the receipts, exclusive of the amount taken from the rates to balance, were slightly less than 6,700*l.* The loss, which fell on the rates, was in that year 3,838*l.*, the amount for the previous year being considerably more. As there are considerable receipts from and payments for live stock, it cannot be said what is the exact loss to the borough from the working of the farm; but it needs to be borne in mind that it is still young, and that it has been entered on in a period of depression for the agricultural interest, and one in which prices of many kinds of farm produce have been very low. As tending to show what the produce of the farm is, it may be added that last financial year there were received 186*l.* for barley, 25*l.* for beans, 69*l.* for hay, 1,109*l.* for milk and butter, 127*l.* for potatoes, 52*l.* for mangolds, 18*l.* for willows, 26*l.* for wool, and 8*l.* for straw. It is evident that though at first there must have been, and there has been, a heavy loss, yet that loss is being reduced, and there are yearly larger receipts from the produce. For some kinds of agricultural produce it is clear that the course of treatment is most fitting, and that from the sewage-farm large crops will be realised. It remains to be seen whether as a farm it will pay its way. It is clear that when farms at a rent comparatively low have barely made ends meet, and have sunk hundreds of pounds, land which has had to be purchased compulsorily at a high value can scarcely be expected to be a commercially good speculation; but it may be said that the farm not only relieves the borough of a difficulty, but in addition it converts what was a nuisance into a blessing. The supply of food is greatly increasing from the land, and is likely still further to increase. And if in the future, with better seasons and better crops, there should be a more remunerative working of sewage-farms, boroughs must expect to have to contribute to them, and that contribution must be taken to be that which represents the cost of the disposal of the sewage, and part of which might have been spent on the older plan.

THE HONESTY OF ENGLISH MANUFACTURERS.

In the opening address delivered at the Society of Arts on the 17th inst., by Mr. F. J. Bramwell, F.R.S., Chairman of the Council, the writer, speaking of the causes of the falling-off in the demand for the products of our industries, said:—

It may be there will be found, and I fear there will be found, but I do trust in only a few instances, that we have lost command of foreign markets, and even of our own markets, because in these instances the manufacturers have not been honest. There was a time when, travelling on the Continent, one was proud to see English manufactures put forward as those to be thoroughly trusted. A foreigner felt that if he bought an article of English make, though it might not be tasteful, at all events it would be what it purported to be,—sound, honest, and trustworthy. I am afraid we cannot now say so of all that is exported from our country, or that is offered for sale within it. I do hope we can say so of most of our manufactures, but we certainly cannot say it of all. But it should be remembered as against those who commit this grievous wrong of casting a slur on the character of any of our industries that they not only do harm to the particular manufacture with which they are connected, but they do harm to the character of the whole produce of the nation. A man who has been trapped into buying a bad English product of one kind is not at the pains to ascertain whether the badness is confined to this particular manufacture, and in all probability he has not the means of ascertaining, but he says, "I bought an article which came from America, and I found it good, sound, and trustworthy. I bought a similar article that came from England, and it broke in fair use, and when it broke its internal rottenness was discovered. In future, not only with regard

to this article, but with regard to others, I shall distrust the English make, and shall prefer the American."

In connexion with this most painful subject of unfair dealing, to my mind there is nothing more humiliating than the confession of widespread dishonesty which the nation had to make some few years since, when, for mere self-preservation, it became necessary to pass an Act of Parliament, directing the appointment of public analysts. The passing of this Act was a confession that, among those who supply food, which is to support life and to preserve the health of those who are in health,—and worse even than this, if possible, that among those who supply the very drugs which the physician prescribes to restore health to those who have lost it,—there were to be found numbers who made the food and the drugs alike the subjects of fraud,—fraud that did not stop short at the mixing with the food or with the drugs materials which were inert, and which did harm by diminishing the nourishing or the curative power of that which was purchased, but fraud which extended to the mingling, in some instances, of materials which were, in themselves, actively unwholesome,—materials which, being taken with the food, converted the food into a source of disease, and being taken as curative drugs, converted those drugs into positive poisons.

Is it not too much to be feared that, in some industries, at all events, that reprehensible conduct which has rendered necessary the appointment of public analysts to protect the population of this country, has been the guide of certain of the manufacturers, and has thereby caused us to export that which is a fraud upon the foreign buyer, and a discredit and an injury to the country that exports it?

I had intended to refrain from instances, but I will endeavour, in general terms, to state one which relates to a very large industry. It appears that in a certain manufacture the purchasers preferred to buy goods that were dyed in one stage of the process rather than in another, as the goods thus dyed were supposed to be better, and they naturally, therefore, commanded a higher price. The finished goods bore on themselves indications which enabled any purchaser at all acquainted with the manufacture to determine at a glance in which of the two ways the article offered to him had been dyed. Then came the deceit. Means were adopted by which the appearance that would have been presented, but for these means, upon the material dyed in the undesirable way, was concealed, so that the appearance really presented was that which would be shown by the manufacture when dyed in the desirable way. It is true that experts in the trade can, after the deceit has been employed, distinguish the one fabric from the other, but the ordinary buyer living abroad, and not suspecting the fraudulent ingenuity that had been exercised in England, and seeing, as he believes, the well-known appearance indicative of the superior mode of dyeing, is deceived, and pays a higher price than he would have paid had he known the truth. It cannot be urged in explanation that this contrivance was resorted to because the appearance presented by the one fabric when in use was superior to that presented by the other. This was not so, as the part of the fabric that was thus treated was the very edge, and was cut off before the fabric was used.

You must not imagine that this deception was practised by a few, or to a limited extent. So far from this being the case, it became worth while to invent machines to supersede the handicraft preparations by which the deception had been originally practised, and these machines were patented. I need not say that such patents are voidable, as being against public policy, their purpose being that of fraud. I am aware I shall be told these are hard remarks to make upon a practice which has now prevailed for years, and to such an extent as to entitle one to say,—"It is commonly done. Everybody does it. Why, therefore, reproach us with that which is a custom of the trade?" I answer, "Because it is a custom for the purpose of deceit."

With respect to commerce, I do not know much about the way in which it is carried on, but I cannot help seeing the statements which appear in the public press from time to time, and if these are well founded, and that they are cannot, I think, be doubted, looking at the fact that they are not contradicted, it would appear that commerce is pursued, in certain instances, under conditions which, equally with those of the manufactures I have been condemning, are a fraud and a disgrace.

BUILDERS' BENEVOLENT INSTITUTION.

An election of pensioners on the funds of this Institution took place at Willis's Rooms, St. James's, on Thursday last, Mr. Thomas F. Rider, president, in the chair. There were nine candidates (five men and four women), of whom four (two men and two women) were to be elected. The poll opened at noon and closed at three p.m., shortly after which hour the scrutineers, Messrs. Thomas Stirling and F. W. Keeble, announced the result of the voting. The following are the names of the candidates, together with the number of votes recorded for them, viz.,—Hugh Richard Bowley, of Clerkenwell, aged 56, 2,002 votes; John Humphries, of Barnes, aged 70, 1,938; James Pilgrim, of Haverstock-hill, aged 60, 310; Thomas Gregory Bartlett, of Battersea, aged 65, 654 (including 80 votes to which he was entitled by reason of having been a subscriber to the Institution); John Page, of Marylebone, aged 67, 1,206 (the whole of the foregoing candidates now for the first time applied to be elected); Mary Ann Garner, aged 64, widow of Mr. William Garner, builder, Harrow-road (third application), 3,483 (including 80 votes due to her owing to her husband having been a subscriber); Selina Thomas, aged 72, widow of Mr. Charles Thomas, builder, of Upper York-place, St. John's-wood (third application), 2,084; Anne Boulton, aged 60, widow of Mr. Webber Napoleon Boulton, builder, Upper Clapton (third application), 1,750; and Martha Mann (first application), aged 60, widow of Mr. Samuel Loveys Mann (of the late firm of Newman & Mann, builders, Upper Thames-street), 6,174, including 390 votes to which she was entitled by virtue of subscriptions to the Institution by her husband's firm.

The President, therefore, declared the successful candidates to be H. R. Bowley, J. Humphries, Mrs. Mann, and Mrs. Garner.

Votes of thanks to the scrutineers (moved by Mr. George Plucknett, seconded by Mr. Cruttenden, and acknowledged by Mr. Stirling), to the checkers of votes (moved by Mr. Dines, seconded by Mr. T. G. Smith, and acknowledged by Mr. Bussell), and to the Chairman (moved by Mr. Phillips and seconded by Mr. Head), were duly carried.

The President, in replying, referred to one or two matters of interest in connexion with the Institution. Firstly, the Institution had, by the will of the late Mr. Larner, become reversionary legatees of that gentleman's estate. After the death of Mr. Larner's widow and daughter, the Builders' Benevolent Institution, jointly with the National Lifeboat Institution, are to share the estate. It appears that Mr. Larner's mother was a pensioner on the funds of the Institution, but was taken off them when the family found themselves in better circumstances. Secondly, a foreman in the employ of a leading London building firm, having on the completion of a job received a gratuity of five guineas, had thought he could not do better (seeing that his father was elected a pensioner on the funds of the Institution some years ago) than hand the money to the Institution which had supported his father in his old age. These incidents were, Mr. Rider thought, of sufficient interest to be mentioned on that occasion.

BRITISH ARCHÆOLOGICAL ASSOCIATION.

The opening meeting of the new session was held on Wednesday, the 17th inst., the Rev. S. M. Mayhew in the chair. The Rev. Preheudary Scarth described an early font, apparently Saxon, in Stanton Church, Gloucester. The Rev. J. A., Lloyd reported the discovery of Saxon carved work during the recent restoration of his church at Broad Hinton, Wilts, and exhibited a full-sized drawing. Mr. Loftus Brock, F.S.A., reported the discovery of a Roman pavement of beautiful design, in the Close, Winchester, of which the Rev. C. Collier sent a drawing. Mr. Lewis exhibited a rubbing of a Saxon coffin-lid found at Bexhill Church, where much Saxon walling has been found above the Norman arches during recent repairs. Amongst other exhibits, the Chairman produced several beautiful specimens of early pottery found in London, including a thirteenth-century green ware jug, of large size. Also an early Chinese carving in jasper, found in excavations at Bishopsgate. Mr. Thomas Morgan, F.S.A., read a paper on the results of the recent Congress at Devizes. The second paper was by Mr. C. H. Compton, on the Cradle Tower in the Tower of London, which has recently been opened out and freed from the modern buildings that surrounded it. The roof is beautifully groined, and, as the reader observed, the tower afforded access from the moat to the Queen's apartments. The whole has been thoroughly repaired under the direction of Mr. Taylor, of H.M. Office of Works.

FREEHOLD GROUND-RENT IN LEICESTER SQUARE.

THE ALHAMBRA THEATRE.

A large number of capitalists was attracted to the Auction Mart on Tuesday by the announcement that Messrs. Cbinnock, Galsworthy, & Chinnock would offer for sale a freehold ground-rent of 710*l.* per annum, secured by the greater portion of the Royal Alhambra Theatre, in Leicester-square, together with two attached residences, Nos. 24 and 27, Leicester-square, with reversion in thirty years to the rack rental, estimated at 5,000*l.* per annum. The particulars describe the theatre as occupying one of the most prominent positions in the West End, and comprising a noble and substantial structure, erected about the year 1850 by a public company under a charter of incorporation, at an enormous cost, and affording accommodation for about 4,000 persons. The whole area of the land, including the site of the two adjoining houses, was stated to be nearly 12,000 superficial feet.

The auctioneer, before asking for bids, enlarged at considerable length on the very great value of freehold land in the locality, as well as on the value of the building itself, observing that in the event of its possible conversion, it was well adapted for Government offices, co-operative, or any other public purpose, and that supposing any such change in the character of the building to be contemplated, the probability was that arrangements could be entered into with the present proprietors of the theatre.

The first bid made was 15,000*l.*, and 17,000*l.* having been offered, there was a pause in the biddings, on which the auctioneer observed that if they estimated it at twenty-five years' purchase on the ground-rent, which he considered it worth, it would amount to more than had been offered, and then they must add to that a considerable sum as the value of the reversion. By further advances the property was brought up to 21,000*l.*, when the biddings again stopped, on which the auctioneer remarked that it was about the only freehold land in the neighbourhood, the land generally in the locality being leasehold; and he reminded them that the selling price of freehold land in the vicinity of Leicester-square at present was 3*l.* per foot, which represented 36,000*l.* as the value of the site at the present day, which must yearly increase. There being no further advance, the property was withdrawn.

SALE OF BUILDING SITES AT SNARESBROOK.

An estate at Snaresbrook, which has just been laid out for building upon, was offered for sale at the Auction Mart, on Thursday, the 18th inst., by Mr. F. G. Hunt. The estate is situated near the Snaresbrook Railway Station, close to Wanstead, and was described as a portion of the comparatively small quantity of land that can now be sold near to Epping Forest. The sites offered were twenty-three in number, having frontages varying from 32 ft. to 60 ft. in length, and from 130 ft. to 200 ft. in depth, They are intended for the erection of a superior class of houses, one of the stipulations being that no house to be built on any of the sites facing the high road to Chigwell shall be of less value than 600*l.*, whilst the houses to be erected on other portions of the estate are not to be of less value than 400*l.* Another stipulation prohibits the carrying on of any trade or business whatever on any portion of the estate. Nine of the sites were sold, two of them having frontages of 64 ft. and 50 ft. each, realising 255*l.* and 250*l.* respectively; six others, with 32 ft. frontages, fetching prices varying from 165*l.* to 150*l.* each; and a site fronting Nightingale-lane, on another part of the estate, and angular in form, with a frontage of 44 ft., realising 100*l.*; the total proceeds of the sale amounting to 1,535*l.*

COMPETITIONS.

Exeter.—Ths compstition at Exetar between the architecte of that city for ths new church at New Town has (ae we announced a fortnight ago) resulted in the choice of the designs of Mr. R. Medley Fulford to be executed, and those of Mr. E. Webb to receive the second premium.

The dsign salectad for execution, with tho motto "Laus Deo," ie a eimple composition in the Geometrical style, having double transepts, not of great projection. The clearstory has two-light windows, with transoms. The walle are to bs of brick, relisved with freestone, and the brick will show in the interior. The piers of the arcade are to be of Devon reddish granite. There is a tower at the north-west angle, having a pack-eaddle roof, with a very ornate flèche rieing from its centre. A passage to each of the vastries north and south is entered under the east window. The nave roof is hoarded in polygonal form, and divided by the principal arched ribe.

"Cui Bono," the second premiated deeign, ie a composition of Byzantine or Lombard character, in brick, the nave having a spacious clearstory with coupled windows. A hold campanile rises at the north-west angle. There ie a narthex at ths west end opening into a baptistery semi-circular on plan. The roof ie of tie-beam construction, with five arches springing from enriched colnmns, with good effect. The author is Mr. E. Webb.

"Confidance" ie a bold and eimple Early English design, with towar and spire at the south-weet angle, transepts, wide chancel aisles, and an apsidal east end. Ite author is Mr. E. H. Harhottle.

"Omnia diligentia eubjiciuntnr" ie a Ceomstrical design. The north transept ie the base of a tower eurmounted with a wood spire covered with lead. Tho area seats 800 and more, as demanded, and a west gallery is shown. This design was submitted hy Mr. Ashworth.

"Si Foitnna juvat" is conspicnous from its lofty north-weet tower having a tall spirslet at one angle, and a pyramidal roof seen over the battlemente. The style is Early Decorated. The length of the nave clearstory is relisved by two gablets, each containing two windows of increased height and nicely managed on the inside. There is a ventilating spirelet in the centre of the nave roof. A narthex extende from the tower along the west end, giving accese to the western doors. The arcadee are intended to have pillars of Devon marble. This design is by Mr. Pearson Hayward.

Pontefract.—In answsr to advertisemente there have heen sent in no fewer than fifty-nine sets (average five to nine sheets in a sat) of drawings, under various mottoes, for a new addition to the very old town-hall of this borough, and dnring the last few days the rate-paysrs, &c., have had an opportunity of viewing these ideae of architecte from all parte of the kingdom. The first premium being only 50*l.*, and the second 25*l.*, the authorities are snrprised to find snch keen competition. The vote in Council restricts the eum to 7,000*l.* as the cost of the new buildings, but eome of the designs are eo elaborate in detail that the stone front of the hall will ewallow up that amount, and make a total of nearly 20,000*l.* Indeed, out of the whole lot it would he difficult to eelect half a dozan sete which any respectable builder would undertake to build for the amonnt specified. The corporation will do well to fairly weigh the various conditions eet forth; and before deciding we hope they will take into their confidenss eome professional architect.

REVOLVING DIVISIONS OR SHUTTERS.

Probably the lsrgest movable division ever fitted up hae heen snpplied to Scotland by Salmon, Barnee, & Co., for St. Bridget'e New Roman Catholic Schoole. It ie for the purpose of screening the altar from the schoolroom, and ie worked by the patent balance-weight motion belonging to the firm, and can, by mesne of the ordinary long arm, be raised and lowered instantly. The dimensione, according to the statements which reach ne, are eo much in excess of what has hitherto heen considered practicahle in the way of revolving divisions or shutters, that the makere may he fairly congratulated on having solved, with their patent balance motion, a difficnlty which hae hitherto heen a serione one in regard to divieions of large apartments.

COMPENSATION CASE.

Mr. Under-Sheriff Burchell, at the Middlesex Sheriffs' Court, last week presided over a special jury in the case of "The Metropolitan Board of Works *v.* Thurgood," which was an appeal from an award made by Mr. Rodwell, M.P., in respect of twelve small tenements in Commercial-place, Whitechapel, required under the Artisans' Dwellings Act. The houses were in a low neighbourhood, and had been condemned. The evidence, as usual, was very conflicting as to the value of the property. The surveyors for the Board estimated the value at 1,250*l.*, and the surveyors on the other side put the value at 2,450*l.*

The amount of the award by Mr. Rodwell, M.P., was not allowed to be mentioned to the jury, and the Under-Sheriff, in smmming up, said the case was of considerable importance, because if the verdict were less than the award Mr. Thurgood would have to bear the expenses, and he (Mr. Burchell) thought that, as a member of Parliament, the sooner Mr. Grantham got the law amended the better.

The jury retired, and on their return assessed the value at 1,900*l.* The award was 2,100*l.* Mr. Grantham, for defendant, said, as the verdict was less than the awasd, he had to ask, under the Act, for 20*l.* as costs. The Under-Sheriff said he should certsinly grant the application. A verdict for 1,900*l.* was accordingly entered.

"THE USEFUL AND THE BEAUTIFUL."

Sir,—Mr. W. Cave Thomae, in the *Builder* of the 20th inet., writing on thie eubject, says,—"Why should we not be content on occasion, as Nature is, *with a little robust and useful ugliness?*" Simply hecause there is no reason why anything should he made ugly. "The elephant is not beautiful"; no, but it ie better than that, it is a noble animal. The finest and grandest works we have are as a rule the most simple,—in painting, architecture, sculpture, and engineering. A work often becomes ugly becanee the foolish designer *tries* to make it beantiful *by adding work to it.* An ugly building could often be made passable by knocking down eome of ite featuree rather than by adding more. Ae a rnle, anything ugly could have been made to look well *at the same cost* if a little taste had heen added, and if its ornamental work had all been omitted. Why is it that the back of a building is often much finer than the front? Because it has been designed for utility and without straining after effect. The exterior of Nswgate is one of the best buildinge in London. Simple and grand; how very different to the style now so much in vogns in the City! The great thing is, not, as Mr. Cave Thomas eays, "to he content with a little nglinese," hut to be particular in avoiding any one ugly point in anything. *The absence of ugliness* is the great point; it doee not matter how simple a building is (the more so the better, I say), let it be useful and well planned, simple and of *good outline*, and ths beantiful will then, and not till then, come in as an accessory.

Mr. Cave Thomae says there is "uglinese in Nature." A very ugly remark which I certainly cannot agree with. G. T.

DISTRICT MARKETS.

Sir,—I am glad to see that thie subject finds place in your columns, and, as an inhabitant of Kensington, I venture to eay that no district stande more in need of such a market than ours. Kensington is a charming place to live in, and few people willingly leave it, but it is a most expensive place, on account of the extremely high price of provisions. These are, indeed, chargad at higher rates here than in the immediate neighbonrhood of Groevsnor-square and Mayfair. I fully agree with the opinions expressad in the first letter which appeared in the *Builder* in respect to Continental markete and their advantages, and the exceesive cost of fish here; and what ie true, donbtless, of other parts of London is in its fullest force in this locality. In respect to the second letter, which I see in your issne, it does not appear that the Company, to whom the writer is the architect, pnrposes to cover the whole subject; at least in aefar ae ie indicated by its title, "The Local Meat Market." I should have prsferred to see the designation a wider one, each as, "The District Markete Company," for instance; for my idea of what is wanted in Kensington, in Chelsea, and in Bayswater, ie a dietrict market in each parish, situated probahly near ite railwaye, where not only meat, but vegetables, fruit, and flowere, fish, fodder, and other suppliee of constant consumption and convenience to the pnblic, might be found and purchased for ready money, without the bnyer having to pay moet nnjnstly for the credit wbich ie given to othere or for those who do not pay at all. I am neither a epeculator, a builder, nor an architect, and I have not a railway share; and it ie merely as an inhabitant of Kensington that I add that there are two extensive plote of ground, at prssant chiefly nntilised, hstween the Gloucester-road Station and the High-street, Kensington Station, which might, it appears to ms, either of them accommodate convsniently to the neighbourhood each a district market ae would he a great public henefit. Thsse plote helong, I believe, to the railways that join and diverge here, and the proximity of a fins pnblic market to them might be enitsble and commodious in eeveral waye, and especially for their conveyance of eupplice to it; hut enoh questione as these I leave to othere more competent to deal with them than I am, and, moreover, I would not attempt to treepass unduly on your valuable epace. Sigma.

ARCHITECTS' SPECIFICATIONS IN RELATION TO WOOD.

Sir,—The writer of the article in the *Timber Trades' Journal* under the above heading is no donht a eufferer from the wording of the epecificatione, which do obtain what their authore rsquire, viz., that all woode shall be of the hest quality only; and with this very necessary provision, any one acquainted with the timber trade of former yeare and that now in existence knowe the great difficulty thare ie of getting really sound and good quality now as compared with the former period. Thie, no donht, is the reaeon of the complaint, and the only reason which hae any value, for that of selecting sizes which can only hs obtained by sawing ie abeord. There wae a time when only 3 in. by 9 in., 3 in. by 7 in., and 3 in. by 11 in., were obtainable, but now almoet every conceivable section can be obtained direct from the timher merchant. John Geo. Carey.

LAW OF EASEMENTS: CLAIM TO LATERAL SUPPORT.

Sir,—Nothing poseihly ie more crude or imperfect than the existing law, or, more properly, want of law or legal definition in thsse caees. In fact, we have to deal with the *lex non scripta*, or unwritten law.

One of the *dicta* ie that every building is, or ehould be, capable of eelf-support, and is not entitled to "extraneone support." Another saye, if you disturh any existing eaement or support you are liable in damagee.

With all these conflicting statements, let me euggest a *viâ media*, whereby the varione intereste may be coneidered. *A priori*, whoevar disturbs the *status quô* shonld do eo at his own risk and peril, and it should be provided that a three months' notice, ae in party walle, should be given, thie notice applying equally to any external wall abutting on vacant ground or land; and any and all costs and chargee in eecuring such premieee, and making good any damage, should be at the sole cost of the building owner.

It may happen that a building is endangered, or the reverse, eo that by being properly underpinned it has a much better foundation than existed previonsly. Many of the eo-called eaements have been simply trespassee that have passed unheeded, ae where a small window hae heen formed in an external wall overlooking the ground of an adjoining owner without conent. In snch matters, where no written consent can be ehown, the contrary might be asenmed.

Under the Building Act of 1844, any one eo forming an opening improperly could, on one month's notice, be required to hrick it up,—a mattor now only to he treated ae a trespass at common law, and thus made more difficult.

Robert Lacon Sibley.

N.B.—The dafect is a want of any mode of lsgal procedure to be followed in theee matters; it is, therefore, essential this should be supplied.

"Appleton's Patent Self-Centre Rule."—The patentee hae hit npon the notion of marking and figuring his rnle in half inchss both waye from the centre, eo that on applying the centre to any given point the operator can read off right and left any nnmhar of inchee or half inches on each eide. For hanging pictures, mounting drawings, and many other operatione, it will certainly be found more handy than an ordinary two-foot rule, and as there is no reaeon why the new marking shonld make the rule any dearer, it will doubtless be largely asked for in preference when it ie known.

THE MODERN BARRACK: ITS PLANS AND CONSTRUCTION.

SIR,—May I correct an omission that seems to have occurred in all the published reports of the paper upon this subject read by Mr. Ingress Bell at the Royal Institute of Architects?

Neither in the Transactions of that body, nor in the professional papers, is any allusion made as to the authorship of the numerous designs of modern barracks exhibited at the meeting. Mr. Bell must, therefore, have failed to make it clear that I was the designer of them all, with the exception of the elevations of the Knightsbridge Barracks.

In these several works I was ably assisted by Mr. J. M. Rogers, A.R.I.B.A., and the other architectural draughtsmen of the Designing Branch, which was under my immediate supervision. I regret that I was unable to be present at the reading of the paper; I should have been able to explain some points which, by the reports, appear not to have been clearly understood.

H. C. SEDDON, Major R.E.

COMPETITIONS.

LIVERPOOL INSTITUTE SCHOOL OF ART.

SIR,—I learn (from this week's *Builder*) that no less than seventy-five sets of designs (embracing 593 drawings) have been sent in for the above building, the contemplated outlay on which is only 10,000*l.*; yielding, therefore, if executed, a commission to the profession of about 500*l.*

In the interests of the profession may I venture to ask each competitor to assist the investigations of the Competitions Committee of the Royal Institute of British Architects, by kindly informing me by letter (under his motto if he please) the actual out-of-pocket expenses incurred in preparing his design, and also, as nearly as he can, the amount of time expended on it by himself or his assistants, and his own assessment of the value of such time.

THOMAS PORTER, Hon. Sec. to the Committee.
No. 2, Westminster Chambers.

BUILDERS' AGREEMENTS.

SIR,—Will you, or any of your corresponding architects' inform me if it is not the custom for architects to draw up agreements, and have them signed and witnessed in their own offices, when relating to buildings they have in hand?

I have recently had two disputes respecting the payment by builders for their agreements and stamps (though the specification stated distinctly they were to pay), and in one case the party employed a solicitor, who stated that I, as an architect, was liable (under some Act) to a penalty of 20*l.* for preparing the agreement and charging for it, as it was an infringement on the rights of the legal profession.

Now, if this is correct, it is a serious thing for architects in small provincial towns, as most of the works are let in separate trades, and I have had work, say for a small house costing under 400*l.*, let in five separate branches,—*i.e.*, the brick-work, wood-work, slating, plumbing, plastering, and painting,—all let separately, and separate agreements signed by each trade. If it is necessary to go to a solicitor with each contractor in a case like the above, I should like to know who will pay his charges, as a proper tion would certainly object.

INQUIRER.

PARLIAMENT-STREET PAVEMENT.

SIR,—In a paragraph headed "Wood Pavement," in your number of the 20th inst., you say,—"It is expected that the works, which are being executed by the Asphaltic Wood Pavement Company, will occupy about a fortnight or three weeks." As manager of the Asphaltic Wood Pavement Company (Limited), I beg to inform you that the work in question is not being done by my Company. The difference between which, and that now being laid in Parliament-street, may be seen by any one passing through Chandos-street, Strand, which is now being paved on the Company's system.

FRED. W. SMITH, Manager.

Books.

Songs and Poems from 1819 to 1879. By J. R. PLANCHÉ. London: Chatto & Windus, 1881.

MRS. HENRY MACKARNESS, the author, herself, of a host of popular books, has collected under this title a number of her admirable father's songs and poems, not merely for the poetic genius shown in them, but as illustrative of his gentle and genial nature, which enabled him to live to the age of eighty-four without making an enemy. It is a charming little book, fully justifying this view, and more. We should have been glad, however, if it had been made to include even more of Mr. Planché's songs than it does. For example, "The Bumper of Burgundy," a song immensely popular in his time, and which, in his absence abroad, was published by Braham, as we have often heard Planché say, without the name of the author of the words. Again, one song, a powerful denunciation of evil, written for the remarkable spectacle "Babil and Bijon," and which was not sung in the piece, is alone given, though many, we think, would be glad to have the whole of the songs that were written for it. So charming are they, that Mr. Boucicault, in his little "Book of the Play," sold in the house during its performance, speaks of his own work as being simply a basket to hold Mr. Planché's flowers. Reference is made in the preface to some of his separately-published poems, and to the list given might have been added a jocose version of "The Sleeping Beauty," which was illustrated by Mr. Richard Doyle. The complete neglect which befell this was a cause of annoyance and surprise to the author, who had a fondness for it, and could never understand why it had not become popular. It would have a better chance, probably, if it were produced now. What Planché wrote twenty years ago usually reads as well now as then. Take, for example, the following lines from "A Christmas Greeting," in the volume before us, which might have been written last week, so fully does it represent the cry of the moment:—

> "The days they grow shorter and shorter,
> The town's worse than ever for smoke,
> Invention, necessity's daughter!
> How long must we blacken and choke?
> Contract with some wholesale perfumer
> To wash off the soot as it falls,
> Or let a gigantic consumer
> Be placed on the top of St. Paul's.
>
> Oh! strive by some channel to turn it,
> Ere down our throttles it rolls;
> Why can't the Gas Company burn it?
> 'Twould save them a fortune in coals.
> Much longer we ne'er can endure it,
> The smother each resident damns,
> Unless something's done to cure it,
> 'Twill cure *us* like so many hams."

This quotation must be our justification, if any be needed, for going a little out of our way to recommend the "Songs and Poems" of a dear and much regretted friend.

VARIORUM.

THE *Magazine of Art*, as bound, makes a handsome, entertaining, and instructive volume. It is equally suited to the library shelves or the drawing-room table. A capital gift-book!——"The Metropolitan Masonic Calendar and Pocket-Book, 1881," and the "Illustrated Price List of Masonic Clothing," both come to us from the indefatigable Geo. Kenning. The fact that a second edition of the Pocket-book was last year called for and absorbed shows that it needs no further recommendation.——A new edition has been issued by Messrs. Longmans of "The Elements of Mechanism," by T. M. Goodeve, M.A. It is an excellent little book of its kind. ——A new edition, also, has been published of the "Moulder and Founder's Pocket Guide," by Fred. Overman (London: Sampson Low & Co.). It is an American book, and to the present issue has been added a useful supplement on Statuary and Ornamental Moulding. —— "Stationary Engine-driving: a Practical Manual for Engineers in Charge of Engines," has been written by its author, Michael Reynolds, with an earnest desire to raise the character of engine-men in this country, and it seems well calculated to effect its purpose.——The new serial story in the *Quiver*, entitled "In Vanity and Vexation," which is already exciting interest, is from the pen of the popular author of "Lost in the Winning," a story which achieved a success a few years ago in the same magazine.——The Christmas Number of the *Pictorial World*, produced under the superintendence of Dalziel Brothers, is likely to prove an attractive one. ——A pile of children's books, magazines, and Christmas "Parts" have reached us. The *Boy's Own Paper* and the *Girl's Own Paper* both come from the *Leisure Hour* Office,—a recommendation by itself. "The Glad Time," with very good illustrations, is the "Little Folks" Annual (Cassell); "*Judy's* Annual" has some amusing sketches. "Four Flirts: their Cards, and how they Played them," by Ernest Warren, is the *Round Table* Annual. It is illustrated by Hal Ludlow, and will have many readers. "Cassell's Almanac" has, as usual, a wood engraving on every other page.

Miscellanea.

Technical Education.—The Cutlers' Company, being desirous to render further assistance in the development of a knowledge of the principles of science as applied to the materials used in the cutlery trade, have arranged for a course of lectures being delivered in the Hall of the Company during the ensuing winter season. Sir Henry Bessemer has kindly promised to commence the course, and will, on the 1st of December, read a paper "On the Manufacture and Uses of Steel, with special reference to its employment for Edge Tools." The admission will be entirely free, but by ticket, which may be obtained on application to the Hon. Secretary, addressed to the Cutlers' Hall.

London Custom House.—Messrs. Robert Boyle & Son, Holborn Viaduct, are at present ventilating this building with their patent air-pump ventilator, under the direction of her Majesty's Office of Works.

Architects in Ireland.—The *Irish Builder* is complaining sadly of the want of *esprit de corps* amongst the architects of Ireland, and writes thus:—"Here in Dublin (and indeed throughout the provinces) we have a class of architects who, with a few, a very few, honourable exceptions, are utterly unworthy of their profession, their country, or of any journalistic representation. It is with a sense of almost humiliation we write these words, for the men we speak of have been tried in every way, and have been found wanting. In this city, we have for some years past the semblance or make-believe of an Irish Institute of Architects; but we would be false to our principles and teachings if we would longer pretend there was any real Institute of Irish Architects in existence. The Central, the London, Glasgow, Edinburgh, Newcastle, Manchester, Birmingham, and some other architectural societies live, and work, and thus afford evidence of their vitality and usefulness, but the so-called Irish Institute exists only by courtesy upon paper or upon a zinc plate. It has done nothing, or next to nothing, for some years past, and from present appearances it intends to do nothing. It has no sessions or meetings, no papers are read, and once or twice, perhaps, in the year a faint echo is heard, as if some voice was crying out from the grave. On these occasions there is a sort of resurrection, at which about half a dozen members assist. The appearance of a new Viceroy in Dublin, or some event which calls forth an address or deputation from some other professions, calls also forth an apparition on the part of the dead or dormant Irish Institute,—and then come night and sleep again."

Plumbers Again.—Last week the roof of the Shireball and Guildhall, Shrewsbury, was discovered to be burning. The fire is supposed to have been caused by plumbers who were working there on Thursday. By two o'clock the fire was got under by the local brigades, assisted by the Wem and Oswestry engines, and the railway engine. Fortunately the whole of the valuable paintings were saved, and as the strong rooms, both county and borough, are intact, the contents are supposed to be uninjured. The town clerk, Mr. E. C. Peele, and the clerk of the peace to the county, Mr. de Courcy Peele, will be great sufferers, as they carried on the business of solicitors, and the whole range of their offices, which were at the top of the building, are destroyed. The whole of the roof and floor under it are totally destroyed, with the exception of the strong rooms. The hall was commenced in the year 1834, and finished in 1837. The erection cost 12,000*l.* The building is insured heavily in the Salop Fire Office.

The Tay Bridge.—The *Scotsman* states that the plan adopted for the restoration of the Tay Bridge involves the complete abandonment and removal of the existing viaduct. The structure to be substituted for the abandoned bridge will be erected on a site in the immediate vicinity, but a little higher up the river, and will be of such breadth as to carry a double line of rails. It is not yet finally settled whether the piers of the bridge shall be of iron or brick; but if the former material be decided on, it will be in the form of malleable iron, security being further provided for by a largely-increased width of foundations. The cost of the works will be very considerably greater than was anticipated in the application to Parliament made last session.

Galvanised Corrugated Iron Roofing.—A correspondent asks us if roofing of this description is rendered more durable by painting. In a pure atmosphere galvanised corrugated iron will prove durable for a considerable time, but in London our belief is that it is necessary to paint such roofs. Messrs. Brahy & Co., who have had a long experience, agree in this. They add, "In the case of zinc, however, which is a little more costly, painting is altogether unnecessary, and a roof covered properly with this material will last as long as three or four iron roofs."

The Royal Historical Society.—In this Society's Rooms, 22, Albemarle-street, on the 18th inst., a considerable number of members assembled to do honour to Lord Aberdare, the president, by presenting to his lordship a terra-cotta bust of himself, from the studio of Mr. Henry Harvey, sculptor, a Fellow of the Society. Dr. Zerffi made the presentation. Lord Aberdare, in the course of his acknowledgment, spoke of the artist as a young man entirely devoted to his art, and with good ideas of what art should be.

Memorial Hall, Dover.—The Memorial Hall and Dover Tabernacle was opened on the 16th inst. The building has been erected for the requirements of a congregation gathered together by the labours of the Rev. J. F. Frewin, and consists of a hall capable of accommodating 500 persons (exclusive of galleries, for which provision has been made), school-rooms for 300 children, double vestries, and offices. The schools are placed in front on the first and second floors; the ground-floor being occupied by the entrance-corridor to the hall, staircase, and kitchen. The buildings are Early English in character. The front is built of red brick with Bath stone dressings, and the roofs are covered with Bangor slates. The heating of the hall has been accomplished by a Porritt's stove. The contract was undertaken for about 1,860*l.*, and carried out by Mr. Bromley, of Dover; Mr. Andrew T. Taylor, of London, being the architect.

Re-valuation of Fulham.—Mr. T. A. Marsh, clerk to the Assessment Committee, has favoured us (*Metropolitan*) with some particulars as to the recent revaluation of Fulham Union. We learn that an increase has taken place in the gross value of 118,328*l.* over the lists previously in force, and of 99,855*l.* in the rateable value. The total gross value was 665,521*l.*, and the rateable value 545,854*l.* Hammersmith parish has increased in gross value by 47,127*l.*, and in rateable value by 40,237*l.*, the total gross value for the parish being 231,597*l.*, and rateable value 190,136*l.* Fulham parish had increased in value by 71,200*l.* gross, and 59,608*l.* rateable, the totals for the parish being, gross, 433,923*l.*, and rateable, 355,718*l.*

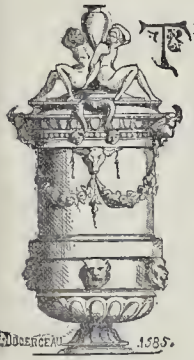
CONTENTS.

*Dr. Schliemann's New Work.**



THIS book is unique. The expression is bold, but it is fully justified by the work. We live in an age of discovery. The very air is full of the awakened voices of the long silent past. A new literature has been recovered in the clay tablets of Assyria; and we speak of the libraries of Assyrian kings with almost as much certitude as of the contents of the British Museum. The products of long-forgotten art have been unearthed, at Mycenæ, in Cyprus, at Ephesus, in Magna Grecia, in Asia Minor, showing close resemblance to many of the objects with the representations of which the present volume is so rich. Again, we have had discussions on ancient history and poetry, and have been taught to live over again the life of the classic past, and to catch the echo of the music of Homeric times. Yet again, we have had autobiographic sketches, and stories of the triumphs of genius and perseverence,—tales of men who, from the humblest origin, have won their way to national or even to European power, and enriched future generations by the heritage of noble examples. Such names have occurred again and again in English history, from the familiar story of Sir Richard Whittington, to the later tales of George Stephenson and Sir Joseph Whitworth.

But in Dr. Schliemann's last work we have all these elements of interest combined. We have, in simple language not unworthy of the pen of Bunyan or of De Foe, the story of the son of the Protestant clergyman of the little town of Neu-Buckow, in Mecklenburg-Schwerin, who was born on the 6th of January, 1822, and whose natural disposition for the mysterious and the marvellous was stimulated to a passion by the wonders of the locality in which he lived. The garden of the parsonage was haunted by the ghost of Ernest Schliemann's predecessor. Behind the garden was a pond, out of which a maiden was believed to rise at midnight, holding a silver bowl. The air of the place was redolent of legend. A robber knight of old had buried his beloved child in the vicinity in a golden cradle; and buried treasures, fearful spectres, and underground passages, were the food of the imagination of the child.

The pastor himself, though neither a scholar nor an archæologist, had a passion for ancient history. He told his son, with warm enthusiasm, of the tragic fate of Herculaneum and of Pompeii, and of the wonders which were brought to light in those volcanic regions by the spade and the pick. He also repeated to the boy "the tale of Troy Divine"; the great deeds of the Homeric heroes; and of the ten years of struggle for one fair and faithless face. When nearly eight years old, Henry Schliemann received as a Christmas gift a volume of Jerrer's "Universal History," with an engraving representing the flight of Æneas from Troy. To the boy the picture was direct evidence. "Jerrer," he cried to his father, "must have seen Troy, or he could not thus have represented it." Not finding his father convinced by the argument, the lad came to the resolve that one day he would excavate Troy.

It may not unfrequently occur that high purposes are thus formed in youthful imaginations. But how often does it happen that they are carried out in after-life? Schliemann did, indeed, fulfil this resolve made when he was eight years old. But one feature of the romance was destroyed. The little maiden, Minnie, who was to be the helper and the reward of his toil, was married just one month before the lover of her childhood found himself far enough on in the battle of life to ask her hand in marriage. The blow was a severe one, but Schliemann found consolation. His companion in the Troad was his wife, an Athenian, who has borne him a son, Agamemnon, and a daughter, Andromache.

The death of Henry Schliemann's mother, when the boy was nine years old, was the beginning of misfortunes. It was followed by some change in worldly estate or position, of which we are only told the result. At the age of fourteen our author was bound apprentice in the little grocer's shop of Ernest Ludwig Holtz, in the small town of Furstenberg, in Mecklenburg-Strelitz. Here he came in contact only with the lowest classes of society. His occupation was the retailing of herrings, butter, potato-whiskey, milk, salt, coffee, oil, sugar, and candles; the grinding of potatoes for the still, the sweeping of the shop, and the like employments. He had been taught Latin, first by his father, and afterwards at the Gymnasium and the Realschule at Neu-Strelitz, but he had not begun Greek. A drunken miller who came into the shop recited about a hundred lines of Homer to the boy, and the melodious sound of the words, unknown as was their sense, made such an impression on him that he bitterly wept his unhappy fate. The three glasses of whiskey, bought with the few pence that made the whole fortune of Henry Schliemann at this time, by which he induced the miller three times to repeat the "divine verses," were bestowed with a result not often to be traced to the product of the still.

From this hard bondage, in consequence of an accident which must have seemed the culmination of his misfortunes, the boy escaped to sea. Always poor, he had never been so utterly destitute as at that moment. He had to sell his only coat to buy a blanket. Fate still frowned. On the night of the 11-12th of December, 1841, he was shipwrecked in a fearful storm off the island of Texel. "I felt," he says, "as if on that bank a voice whispered to me that the tide in my earthly affairs had come, and that I had to take it at the flood." On the following day his little box, containing a few shirts and stockings, and his pocket-book with letters of recommendation, was picked up, the only salvage from the wreck, by reason of which the boy earned from his companions the name of "Jonah." He reached Amsterdam without a coat, suffering bitterly from the cold, with the idea of enlisting for a soldier. His means being utterly exhausted, he feigned illness,—little room, we should fancy, for feigning,—and was taken into the hospital at Amsterdam. While there, the account of his misfortunes excited sympathy; a subscription was set on foot for him, which produced 20*l.*, and he obtained a situation in a merchant's office.

There his work consisted in carrying letters to and from the post-office, and in attending to the stamping and the cashing of bills of exchange. Thus, sure of food, he set himself to educate himself. First he took lessons from a famous caligraphist, and learned to write legibly. Then he began to study the English language. His salary amounted to 32*l.* per year, half of which he spent on his studies. His breakfast consisted of rye-meal porridge, and his dinner never cost more than twopence. His lodging, which cost eight francs a month, was a garret without a fire, where he shivered in winter, and was parched with heat in the summer. His method of education was original. His plan was to read aloud, without translating, and to write essays on subjects of interest, which he corrected under the supervision of a teacher, and then learned by heart. He went twice every Sunday to the English Church, and repeated to himself in a low voice every word of the clergyman's sermons. As he went on his errands he read and repeated to himself, and then committed to memory, the whole of the "Vicar of Wakefield," as well as of "Ivanhoe." By dint of labour like this he acquired in half a year what he calls a thorough knowledge of the English language. It may be added that Dr. Schliemann's pronunciation is still that of a foreigner and of a German; but that if the work before us proceeds, as we believe is the case, from his own unaided pen, he is justified in the previous remark.

The next six months were devoted in the same way to the acquisition of French. His choice of books was happy,—"Les Aventures de Télémaque" and "Paul et Virginie." "This unremitting study had in the course of a single year strengthened my memory to such a degree that the study of Dutch, Spanish, Italian, and Portu-

* Ilios: The City and Country of the Trojans. The results of researches and discoveries on the site of Troy and throughout the Troad in the years 1871, '72, '73, '78, '79; including an Autobiography of the Author. By Dr. Henry Schliemann, F.S.A., F.R.I.B.A. With maps, plans, and about 1,800 illustrations. London: Murray. 1880.

gnese sppeared very essy; and it did not take me more than six weeks to write and speak each of those languages fluently." Such is his own account.

In 1844 he obtained a situstion as correspondent snd bookkeeper in the office of Messrs. B. H. Schröder & Co., of Amsterdam, at a salary of 48l., which wss soon raised to 80l. Inspired partly hy the desire to make himself of more service to his employers, he now hegan the study of Russisn, and hired a poor Jew, at four francs a week, to come every evening for two hours to listen to Russian recitstions, of which he did not understand a syllshle. These nightly recitations, delivered in a loud voice, annoyed the neighbouring tenants; and while studying the Russian language Schliemsnn was twice obliged to find himself new lodgings.

In Jsnnsry, 1846, his principals sent him as their agent to St. Petersburg. There he soon rendered himself so indispensable to his employers as to find himself practically independent. Then he wrote to ask for the hand of Minnie; and the disappointment which he experienced rendered him for some time nnfit for any occnpation, and sick in hed. From his recovery he pressed forward with seven-lesgued strides to fortune. In 1847 he was inscribed in the guild as a wholesale merchant. It is characteristic of a man who could make new friends while remaining faithful to his old ones that for eleven yesrs he kept the agency of Messrs. Schröder & Co. Thoronghly understanding indigo, he confined his operations to that commodity. At the end of 1852 he estshlished a hranch house at Moscow for dealing in indigo; and, as he was always overwhelmed with work at St. Petersburg, it was not until 1854 that he found it possible to acqnire the Swedish and Polish languages.

For the remarkahle escape which he had in this yesr from the loss of his entire property hy fire, we must refer to his autohiography. In 1856 he found himself unable to restrain his desire to learn Greek, and at once set vigorously to work, for a couple of years, during which he read almost all the classical authors cursorily, and the "Iliad" and the "Odyssey" several times. In 1858 he renewed the study of Latin, and, further, arrived at the nnusual conclusion, "I thought I had money enough!" He then travelled in Sweden, Denmark, Germany, Italy, and Egypt; sailed np the Nile to the second cataract, learning Arabic hy the way; travelled across the desert from Cairo to Jerusalem; traversed Syria; visited Smyrna, the Cyclades, and Athens; and was on the point, in the summer of 1859, of visiting the Ithaca, when he was seized with fever. Business affairs then again claimed his attention, nntil, at the end of 1863, he found himself in possession of snch a fortune as his ambition had never ventured to aspire to. His old dream of Troy then recurred to his memory. But, hefore settling himself down to archæology, he thought hest to see a little more of the world. So he started in April, 1864, for Tunis, to visit the ruins of Carthage. He then went, *vid* Egypt, to India; traversed that country from the Himalayas to Ceylon; went to China, to Java, to Japan; and so to San Francisco. Thence, through Nicaragua, the eastern United States, Havannah, and Mexico, he made his way to Paris, where, in the spring of 1866, he settled down to study archæology henceforth with no other interruptions than short trips to America.

At last, in April, 1868, Henry Schliemann was able to realise the dream of his life, and to visit at leisure the scenes of those events which had always had such an intense interest for him, and the country of the heroes whose adventures had delighted and comforted his childhood. He started, hy way of Rome and Naples, for Corfu, Cephalonia, and Ithaca. This last-named island he csrefully examined, hut the only excavations he made there were in the so-called Castle of Ulysses, on the top of Mount Aetos. He afterwards visited the Peloponnesus, and examined the ruins of Mycenæ. Thence he went to Athens, and started from the Piræus for the Dardanelles, whence he proceeded to the village of Bonnarhashi, at the southern extremity of the plains of Troy. This spot had, in recent times, heen regarded as the Homeric Ilium, on the ground of the asserted existence of two springs at the foot of the village, which were taken to be the two, one of cold and one of warm water, mentioned by Homer. But it turned out that instead of two there are hetween thirty and forty springs, all of a nniform temperature of about 62° Fahrenheit. The Turks call the plsce Kirk-Gios; that is to ssy, forty eyes or springs. The spot, moreover, is eight miles as the crow flies from the Hellespont,—more than double the distance of Troy, as collected from the "Iliad." Bonnarhashi heing thus negatived, Schliemann examined successively all the heights to the right snd left of the Trojan plsin, and was at last strnck hy the imposing position snd natural fortifications of the hill called Hissarlik, which formed the northwestern corner of Novum Ilium, at an elevation of 162 ft. ahove the level of the sea. Here he decided to excavate; hut it was not till April, 1870, that he was able to return to the spot, and so commence a preliminary excavstion. Sinking through a mass of *débris*, he struck, at a depth of 16 ft. helow the surface, a wall of huge stones, 6 ft. 6 in. thick, which he wss subsequently enahled to identify as part of a tower of the Macedonisn period.

The requisite firman from the Porte was not ohtained until Septemher, 1871, and on the 11th of the following October the work was at length commenced. Eighty lahourers were employed, and the excavation was carried on till the 24th of Novemher, when it hecame necessary to snspend it for the winter. Returning to Hissarlik at the end of Msrch, 1872, Schliemann resnmed the work with 100 lahourers,—a number which he soon increased to 130, and then to 150. He was provided with the hest English wheelharrows, pickaxes, and spades, and paid his labourers each ahout 1s. 6d. per day. On the top of the hill he erected a wooden house with three rooms, a magazine, and a kitchen, and covered the huildings with waterproof felt to protect them from the rain.

For the details of the work of 1872, which was carried on till the 14th of August, we must refer to the volnme itself. On the 1st of February, 1873, the excavations were resnmed, in the teeth of an icy wind. It was in the course of this year that Dr. Schliemann discovered that the Hellenic Ilium, or *Novum Ilium*, of which he found such interesting memorials, extended over a much larger spsce than that which had been covered hy the preceding and more ancient cities. It wss in this year that the important discovery of the treasure was made. Many of the objects then found were exhihited at South Kensington, and commented on by us at the time. The largest silver vase alone contained nearly 9,000 objects of gold. The excavations were discontinned on the 17th of June, 1873.

In the heginning of 1874 an account, in German, was published at Leipsic, of the discoveries at Troy; and a French translation appeared at the same time. An English translation was pnblished hy Mr. Murray in Novemher, 1874, edited hy Mr. Philip Smith, under the title of "Troy and its Remains." In this work the hurnt city, which Dr. Schliemann regards as the Ilium of Homer, was reckoned as the second from the virgin soil. It now appears to be the third, ont of a series of seven successive periods of huilding.

In Fehrnary, 1874, Dr. Schliemann commenced the exploration of Mycenæ hy sinking thirty-four shafts in its Acropolis. The pnhlication of the work on Mycenæ in English, German, and French, occupied the whole of 1877, and the spring and summer of 1878; and an examination of Ithaca was then made. At the end of September, in this year, excavations were recommenced, on a large scale, at Troy, and csrried on until they were stopped hy the winter rains on the 26th of November. On the 1st of March, 1879, the work was resumed, and in company with Professor Virchow, of Berlin, and M. Emile Burnouf, of Paris, Dr. Schliemann made a careful exploration of the Troad. The pnblication of the large and heantiful volume hefore us, with its numerous illustrations (all referred to in the text), shows that no time for repose has been allowed hy the author from either his engineering or his literary work.

Thus far we have derived our information from the introduction to the hook. There is a preface, hy Professor Virchow, preceding the introduction. Then follows the main hody of the work, divided into twelve chapters. Of these, the first deals with the country of the Trojans. The second is on the ethnography of the Trojans; their several dominions in the Troas; and the topography of Troy. The third is on the history of Troy; the fourth on the true site of Homer's Ilium. Each of the five succeeding chapters is devoted to one of the pre-historic cities on the site investigated. Of these, the third, or hurnt city, is identified hy Dr. Schliemann with the Troy of the "Iliad." The sixth city, most prohsbly a Lydian settlement, and the seventh city, the Greek Ilium, or Novum Ilium, occupy a chapter apiece; and the twelfth chapter deals with the conical mounds in the Troad, called the Heroic Tumuli. This part of the work occupies 678 psges. It is followed hy an appendix, and a copious and well-arranged index, hringing the volume np to 800 pages. There are nine sepsrate papers in the appendix, hy Professor Virchow, Professor A. H. Sayce, Consul Calvert, and other writers familiar with the snhjects. One of these, a short article, hy Mr. A. J. Duffield, on the "Lost Art of Hardening Copper," is of interest, as giving reason for the opinion that it is to an admixture of rhodium or other metals of the platinum group that the hard quslity of ancient tools and weapons is to he attrihuted. A cstalogne of the plants hitherto known in the Troad adds to the information so copiously sfforded hy the volume.

We have passed over the details of each engineering campaign, on the ground that it would he more instructive to the reader to devote such space as we could command to a hird's-eye view of the results of this costly and adventurous work, arranged according to the chronological, or at least the successive, order of the seven cities, of which the remains have now heen exhumed.

The hill of Hissrlik, rising, as hefore mentioned, to a height of 162 ft. above the level of the Mediterranean, is situsted ahout three English miles to the south of a point on the cosst of the Hellespont, marked hy a tumulus, which hears the name of the tomh of Ajax. About the same distance to the west of Hissarlik is the shore of the Ægean Sea. The hill is the hesd of a low range of hilly country, trending to the south-west; at the foot of which lies the bed of the old Scamander, into which the Thymbrius falls, at ahout five miles to the south of Hissarlik. The Simois runs from east to west, nearly parallel with the shore of the Hellespont. It falls into a marsh to the north of Hissarlik, which drains into the Scsmander. The Plain of Troy stretches from the course of the old Scamander to that of the new river of the same name. Its width of nearly a mile expands into an area of a mile and a half wide at the foot of the hill of Hissarlik, sffording a sort of amphitheatre, well suited for a field of hattle. Besika Bay, of some repute of late, is on the coast of the Ægean Sea, ahout four miles to the south of the parallel of Ilium.

The hill of Hisarlik is covered with the *débris* of snccessive cities, to the depth of 52 ft. 6 in. The top of the native rock is now 59 ft. 6 in. above the plain at its hase, or 109 ft. 6 in. above the level of the sea. The stratum of made earth and rubbish forming the *débris* of the first city lies to a depth of 7 ft. 6 in. on the rock, or at a depth of from 45 ft. to 52 ft. 6 in. below the surface of the soil.

The remains of all the prehistoric cities, as has heen ascertained by twenty shafts sunk over the area of Novum Ilium, are limited to the precincts of the hill which formed the acropolis of this latest and largest city. The earliest city does not give any signs of having heen destroyed by fire. Nor have any external walls heen found which could he properly attrihuted to the earliest date. The pottery of this city is of a special type, principally, though not altogether, made without the nse of the potter's wheel. A lustrous hlack snrface has been given to many of the vessels, and linear patterns, incised in the clay and filled with white chalk, are used for decoration. Vessels with three feet are found, and a lustrous red cup, with one handle, is figured; it stands on a foot. But the great majority of the vases of this date are round at the bottom, so as to he unfit to stand on a hoard or level surface. They are also generally furnished with vertical tnbular holes, made in excrescences at the sides of the vessel. The application of the microscope to some vegetahle matter remaining in some of these holes shows that they served for the passage of linen cords, by means of which the vessel was snspended. This may often he the case with such vsses as are called by the name of *Aryballos*, used for drawing water from a well. But the general prevalence of the arrangement indicates that the vases must always have heen snspended when full, a fact which leads to the idea that such a method of disposing of them must have heen in use before the introduction of tables, or even of shelves. Querns, pestles, and grinding-implements of trachyte, hasalt, and

compact limestone; axes of jade and diorite; single and double edged saws of flint; arrow-heads of copper, and moulds of mica slate for casting them; pins, punches, and various ornaments of copper; knives of copper, one of which is gilt; pins, awls, and needles of bone and of ivory, and knuckle-bones, or *astragali*, used for a well-known game, show that a state of civilisation far from being despicable had been attained by the builders of the earliest town reared on the site of Troy.

The second city, of which the *débris* forms a stratum some 12 ft. thick, was inhabited, as is proved both by architectural remains and by pottery, by a very different race of people from the builders of the first. These second settlers built both their city walls and those of some of their houses of large stones, while their predecessors laid their foundations, composed of small uncut stones joined together with earth, on the top of about 8 in. of black earth that covered the surface of the rock. Cakes of clay were also used, in order to level the ground and serve as a sort of packing for the huge stone blocks. Some of the houses in this second city have evidently been destroyed by fire. A female skeleton, tolerably well preserved, was found in the ruins of one of these burnt houses; and ringe of gold wire and a pin of electrum were found near the remains. The skull is brachycephalic, and the jaw is decidedly prognathous. Vases with what Dr. Schleimann calls an owl's face and female attributes, but on which Professor Virchow, like ourselves, rather observes a rude indication of a human face, here occur. Handles are given to the vases; and tripod pots on round rests, such as are now in use, are found, instead of the vertical tubular holes of the earlier pottery. Wheel-made plates abound, and a curious form of drinking-horn, with two large handles, also makes its appearance.

In the third city, the remains of which form a stratum of 10 ft. thick, slightly baked bricks appear as building materials. A minute description is given of the structural remains of this third city. It is evident that it was destroyed by fire, and it was from its ruins that the great treasure of golden, silver, and electrum vases and other objects was recovered. From the bones found, it is evident that, with the exception of the household cat, all the domestic animals now known were kept by the inhabitants.

Curious figures of terra cotta, supposed to be idols or amulets, abound in these ruins. A very archaic figure of lead, with the legs joined like the pedestal of a Hermes, has also been figured. The vases are often of large bold form, furnished not only with handles, but also with a sort of horns, or ears, probably of a symbolical nature. The Svastica, or gammated cross, is found as a decoration, and the subject is treated at length. Crown-shaped covers to vases occur; and rude conventional imitations of animal forms are not unusual for the vessels. Stone axes and hammers, and flint saws, still were used, as well as copper shields, cauldrons, and vases. Battle-axes and lance-heads of bronze, and two-edged bronze daggers, are found; but it is an extraordinary fact, and one that proves the pre-Homeric date of this third city, that not a single sword has been discovered in its ruins. The splendid treasure here found is described at length. The skulls of two warriors are figured. They had helmets on their heads, but it is not said if they were similar. They were probably too much decayed to show. As to the skulls themselves, they are of two very different types, one of them being much flatter than the other, as well as much more prognathous, or prominent in jaw. A third skull, that of a girl, approaches a Greek type.

The inhabitants of the fourth city, of which the ruins occupy a depth of 10 ft., were of a lower order of civilisation than those of the third. The pottery is coarser and of a ruder fabric, although the same general forms were in use. "The masses of shells and cockles accumulated in the *débris* of the houses are so stupendous that they baffle all description. . . . . A people which left all their kitchen refuse on the floors of their rooms must have lived in a very low social condition."

Above the stratum of ruins of the fourth city is a layer of *débris* of about 6 ft. thick, evidently consisting of the remains of houses built of wood and clay. The rude stone hammers and axes, so common in the fourth city, are now no longer found. The patterns of pottery manifest a general decline. The mode of life was changed; for the kitchen remains were no longer suffered to accumulate in the houses. Knives and axes of bronze are like those found in the third city, except that the latter are shorter, rarely exceeding 6 in. in length. Needles of bone occur, but are not plentiful.

Above the stratum of ruins of the fifth prehistoric city, and just below the ruins of Novum Ilium, is found a vast quantity of very curious pottery, partly hand-made, partly wheel-made, so utterly different from the pottery of the preceding cities, as well as from that of Novum Ilium, that the explorer hesitates whether to refer it to historic or to prehistoric times. From the resemblance which it bears to the hand-made vases found in Italy, and called either Arobaic Etruscan or pre-Etruscan, Dr. Schliemann thinks that an indication of Lydian origin is afforded; and he calls this sixth settlement on the hill of Hissarlik the Lydian city.

With the last remains,—those of Novum Ilium,—we come into historic time. In B.C. 480, we are told by Herodotus, Xerxes, in his expedition to Greece, went to sacrifice in the temple of the Ilian Athene. For the account of this city, its noble relics, and its Greek inscriptions we must refer the reader to the book. It is one of those volumes of which it is impossible to give an abstract, within any reasonable length, because it is so full of new and highly suggestive matter. Our object has been rather to indicate the origin of the research, the method employed, and the general outcome of the whole, than to attempt a *précis* of a work so full of luminous and novel detail. We shall be content if we have awakened in our readers that curiosity which will allow them no rest until they have obtained the book. We can only now echo the closing words of Professor Virchow,—"Thrice happy the man to whose lot has fallen to realise in his maturity of manhood the dreams of childhood, and to unveil the Burnt City. Whatever may be the acknowledgment of contemporaries, no one will be able to rob him of the consciousness that he has solved the great problem of thousands of years. . . . May the work which he has terminated become to many thousands a source of enjoyment and instruction, as it will be to himself an everlasting glory."

We have only to add that publisher and printer are fully entitled to a share in the gratitude of the public for the production of this splendid and, in the best sense of the word, thorough work.

A FRENCH TREATISE ON WARMING AND VENTILATION.

THIS is a very formidable volume.* It is a treatise aiming at a thoroughly scientific treatment of the subject of warming and ventilating inhabited buildings; not dealing only with the various methods which have been employed for warming and ventilation, but starting from first principles,—from the consideration of the movement of air, and the method of formation and communication of heat,—and reducing the facts connected with these subjects to formulæ and diagrams. According to the taste for regularity of literary arrangement by which the French are so much influenced, we have under almost each heading the formal division of the subject under the several classifications of "Formules théoriques," "Conséquences pratiques," and "Tableaux graphiques," in which latter the "Conséquences pratiques" are reduced to diagrams, the results of which are supposed to be appreciable at a glance. In some cases the intermediate steps are omitted and we go at once from "Formules théoriques" to "Applications"; but the same rigidly logical method is adhered to throughout; and we are not allowed a section of a grate or a ventilating apparatus until we are supposed to have swallowed a sufficient number of formulæ to be able instinctively, almost, to estimate the capacities and incapacities of each form of mechanism in each material.

In this country we are apt to make too light of mere theory in dealing with practical matters of this kind; in French treatises such as this we find a tendency to overload the consideration of the subject with theory. No one in search of a practical solution of the problems of efficient warming and ventilation would be very likely to spend his time in going through the pages on pages of figures and formulæ here contained; nor do we feel by any means sure that he would be much nearer certainty in attaining his ultimate object by so doing. It is no more than mere common-sense to bestow adequate consideration upon the methods of radiation of heat, the conductivity of various substances, or the phenomena of the movement of air under various circumstances, before attempting to gain a satisfactory method of heating or of ventilation. But we question very much whether the attempt to reduce these phenomena to the strict minuteness of mathematical formulæ and of graphic representation in diagrams is not a delusion, calculated rather to waste time than to insure satisfaction. Supposing, for the sake of argument, that all the formulæ and conclusions are correct deductions from experimental investigation, the very experiments from which they are deduced are liable to so much unaccountable and unestimated variation of conditions that, unless they are the average of an immense number of experiments, we should in any case be sceptical as to their absolute accuracy. Granting this, however, it is literally impossible to insure precisely the same conditions for the practical application of the formula. Heat and the movement of air are phenomena so little amenable to management and discipline beyond a certain point, that there must always be a large margin allowed for any calculations as to the conditions for producing a certain definite distribution of heat or a certain movement and replacement of air; and even to have all mathematical expressions of the flow and movement of air at one's fingers' ends would not preserve us from the complications arising from quite unforeseen and uncontrollable fluctuations in the conditions under which we had to realise one result. The general knowledge, for example, that the flow of air in a tubular inlet must be retarded by the existence of a right-angle or any other decided angle in the conveying tube, is sufficient in general terms for all practical purposes; nothing is really gained by reducing it to a precise mathematical statement according to accepted data; we can never be sure that the statement will be absolutely correct for any length of time. To calculate precisely the movements of so variable a body as air in this way is something like calculating the exact form and velocity which a breaking wave must take from data of the density of water, depth near the breaking-line, nature of the beach, and strength of the wind; we might do this theoretically, but practically we know that the wind force is continually varying, and that the movement of the wave is liable to be influenced in a hundred different ways by the operation of other disturbances of the water in its vicinity. Most of what is given by these "Formules théoriques" can be deduced, as far as it is really practically applicable, by observation, without halting halfway to fix the observation in figures and diagrams. These latter form, no doubt, a language in which to state a theory if accuracy of expression is specially desired, and they form, when founded on a great number of experiments, a convenient expression of the total results, and as such we leave them to the study of the reader in this case; but we much doubt whether any one will ever either warm or ventilate a house by mathematical formulæ and with mathematical certainty of result, unless we were to have separate formulæ and separate appliances for every change of heat and barometrical pressure, not to mention the thousand and one variations in regard to material, aspect, length of conducting passage, and size of apartments, &c. &c., in which each habitation has its own idiosyncrasies.

It would in any case carry us quite beyond our limits to go into the theories and formulæ stated in these pages. It will be more to the purpose here to notice some of the points in the practical part of the treatise, where they seem to suggest improvements on our usual practice in this country. One of the very first things we come to in the chapter on construction of fireplaces is in regard to the section of flue to be adopted. We are reminded here of the curiously unreasonable form of rectangular oblong which we habitually adopt, and of which the only possible recommendation is that it is more convenient to the bricklayers than others, except the 9-in. square, which is supposed to be too small, and the 14-in. square, which is for most cases too large. As a matter of fact, we believe the area of the 9-in. square flue would be sufficient for most house-fires, and that the 14-in. by 9 in. is often indirectly the cause of smoking, from its being larger than necessary, and larger than can be easily warmed and supplied with up-

a

current by the fire. But our French authority never thinks of a flue with square angles. A square flue with the angles rounded he will accept, or a circular flue, or an oval flue; but the flue with angles to catch and collect the soot is not in his books at all. There can be no doubt that for keeping a flue clean, and promoting a regular current or draught in it, there can be no plan so good as the circular one, which, however, is only now and then applied in England, in special cases. Circular it should be, with smooth sides of tile, so as to give as little hold as possible to the soot on its surface, and, at the same time, present a surface which the cleaning brush will easily operate upon with a complete sweep, instead of leaving angles where the soot lodges, and half escapes the brush. The "tallboys" with which it is proposed to crown the chimneys for better draught, do not present, in the illustrations given, any improvement on the usual hideousness of this type of article in England. Two or three of the more practical English contrivances against down-draught in windy weather are figured for the benefit of French readers.

In the following chapter on the principal systems of French constructors, it is noticeable that one of the marked specialties of the Galton stove in England, the upcast flue for warm air carried up the middle of the smoke-flue and receiving heat from the smoke, seems to have been adopted in more than one form in France. It occurs in Peclet's fireplace in very nearly the same form, and in the "Cheminée Cordier" the idea is carried further, a number of small tubes in the flue being substituted for the one large one. This is, of course, better in the way of drawing heat from the smoke-flue; at the same time it is more complicated and expensive, with perhaps not a compensating degree of advantage. The Cordier fireplace is unlike anything in use in this country, as far as we have observed; its special feature, besides the tubes in the flue above mentioned, consists in a kind of grating of hollow tubes leaning slightly forward over the fire; between these tubes the smoke escapes into the flue, while the greater part of the heat which in the ordinary fireplace escapes up the chimney is utilised in communicating heat to these hollow tubes or bars, and consequently to the air in them, which then passes up into a larger main tube running across the top of the apparatus and thence through openings into the room, at what point the diagram does not clearly show: indeed, we may say that many of the diagrams are very poor in regard both to style and minuteness of illustration, and in this respect quite out of keeping with the size and intended importance of the book. The framework of tubes, it may be observed, is hinged at the foot so as to be thrown back against the back of the fireplace-opening for better convenience in cleaning it and the grate. As a contrivance for catching surplus heat on its way into the chimney, provided, of course, the tubes are never allowed to become so heated as to burn the air, this seems a very ingenious and apparently efficient device, and is worth attention in this country. The "Cheminée Laury" is another modification of the same idea as the "Cordier"; instead of the hollow bars there is, arising from the back of the fire and partly overhanging it, a series of console-shaped pieces of metal with their edges towards the room. These both radiate heat into the room and also communicate warmth to the air in a tube, which, as in the Cordier, passes across the top of the fireplace and discharges warmed air into the room on either side of the fireplace and about the height of the mantelpiece. The "Cheminée Joly" has an iron shell, forming the apparent back and side of the fireplace, with an undulating face towards the fire and projecting laminæ in the rear; behind it is an air space, into which these laminæ project, and where the air is warmed and subsequently admitted into the room. This is, of course, the same principle as the Galton stove, only without the fireclay and with some difference in detail. At the close of this chapter, attention is drawn to a matter often, we might say generally, overlooked, viz.:—the difference between the requirements of a fireplace in cold and comparatively warm weather. If the chimney orifice is suitable for a good draught in cold weather and with large fires, then to keep up the same draught in warm weather we must keep up a larger fire than we require. To avoid this, means of altering the size of the opening from the fire should always be provided, and, moreover (a point often overlooked), should be contrived so as to be easily manageable from the front of the fireplace.

A chapter follows on foreign fireplaces, in which England occupies decidedly the largest place. The Lloyd, Sylvester, and Boyd grates are described and illustrated: the latter seems to be approved of as simple and effective; but while commended for the avoidance of burning the air by too hot surfaces, it is added that the fire-brick surfaces transmit much less heat than iron ones, and that the surface in contact with the air to be warmed must be considerably augmented in order to get the same amount of heat as in the metal-lined fireplace. This is true, but M. Planat seems to forget the compensating advantage of fire-brick in retaining the heat so much longer and giving it out so much more equably than iron, so that the fire requires less attention and to a great extent retains the same heating power for a long time after the fire itself has run low. It is more slow to heat, but more slow to cool, and therefore not subject to the continual variations in heating power to which a metal fireplace is subject. The Galton fireplace is fully figured and described, and much praised, its only fault being to occupy too much room, which has, in fact, prevented its frequent use in small dwelling-houses, although its admirable qualities as a fireplace for large barrack-rooms and other such establishments is universally admitted. Almost the only Continental grate out of France which is illustrated is the Badmar,—much used in Russia and Germany,—a very complicated affair, the plans and sections of which are too small and inadequate to render its action very intelligible. It is observable that here again the plan of carrying air up the flue in a separate conduit, to be heated by the smoke, is carried out, but with this difference: that in this case the smoke is carried up the centre metal flue (to discharge into a built flue in due time), and the air is carried up round it; thus reversing Captain Galton's arrangement in this part of his stove. It is added that the Badmar fireplace has the advantage that in summer, when not in use for burning fuel, it serves as well for ventilation as for warmth in winter; but we are not told how the circulation of the air through it is to be maintained in this case. A short chapter on the causes of smoky chimneys professes to take each of these causes separately and suggests the remedy; the author enumerates among these causes the want of a sufficient supply of air to replace what the fire should exhaust, a matter which is generally regarded in relation to combustion only.

The chapter on warming by hot air gives sections of several very elaborate systems for making the most of the heat in comparison with the amount of fuel used to generate it, some of which are worth the attention of those who are practically interested in the question. In the summary at the close of the chapter M. Planat expresses the opinion that the balance of advantages is in favour of brick or terra-cotta surfaces for communicating heat to the air, rather than of the iron ones which are so much more commonly used. He admits the comparative difficulty of arranging the surfaces of this slower conducting material so as to collect and communicate the greatest proportion of heat; but he states that from experiments made in 1869 by M. Tresca, sub-director of the "Conservatoire des Arts et Métiers," on heating apparatus of this material, it was found that they could be so constructed as to utilise 80 per cent. of the heat proceeding from the fire, which certainly seems a very satisfactory proportion. The advantage, in a sanitary point of view, of air heated by contact with brick and fire-clay surfaces over that which has been scorched, as one may say, by the quicker conduction of iron, is known to all, we imagine, who have any practical experience in the matter. M. Planat also gives a table showing that in experiments with various forms of heating apparatus, both of brick and iron, made under his superintendence, the brick shows a decided average advantage in point of economy of construction considered in relation to results; the term "brick" (*la brique*) standing, we presume, for what we generally call fire-clay, and which the French term "terre réfractaire," though the same reasoning may probably be applied to built brick heating apparatus on a larger scale. M. Planat adds a caution that the draught through brick flues is not so good as through iron, and that therefore especial care must be taken to ensure a complete and efficient draught.

In the matter of stoves, to which a separate section is devoted, it may be noticed that ideas which are comparatively new here, are already old elsewhere. We have only just seen tile-faced stoves made a specialty by one firm in England, but they are here in several varieties; in which we observe that the utilisation and collection of heat is effected by a number of surfaces in the interior of the stove, in every case figured here, instead of by mere thickness and mass of the material. Possibly the ultimate result is nearly the same; the thick-walled stove as made at Lambeth collects the heat more slowly, and takes longer, consequently, to come into effective operation; but, on the other hand, it maintains a very uniform temperature when it is once got up, and preserves it for a long time, even with a fire which has been allowed to get low. The "Poêle Phénix," employed in France, is an ingenious and very simple arrangement for a self-feeding metal stove burning coal; the coal is all deposited in a central chamber or coal-shoot running the whole height of the stove, and something like an inverted hopper, rather broader at the bottom than the top. The bottom of this receptacle hangs a few inches clear of the fire-bars below, and the lowest stratum of coal burns on the bars, the flame and heat escaping round the sides into the space between the coal-shoot and outer side of the stove; as the coal on the bars is consumed, the mass of unburned coal in the coal-shoot gradually descends by its own weight on the fire-bars, and thus the volume of coal is continually being burned away at its lower end, and proportionately dropping on to the fire, till it is all consumed. That is to say, it does all this in theory, and it no doubt will do so in practice, if one can ensure that the flame shall not, when the coal is loose and presents more interstices than ordinary, take a lead up the centre coal-shoot also, and waste a quantity of fuel by consuming it surreptitiously before its time However, as the coal-shoot is closed at the top and has no draught, and if there is a good draught provided out of the side portion of the stove, the probability is no doubt in favour of its action; and, granted that it will practically act as intended, it is no doubt a remarkably simple and compact arrangement for a self-feeding stove. Something of the same kind has been seen in England, but did not come into use. The Gurney and Musgrave stoves are figured, or described, with no expression of opinion. An Austrian stove, the "Geburth," has a curious arrangement whereby the metal stove-flue is returned upon itself with a variety of elbows and junctions, apparently with the view of gaining a sufficiently long flue for draught without making it a conspicuous object traversing the room. This might be commended to the attention of the clergyman who wrote to a certain society concerned with the protection of old buildings to ask what he should do with a long stove-pipe which had been carried the whole length of his Mediæval church, and out through the west wall, and how he should get rid of this disfigurement, and received a reply cautioning him against rashly meddling with an interesting relic of the habits of a previous generation.

A great number of different stoves are illustrated in the succeeding pages, to which it is worth while to refer, but which we have not space to particularise here, except to remark that there is one stove specially designed for burning coke, contrived by the Parisian Gas Company, which may be worth the attention of those who are now trying to promote smokeless fires in London. The conclusion of M. Planat is that all these forms of stove have their advantages, and that it would be difficult to name one as specially or entirely superior to the rest. The subjects of warming by hot water and steam, and that of ventilation, are separately treated, and we may say something in regard to M. Planat's views and suggestions thereupon in another number.

Art of Old Japan.—At the *soirée* of the National Indian Association, on Thursday evening last week, there was on view a portion of Mr. Pfoundes's Japanese collection of photographs, native illustrations, albums of sketches, &c. A series which attracted much attention consisted of interesting illustrations of the "System of Art" and "Progressive Lessons of the Japanese." It does not appear to be sufficiently widely known even amongst collectors, that there has long existed a perfect "system" as well as invariably "a motive," allegorical, poetical, or otherwise, in the "Art of Old Japan."

ON ARCHITECTS, PAST AND PRESENT.

THAT we should be every now and then reminded of the transitory nature of things mundane is only to be expected in a world wherein all things are ever on the change, and wherein one of the great laws of its constitution evidently is that nought in it is intended to remain always as it is, but must needs be perpetually, though it may be silently, passing away,—to be again, perhaps, renewed under other and still ever-changing forms. We are surrounded on all sides by evidences of this fact,—not only as respects individuals and single and isolated things, but in far more general and much wider and more universal ways. Nought is free from this law of nature,—nothing can escape it. The very earth itself on which we live is as much subject to it as are the animated forms and living things in it. This change may be slow, but it is not the less certain. If this be so,—and who shall doubt it?—the principle involved is not the less true and sure if applied to matters artistic and architectural; for where can there be found in the whole circle of things greater evidences of change and "progress,"—if that be the more significant word,—than in the successive changes as told in their histories of the *styles* of architecture, and in the lives and life's workings of those who bring them and their changeful phases into actual existence, and who fit them in each age to ever new purposes?

There are, at the present moment, not a few thoughts on this law of change which press on us; and we would call attention, if only for a passing moment, to the very singular, though perhaps not enough thought-of, changes which from the first beginnings of it have taken place in the course of the progress and development of Gothic or Pointed architecture, both during its natural development in the centuries wherein it was consecutively practised in its various phases, and in its later revival in these our own days, and as brought again into active and useful service by the men of the present day, and by those whose loss we are now deploring. It must be a subject worth some thought, and must needs be full of instruction in many ways. Take but any one style or "system" of architecture, no matter where practised or of what date in the world's history, and the more deeply and closely it is studied, the more changeable in its history it will be found as the years of its but perhaps too brief existence rolled by. There was no permanence of form in the older architectures; all was a growth or progress from first beginnings to, at times, all but perfect work, to decline and finally complete extinction and passing away into other forms. The Gothic is a sufficiently notable instance of this, from its "Early" beginnings to its "Late" decline and final extinction.

We cannot pause here, or venture to comment on the singular origin, and really wonderful course, of what is termed the Norman or Romanesque architecture which preceded the Gothic,—a phase of art, as we are inclined to think, hardly done full justice to, growing, as it did, out of a previous and more advanced art and architectural style. It spread, as we know, all over Europe, and assumed a variety of characteristic expressions. Springing out of the antique Roman art, it did its own work not a little effectively and well, till finally lost in that Early Gothic which succeeded it and which itself grew out of it. It forms in itself quite a complete art and architectural history, and in it may be found well illustrated that great law of change of which we speak as dominating art and architecture. It varied in its expression, not only in each country in which it was practised, in a most wonderful manner, but it changed from year to year in each of those countries, individualised as each one of them then was. We can hardly over-estimate its importance and value as a mode of art expression. It forms a complete history in itself. We refer to its past history. It has, too, as all know, its "present"; for it has with the Gothic been called again into useful and serviceable existence, and by none more effectively than by the late lamented Honorary Secretary of the Institute, with whom, as we know, it was always a favourite.

Thus it is that a glance back into and at the origin of the perfected forms of the old architectures, and at those who are no longer present to work at them, may and must possess a special interest. In these our own modern days, the different phases of Norman and Gothic, from Early to Late, have been applied to all but every purpose,—to cathedrals, churches, houses, and to buildings of all and every class, and certainly no small skill and ingenuity has been expended in so applying them, and considering the vast differences between the requirements of the past, when these styles of art and architecture originated, and our own wants of the present day, very much is to be said for the skill of those who have so applied them, and fitted them to altogether new and untried purposes. Nothing, it is curious to note in Gothic days, or during the centuries wherein it so happily flourished,—nothing occurred to mar or interrupt the complete domination of the Gothic idea of art. Its ascendancy was complete, and it reigned supreme until its final decline and extinction as a living style of art, and but for its "revival" in this our own day, by modern men, and by those and such as those who have but now passed away, it would have been as dead, for all active and useful and present purposes, as that of Egypt itself. If, therefore, the present of such original art ideas do not equal or even surpass the past of them,—why is it?

And there is yet another reason why at the moment this subject of the older architectures and arts, and of the artists who designed and worked at them, as contrasted with our present mode of doing the like work, and in the providing for special modern and of to-day wants, should be of more than usual interest; and it is that, while the lives and life's-work of the modern men of to-day are open to observation and inquiry, the lives and mode of work of those who designed and worked out the old architectures, from which we get so much, are all but lost. We know but little indeed of the methods of work and daily practice of the old architects and builders and workmen. In these days all is plain, but as to the old time, wherever the work might be, we are all but in total darkness. We can see very little of the *modus operandi*,—but little as to how far drawings helped. Many old structures we have seen, if very carefully and closely looked at, would seem to have been built up all but by accident or guess-work; nothing answers to the foot-rule, no line of the building is quite straight, nor parallel to the one opposite, yet is there in it a certain evidence of the presence of him who thought it out, just, indeed, as there is in a painting, of the ever-present thought and hand of the painter of it. It may be, and without doubt is, very difficult to define this in words, but it is sufficiently plain when pointed out, and, once seen, cannot afterwards be missed.

If, therefore, the history of the old and past styles of architecture, and the *modus operandi* of their production, when at their best, and of the lives and professional procedure and artaction of those who designed them, and their details, would be, if well told, of surpassing interest, then would be the history of modern art and architectural practice,—the same in intent and use, though in many ways so different and unlike. If in older and past days it must be a matter to wonder at the isolation of each particular and individual style, and the consequent limited range of view of those who worked it out, so must it be in these our days, and equally wonderful to ponder on the vast extent of our modern art and architectural outlook, and the many styles looked at and studied, and at times,—and every here and there,—"practised." Indeed, might we not here almost ask what style of architecture has there been anywhere that has not had its modern votaries, and that has not been, as far as that was indeed possible, more or less imitated and brought into active service, if not literally, and with closely-copied details, at least as far as was possible in idea? It forms quite a new chapter in art-history,—succeeding the past,—and a very curious one, though it may seem familiar. *In memoriam*, therefore, of those who have but now passed away, it may be well to ponder awhile on these common difficulties.

A Man suffocated in a Sewer at Birkenhead.—An inquest has been held on the body of a man named Michael Devaney, a labourer, who met his death in a sewer in Cleveland-street, Birkenhead, by inhaling foul gas. The jury returned a verdict of "Accidental death," adding the following presentment:—"The jury consider the Corporation have been guilty of great neglect in permitting such an accumulation of sludge in the sewer as had been elicited in the evidence, and such an amount of deposit ought not at any time to be allowed to exist."

THE SOCIETY OF BRITISH ARTISTS.

WHERE do all the pictures go that are painted? Not only do the smaller water-colour societies all exhibit twice a year now, but the large rooms of the Society of British Artists, whose exhibitions generally number from 900 to 1,000 works, are now also filled twice in the year. It is wonderful how so many people can afford to devote so much time to pictures, only a small proportion of which are sold. And perhaps, considering all that is required to make a picture, it is wonderful that, on the whole, there should be so good an average of paintings as there is. But one becomes, of course, increasingly fastidious under the influence of these profuse displays of paintings. There is no doubt that in every exhibition in London, even in those which no one professes to regard as first-class exhibitions, there are a large number of paintings which, if one considers them on their own merits alone, represent each a very considerable amount of training and ability, the surmounting of a great many difficulties in perspective and in the use of colours to produce the effects intended, the possession of a degree of talent more than is required, in many other walks of life, to ensure a respectable success; and in the best class of exhibitions there is generally not a picture hung of which this may not be said. And if we had just invented painting, all these respectable efforts would have due value; any man who could paint a picture would be a marked man, and would receive the respectful admiration of his friends and neighbours. But now it is with pictures as it is with books, or almost so. It is understood now that any one who chooses to write a book may do so, and so many people do choose that it is rather difficult to find any man of fair general education or with any special knowledge who has not written a book of some kind. The writing of books and the painting of pictures, it has been discovered, are, up to a certain point, within the power of a large number of people, if they choose to try hard enough. It is an understood thing that a certain standard of excellence in the imitation of nature may and will be reached by every one who sends a picture to an exhibition,—a higher standard often in mere execution than was reached by some of the greatest painters of antiquity. We have come to accept this fact, and accordingly we no longer attach much value to pictures which are merely correct in colour and perspective, and tolerably like what they are meant to represent. It may require a good deal of pains to execute even these, but then we have had the feat performed *ad infinitum*, so that it has no longer any value. The artist whose work is passed over by the critic with indifference or dislike may, no doubt, tell the critic that he could not paint even as well as that. The critic will reply, "No, and I have no wish to." The feat is not worth doing. That natural objects can be approximately imitated with paint and a brush we now all know, and have seen it done many hundreds or thousands of times; we want something more than that from a picture now. We want either a special idea illustrated, or, if the picture is only an imitative one, we want some special excellence and completeness of imitation, beyond what every man who has learned the commonplaces of manipulation with a brush and a palette can do.

Exhibitions are becoming, in short, too numerous and too mediocre. Referring to the one now under consideration, one may reasonably ask what is the use of filling all the walls of these large rooms in Saffolk-street twice a year with paintings, a majority of which are mere common-places that no one cares for? We do not ask the question by any means in the way of a special "set" at the present exhibition, which is rather better than ordinary, and contains some good things. And all exhibitions cannot be kept up to the highest standard, of course. But if the promoters of the Society of British Artists' exhibitions would be content with giving a smaller exhibition, and would be more particular and restrictive in their selections, there would be a better reason for the existence of the exhibition. A fair collection might be picked out of those that are there this year; and there are a few very good ones. But what is the use of hanging the mass of them we fail to see; unless it be to gratify an innocent pleasure which the authors of them feel in being hung at all in a public room.

It is just because there are some better works than usual in the exhibition that one regrets

having to pick them out of such a medley. Among them Mr. Gadshy's "Roses" (13) is a pleasantly-painted pictnre of two girls, the face of one of whom has much feeling and expression. At the opposite end of the room is a capital work by Mr. Reid, one of whose paintings was pnrchased a year or two ago with the Academy's Chantrey Fnnd. This one is "Lost and Fonnd": the story of a little girl who strayed in the fields and fell asleep there. An old rnstic approaches from the right,—a study very similar to one in the painter's Cbantrey-fnnd picture. The treatment of the landscape displays that spotty manner which spoiled a good pictnre of Mr. Reid's in the last Academy; bnt it is a good work. Mr. A. Hill's "The Fihula" is a realistic study of a model, with a classic pose and background; good as a study. Mr. Cattermole's "The Law of Venice" is a small oil-painting, the title being again a name for a pictnre of some half-length figures in Venetian robes; a good little work, as might be expected, bnt rather deficient in "motive." "Thistledown" is the title of a fine landscape by Mr. Grace, one of the best members of the Society. A pleasant study of children, and carefully finished in detail, is that by Mr. J. C. Waite, "I Can't See It,"—the sentence uttered by a little girl who is looking through a telescope, while her brother, in sailor-dress, sits before her. Mr. Garland's "A Contented Mind" is another pretty child-picture, in which the interest is partly also in the furnitnre and other accessories. Better than either of these is "My Last Bonnet," by Miss Cornelissen,—better in character, though not so carefully finished: it is the face of a small chnbby child with a large bonnet on. Mr. Stuart Lloyd's "Dunnose Head" is a good landscape; so is "A Summer Afternoon in Surrey," by Mr. Aubrey Hnnt. The "Haunt of the Wild Fowl," by E. Ellis, is better than either. Mr. Ellis is a fine landscape-painter, who shows in most of his works qualities above the average. Mr. Henley's "The Bee and the Drone" is a pleasant study of a monastic interior with two monks, in whose figures and expressions there is much quiet character. Mr. Girardot's "Faces in the Fire," and Miss Florence Martin's "A Duet," are both well-imagined pictures,—interiors with figures,—not quite fulfilling their authors' intentions; the last-named shows two figures of girls, seen in profile, against an open window, one playing an organ; there is very nice feeling in it. The exhibition includes some good flower and bric-à-brac pieces; Mr. Muckley's "Lilies and Roses" is a very fine work of its kind, and Miss Miller's "May" is good. "A Wintry Gleam: North Wales" is another specimen of Mr. Ellis's powers in landscape; and in the same room Mr. Gadshy's "Forty Winks," a study of a sleepy little child in mob-cap and mittens, should be looked at. A sleepy dog, by another artist, Mr. Trood, under the title "Drowsy," is an admirable bit of animal character and drawing. Mr. Walter Stacey has a small work called "A Threshing Floor," very good in composition and character. Several of Mr. Wyke Bayliss's finely-finished and very accurate architectural interiors are scattered about the rooms, and are all worth looking at, though we think Mr. Bayliss has, in some of them, been trying a little too much for effects of light which appear rather too palpably contrived; bnt his treatment of architectural detail is excellent, both from the architect's and artist's point of view. Among some small sculptural sketches on the centre pedestal of the large room are two very good heads,—"Sappho" and "Pandora," by Mr. MacLean, and a capital little sketch of a sleeping boy, by Mr. Mullins; Mr. MacLean also sends a terra-cotta study of a portrait statue of a child reading, which is excellent in character, though not graceful. There are some good things among the water colours, which, on the whole, however, do not seem to be equal to the usual run of the exhibition (of which the water-colours show usually much the best standard), while the oil-paintings are above the usual standard. But we repeat the opinion that the exhibition would be likely to rank much better if the Society contented themselves with a smaller quantity, and demanded better quality in the mass of the works as a condition of acceptance.

A Marble Bust of Charles Summers, sculptor, who was born at Charlton, Somerset, 1827, and died in Paris in the year 1878, as the inscription on the pedestal states, has just been placed in the vestibule of the Shire-hall at Taunton.

SANITARY SCIENCE IN ITS RELATION TO CIVIL ARCHITECTURE.

ROYAL INSTITUTE OF BRITISH ARCHITECTS.

A PAPER on this subject was read by Mr. E. C. Robins, F.S.A., Fellow, on Monday evening last, Mr. John Whichcord, President, in the chair.

Mr. Robins commenced by observing that no subject of study could be more honourable than that of the principles of sanitary science, and of the laws which governed the application of those principles in the development of our national architecture. Those architects who for the last thirty years had practically proved their interest in sanitary science in so far as it related to architecture could not be otherwise than pleased with the obvious improvement in recent public opinion and the quickening of the professional conscience thereon. The articles in the *Builder*, published in the year of the cholera, 1852, had first led him to take a personal interest in the subject, and he became a member of the Regent-square Local Board of Health, King's-cross, which had a district forming a nineteenth part of the large parish of St. Pancras. That Board published in 1854 a report of inquiries undertaken by it, showing the necessity for the employment of properly-qualified surveyors and sanitary inspectors. Mr. Chadwick was of opinion that the subject of house drainage should be cultivated as a specialty, and attributed to the neglect of that course many existing evils. Sanitary science was not, indeed, so old but that architects of the last century might have been found as ignorant of the principles of house sanitation as medical men themselves once were. The object of the present paper was to consider, (1.) What had been defects in sanitary construction; (2.) What were the remedies now generally available; (3.) What further improvements were required. In London a system prevailed which compelled the professional architect to provide against the insanitary condition of the main sewers: he had to fortify the modern dwelling-house against sewer gas, which contaminated not only the air breathed by the inmates, but also the water they drank. It was not necessary to enter into much detail respecting sanitary defects; a summary was provided in a pamphlet entitled "Dangers to Health," written in a grimly-humorous way by Mr. Teale, surgeon to the Leeds Infirmary, and dedicated to his medical brethren. Such defects consisted not only in those things for which an architect might be blamed, but also in the faulty workmanship of artisans: in the bad jointing of iron and stoneware piping, in false levels and bad laying of drains, in perverse connexions on the wrong side of traps, in ill-supported vertical soil-pipes, in the thousand evils emanating from the want of trained foremen and workmen. At the Conference on Public Health held in June last by the Society of Arts, Mr. Rawlinson had stated that house drainage was at the root of all sanitary reform, and that "he was pleased to inform them how the Earl Spencer had kindly permitted the inspection of the system of drainage adopted at his Lordship's house in St. James's-place"; and Mr. Rawlinson added that Lord Spencer's town house was the most perfectly-drained house in London or elsewhere. The evidence given by Messrs. Eassie, Rogers Field, and Griffith before the Society of Arts was referred to. The principles summarised by Mr. Griffith were quoted,—principles which were quite in harmony with many architects previous practice. They were (1.) Communication between main sewer in street and house-drain should be disconnected or severed by an open-air space being left between the house-drain and sewer; (2.) The house-drain, air and water tight, should be laid to such a fall as to be self-cleansing, free from deposit, and ventilated; (3.) The soil-pipe should be fixed inside the house and taken up full size above the roof; (4.) The waste-pipes should discharge into the open air instead of into soil-pipes or a D-trap; (5.) There should be no means of drawing water from a cistern supplying a water-closet, other than through the closet; (6.) The waste-pipes from sinks, baths, lavatories, &c., should be S-trapped underneath, and made to discharge immediately into the open air, over trapped gullies; (7.) There should be no connexion with the main house-drain, when laid underneath the house, except outside the main walls of the building; (8.) "Pan closets" with D-traps should never be used, nor should D-traps be fixed under sinks, &c. The evidence of Messrs. Eassie and Rogers Field coincided in all material points with that of Mr. Griffith. With reference to the second division of his paper, the author prefaced the subject of warming and ventilation by quoting a remark made to him by Professor Jenkin, to the effect that the study and control of the pressure of the atmosphere, and not the temperature, is as the key to all sound ventilation. As that pressure was increased or diminished in its utilisation, so ventilation was promoted or retarded. Following the suggestion of Dr. Parkes, it was desirable to restrict the thing known as ventilation "to the removal by a stream of pure air of the pulmonary and cutaneous exhalations of men, and of the products of the combustion of lights in ordinary dwellings, to which must be added in hospitals the additional effluvia which proceeds from the persons and discharges of the sick." It was not only important that the air should be changed, but also that it should be drawn from a pure source and carried through clean channels. By the term "ventilation" the author meant a passage for the wind, change of air, or atmospheric recuperation. A way in was wanted for the air, and a way out for it in every building or portion of a building. Natural ventilation was the simple process of allowing the external atmosphere to mingle with the internal atmosphere of a building; scientific ventilation was the same thing, but with this difference: in the former case the air was free to mingle or not as it pleased, and in doing so it created many inconveniences; in the latter, direction was given to currents of air produced by interchange, and a healthy commingling of the oxygen with the carbonic acid gases was secured without the dangerous and disagreeable accompaniment of draught. The business of ventilation was to direct the pressure of the currents of air admitted and required to overcome stagnation under conditions where no draught was admissible. The natural process by which the temperature of the air was raised was twofold,—by radiation and by conduction. Radiated heat had the peculiarity of passing directly through any intervening space, without parting sensibly with its heat, and warming the first obstacle to its passage, such as a wall or window, with which it came in contact; conducted heat was the warmth given off from any surface by direct contact with any substance, whether air or otherwise. The conducted heat of an open fire passed into the air, escaping by the chimney flue, and was lost for heating purposes; the radiated heat of the open fire was alone available for raising the temperature of a room. Draught, however, was almost inseparable from the use of open fires, especially when they were placed directly opposite doors, whereby large quantities of air were drawn across the floor and passed up the chimney. With reference to the size and position of "inlets" in rooms, it was desirable to make the area of each opening not larger than from 50 to 60 square inches, and they should be placed on the same side of the room as the fireplace. The introduction of air by vertical shafts, suggested by a Mr. Whitehurst years before Mr. Tobin was heard or even thought of,* was a sound principle, suited to the requirements of ordinary rooms which were heated by the open fireplace only. Mr. Robins then drew attention to several varieties of stove and grate, some invented by architects. He described the heating and ventilating processes adopted by the late Mr. Wyatt in the new Hospital for Consumption at Brompton. Dr. R. E. Thompson, who had greatly interested himself in these processes, had, in a letter to Mr. Robins, thus summarised his views:—"I think that air should be admitted at the level of the various floors, and not from an underground chamber; also that the air so admitted should come from the east and west sides if practicable, and in any case should be passed over tubes of hot water. Air of uniform temperature is disagreeable and oppressive; it is better that the upper air should be colder than that of the floor, and that the warm air as it rises from the floor-level should be cooled and agitated as it mixes with the upper air by the incoming cooler air. The foul air should be extracted by the open fire, and by the extracting-flues at the top of the room, which should be heated by gas-jets below,

* Mr. Robins quoted from a pamphlet by Mr. Whitehurst, bearing date 1794 (the author died in 1788), entitled "Observations on the Ventilation of Rooms, on the Construction of Chimneys," &c., the following passage:—"The air-ducts to be about 3 ft. or 4 ft. long, and 5 in. or 6 in. in diameter, and fixed in either corner of the room most remote from the fire and communicating with the external air. The air will ascend in a perpendicular direction to the ceiling, and being gradually dispersed, will soon acquire the temperature of the room."

or made to communicate with the hot-air chamber above and in connexion with turrets forming ventilating towers." With regard to water-closets, Dr. Thompson considered that the space they occupied should be heated to a higher temperature than the passages leading to them, and that a separate means of extraction should be adopted. With regard to systems of underground reservoirs or chambers for the accumulation of heated air to be transmitted through shafts to the different rooms of a building, everything depended on the cleanliness of those heated air-chambers; indeed, Mr. Robins had heard of one in which decayed organic and vegetable matter had been allowed to accumulate; another in which a defective soil-pipe had discharged into it part of its contents. Alluding to the various systems of heating, the author said that twice in his practice he had been obliged to substitute hot water for hot air, both instances being in churches. Two leading principles governed the supply of hot water for heating purposes, termed high pressure and low pressure. The latter provided for the supply of water at a low temperature, which cannot reach boiling-point, in more or less large pipes; the former, circulating water at a high temperature in strong wrought-iron pipes of very small bore, rarely exceeding 1 in. in diameter. After referring to various examples in his own practice, Mr. Robins concluded with the assurance that the practice of civil architecture could not be divorced from the experiences of sanitary science. There was plenty of room for specialists and *dilettante* expounents,—indeed, co-operation in overcoming the results of past carelessness was most needful; but the fact remained that dwelling-houses, to be made healthy in the future, were and would still be the special province of professional architects.

Professor Corfield, on the invitation of the Chairman, opened the discussion, and observed that he was glad to have the opportunity of saying in that place what a deep debt of gratitude he owed to many members of the architectural profession for the cordiality and courtesy with which they had met him on very many occasions with assistance in matters relating to the sanitary construction of buildings. A great deal had been said lately against architects, who had been told that they did not know their own business, that they knew nothing whatever about drainage arrangements, and, in short, that all the evils connected with bad drainage were to be laid to their blame. He could safely say, however, that he had never met an architect in consultation on such matters without finding him intelligently solicitous for the welfare of the people who employed him, and earnestly desirous to do all he could to make his buildings healthy for those who lived in and used them. Mr. Robins had said, in concluding his paper, that the practice of civil architecture could never be divorced from the experiences of sanitary science. He (the Professor) would go further, and say that if it were not for the experiments that had been made by scientific men with the view of discovering the true principles of sanitary science, no improvement would ever have been made in the healthiness of our houses. For a long time the received method of procedure in matters of house-drainage was practically to bottle up the foul air of the sewers rather than to prevent it accumulating at all. After a time it was found necessary to provide some means of escape for the foul air, or it would make its escape in directions which were sometimes not suspected. Having done this much, we should probably have gone on in the same course for another hundred years had it not been for an important series of experiments conducted by scientific men, who proved that typhoid or enteric fever,—a disease not known by that name forty years ago,—could be produced by germs contained in sewer air, as he preferred to term it, and not sewer "gas" (it being as incorrect to speak of the air of an hospital ward as hospital "gas" as to term the air of sewers sewer "gas"). Until that fact was definitely proved, little or no public attention was paid to it, nor, indeed, was public opinion aroused on the subject until one or two members of the royal family had suffered from disease brought on, as it was believed, by sewer air. The poison of typhoid was not a gas or vapour, but consisted of particles, and it was quite possible that those particles were living things, or germs having vitality in them. It had been proved that those particles existed in the air of sewers, and it should be the object of such practical sanitarians as architects should be, to exclude those particles from all chance of admission to the interior of a house. He had certainly been astonished to hear Mr. Robins say that many of the essential principles now insisted on by the so-called specialists, and demanded by the laws of sanitary science, had been carried out for several years past in the better class of houses in London. It was his (the Professor's) experience that thousands of houses erected during the last few years in London were quite unfit to live in, so far as the drainage arrangements were concerned. It was only as the result of very important series of experiments that the necessity of the complete disconnexion of house-drains with the common or main sewers was demonstrated. It had been clearly shown that water-traps alone were insufficient to exclude sewer air if in direct connexion with such air, for it was absorbed by the water on the under side of the trap, and, when the water was fully charged with it, it was given off from the top surface of the water in the trap. Dr. Frankland had shown that when water containing or impregnated with foul matter was mechanically disturbed or shaken, the particles of foul matter gave off particles of air which were dispersed into the atmosphere, which became contaminated with those particles. By due attention to the principles of sanitary construction, the architect could be absolutely certain of excluding the entrance of typhoid fever into a house by the medium of the drainage system; and, moreover, in a house scientifically, and therefore healthfully devised in its sanitary arrangements, should a case of typhoid induced outside the house occur amongst its inmates, the spread of the disease amongst the other inmates could be as absolutely prevented. A case of typhoid fever was lately introduced in a large school, and he was consulted as to whether it would be necessary to disperse the scholars. When he found that the sanitation of the school was thoroughly in accordance with the most advanced practice of sanitary engineering, he was able confidently to say that it was not necessary to send all the scholars home; and the result justified him in saying so, for not a single scholar besides the one who brought the disease in with him suffered from it. Such immunity from infection under similar circumstances could not have been counted upon ten years ago, if, indeed, it could have been expected five or six years back. There was great difficulty, however, in rendering healthy houses which had been originally constructed and drained on faulty or defective principles, and sometimes little short of pulling them down entirely and rebuilding them would cure them of their inherent defects. One danger to be guarded against was that of amateur meddling with the sanitation of a house. Many useful and popular books had been written on the subject, graphically pointing out the evils of bad air and bad drainage, but to place such a book in the hands of the average householder, and to tell him to put his house in order in accordance with its teachings, was as absurd as to bid him to read a manual on amputation and then to set him to cut off a patient's leg. The circumstances of each case varied so greatly that no one would be safe without taking proper professional advice. One important practical point generally overlooked was that of the necessity of providing a syphon trap to kitchen and scullery sinks, even though the sink-pipe were made to discharge over an open gully in accordance with the now recognised right practice, for at night it would be found that unless such a trap were provided, a large proportion of the air finding its way into the house would pass through the open sink-pipe, and as the interior of the pipe was naturally liable to get foul, the air entering the house through it would inevitably be contaminated to a degree in proportion to the foulness of the pipe. He had traced several cases of sore-throat and diarrhœa to the omission of such a trap. Obviously the waste-pipes of sinks, even when discharging into the open air, were not, under any circumstances, proper inlets for fresh air.

Mr. E. R. Robson (architect to the School Board for London) said that wide as was the scope of Mr. Robins's paper, he regretted that it had not entered upon the subject of site and of the necessity of keeping houses dry. With regard to the question of drainage, he was perfectly certain that Professor Corfield need not go back more than six or seven years to arrive at a period when soil-pipes and house-drains were universally without ventilation and disconnexion from the main sewers. One very important point to be borne in mind in connexion with the subject was that the cisterns which supplied the water-closets should never be allowed to supply the water used for drinking and culinary purposes. This was, however, generally forgotten or ignored, with serious results very frequently, for although typhoid fever might occasionally be engendered by sewer-air, everybody knew that the primary cause of typhoid fever was bad water. The point as to trapping open sink-pipes on the inside, to which Professor Corfield had referred, was quite new to him. As to the large question of warming and ventilating, he thought it meant sunshine and fresh air as near as they could be obtained artificially. It appeared to him that all they had to do was to follow natural laws in the main. Natural laws had not hitherto been generally followed in artificial warming and ventilation. The open fire was no doubt the most charming way of warming a room, so far as appearance went, but it had the demerit of warming the mantelpiece above it, which was already warm, but it did not warm the window where the cooling surface was. To counteract the cold caused by the window the fireplace should be put underneath it. Above all, he thought it was of the first importance that the corridors and staircase of a house should be thoroughly warmed and ventilated, so as to form in reality a reservoir of warm fresh air outside the rooms. For the London School Board he was now engaged in superintending the erection of two schools, one of them to be warmed by Mr. Boyd's "Hygiastic" grates, and the other by Leeds's American steam-heating system. When those schools were completed and in working order he would communicate to the Institute some particulars and results of each method. The use of steam for heating purposes was, as the members of the Institute would know, greatly restricted by the inconsistent and obsolete regulations of the Metropolitan Building Act. As to the so-called "Tobin's" ventilators, although it was perfectly true that they were long previously suggested by Mr. Whitehurst, yet the merit of urging their extensive systematic application was undoubtedly due to Mr. Tobin. He differed from Mr. Robins when that gentleman said that inlets and outlets for ventilating purposes should be equal, for unless the outlets had an absolute exhaust, the inlets must always be larger than the outlets. He deprecated the adoption of the dirty chambers (for they always got dirty very soon) sometimes used in the basements of buildings as reservoirs for the air to be warmed. He differed radically from Mr. Robins when he advocated the warming of fresh air by means of stoves placed in such chambers. In all schools heated in that way he always found the teachers complain of lassitude, fatigue, and weariness. Unless the air was heated in a direct manner, just as the atmosphere was warmed by the heat imparted to the earth by the sun, or as the air of a room was warmed by the heat given off to it from the objects warmed by the fire, the principle proceeded upon was wrong. It was necessary to keep to direct radiation; in other words, the radiating points must be in the room to be heated, and not in chambers or places remote from it. He noticed some allusion in the paper to American practice, but he wished that American practitioners would give us not merely the results they were said to have achieved, but their formulæ. One gentleman, for instance, talked of admitting fresh air over hot pipes, but on a frosty day the result of the entrance of the cold air would be to cause one side of the pipes to get cold while the other side remained hot, and under such conditions iron pipes were only too likely to go to pieces.

Captain Douglas Galton, C.B., said that there was one cause of disease in many houses which was, he thought, quite as serious as sewer air or gas,—he meant the ground air arising from the unhealthy "made" ground upon which so many of the dwellings of the people were erected. Where such an impure foundation existed, it would account to a very large extent for some of the evils alleged to arise from the use of an air chamber in the basement for ventilating and warming purposes. The paper which Mr. Robins had read was one covering such an enormous extent of ground that it was impossible to adequately discuss it in one evening, but the thanks of the meeting were due to Mr. Robins for having brought the matter forward in such a comprehensive manner. He (Captain Galton) had recently been over to America, where he took the oppor-

tanity of seeing what was being done in the way of sanitation and architecture. The American architects seemed to have greater scope afforded them for showing what they could do than was accorded to the architects of this country. In two buildings,—a church and a theatre,—which he visited in New York, the arrangements for ventilation certainly far surpassed anything which had been done, or, he thought, even suggested, in this country. He believed the apparent perfection of arrangements in question was due, not to greater genius on the part of the American architects, but to the full scope given them to do what was needful, without stint of money. The church to which he alluded was that of Dr. Hall, a Presbyterian place of worship containing sittings for 2,000 persons. The ventilation was effected partly by means of propulsion and partly by extraction. The same means were used in the theatre,—the one in Madison-square,—and both buildings were ventilated with far greater perfection than had been attained in any building in this country. He had also been very much struck with the perfection to which the Americans had brought their system of heating by means of steam. Steam for warming purposes possessed a great advantage in the high temperature attainable with it in a very cold climate like that of the winter of North America, but its use was attended with certain inconveniences. The advantage of the hot-water system over steam was that it was possible to regulate the temperature of the pipes to any desired extent. With steam the temperature was necessarily high, although there had been introduced a system of using steam for warming purposes at a low pressure, —a system rather the reverse of the Perkins system of heating by hot water, for the steam was worked under a method of exhaust, so as to get it at a low temperature; it did not appear, however, to have been very successful or widely adopted. In this country he thought that, all things considered, it was a better plan to adopt the hot-water system than to resort to the more economical method (on a large scale) of steam heating. No doubt it was possible to produce a greater result at a lower expenditure of fuel in the case of steam heating than by the use of hot-water heating, but to secure even the advantage of economy the heating arrangements would have to be on a large scale.

Mr. Ewan Christian said he, too, had lately been in America, and he could cordially endorse what Captain Galton had said as to the comfort of Dr. Hall's church. He attended service there in October, and was never in so pleasant a place of worship, for he was able to attend to the proceedings in a manner in which he had never been able to follow the service in any English church whatever. He was also struck by the manner in which steam heating was carried out in Detroit, where, during the winter, when the temperature was 20° below zero, all the buildings within a radius of a mile from the steam generators were maintained at a temperature of 65° by means of steam-pipes radiating from a centre, and what was more, the surplus steam was used to work the lifts and hoists of the stores. With regard to the question of water-closets and traps, he believed Mr. Norman Shaw had solved the problem by his system of open soil-pipes without traps. He had tried it, and found it to answer admirably. Professor Corfield's warning about untrapped sink-pipes discharging into the open air was new to him. On the question of warmth, one very important means of securing it consisted in hollow walls, which, by interposing a blanket of air between the inner and outer parts of the wall, kept a building cool in summer and warm in winter. There was no reason why hollow walls, if properly built, should not be as strong as solid ones. The same reason that made it desirable to have hollow walls where possible, made it undesirable to build church roofs with the slates laid direct on to the boarding which formed the inside covering: cavities or hollow spaces should be interposed between the inner and outer skins of the roof. Some time ago he was consulted by the Archbishop of Canterbury as to some mysterious smells which were experienced in his grace's house at Addington. He found that the smells existed a very long distance from any possible source of leakage from soil-pipes or sink-drains, and he found it difficult at first to account for their existence, particularly as he was told that there was no smell whatever in the basement, the servants being entirely free from the annoyance. However, he carefully examined the basement, and found that the drain ran right underneath the house, and that, there being a leakage at the junction of the soil-pipe with the drain, the foul air ascended along the ontside of the soil-pipe and passed behind the battening of the upper rooms all over the house, being drawn hither and thither by the fires which were lighted in the different apartments. Even when the source of the evil was stopped, the foul air which had accumulated behind the battening was found to hang there so persistently that nothing could dislodge it but the pulling-down of the plaster and battening, and the complete opening-out of the surfaces of the walls. Seeing the difficulty which there was in getting people to treat ventilating appliances properly, he thought it was advisable, wherever possible, to depend on nothing more elaborate than an open window and a roaring fire.

Captain Galton said if he might be permitted he should like to add to what he had already said by giving a striking instance in corroboration of what Professor Corfield had urged as to the necessity of trapping sink-pipes that discharged into the open air. It was easy to conceive that sink-pipes would get foul, for at University College Hospital a series of tanks in the roofs, supplied with water from the water company's main for use in case of fire, were provided with overflow waste-pipes discharging into the open air above the ground-level. These waste-pipes, although nothing worse passed through them than the water supplied by one of the London companies, in two or three years got to be so insufferably foul and offensive that the air passing up through them into the roofs became quite tainted, and the evil had to be remedied by the use of syphon traps.

Mr. G. J. Symons, F.M.S., said that the paper read by Mr. Robins was very suggestive of the vast ramifications and range of the work and study of the architect. With respect to the condemnation so often passed upon the sanitary condition of houses erected under the superintendence of architects up to within the last few years, it was not, he thought, to be inferred that the architects of past generations, or even those of the present generation, had been to blame, for they had doubtless acted up to their lights and up to the standard required by the knowledge of the period. Again, he believed it was an undoubted fact that for the erection of a very large proportion of London houses the architects were not in the least responsible, as they were erected by speculating builders without the intervention of architects, who were probably rather too expensive for the average builder to avail himself of their services. If that were so, perhaps he should be pardoned for suggesting for the consideration of the Institute whether it would not be possible to establish some sort of inferior order of architects, who would be content, for a reasonable remuneration, to devote particular attention to the sanitary requirements of the houses of the people? Only the other day he wanted to build an office at the bottom of his garden, but he was afraid to go to an architect, as he feared to incur too great an expense. He and a builder laid their heads together, and succeeded in sticking up something. No doubt an architect would have done it better, and possibly as cheaply, but there could be no doubt whatever that the architect was looked upon as a very lofty and exalted being, rather above the means of the ordinary builder. He thought that the miles and miles of things,—he could not call them houses,—which disfigured our suburbs, and were built apparently with the express intention of tumbling down at the expiration of the ninety-nine years' lease, afforded proof positive that for some reason or other the builders were afraid or unable to employ architects. With regard to the ventilation of large public buildings, there was a firm in Glasgow,—he thought the name was Penicuik,—one of whose members told him that he had been engaged in ventilating a large room in Edinburgh, intended to seat about 3,000 persons. The method adopted was simply that of having two large iron vessels, somewhat resembling a pair of gasometers, balanced by pulleys, and each alternately rising and falling, in the roof-space. By pneumatic action these vessels were so contrived as to be continually engaged in exhausting the foul air from the upper part of the hall through valves fitted in the ceiling. This contrivance, he had heard, proved to be very successful, and it had the merit of being always workable, independently of the pressure on temperature of the atmosphere.

Professor Ayrton said he had listened with very much interest to Mr. Robins's paper. It occurred to him that one reason why Science had not done more for the comparatively new subject, as he might call it, of house sanitation, was that people had rather regarded the diseases which were now proved to very largely result from bad sanitary conditions, as natural and inevitable. He did not think that too much reliance should be placed on people's sense of what was unpleasant or the reverse, for he thought there were often unhealthy conditions prevailing in London and elsewhere without their being noticed by the public, who had grown accustomed to them, just in the same way as, in some countries abroad, people were found to live apparently in perfect comfort in atmospheres that would kill an Englishman. The Japanese, for instance, warmed their rooms by charcoal stoves without chimneys. The result was that, although the rooms were comparatively open, their atmosphere was unbearable to an Englishman, and it was not surprising to learn that disease was very largely prevalent in Japan. He had found, while travelling in America, that the ordinary American stove, whether of cast or wrought iron, was excessively unpleasant, for not only was the air of rooms heated by it made very hot, but the heated wrought iron allowed carbonic acid gas to pass easily through it. Knowing that such stoves were largely used, it need not be wondered at that the Americans were not, as a rule, particularly healthy people. Was it not possible, then, that there might be several things existing in our own country which we should in the future regard as very unhealthy, but of which we had at present no sensation of unpleasantness because we were accustomed to them? With respect to warming, he thought that as we were now coming to the age of electric lights which imitated the sun, in like manner we were coming to see that radiated heat was the only proper and healthy mode of warming, the air being at the same time cold. At the suggestion of Mr. Robins he had been turning his attention to the subject of the passage of air through pipes, and he had come to one point as to which, probably, some members of the Institute could assist him. He wished to know whether it had been ascertained by experiment what was the least velocity of air round a warm human body which was tolerated without being called a draught? Of course, it depended on the temperature, but what was the velocity for a given temperature that people would tolerate?

Colonel Prendergast hoped that the discussion would be adjourned to a future evening. The paper had dealt with two distinct matters, drainage and ventilation, either of which was in itself quite sufficient to occupy an entire evening. Nearly everybody who touched the question of warming and ventilation was apt to forget the persons who were going to live in the buildings dealt with, and some of the inconveniences and discomforts which were found to arise resulted from the employment of two or three sets of persons. To take the case of the brand-new barracks at Knightsbridge. The men's rooms there were provided with the admirable grates devised by Captain Galton, but nevertheless the rooms were found to be so wretchedly cold at night that the men had to be allowed extra blankets. Why was this? Simply because the doctors on the one hand, and the ventilating engineers on the other, had done their best to render nugatory the warming power of the stoves,—the doctors by insisting on having windows on both sides of the room, and the engineers by putting the ventilating grates between, but on a level with, the beds. What did he find to be the result when he visited some of the rooms the other night? Simply that the men, unable to bear the cold currents of air induced by the too-complete system of ventilation, had stopped up every extraction shaft. Surely it was within the power of science to put forward some sort of formulæ by which these results could be avoided? One very important phase of the question was that concerning the houses in which the masses of the people lived, and he thought that the means by which the sanitary condition of existing houses could be improved were eminently worthy of the consideration of the Institute. In his own house he had made an experiment which had proved to be very successful. As his hearers would be aware, in the narrow frontages of London houses, particularly if they were ornamental and of stone, it was exceedingly difficult, and sometimes impossible, to make

openings for purposes of ventilation. In the case of his house, he had built a tunnel underneath it from back to front, into which the external air was admitted and filtered, but not warmed, and from which it passed up through what were called "sweeping flues" to the apartments where it was required, and after being warmed in terra-cotta chambers at the back of grates (made by Mr. Rosser), was allowed to pass into the rooms; which were also provided with separate shafts for the extraction of the vitiated air.

Professor Hayter Lewis moved the adjournment of the discussion, and

The Chairman, in putting the motion, said it might be desirable to state that, as regarded the metropolis, the evils to which Captain Galton had referred as arising from the erection of dwellings on unhealthy "made ground," would, it was hoped, be prevented in the future, as the Metropolitan Board of Works had, under a recent Act of Parliament, obtained power to frame and enforce by-laws prohibiting the practice. The thanks of the Institute were due to Mr. Robins for his paper.

The motion was carried, and it was announced that the discussion would probably be resumed on the 17th of January.

It may be added that there was a large attendance of members and visitors.

ROMAN REMAINS IN LEICESTER.

THE JEWRY WALL AND THE ROMAN PAVEMENT.*

THE ancient buildings in Leicester may be broadly divided into two classes, those which have their regularly appointed guardians and custodians, and those which have not; and in the latter class will be found two of the most interesting fragments in the kingdom, the Jewry wall and the Roman pavement. In a recent report of the Museum Committee to the Town Council, it was suggested that the Roman pavement should be removed from its site in Jewry-wall-street. The report states an opinion that the pavement would be seen to greater advantage if it were laid on the floor of the new annexe at the Museum, and that in its present position it is suffering from damp, and is seen by a small number of persons. The answer to these arguments is that they are not proved, and not fully true. The pavement does not and will not suffer from damp, if proper means are taken in its present locality. After lying for 1,700 years it would be strange indeed if it should now suffer from that cause, or if it were not more likely to suffer in a modern building, away from the foundation where the Roman designer and builder originally laid it. It suffers, indeed, but it suffers from neglect in common with every other work of its class in the town of Leicester. It is not well seen, but it would be easy to remove the floor which is now only a few feet above it, so that a visitor could stand upright, and survey it with light and advantage, instead of having to creep upon "all-fours" in a dark cellar.

So far the report. If any other reasons exist for removing the pavement, the onus of proof lies with the movers, and there ought to be no difficulty in stating them. If a pavement, for instance, is wanted to adorn the floor of the annexe, a copy might be placed there. On the other hand, the difficulty of proving a negative is proverbial, and yet there are several apparent reasons for not removing.

1. The impossibility of doing so without injuring the pavement; there is a bloom of age, as well as a bloom of youth; it is as impossible to restore one as the other, and as easy to destroy. The removal of such a work is necessarily a partial destruction even with the greatest care in the operation, and the best luck.

2. There is, as the pavement now lies, an absolute identity of interest between the work itself and the page of history which it illustrates; it is not a mere antique, it is full of interest and instruction for the student, the antiquary, or the historian. Possibly forming part of the atrium or vestibule of the most considerable villa of the Roman town of Ratæ, dating from near the beginning of the Christian era, it is even now fresh in colour and unsurpassed in design by the skill of artist or workman. Was it the house of the Proprætor Suetonius, in whose time the armed hosts of Britain flung themselves to destruction upon the serried phalanx of the 14th legion; or was it later, when the Emperor Hadrian visited his town of Ratæ, or when Severus halted on his way to die at Eboracum? Near it, where now the comparatively modern church of St. Nicholas is to be seen, stood the Forum, adorned with temple and basilica, whose fragments lie scattered about the Museum, and there surely stood the original of that massive fragment of antiquity, the Jewry-wall, which yet remains, fast crumbling away, indeed, under the influence of the elements, a problem still unsolved as to its origin and purpose.

At the commencement of this paper the Jewry-wall was placed first in the list of ancient buildings, and it is probably first in interest, if we may judge by the numerous theories which have been advanced respecting it.

According to Geoffrey of Monmouth, who is believed to have written his British history about A.D. 1140, the town of Leicester was founded by King Lear, who built a temple there 1,000 years before the Christian era, where he and his daughter Cordelia were buried, and the Jewry Wall is supposed by some subsequent writers to be a remnant of that temple.

Mr. Burton's account is as follows:—"That this was a city in the Britons' time, before the coming of the Romans, I should conjecture from the name thereof set down by Nennius in his Catalogue of Cities, viz., Caer Lerion, that is, City upon Leir. That this was a great Roman station the Roman antiquities frequently found here will give strength and confirmation. First, the ancient temple dedicated to Janus, which had a flamen or high-priest resident here, in which place a great store of bones of beasts, which have been sacrificed, have been dug up, and the place is still called the Holy Bones."

Mr. Hollings, in his very able lecture on Roman Leicester, states an opinion that it is a fragment of Roman basilica or of a bath.

Mr. Thompson, in a very ingenious pamphlet, endeavours to show that it was part of the exterior wall and western gateway of the Roman town, and this theory is also stated in Throsby's history of Leicester.

It is no easy problem, therefore, which has baffled the skill of these eminent writers, and given rise to so much difference of opinion. There are four distinct accounts. Can we decide which is the true one, or which approaches nearest the truth?

The first theory is treated by all subsequent writers as apocryphal, but they also agree that we are probably indebted to the story for the play of King Lear, and, therefore, apocryphal or not in its origin, it becomes of considerable interest in forming another link with Henry VIII. and Richard III., between our ancient borough and the works of our greatest writer.

The second theory is more than questionable. It was not a Roman temple; it is at once too large and too massive, and has besides no indication of the adytum, or portico, or other essential parts of a temple. A Roman temple was a comparatively small building on plan, and the Jewry wall is evidently the fragment of a very large one.

The Roman basilica was a regularly designed building, with two stories of columns, not unlike the plan of a mediæval church, omitting the chancel, but with no arched recesses such as we find in the Jewry Wall. It is less easy to show that it was not a bath, but it is unnecessarily massive for such a purpose, and there is no arrangement of plan with tiles, and flues, and earthen pillars, such as we should find, according to Vitruvius, in a Roman bath.

Mr. Thompson's theory does not commend itself any more than the others. He proceeds on the supposition that Ratæ was originally laid out as a regular military encampment, like Eboracum, for instance, whereas, in fact, Leicester (Caer Lerion) was a considerable place before the coming of the Romans, as stated by Mr. Burton already quoted in this paper; and the walls which the Romans erected on the south and east and north were apparently determined in shape and direction so as to include and enlarge the older town, and the builders appear to have relied upon the river on the west, in addition to some defensive works about the site of the Castle and mount, and again about the Jewry Wall, which will be found to occupy the highest ground between the Castle and the west end of the north wall along the river bank. Again, the wall has no indication of a main opening, or any flanking towers, and there are no similar remains about the well-known sites of the other three Roman gateways, and no continuous indications along the supposed site of the western wall.

Are we, then, to fall back for explanation upon the story of King Lear? Are we to see the Jewry Wall as Geoffrey of Monmouth saw it, and as Shakespeare saw it? In the absence of any reasonable account of its Roman origin, we may prefer the twilight of fable to the darkness of error, and assign it to early British times, admitting that it was, very probably, adopted and adapted to military uses by the Roman Conquerors.

And in any case, we may admit that the ancient monuments of Leicester are sufficiently interesting to justify our guarding them with every possible care; and we may conclude that we ought to find the properly qualified guardians in the ranks of this society. Possessing on the one hand an authoritative connection with the Town Council, and on the other claiming assistance from all the available literary, and artistic, and practical skill in the town, it would, indeed, be remarkable if we should, in the words of Mr. Hollings, "while enriched by objects of interest sufficient to distinguish us from most other towns in the Empire, acquire the not very enviable distinction of being the least able to appreciate their possession."

* From a paper by Mr. W. Jackson, architect, read in the Archæological Section of the Leicester Literary Society.

NATIONAL ART MUSEUMS FOR THE PROVINCES.

THE success that has attended the system by which the South Kensington Museum has for some years past been enabled to send to the provinces well-chosen "loan collections," has not unjustly been regarded in the Department of Science and Art as a satisfactory symptom of the interest, rudimentary as it may be, expressed throughout the country in the efforts that are being made to spread a more practical acquaintance with the meaning and object of art,—that term now so widely used, but still so ill understood. That the first phase of this interest should have shown itself in the encouragement of a *dilettante* taste is little calculated to surprise; it was, indeed, the natural consequence of a movement that more immediately appealed to the cultivated classes. It is now a necessity for those in authority to lead this widely-expressed interest into more practical channels; this need has been felt, and the means alone remain to be studied as to the best mode of proceeding.

When Mr. Mundella some months since, as will be remembered, was appealed to for aid in the extension of the loan system of the South Kensington Museum to the National Gallery collection, he expressed a belief that the undoubted impetus given by this means in the provinces would be even further increased by the union of the whole system under a responsible Minister, whose sole duty should consist in the supervision and fostering of the art interests of the community throughout the country. We have before now expressed the same opinion. The manifold interests of art, far more extended than is generally believed, would be peculiarly benefited by a wholesomely-exercised protection and nurture that it has long since been considered necessary to extend to the great commercial interests of the country through the Board of Trade. A conclusion so natural requires, indeed, merely time to work out.

Our present purpose is to speak of the art collections that are so necessary in the provinces, and which are so unhappily termed "provincial" art museums. Let us consider these museums, and let them consider themselves, as worthy to be national institutions, each a factor in the general sum of the nation's success and fame. The great collections on the Continent, in the provinces,—we have in mind particularly at this moment the museums throughout Germany,—are all mostly "National" collections; at Munich, the "National Bavarian Museum"; at Nuremberg, the famous collection not unfitly termed the "German Museum"; and many others that might be prominently adduced. Here is a first duty and a first pride to make our so-called "provincial museums" national institutions which shall show, each by its effect on the particular part of the country in which it is placed, the value of such institutions, not as mere exhibitions, but as effective means of educating the producing classes. These it is that must be reached and beneficially affected, and the means for most effectually attaining this end are those that must be studied.

In a recent issue of the *Examiner*, in the course of an article on the subject of provincial art museums, the writer remarks, "We have

been striving for twenty years, hy meane of State aid and costly machinery, to encourage art in England, and to arouse and intensify that natnral æsthetic feeling which undeniably ie in the people." Theee efforte have nndonhtedly met with enccess; hut may it not he asked, has thie enccese heen in any degree commenenrate with the really enormous outlay of thongbt and money that hae been expended on the enhject? We may reet assured, however, with the comfortable,—or rather, perhaps, nncomfortable,—certainty that England has not heen the eole gainer hy our labonre, and that other countries not difficult to point out have largely profited not only hy the intellectnal expenditnre that has heeu bestowed on, but hy the large outlay of capital that has heen exercised in, the pnrsuit of the develop. ment of practical art-cnlture. It has long heen a recognised opinion that in the liberal State aid that hae been afforded to our important educational establishment at South Kensington, other parte of England were not sufficiently gainers hy ite at one time exclusive management for the benefit of Londoners, and the recently-introduced system of lending objects to provincial mnseume at once met with nnivereal approhation; hut complainte have been made, and not without reason, and proper donhts have been expressed, as to the real practical advantages that local mnseums have thns gained. The temporary nature of these exhibitions has always heen a principal drawback to their utility, while the want of intelligent claesification hae reduced the instructive nature of the collection, already imperfect, to a minimnm; we may, in fact, rest assured that as long as museume remain what are nnderstood as "mnseums," very little more than idle curiosity and the suspiciously eterile tastes of a few *dilettanti* will be fostered. What bas heen undonhtedly, it is impossihle to deny, the endeavour of our Science and Art Department, ie to render the museme under ite charge eesentially inetrnctive: it remains to question whether the meane adopted are not eomewhat open to criticism.

We live in an age when the fierce light of criticism is thrown npon nearly every enhject. Here ie a qnestion of something more than ordinary importance, relating to what we are daily learning to discover forms one of the vital elemente of the conntry'e prosperity. A false pride, or a desire to conceal or a hesitation to admit imperfections, mnst not he enconraged. Our South Kensington Museum, the parent establishment, has not been itself exempt from criticism, and nngrateful indeed as it may appear to find fault with an institntion where, with each lahour, have been brought together such an accumulation of treasures, it is not difficult for those who have some little experience of collections abroad to point ont where the South Kensington Mnseum ie deficient as a eystematic teacher of the altogether uninformed,—of that nnmerone clase the artisans, the real hard-working prodncers, whose condition and whoee usefnlness, and whose share in the advance of the nation's prosperity, and hence whoso happiness, we are all sincerely desirone to promote.

Many years before any thonght wae given to the formation of what we have so long known as the South Kensington Mnseum, the anthorities of our long-revered British Museum in Great Russell-street fnlly recognised the importance of classification in the arrangement of their treasures, and the learned and hard-working directors of that great institntion have done much to aid those who are desirous to acquire a knowledge of the principal divisione or periode of antique art, eo that the Britisb Mnseum hae become a complete book of reference for the etudent of classic art and archæology.

Very early in the existence of the South Kensington Mneeum, it mnst have ocnrred to ite managers that their establishment wonld never he complete till a perfect classification of all their objects conld he secnred; and when, in 1867, the managers, who in that year were so conspicuous at Paris, traversed day hy day the *histoire de travail* at the Exhibition, they mnst have felt that until the South Kensington Museum could show a eystematic arrangement like that, they could not lay claim to feel anything like eatisfaction with their work; and donhtless they have alone heen prevented from carrying out snch an arrangement hy the embarraeement connected with the loan part of their ehow, and hy the difficulty of separating the varione propertiee and placing them in their reepective order. Until some system is in vigonr the Sonth Kensington Mnseum will continue to be, with all its wealth, but a very imperfect teacher.

It is hy a watchfal attention to thie feature of classification that the mnsenms in the provincee may become ae valuahle from an edncational, if not from an intrinsic point of view, ae the parent establishment in the metropolis, and the examplee afforded in many inetancee that snggest themeelvee strikingly prove the truth of thie statement. Commenced on a well-ordered system, which it ehonld he the duty of experienced anthoritiee to lay down, it wonld he difficult for any confusion to take place. In the commencement lies, indeed, the chief point, as the Sonth Kensington authoritiee know only too well; objects ponring in from every quarter, —twenty-three yeare have sufficed to gather together the wonderful collection,—order and classification have become to an extreme difficnlt, and the embarrassment felt hy the directors can be understood hy all who have endeavoured to arrange in any order an accumulation of objects or of facts.

The clasification chosen and laid down,—a chronological order carried out ae far ae poesible in each great hranch of indnstry,—the objects, on their arrival, arrange themselvee as do in a well-ordered library the nnmerons hooke that are daily received, and which, witbont system, would soon end by becoming hnt an inextricable mass of printed paper. A mnsenm ehonld, indeed, be a book of reference, ae easily nsed ae the enclyclopædia or the dictionary. Of what practical nse could we imagine those to be were they arranged as are at present the greater part of the mneeume we all have visited? The peonliar valne of each a clasification needs alone to he seen to be nnderstood and appreciated. When the objects are thne arranged, each telle ite history with a peculiar emphacie that ie eminently calculated to interact, and the gradual development, the advance or decline, of any branch of industry or art can he etndied with profit.

That such museume well classified could be arranged in the provinces is proved by the existence of more than one estahliehed on this principle abroad, and of which the technical museme of Limoges and Lyone,—the former with ite admirable collection of epecimene of the enameller'e art, the latter with its ehow of the active weaver'e industry of the pact,—form etriking and familiar examples. It should undoubtedly he the endeavour more particularly of each town to posesss a technical museum in which the chief local indnstry ehould be specially represented, a featnre wbich need in no way interfere with the completion in other points of the collection. Before long, with the admirable system of exchange of casts, and hy the aid of galvano-plastic copies and the photograph, we may look forward to the time when the smallest mnsenm will he ahle to own an excellent working collectiou of well-ohoeen objects illustrative of the great art industries of the past. By an enconragement of the system of presentation on the part of rich citizens, which, in the provincial museume of the Continent, forms so admirable a feature; by a wide extension of the excellent system of lectnree wbich now for so many years hae been practised at the Sonth Kensington Mneeum, and which, in the provincee, might and ehould he delivered by the curator; and with our art echools and our technical schools in full working order, the mnsenms ehonld play an important part in education, and he indispensable alike to profeesore and pupils.*

In the provincee, where in thie direction all remains yet to he arranged, a method could he laid down, and, once laid down, wonld he easy to follow; commenced faultlty, and the future difficultiee will only become daily more and more obstructive. The provinces build up a nation's taste, a nation's wealth; the capital is but a nation's pride, and, above all, it aspires to lead; we are, however, firmly convinced that here lies a matter in which the provincee might with proper oare read a not unprofitable lesson to the metropolie. Let them not split on the rock of mere imitation, or else, taking the subject more eepecially under conoideration, their mnseume may well feel insignificant beside the great parent estahlishment in the capital. A provincial town might possees, hy due attention to the necessities of the oase, dependent on local industries, a museum of infinitely more practical valne, which ehonld contain bnt one-thousandth part of the treasuree which any of the famed collectione of the world at preeent possese. Such museume exist, and nnlese they are more largely spread in England we ehall snffer in the race in which our competitore already have over us more than one unnsual advantage.

Our appeal is, then, for the estahlishment of national museume in the provinces,—musenms the contents of which ehall be intelligently classified in such a manner ae not to form what museums have always been till recently, and what they too often still remain,—mere collectione of objecte vaguely denominated by an indifferent public as "ancient" or "old,"—but collections which shall serve ae valuable means of instruction, and which will in thie manner in no way lose their interest as placee of amneement, or as jnst objecte of national pride. On the contrary, collectione eo arranged wonld afford in a far more satisfactory and complete manner than at present the means of comparison. Strangers and foreignere wonld be ahle rapidly to see in what featuree each collection excelled, in what objecte it was richest; intending donore wonld observe in what essential the local museum was wanting, and in time succesive curators might not nnfairly aspire to attaining the limit of perfection in the order and arrangement of the collection under their care. Museume thue arranged wonld form, indeed, part not alone of the local, bnt of the national wealth, and ae such would afford ample ground for national pride. But at preeent, ae our eo-called "provincial musenms" exiet, the best of them etand hut eorry comparison with the great collectione of the capital.

It is a long time before one learns to visit a museum; indeed, it is an art tbat many never acqnire. It ie alone when we have determined to stndy during a certain time one branch of art or indnstry that we can hope to really profit hy frequently passing any time in an nnclassified mnseum, and then what self-control does it not reqnire, in one'e eearch after that one etudy, to pass by marvele of patient heautiful work, and how often, indeed, is one tempted from one's path? That the mere examination of rare objects heaped together, regardleee of clacsification, age, country, or relative merit, ie a eomewhat idle pnrsuit, calculated with too many to merely pass away the time, and with too many others to gratify a mere *dilettante* taste, it ie impossible to deny; and though it may he nrged tbat there are many who are able to profit eveu hy the examination of objecte of art thus arranged, it is not for each alone that our great collections are open. Our museums must become more directly instrnctors of the productive classes,—schools where every possible facility ie afforded, where etudy may he encouraged with the merest tyro, where no one need he rebuffed or intimidated by the apparent difficulty of the task before him. That our echools ehould lead us up to a certain point in this education is a consummation most devontly to be wished, but that is a hope that must be left to the near futnre to put into execution.

When our mnseums are eo arranged that the architect, the sculptor, tbe painter, the modellor, the wood-carver, the iron-worker, the worker in metal generally, the goldemith, the jeweller, the leather-worker, and workers in all the branches of indnstry whoee existence ie so dependent on art inspiration, can with ease refer each to the separately and chronologically arranged epecimene of his own particular art,—when well-written handbooks or catalogues, which ehonld be the same (this ie a want that the British Museum and the South Kensington Mnseum have already well eupplied), are at the disposition of thoee desirous to enter more clearly into the development of the art in wbich they are interested,—then we may hope to obtain from them the real advantages they can he made to afford.

* The collections sent on loan have always given the South Kensington Museum authorities some trouble, owing to the unwillingness on the part of collectors generally to have their objects separated. Might not, as such is so often the case, all exhibits on loan be shown in a special room or court, where they would not interfere with the classification of the rest o' the collection?

Noxioua Vapours.—On the 25th ult., an influential deputation from the Lancashire and Cheshire Aeeociation for controlling the escape of noxious vapoure and fluids from manufactories had an interview with the Right Hon. J. G. Dodson and Mr. Hibbert, M.P., at the Office of the Local Government Board, Whitehall, to nrge npon Government the expediency of dealing with the subject of noxioue vapoure in the enenirg eeeeion of Parliament.

INJURIES BY GAS AND DEFECTIVE GAS FITTINGS.

SOMETIMES when persons are injured it is impossible to fail in stating on whom the liability rests, and the amount of loss which has been incurred. In those cases in which there is any doubt, a legal judgment which in any way goes to promote certainty is an event upon which we may congratulate ourselves. It is for this reason that the recent case of Parry *v.* Smith (4 Law Reports, Common Pleas Division, 235) deserves notice. And the proposition which this case seems to us to lay down is that any one who uses or deals with a dangerous thing is liable for injuries caused by it, even if there is no contract existing between the injurer and the injured. This, therefore, is at once different, and yet like those cases in which a public right exists, and in which it is the duty of persons to prevent that public right from being infringed; as, for instance, if a person hangs a lamp over his doorway, and it falls and injures a passer-by, when he must be prepared to indemnify the passenger for injuries that have been incurred by him. The facts in the case to which we have referred were proved without much doubt. The defendant had been employed to repair a gas-meter in a cellar on premises where the plaintiff was a servant. The meter was taken away for repairs, and replaced by a temporary connexion consisting of a flexible tube, which was pushed into the inlet pipe and the other end into the pipe which communicated with the house. During the time that this temporary connexion was in operation, the plaintiff in the course of his employment went into the cellar in question with a lighted candle. Directly he opened the door an explosion took place, by which he was seriously injured, and consequently the cause of an action at law was produced. It was decided by the jury that the gasfitter had been negligent, but it was contended on his behalf that no right of action existed because no privity of contract, as it is legally termed, existed between the injured and the injurer, because what had been done did not amount to a public nuisance, and because there had been no fraud, misrepresentation, or concealment on the part of the gasfitter. The question raised is one, therefore, of obvious importance, considering the extent to which gas is now used in all modern buildings. And we may say at once that Mr. Justice Lopes, before whom the case was tried, decided, after a careful argument, that the gasfitter was liable to indemnify the injured man, on the ground that a duty attaches in every case where a person is using or dealing with a dangerous thing, which, unless managed with the greatest care, is calculated to cause injury to by-standers. Therefore, as long as this decision remains unchallenged, it is clear that work which has been done to gas communications may bring liability with it, not only as between the house-owner and the gasfitter, but also as between the gasfitter and any one who may have occasion to be near the place where the gas is. We say "as long as this case remains unchallenged," because it is, as Mr. Justice Lopes pointed out, the only one which at present bears directly on this particular point, so that it is quite within the bounds of probability that hereafter a similar case may arise before another tribunal and may be decided differently. At the same time it is well here to mention another point which is not unlikely to arise in such cases as the one upon which we are now commenting, and that is that when a general contractor undertakes to do work, and he makes a sub-contract, as is so often done in practice, with a regular gasfitter, then the gasfitter and not the contractor will be the person by whom any liability for injuries caused by bad gas-fittings or similar negligence must be borne. This is, of course, what may be termed a side point, but it is one of the first importance when we come to consider upon whom rests the liability for such accidents as we have mentioned. In a case which occurred some forty years ago, in which gas exploded in a club and injured the butler, this very point was raised, and it was decided that Mr. Cubitt (the case was that of Rapson *v.* Cubitt, 9 Meeson & Welsby, p. 710) was not liable, but that the injury was caused by the sub-contractor, to whom the butler would have to look for redress.

Again, it is necessary to observe that the law at present must, when no contract and no public duty are violated, be considered as limited as regards this question of injuries to things which are dangerous in their nature. For in the case of Collis *v.* Selden (3 Law Reports, Common Pleas, p. 495), it was decided that a man who carelessly hung a chandelier in a public-house was not liable for injuries which it caused to a man by falling upon him. Here no public right was violated, and no contract or privity existed between the plaintiff and defendant, nor was the thing which did the injury one dangerous in its character. Of course, if the man had been injured whilst the workman was actually employed on the work, the case would have been different, because we need hardly say that negligence by a workman, which causes injury to a man, makes that workman or his employer liable to the person who has been injured. To pursue this subject of injuries into greater detail, it would be necessary to enter into a technical legal discussion, which, though of interest to lawyers and jurists, would hardly gratify the readers of the *Builder*. Our object in the foregoing remarks has been to point out the liability which attaches to those who may use or be employed upon dangerous materials, and especially, as the case of Parry *v.* Smith shows, to those who have to do with gas and gas-fittings in buildings.

OBITUARY.

Mr. Mark Firth, whose munificence has done so much for Sheffield, died on Sunday last. His first gift of any magnitude was 1,000*l.*, which he added to a legacy of 5,000*l.*, left by his brother Thomas for the erection of a college for the training of young men for the Methodist New Connexion ministry. In 1869 he erected Mark Firth's Almshouses at Ranmoor, near his own residence, at a cost of 30,000*l.* His next munificent act was the gift of Firth's Park to the town; he purchased the Page Hall estate for 29,000*l.*, and set apart thirty-six acres for the benefit of the people of Sheffield. The park was opened by the Prince of Wales. The foundation of Firth's College, in Sheffield, opened by Prince Leopold in October of last year, will be fresh in the recollection of our readers. The college, which forms a prominent part of a pile of imposing educational buildings in the centre of the town, was erected and fitted by Mr. Firth at a cost of 20,000*l.* The endowment fund now amounts to 20,000*l.*

FROM ABROAD.

A PUSCHKINE Exhibition has been opened in St. Petersburg in the rooms of the Society for the Encouragement of Artists. Upon entering are observed the portraits of the poet and his wife, as well as busts and autographs. After the portraits came a long series of landscapes, whose subjects were inspired by the works of Puschkine, engravings serving to illustrate his works, a drawing of the recently erected monument to the poet (illustrated in our issue of Oct. 2nd), drawings of the house he inhabited, and of the localities which were dear to him. Autographs occupy an important place in the exhibition. There are also shown historical notices written by Puschkine on the occasion of his stay at Kischinew in 1822, several sketches in crayon by him, complete editions of all his works, and translations of them into all the languages of Europe. There are besides, a considerable number of musical compositions. Amongst the objects having belonged to the poet are the rapier which he bore on the day of his duel, his cane, a lock of hair with an inscription of M. Tourgnéniew, stating that the hair was cut off in his presence after the death of the poet, and a ring which had been presented to him by Princess Yorontsow. The Imperial Lycée has enriched the exhibition with many *souvenirs* of the youth of its illustrious pupil.

The International Congress upon Industrial Copyright, which has been assembled in Paris for the last month, has recently held its last sitting. The proposal that international patents should be granted for industrial inventions, trade marks, &c., has been unanimously adopted. Twenty-three States were represented at the conference, Germany and Spain being the only European powers which did not send delegates. They have both, however, expressed their willingness and desire to be represented at the next congress upon this question.

The *London Gazette* contains an order in Council with regard to the new treaty between England and Spain upon the same subject. By this treaty the authors, inventors, designers, engravers, and makers of the following works,—that is to say, books, dramatic works, musical compositions, drawings, paintings, sculpture, engravings, lithographs, and any other works of literature and the fine arts in which the laws of Great Britain give to the British subject the privilege of copyright,—shall, as respects works first published within the kingdom of Spain, have the privilege of copyright therein for a period equal to the term of copyright which authors, &c., of works first published in the United Kingdom are by law entitled to, provided the works referred to have been registered, and copies thereof shall have been delivered according to the requirements of the Acts (passed in the 7th-8th, and the 15th-16th years of the present reign), within three months after the first publication in any part of the kingdom of Spain; or, if such works be published in parts, then within three months of the publication of the last part thereof.

ARCHITECTS AND BILLS OF QUANTITIES.

THE following minute has been issued by the Council of the Royal Institute of British Architects:—

"*Sharing Commissions with Quantity Surveyors.*—It having recently been stated to the Council of the Royal Institute of British Architects that the charges made by quantity surveyors are sometimes shared by the architect, and such a practice, if it really exist, being open to great and obvious objection, the Council hereby publicly declare that, for the future, such practice, if proved, will be deemed conduct which, in the opinion of the Council, is derogatory to the professional character of any Fellow or any Associate of the Institute."

ARCHITECTURAL UNION COMPANY (LIMITED).

THE report of the directors (Messrs. David Brandon, Arthur Cates, James Edmeston, Joseph Jennings, T. Hayter Lewis, and Sancton Wood) submitted at the twenty-third ordinary general meeting of shareholders, held at their premises, No. 9, Conduit-street, on Wednesday afternoon last, contained the following passages:—

"In the report of last year, the shareholders were informed that the lease of the ground-floor and basement would expire at Christmas last, the rent for the whole then occupied being 225*l.* per annum. The directors are now able to report that the shop, with the front part of the basement only, has been re-let from Christmas last, on lease for twenty-one years to Messrs. Hutchins & Romer, at a rental of 175*l.* per annum.

"The arbitration-room mentioned in the last report (with the two consultation-rooms), has been completed, but the directors regret that, at present, it has hardly been used at all for the purposes intended. It is to be hoped that there will be an improvement in this respect, as otherwise they will be obliged, in the interest of the shareholders, to let it for some business purpose, which they desired to avoid when the alterations were made.

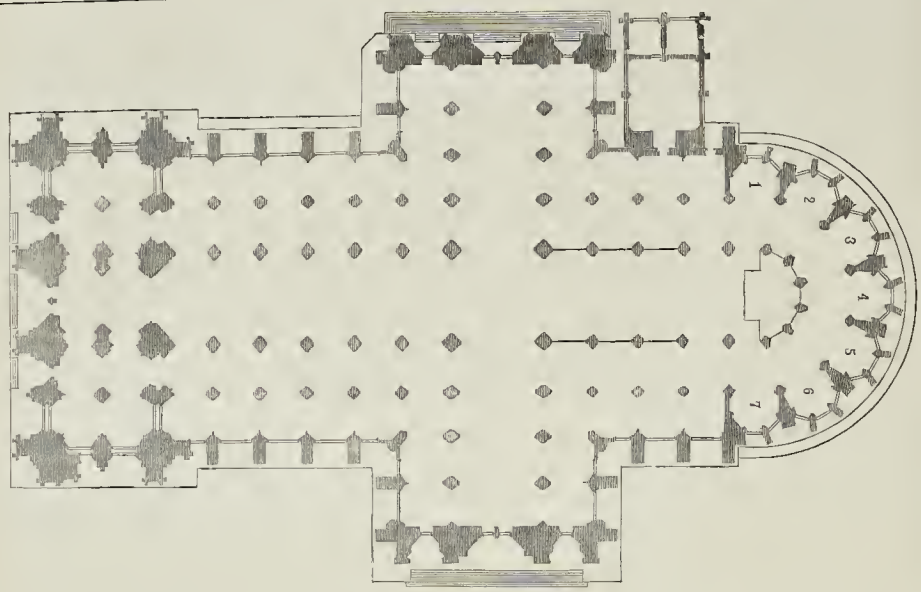
"The directors are glad to say that in the re-arrangement of the lettings which has taken place to meet the wishes of the leasehold tenants, no loss of rent has been incurred, but that the present rental is in excess of what has been hitherto obtained, without taking into account anything to be received for the arbitration-room, which will certainly yield a very handsome interest on what has been expended in the improvements.

"The renewal lease of the company's premises has been duly executed by the City of London."

The report was adopted. The following directors retired by rotation, viz.:—Messrs. James Edmeston and Sancton Wood, but they were re-elected; and Messrs. Geo. J. J. Mair and Wyatt Papworth were re-elected auditors.

On the recommendation of the directors, a dividend of 12*s.* per share, free of income-tax, was declared.

Mr. and Mrs. German Reed's Entertainment will close after Saturday, December 18th, and re-open on Boxing-day at three and eight. "The Turquoise Ring" will be temporarily withdrawn, and an entirely new holiday programme will be given on Boxing-day at three. Full particulars will be duly announced.



[*Scale about* 75 *ft. to* 1 *in.*

PLAN OF COLOGNE CATHEDRAL.

COLOGNE CATHEDRAL: THE INTERIOR AND ITS FURNITURE.

As a further instalment of the illustrations, which we promised our readers, of Cologne Cathedral, we publish this week a large interior view drawn by a German artist, which will convey the general impression of the interior of this vast and noble church. The great height and grand arrangement of the aisles of the nave are well shown from the point of view selected. The whole of the building is seen at a glance, except the two western bays, between the great towers. The variations in design between the earlier choir and the more florid nave are also distinguishable. These chiefly consist of the enrichments over the pier arches, composed of crockets and finials, and the foliated cornice below the triforium. The vaultings of the nave and its aisles differ also from those of the choir, as in the former the soffits between the vaulting-ribs are more convex, conveying rather the impression of a return to domical vaulting.

Although the nave of Cologne Cathedral possesses double aisles, yet there can be no doubt that the outer aisles were intended to be subdivided into chapels by light screens. This is obvious from the large aumbries (one of which occurs in each bay), intended to hold the vessels appertaining to the altars of the various chapels. Whether it is in contemplation to carry out the original design in this respect we are uninformed, and probably the matter is not yet settled; the nave seems to require furniture of some kind or other, as at present it looks rather bare.

It may not be out of place here to say a few words, from our own notes made on the spot, upon the furniture and fittings at present existing in the cathedral, which have not received so much notice as they really deserve, and are frequently overlooked by those who visit the church.

To commence with the high altar. This is partly ancient fourteenth-century work and partly Renaissance work of the seventeenth century. To the former period belongs the magnificent carved-marble frontal of the altar, adorned with thirteen foliated and canopied niches, twelve of which are occupied with statues of the Apostles, and the centre by a representation of the Coronation of the Virgin. It has been suggested that this was originally a "retable" or reredos, but we see no reason for supposing that it ever occupied any other position than that which it does at present, especially as altar-frontals adorned with niches and statuary are to be seen elsewhere in Germany and France; instances occur at Marburg, Erfurth, and at Folgoat. The Renaissance tabernacle and wings to the altar are fine in their way, but out of keeping, and the same may be said of the metal screens, two side-altars in the choir, and cantor's desks. However, these ought not to be removed, as they help to hand down the history of the building to our time, and have a certain amount of merit, and we cannot help saying that, although in a poor style of art, they are vastly superior to the modern "would-be Gothic" of the altar under the crossing, which is a positive disfigurement to the church, and it is a pity that, if an altar in this situation is required, it is not made movable.

The choir-stalls are remarkably fine, and look singularly early in character. They probably, however, do not date before the middle of the fourteenth century. They have no canopies, and the inner sides of the stone screens are concealed by tapestries designed by Dr. Bock, behind which are the remains of ancient frescoes. The outer sides of these screens are adorned with rich tracery patterns, bearing considerable remains of ancient coloured decoration.

The north outer choir aisle contains an altar of the Renaissance period, over which is a Byzantine crucifix, which probably belonged to the former cathedral, and a wall-painting of the Crucifixion (fourteenth century). Between the columns dividing this from the inner aisle is a very fine fourteenth-century monument, bearing the recumbent figure of a bishop. Above this is a beautifully-painted beam, bearing a series of sockets for votive candles, and some elegant iron scroll-work (fourteenth century).

The first apsidal chapel, marked No. 1 on our plan, contains a good double aumbry, a Late Renaissance font of marble, and a fine Early Renaissance monument to Prince-Archbishop Schwartzenberg, A.D. 1561. The altar of this chapel has a very pretty silk antependium.

The screen which separates this and all the other apsidal chapels from the aisle is fifteenth-century work. The lower portion is composed of pierced stone tracery, and the upper part of a very simple iron grille with a foliated brattishing; the grille is painted vermilion and the brattishing gilt.

The second chapel has an interesting fifteenth or sixteenth-century tryptych of wood, painted; over its altar, and in the centre of the chapel, is the very remarkable monument to Archbishop Philip von Heinsberg (d. 1191). The present monument, however, dates from the fourteenth century; it is surrounded with little embattled towers, emblematical of the fact that he erected the town walls. One of the old plans for the cathedral façade is to be seen in this chapel. The third chapel contains a magnificent triptych altar-piece of the fifteenth century, richly painted and gilt, and the ancient plan of the western towers found at Darmstadt. Also the fine altar-tomb of Bishop Conrad von Höchstetten, the founder of the present cathedral.

The fourth chapel (see plan) was formerly occupied by the shrine of the three kings.

The fifth chapel contains the magnificent "Dombild," a superb triptych picture, representing the patron saints of the chief churches in Cologne. The painter is unknown, but the picture bears the following letters upon its wings:—"M. N. O. X."* Whether this was the name of the painter, "M. Nox," or whether they were his initials, is uncertain. The date of this splendid work is supposed to be about 1426. There is a curious altar-tomb or shrine, with a wooden top or lid in the centre of the chapel.

The sixth chapel contains an ancient carved triptych altar-piece, with a representation of St. George and the Dragon, and a fine altar-tomb of white marble of the fifteenth century.

The seventh chapel contains a carved and painted altar-piece of the sixteenth century, a fine double piscina, and an altar-tomb with a slab inlaid with mosaic (fourteenth century). The south choir aisle contains two magnificent altar-tombs, one defended by a hearse or grille, and a modern Gothic altar with a fresco by Overbeck.

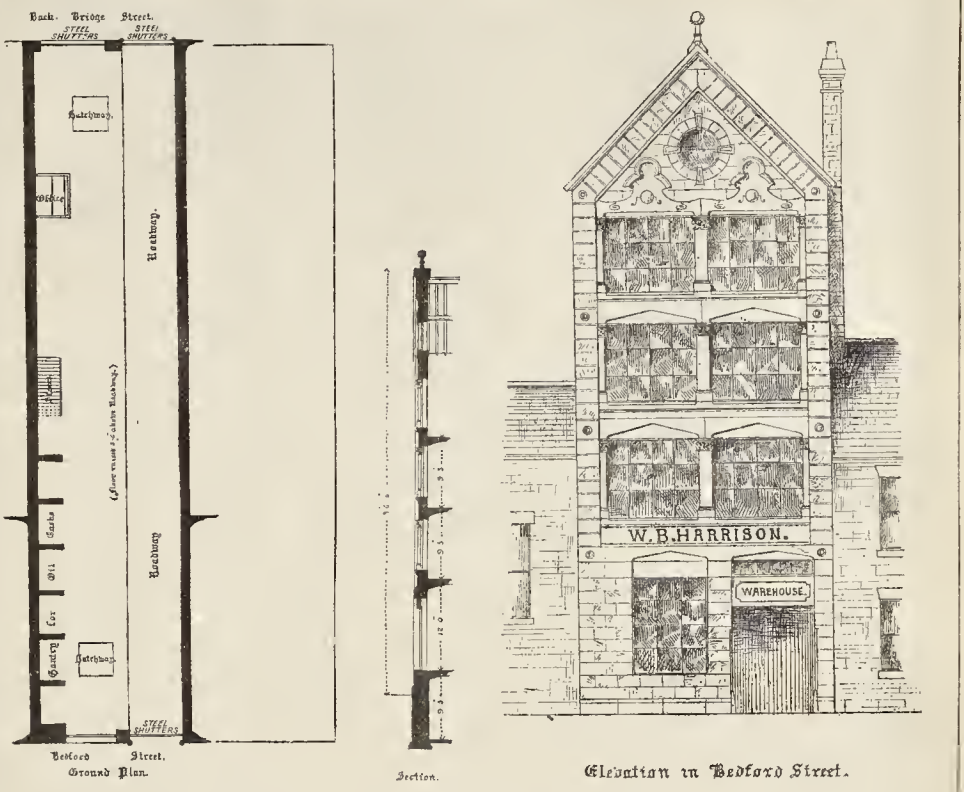
In the east aisle of the south transept is the very splendid altar of St. Agololphus, a richly-carved and panelled triptych, about 30 ft. high, adorned with pictures, statues, and very complicated canopy work.

The sacristy contains an ancient stone altar and a "Sacramentshaus," or tabernacle, of stone, adorned with rich canopy work.

* Whether a careful examination would result in the discovery of other letters, the whole forming an inscription, is a question. De Lassaulx thinks the letters form the name of the painter.

INT

IOR OF COLOGNE CATHEDRAL: LOOKING EAST.



A WAREHOUSE IN SUNDERLAND.—MESSRS. TILLMANN, ARCHITECTS.

WAREHOUSE, SUNDERLAND.

THIS warehouse is situated in Bedford-street, is four stories in height, and extends from that street to Back Bridge-street; it measures about 21 ft. 6 in. in width and 93 ft. long. The arrangement has been carefully considered to meet the requirements of Mr. W. B. Harrison, the proprietor, an oil merchant. The front is of polished ashlar stonework. All the walls are built of brick. The floors are constructed of wrought-iron girders, between which are laid concrete arches. The basement floor is 6 ft. below the street-level, and forms very extensive cellarage. The lavatories for the men are on this floor. On the ground-floor is a roadway, running from street to street, paved with wooden blocks. A loading and discharging platform is fixed at the height of a rolley above the roadway. The space between the platform and roadway being left open provides the cellars with a very efficient means of ventilation. On the platform there is a row of large oil-tanks, 40 ft. long, with a heating apparatus (by Messrs. M'Kenzie & Moncur, of Edinburgh) fixed underneath, to prevent the oil freezing in winter. An office is fixed at one end of the building, where also are weigh-machines, &c. Above the roadway there is a gallery suspended from the first floor, thus saving the space used by the roadway. All the entrances are closed by patent self-coiling steel shutters. The windows are made of wrought-iron strongly put together, with the centre portion to open and shut for ventilation, and glazed with rough plate-glass. The top story, in addition to being lighted by the windows at back and front, has continuous skylights on both sides of the roof, running the full length of the building. At each end of the building there are hatchways for lifting goods from one floor to another. The lifting apparatus is worked by a silent "Otto" gas-engine, which is fixed on the top floor.

The contractor for the whole of the works was Mr. Mark Howarth, of Sunderland. The building was designed by, and carried out under the superintendence of, Messrs. J. & T. Tillman, architects, of Bridge-street, in that town.

BARRY'S PICTURES AT THE SOCIETY OF ARTS.

AFTER Mr. Comyns Carr's lecture, "On the Influence of Barry upon English Art," a quotation from which was given in our last number,

The Chairman (Sir Henry Cole), said he should be glad to say a word or two, to illustrate a few of the most important points which Mr. Carr had brought forward, before a vote of thanks to him was proposed. The comparative failure of Barry had been ascribed to the temper of the times in which he lived. Now, it had been his (the chairman's) lot to see most of the European galleries, and the impression made upon him by Barry's pictures was that they were, at any rate, as good as any class of pictures of the same time to be found in any of the great European galleries. He could not call to mind in the Louvre or the Luxembourg, where the French painters of the period were represented, any paintings which could be considered as good or better. He recollected some stiff-looking pictures by David; and, without saying that Barry's were perfect, he certainly thought they were equal to anything to be found in the French school. There were none in the German school of that time so good; the Italian school was as weak as water, and the Flemish was open to the same kind of criticism. It used to be very much the fashion to decry the English school, and within his own recollection the French doubted whether there was any English school at all until 1855, when we, for the first time, sent pictures to France; and then they awakened in a sort of wonder to the fact that we could show pictures like Landseer's, Mulready's, Leslie's, and others. They even went so far as to say that if Mulready's paintings were put up to auction in Paris, they would fetch as high a price as any by French artists. But looking at what the times were in which Barry lived, what could be expected? At that time we were plunging into the American War; how could painting be encouraged when the people were taken up with thoughts of how they could fight with their relatives across the Atlantic? A little later, and we had the French Revolution, and the political men of those days thought it wise to spend four or five millions in trying to put it down. How could you have paintings in such a time? Then came a series of Irish rebellions; and then Napoleon, with his perpetual wars, and our enormous expenditure to put him down. We had a clause in the treaty of Vienna that no Napoleon should ever sit on the throne of France, and yet he had seen the Queen of England and her Consort in Paris embracing one of the same family, as was the fashion amongst monarchs. He thought, therefore, the art of the times was very much influenced by other things besides art. In the first place, the artist must live; and if he believed in another world, he must paint according to his ideas of that world. At the present time domestic life in England was the dearest thing we had, and almost all our pictures were, more or less, illustrations of that domestic life. He maintained that our art was quite as good as French, German, or Belgian art, and a great deal better than the Italian. Mr. Carr had referred to the difficulties Barry met with in regard to painting St. Paul's; but that was not

an experience peculiar to him. After the Prince of Wales recovered from his illness, and went to St. Paul's to return thanks, the members of the Society subscribed 300*l.* or 400*l.* to put up a memorial window. They got permission of the Dean and Chapter, obtained a design, and thought the window was going to be put up. Then there came a curious set of arrangements for decorating the cathedral, and stopped its adoption. The design of their window represented a miracle above, as the principal subject, and portraits of the Prince and Queen below; but the artist who was entrusted with the grander scheme said that did not suit him at all; he wanted a bigger miracle than their artist had chosen, and from that day to this they had never been able to move a step. There was a force in the Church which could not be overcome, and Barry met with the same kind of difficulty. There was one feature in Barry's paintings which struck him as throwing light on painters' work in general, and particularly Mulready's, and that was the great, earnest sincerity with which he did his best. Almost the last words he heard Mulready utter were these, "If you want to be a painter, you must not spare elbow-grease; it is as hard work as anything people have to work for." Miss Amelia B. Edwards, in her admirable novel, "Lord Brackenbury," expressed the same idea in these words:—"Art tolerates no divided duty. A man must give his whole soul to it,—his whole time, his whole powers of observation, of memory, of comparison, of study. Even so the thing he does must always fall short of the thing he had hoped to do. The greatest painters who ever lived spent their lives, we may be certain, in the vain pursuit of an unattainable ideal. But, at all events, they did so spend their lives. They worked at least as hard as if they had been masons, plumbers, or joiners." He thought those were words which Mr. Carr himself might have used.

Mr. Hyde Clark said they must all desire to thank Mr. Carr for the eloquent address he had delivered, and not less to thank the chairman for his remarks. Perhaps, at one portion of the paper, they might have had the idea that Mr. Carr was underrating Barry in relation to his circumstances and his age, but in the end they must have arrived at the conclusion that he appreciated the artist and his efforts as much as any one. The question put was, Did Barry labour in vain; and did the Society labour in vain in associating itself with Barry in these efforts? It seemed to him that Mr. Carr had, to a great extent, answered that question, and that the chairman had fully justified the action taken by the Society 100 years ago. It was a long time to look back to, but Mr. Carr had found means to connect their interest even with that remote period. The interesting passage in which he gave the introduction of Martin Archer Shee to the author of the works around that room brought them into connexion with the men of the present day, and the reference to Sir Martin Shee seemed, to a certain extent, to answer the earlier question of the lecturer. He said there was a strange contrast between the two men, and, at that moment, he seemed to indicate a doubt whether Barry had succeeded or failed, and to suggest that he had failed, while Shee had succeeded. Those who had been in Shee's painting-room in the later years of his life, when he was painting portraits at the age of eighty, could scarcely consider his career a success. He (Mr. Clarke) remembered Shee saying to him once, "You are often now brought into contact with Mr. Haydon, and he, as a matter of course, abuses the Academy. I recollect when I myself was in difficulties with the Academy. I believe Mr. Haydon's grievance against the Academy is that, on one occasion, when he had sent two pictures to the exhibition, he happened to accompany them, and he heard an Academician call over the staircase to the porter, 'Whose paintings are these?' 'Mr. Haydon's, sir,' was the reply. 'Mr. Haydon's pictures to the coal-hole!'" Shee added that he had had a similar adventure. When he was a very young man, and painted some of those great works of genius which young men are most capable of producing, it so happened that two works he sent to the Academy were rejected, in a year when there were a great many rejected works. The idea occurred to some one of exhibiting all these rejected works, as a challenge to the judgment of the Academy. Those who got up the exhibition sent for his pictures, and they were to appear; but then it struck him that, after all, though he had been scandalously treated, it was, perhaps, not wise of him, as a young man, to put himself in competition with his seniors, and therefore he sent for his pictures, and got them back, not without difficulty, for they were in the catalogue. "Now," he said, "see where Mr. Haydon is and where I am. I have no doubt if Mr. Haydon had displayed a little more tolerance he would have been president of the Academy instead of myself." These words had a bearing on the earlier part of Mr. Carr's paper. Which was the man who succeeded, Barry or Shee? Shee enjoyed all the advantages of life. That charm of manner, which remained with him to the last, secured for him every social enjoyment and advancement in his art to the presidency of the Academy; but he (Mr. Clarke) believed, nevertheless, that the reputation of Barry would remain when the name of Shee would only be remembered by Byron's reference to it. The real test of Barry's position was that which the chairman had applied to it. He must be judged by the men of his day, and even by those before his day, and he would as willingly compare him with Sir James Thornhill as with any one. At any rate, with careful consideration, no one could fail to arrive at the same conclusion as the chairman, that in relation to his own day Barry occupied a truly great position. What did Barry realise? He succeeded no more than Haydon, and than many ambitious men, in accomplishing all the purposes of his ambition; but he did much. He prepared the way for a school of historical art in our own day. He was trammelled by the classical and academical ideas of the day, and those same notions pervaded the French school down to the last works of David. It was only broken by the force of events. Although Napoleon was represented as a Roman emperor, it was necessary to present him in his grey coat. It was in reality Napoleon and Wellington who, to a great degree, overcame the tradition of art, and rendered it more natural, and in the respective countries more national. If Barry was not able to do more, they knew by the records of the Society that he was desirous of securing the natural; for there were payments made for models, and every figure was, according to his ideas, presented according to nature. Even if he somewhat failed in his high aims, they must acknowledge his sincere desire to introduce a better element into art. One feature in Barry's work was particularly deserving of notice, that was, the introduction of portraits of illustrious men. If there was much absolutely classical, on the other hand how much was there national! He would conclude by moving a cordial vote of thanks to Mr. Carr for his valuable and interesting paper.

Mr. Laing was rejoiced to find that both the chairman and Mr. Hyde Clarke had spoken in praise of Barry. For the last fifty years he had been in the habit of coming to that room, and those pictures had been lessons to him throughout his life. He was glad also to think there was a movement in the right direction in the Society, and that the cause of art had been brought forward; for he feared that, for some considerable time, they had been paying very little attention to one of the principal objects with which the Society was founded,—the encouragement of fine art. He had much pleasure in seconding the vote of thanks, and bearing his humble testimony to the great painter whose works adorned the walls of the room.

The Secretary (Mr. H. T. Wood) said it might interest the members to see an old volume which the Society possessed, and which he had on the table, containing the MS. of a great deal of Barry's correspondence on the subject of these pictures. It began with the actual letter sent by Barry to the chairman of the committee, stating who the artist was who was willing to undertake the duty of decorating the room, when the ten artists who had been invited had declined. There were many other letters, but, perhaps, the most interesting paper in the volume was an account written by Barry himself of the circumstances which induced him to come forward, and of his object in painting these pictures. When the pictures were cleaned recently, he (Mr. Wood) had made it his business to look through all the old papers, and see if he could collect any facts not already recorded about the pictures. The minutes and other documents, however, had been so frequently gone over before with the same object, that he did not know that he was very successful in finding much that was new, but what little he did find, he put in the form of a pamphlet, which was given to all the members who cared to have it. His only object in alluding to it was to say that, coming with no previous knowledge to the study of Barry's history, he could not help arriving at the same conclusion to which Mr. Carr, with his ample knowledge, had been led, as to the extreme sadness of Barry's story. In that room, where they were surrounded by his great masterpieces, where he spent so many hours of hard work, the room to which men brought his dead body that they might pay it some of that tribute of respect which they almost grudged the artist while living, it seemed a pity that they could not awaken more enthusiasm for the artist who was full of such noble aspirations. One could only look back and regret that the fulfilment was not equal to those aspirations. Still, the Society of Arts might take some credit to itself for having faithfully discharged the trust left to it by Barry, and for having done what it could for his memory. Even if he had painted the pictures in St. Paul's, which he was so anxious to do, it was doubtful if his fame would have been higher than it was to-day. The Society had always cherished his pictures, and taken such care as it could of them, and now the present Council had undertaken the restoration, the result of which was before them. He would like to add that their chairman of the evening, Sir Henry Cole, had been a member of the committee appointed to superintend the cleaning, and it was in no small degree to his careful personal attention that so successful a result had been attained.

The Chairman, in putting the resolution, said he had no doubt that, owing to this lecture, Barry would be better known than he had ever been before, and that they should not again hear, for many years, the speech made, when some one said he was going to the Adelphi to see Barry,—"Barry built the Houses of Parliament, and not the Adelphi." That Society gave prizes and medals for the encouragement of art before the foundation of the Royal Academy, and he could not help thinking that even if the Royal Academy had a series of pictures as good of their kind, or if they could, within a reasonable time, produce a monument of the art of the present day to equal what Barry did in his day, they would have reason to be thankful.

The motion having been carried unanimously,

Mr. Comyns Carr, in response, said he would not detain the meeting, except to say that he did not wish it to be thought that he differed at all in his appreciation of Barry, or of the efforts he made, from the speakers who followed him. He cordially agreed with nearly everything that had been said by those who had, perhaps, spoken more effectively in praise of Barry than he had done. He cordially agreed with the Chairman that his achievements were very great in relation to the art of his time. He had no tendency to underrate the value of our English school; he had tried to point out that at the time when Barry was working there were magnificent achievements produced in that school, and if it was not Barry who produced them, it was because an indomitable current of ideas set in another direction, and because Barry, with heroic effort, was fighting against the stream.

LANDSCAPE ART IN THE FRENCH GALLERY.

Sir,—Although you have already noticed the present collection of pictures in Mr. Wallis's twenty-seventh annual Exhibition by British and Foreign Artists, I hope you will let me add a few words on a special point. The gallery contains 200 pictures, much the larger number being by foreign artists. The strength of English art is supposed to be in landscape, with Turner high up at the head of the list. A few, however, may be named worthy to take rank below, as Calcot, Constable, Copley Fielding, Creswick, De Wint, D. Cox, old Linnell, and Müller. These are a few of the select from a tolerably large school of landscape artists, but by no means all, especially if we ventured to include living artists from the Royal Academy and water-colour schools, but it is not my purpose to write a catalogue of landscape artists. The Dutch excelled in landscape before the English school had birth; and, for purity of tone and atmospheric effects, the best of the Dutch school have as yet no rivals. Painting can only be carried to a limited standard of perfection, however subtly treated, as there are effects in Nature which no art can reach. Turner learned this long before he died:

hence his wild, despairing attempts in colour, so bewildering and confounding to the uninitiated, and so beloved by a few select students and the best engravers. There are several landscapes in this winter's French Gallery worthy of careful study, quite as much for what they show as for what they promise; these are by a young German (or Bavarian) artist, K. Heffner. In the Gallery there are pictures by him, Nos. 9, 42, 59, and 75. The first, No. 9, is a bright daylight landscape, the middle-distance a glittering yellow and green; with water in the foreground and distance sparkling under the modified light of a bright but vapoury atmosphere. A coppice of pollards, bare of leaves, shows a late autumnal day. No. 42, "A Rift in the Clouds"; No. 59, "A Flitting Gloam before the Storm"; and No. 75, "In the Gloaming," may be grouped for study and comment. In No. 42, we have a night aspect, under the magic effects of a vapoury atmosphere and full moon. The general tone of clouds and landscape is dark grey; patches of nimbus clouds float along, through a rift in which the full moon shines out for a moment, silvering the margins of the drifting clouds. There are a boat and figures in the foreground, giving life to the scene, with groups of leafless trees in the middle distance. It is not a violent storm, but a weird wild night, alternately fair and showery, with most of the latter. On the right a house is seen amidst the shrubs, and water gleams both in the foreground and in the distance. Atmosphere and landscape throb under the sudden gleam through the "rift in the clouds." No. 59 is the most important work in dimensions and area of canvas, and is a charming broad daylight effect upon a wide stretch of flat watery shore. David Cox, in his "Over Sands" sketches, depicted such a landscape, and it would have gladdened the old man's heart to have seen these works of the young Bavarian artist. The coming storm is indicated by a dark bank of clouds on the distant horizon, which will soon ride hissing up with the wind, drenching the watery landscape. The whole atmosphere is full of lofty broken cumulus, through one small break of which the sun sends his rays, making the distance (water and grass) sparkle for the moment. Cattle cross the shoal water of the middle distance from the right to a lone moorland on the left, over which a few sea-gulls flit; an old flat-bottomed boat is stranded in the foreground. The whole picture is full of atmosphere. No. 75, "In the Gloaming," is a flat grey landscape, with a line of pollards on the left, shoal water in the middle, with cows crossing, and tops of windmills in the distance on the right. The sky is overcast with grey broken cumulus, whilst on the horizon the setting sun tinges clouds, land, and water, with thin streaks and flecks of gold, the rifts in the clouds showing tinges of sky orange and green. Here again, in this picture, the young artist has justified his title by the effects represented. Daylight is fast fading: it is "the gloaming,"—the prolonged twilight of a Northern day. As an Irish labourer once remarked, "Night is creeping about the ditches." In these charming pictures there is no mistaking the aim and purpose of the artist. The landscape aspects are wintery; the atmospheres are full of vapour; the clouds have parted with some of their stores of water, but have been by no means emptied; showery weather may be predicted; topcoats and umbrellas will be necessary. It has been said that a good picture is a "window in a wall." The possessors of these charming works will most certainly, in this sense, have an added window in their walls. Thanks are due to Mr. Wallis for affording us such a pleasant study and intellectual treat, and we shall look anxiously for further works by the young and gifted artist. R. R.

Fires.—The goods depôt recently erected by the North British Railway Company at Forfar was totally destroyed by fire on the 25th ult. The building was a wooden one with slated roof. The estimated damage is about 3,000*l*.——On the night of the 23rd ult. St. Mary's parish church, Hawick, was discovered to be on fire. The roof was completely destroyed, and the seats and walls were damaged. It is supposed that the fire originated by a joist projecting into the flue of the heating apparatus, which was used two days before.——A destructive fire has occurred at Mutley, Plymouth, the workshops and timber-yard of Mr. Philip Rundle, builder, being destroyed.

NEW BRIDGE AT HILGAY FEN, OVER THE OUSE.

A new bridge erected here for a company by Messrs. T. Shaw & Co., 141, Cannon-street, London, was opened a few days ago. The erection was commenced not three months since, and the contract expired on the 20th of November. The bridge will be the means of shortening the communication of Hilgay with the world outside by something like three miles. The bridge, which is of massive structure, is what is termed a lattice-girder bridge, of three spans, and is supported by cast-iron cylinders, 3 ft. in diameter, sunk below the bed of the river to the depth of 10 ft. 6 in. The foundation is of the hardest blue gault, better than which can nowhere be obtained. A lattice-girder of 90 ft. forms the centre span, and two girders, one 30 ft. and the other 40 ft., form the side spans. The 40 ft. span on one side is because of the peculiar bend of the river at this point, and it was also designed to give barges passing down the river the full benefit of the extra depth of channel on one side. The distance between the abutments, which are of white brick, is 160 ft. The cast-iron cylinders supporting the centre and side girders were filled with Portland cement concrete, and were secured to the bed of the river by means of a screw at the bottom, worked by a cast-iron capstan-head. In the capstan-head were inserted eight spars of tough elm. Two ropes were wound round the extremity of these spars, thus forming a wheel of eight spokes, and 20 ft. in diameter. When we take into consideration the pitch of the screw, which at the bottom of the cylinder was 9 in., and the large diameter of the capstan-head, which was hauled by 2 ft. 6 in. hawsers, attached to double-purchase crabs, we may imagine the amount of weight which was required to vertically depress these cylinders. It should be mentioned, in justice to that gentleman, that the works have been under the superintendence of Mr. J. Bloomfield, on behalf of Messrs. Shaw.

CITY AND GUILDS OF LONDON INSTITUTE.

A general report as to the affairs and position of this Institute has been issued by the Council. It appears that by the kindness of Gresham Committee, a room in Gresham College has been placed at the disposal of the Institute, together with the use of the library for meetings, and for the transaction of other business not interfering with the convenience of the Gresham professors. The Institute has been duly registered under the Companies Acts, 1862 to 1880. The Council are pleased to be able to report that the question which was so long left unsettled with regard to the future site of the central institution has been definitely decided by the grant to the Institute of a plot of land at South Kensington, about 300 ft. long by about 110 ft. deep, after allowing for a 40-ft. roadway in the rear, from her Majesty's Commissioners of 1851, for 999 years, at an annual ground-rent of 1*s*. The Council have entrusted the preparation of the plans and the construction of the building to Mr. A. Waterhouse, A.R.A. In accordance with suggestions thrown out in earlier reports, the Institute has voted a certain amount of its funds towards the support of existing institutions, which are affording technical instruction to those who are engaged, or are about to engage, in industrial pursuits. The institutions to which the Council have made grants are the following:—University College and King's College, London, the School of Art Wood Carving, the Mining Association of Devon and Cornwall, the Nottingham Trade and Science Schools, the Artisans' Institute, the Birkbeck Institute, the Union of Lancashire and Cheshire Institutes, and the Horological Institute. The Council have taken steps to render available for the purposes of the Institute the conditional grant of 10,000*l*. from the Drapers' Company, to be devoted to the erection of a Technical College in Tabernacle-row, which shall afford accommodation for the schools of technical chemistry, technical physics, and of applied mechanics. The Council propose that the Board of Governors shall set apart a sum of 5,000*l*. out of the funds at the command of the Institute for this purpose. They have agreed to rent for a term of 99 years from the Council of the Middle Class Schools Corporation a plot of ground of about 120 ft. in length by about 70 ft. in depth, at an annual rent of 200*l*.; the rooms at present occupied in the Cowper-street School being retained by the Institute for a period of at least five years at a further rental of 200*l*. a year. The building of this college, in accordance with plans which have been already approved by the executive committee, has been entrusted to Mr. Clifton, and it is expected that the necessary arrangements for the laying of the foundation-stone will be completed within the next few weeks. Since March last improved technical instruction has been given in the temporary class-rooms of the Institute in the Cowper-street Schools. During the present year instruction in certain branches of industrial art has been given in two houses in Kennington Park-road, which have been fitted up with the requisite appliances for teaching.

SALE OF FREEHOLD PROPERTY IN CATHERINE STREET.

Last week a freehold property in Catherine-street, Strand, nearly opposite to Drury-lane Theatre, was offered for sale at the Auction Mart by Messrs. Winstanley & Horwood. It consisted of the business premises and dwelling house formerly known as No. 9, Brydges-street, containing four floors and a basement, and at present let to weekly tenants at rents amounting to 81*l*. 18*s*. per annum, the landlord paying all rates, taxes, and insurance. The property was sold for 920*l*.

EXTENSIVE SALE OF WEST END PROPERTY.

One of the largest sales of property which has for some time past taken place at the Auction Mart, was held on Thursday, the 25th ult., when Messrs. Collier & Bowdich submitted to competition several valuable freehold investments in Manchester-square, comprising twenty-six houses, shops, and other premises, bounded on the east and west sides by the Portman and Portland estates. The property is situated in South-street, George-street, and Manchester-mews South respectively, and was offered in twenty-six separate lots. It was described as a freehold site, such as could rarely be obtained in the district, having an area of about 26,000 superficial feet. The present ground-rents and rentals were stated to amount to 266*l*. 4*s*. a year only, but that as the leases expire in 1886 the purchasers would, in five years and three-quarters, become entitled to possession, or to the rack rentals, estimated to amount, for the entirety of the property, to 3,000*l*. per annum. It was added that by reason of the costly houses recently erected, and the important improvements in progress in the immediate neighbourhood, there was every probability of the property greatly increasing in value. There was a very large attendance during the whole time of the sale, which lasted between two and three hours, with an eager and spirited competition for the several lots, all of which were readily sold for an aggregate sum amounting to upwards of 43,000*l*. Thirteen of the houses and shops are in South-street, and realised prices varying from 1,375*l*. to 1,990*l*. each, or an aggregate sum of 20,690*l*.; the twelve houses in George-street were sold at prices ranging from 1,240*l*. to 1,900*l*. each, with the exception of three of the lots, which realised still higher prices, Nos. 20 and 22, the estimated annual value of which was set down at 130*l*. and 180*l*., being sold for 2,020*l*. and 2,770*l*. respectively, whilst No. 14, which, in addition to a very large house, also contains extensive builders' premises in the rear, fetched 4,000*l*., the total sum realised for the George-street property being 21,495*l*. The remaining lot, comprising stabling and workshops in Manchester-mews South, was sold for 900*l*.

Subdivision of the Electric Light.—At Wednesday night's meeting of the Society of Telegraph Engineers, held at 25, Great George-street, Westminster, the President (Mr. W. H. Preece, Electrician-in-Chief to the Post-office) in the chair, a paper on "A System of Sub-dividing the Electric Light" was read by its inventor, Mr. J. W. Swan, M.S.T.E., of Newcastle-on-Tyne. The lecturer had previously dealt, before the Philosophical Society of his native town, with the subject of the production, and the best means of preserving this light, as mentioned by us at the time, and his later paper was a resumption and amplification of the former one.

TONBRIDGE, KENT.

Ferox Hall, an old mansion on the outskirts of Tonbridge, the residence of Mr. T. A. Beeching, the banker, has just been restored and considerably enlarged, Messrs. Wadmore & Baker being the architects. The works, which have just been brought to a conclusion, embrace the addition of a new garden-front and an extensive wing, stretching towards the stables and offices. The hall itself is one of those old red brick and tiled buildings of the latter part of the seventeenth century whose substantial pilasters and cut brick capitals give a quiet dignity to the surroundings which much more pretentious work often fails to secure. The new wing corresponds pleasantly with the ancient work. Its octagonal bay is surmounted by a lead bulb-roof. The chimneys are all carried well up. Over the entrance to this front is a carved sun-dial, bearing in suitable characters the legend, "You may waste, but cannot stop me." There are three sets of mullioned square bay windows to the garden-front. These, especially the principal one, are decorated with carving. The materials used in the new work are red bricks, similar to the old work, while the dressings are of local sandstone. The various quoins are rusticated, virgin cork bark being the *motif* for the rustication. Within, much care and no little expense have been bestowed upon the details. The principal rooms downstairs have their walls panelled with oak wainscoting, and so have the passages. The floors are of oak also. The various mantelpieces are of oak, Sequoia wood,—a Californian material something like cedar,—being also introduced into the fittings with good effect. There are some plaster ceilings modelled and panelled in the old style. Upstairs the wood fittings are of pitch pine. The kitchens are furnished with some capital ranges supplied by Messrs. Benham & Sons, of Wigmore-street, London. The exterior stone carving, and all the internal wood carving, has been executed by Mr. Harry Hems, of Exeter. The general contractors were Messrs. G. Punnett & Sons, builders, of Tonbridge.

ELECTRIC LIGHTING.

London.—On the evening of the 26th ult. a number of gentlemen interested in the progress of electric lighting visited the workshops of the Anglo-American Electric Light Company, in Vine-street, York-road, Lambeth, where the Brush system, in some of its later developments, is henceforth to be seen in actual operation. Besides the electric lights of the factory,—in themselves a sight of great practical interest,—there was shown a powerful new light, which is about to be sent to the Admiralty. This one light has an illuminative power equal to fifty thousand candles. This system of lighting is one of the three which are to be put on trial simultaneously in the City in the course of next year. It is at present to be seen at Liverpool-street Station, as well as in the company's works.

Woolwich.—The War Department officials at the Royal Arsenal, Woolwich, are at the same time extending their arrangements for the supply of gas to their works and buildings, and carrying out a series of experiments with the various systems of electric lighting which have been introduced to public notice, with a view of determining how far, and under what conditions, either mode is especially adapted to their requirements. Sixteen Brush lamps, all kept in action by one machine, are now in constant operation at the Royal Laboratory Department, some illuminating a large workshop for carpenters, while others are in adjacent rooms of smaller dimensions. This plan is stated to have proved at once the most satisfactory in its results, also the cheapest yet discovered, but the cost of producing the light is at present far too great to allow of its competing, on anything like equal terms, with gas. Consequently the authorities have just made extensive additions to their gas-works, from which not only the Arsenal itself is supplied, but the various barracks and dock-yards, the camp, and even the Herbert Hospital at Shooter's-hill, are lighted.

Hull.—A meeting of the Lighting Committee of the Hull Corporation was held on the 26th ult., "to approve and put into operation the Electric Lighting Bill obtained by the Corporation in the last Session of Parliament." The borough engineer submitted plans providing for six 6-000 candle-light power lights, one 2,000, five 400 for street lighting, and also one of 2,000-candle power, and two of 400 for the Town-hall. The proposed electric lights would supersede the lighting power of 105 gas-lamps of 16-candle power. Messrs. Siemens Bros. estimated the cost of the requisite plant for the extent of the electric lighting described, including steam engines and boilers, dynamo-machines, leading-wires, masts, brackets, lamps, lanterns, and insulators, at 3,700*l.*, in addition to which the engine-house and site would cost, say 1,300*l.*, making the total first cost 5,000*l.*, and they estimated the annual maintenance of the street lamps at 672*l.*, and the carbons for the Town-hall lights at 5½*d.* per hour for every hour the whole are lighted. With respect to the street lighting, therefore, the sum of 672*l.* per annum, plus the first cost of plant, would produce lights equal to 40,000-candle power as compared with 1,650 candle-power for the 105 gas-lamps to be displaced, and costing 420*l.* per annum, whilst the same apparatus would also provide lights for the entrance-hall, reception-room, and council chamber in the town-hall. It was resolved to take steps to make trial of the electric light for twelve months.

STATUES.

Earl Russell.—The subscription statue of the late Earl Russell has been placed in the Central Hall of the House of Lords. The statue is from the studio of Mr. J. E. Boehm, A.R.A., and stands on a marble pedestal.

Sir Francis Drake.—At a town's meeting held in Plymouth on the 26th ult., for ascertaining the views of the burgesses on the best method of celebrating the tercentenary of Sir Francis Drake, three resolutions were submitted: the first, that the contemplated memorial should take the form of a statue, or group of statues, within the borough; the second, that there should be a statue in connexion with a public museum and art-gallery, together with a science and art school; and the third, that a large and representative committee should be appointed to further consider the details of the proposed commemoration, and to report to a future meeting. The original motion for a group of statues, to take the form of a national memorial, was carried by an overwhelming majority, and a committee was appointed to carry the resolution into effect.

PARKS AND OPEN SPACES FOR THE PEOPLE.

Keswick.—A largely-attended meeting of the inhabitants of Keswick was held the other day in support of a movement for purchasing Fitz Park as a recreation-ground for the town. There appears to be a good prospect of the success of the project, a large proportion of the purchase-money (between 3,000*l.* and 4,000*l.*) having been already promised.

Kingsland.—A public meeting was held last week at Kingsland for the purpose of endeavouring to preserve Kingsland-green as an open space. Mr. John Kolday, who occupied the chair, said that every one knew that London was already very densely populated, and every scrap of ground in its immediate vicinity was bought up at a large value for building purposes. Therefore he thought they were perfectly justified in trying to prevent the only remaining piece of ground in the vicinity of their parish from being covered with buildings. Dr. Aveling then moved:—"That, in the opinion of this meeting, the retention or acquisition of open spaces in our metropolitan suburbs is most desirable on sanitary grounds." In his address he advised the parishioners to purchase the land out and out, and thus preserve it to their children as a recreation ground for ever. Mr. Runtz (of the Metropolitan Board of Works) supported the motion, and advised the parishioners to state their case to the Hackney District Board, who, if they approved of it, would borrow the money necessary from the Metropolitan Board on the usual terms. The resolution was adopted, and the meeting appointed a committee to carry out the business connected with the movement.

London.—The Metropolitan Board of Works give notice of their intention to make application to Parliament in the ensuing session for leave to bring in a Bill to effect the purchase and thus secure to the public the entire use of the Hackney Commons,—comprising London Fields, Hackney Downs, Wells-street-common (commonly called Hackney-common), North Mill-field, South Mill-field, Stoke Newington-common, Clapton-common, and parcels of waste land at or near Dalston-lane and Grove-street,—which form the subject of the scheme with respect to Hackney-commons confirmed by the Metropolitan Commons Supplemental Act, 1872.

HARBOURS.

Bristol Channel.—An influential committee has been formed with a view to urge upon Government the construction of a harbour of refuge for the Bristol Channel at Mumbles Head, near Abernethy. It is stated that over eight million tons of shipping pass up the channel annually, or one-sixth of the whole tonnage of the United Kingdom. The estimated cost of the work is 400,000*l.*, and it is calculated that a toll of ½*d.* per ton annually would provide the capital required.

Fraserburgh.—Preparations are now being made for the deepening of the north and south harbours of Fraserburgh, and the widening of the quays. Mr. Bostock, the resident engineer, left last week for London to confer with the consulting engineer, Mr. Abernethy, and submit a number of plans and proposals for his advice. It is expected that the work will be commenced early in December. The cost of the contemplated improvements will be about 30,000*l.*, which sum has been borrowed from the Public Works Loan Commissioners.

WATERWORKS.

Cromer.—We are glad to learn that the efforts to obtain a supply of good water for Cromer have at length, after many difficulties, been crowned with success. Continuous pumping has now been going on at the works for seven weeks, without being able to reduce the level of the spring; indeed, the difficulty has been to keep down the water in the well by means of the main pumps. So much for the supply. That the quality is equally satisfactory is seen by reference to the analysis which has been made. Many of the houses in the town are already supplied, and owners and occupiers are daily sending in orders for services to be laid on. There will be a meeting of the company soon, when it is hoped the public will cordially respond to the invitation to subscribe. Provision has been made in case of fire, there being more than forty hydrants about the town.

PARLIAMENT-STREET WOOD PAVEMENT.

Sir,—The new pavement in Parliament-street, just completed, cannot have a fair chance of showing the advantages of this form of pavement,—namely, freedom from mud in wet weather and from dust in dry weather,—as, in consequence of the macadam at the Bridge-street end and the Whitehall end, the surface of Parliament-street will be subjected to the mud and dust carried and blown in from these street surfaces. On this day (Nov. 27th) four powerful horses are dragging a huge roller over some tons of broken stone, crushing them into partial powder,—the more readily to become mud and dust. If it were possible, an Act of Parliament ought to forbid the use of broken stone in streets having a quick and heavy traffic, if only on the plea of economy.

Civil Engineer.

SCHOOLS AND INSTITUTES.

Sir,—I think you would do much good to builders and architects, and also to Sunday-schools, if you would point out from time to time the unsuitable buildings in which such schools are held, and suggest improved plans. Another direction in which there is scope for useful work is in Church Institutes. They exist in Leeds, Bradford, Hull, Wakefield, Bolton, and other towns, and we contemplate one in Liverpool.

A.

BAROMETERS.

Sir,—*Apropos* to the Glycerine Barometer of Mr. Jordan, it may interest you to learn that there is an automatic self-registering mercurial barometer at the Birmingham and Midland Institute, in which the ordinary inch of rise and fall is enlarged to 5⅝ in. so that the very slightest movement is accurately recorded on paper.

E. G.

THE USEFUL AND THE BEAUTIFUL.

SIR,—It is very important for the sake of art-progress that the following important position, viz., that the beautiful is not the sole purpose either of nature or of art, should be widely accepted. I have somewhere in my correspondence quoted, from a letter of Sir John Herschel to me, the astronomer's testimony to the same effect, and "G. T." seems, as well as one can gather from his entanglement of notions, to hold the same opinion; for he admits that the elephant is certainly not beautiful, only, he unfortunately adds, "it is better than that, it is noble." Now, the word *noble* can only in the very loosest way be applied to an animal which is apt to treasure and revenge even a slight injury, as one of the species is recorded to have done when it soused the poor Asiatic tailor with muddy water, and precisely as some ignoble humanities resent the prick of a pen. At all events, "G. T." admits that nature has other objects in view than the production of the beautiful. Would he also transfer the epithet "noble" to the rhinoceros, the hippopotamus, and the gorilla? Because if he would, it would show that he will not call a spade a spade, and it is useless to argue with him. The rhinoceros and the hippopotamus, moreover, fulfil "G. T.'s" one simple condition for producing the beautiful,—they have a "good outline," without convincing the man of taste or the general public that they are beautiful. It is because ugliness is possible in nature that art discussions arise, and that æsthetic principles are required for the artist's guidance. There would be no occasion for any further art "gabble," or even for art production, if ugliness were impossible.

"G. T." says "a work often becomes ugly because the foolish designer tries to make it beautiful by adding work to it": he ought to have said "uglier," for his words would then have represented my contention with regard to those bridges of Telford and Stephenson, which were the origin of this discussion; there was no question as to their fitness for their several purposes,—the wail was that they were ugly, that those engineers had increased the number of uglinesses in nature, and that this need not have been so had the designs for the bridges been nursed by some motherly architect, who would have brought them up as good and tasteful bridges ought to have been brought up. The exhortation in my previous letter was, Be content, on occasion, with a little robust ugliness,—a naughty, ugly, engineering work or two,—where perfect fitness has been achieved; for I have already shown in the pages of the *Builder*, in opposition to the modern morbid æstheticism, that the rigorous conformation of the manufacturers to utility is a wiser national aim than the attempt to overlay and sophisticate everything indiscriminately with fine art. It was the former motive which made our wares so celebrated in the marts of the world. The pursuit of fitness is the most solid manufacturing virtue,—a virtue which the greater portion of mankind can appreciate. A production rigorously adapted to its purpose will exhibit either no beauty at all, or as much as properly belongs to it. Whatever else is superadded is *appliqué*,—stuck on,—in deference to the tastes of the morbidly æsthetic few.

In conclusion, Mr. Editor, allow me to say that, had "G. T." turned to his Shakspeare, he would have found his theory,—that there is no ugliness in nature,—refuted by the great master; for does not the philosopher apply the epithets "ugly" and "venomous" to the toad, and make that "ugly remark" with which "G. T.," as yet, is unable to agree?

W. C. T.

"NOISES."

SIR,—In your article in last week's issue on the above subject, you say, "Light falling on selenium leads to a commotion among the particles of the metal, which is alleged to be audible. There is no reason to suppose that other solid substances are proof against similar disturbances." It is, therefore, interesting to ask,—Would ice, being an electric or non-conductor at a temperature of 0°, like sulphur, produce such a result? If so, the discoveries of the learned Professor Bell account for the sound produced by the Aurora upon the "ice packs," described by Arctic explorers as resembling the rustling of silk.

In a work by G. Murray Smith, F.R.G.S., on "Arctic Expeditions," p. 370, he mentions the above as a fact, testified by numerous reliable witnesses, amongst whom are Messrs. Ritch and Dease, formerly of the Hudson's Bay Company, and Admiral Pullen. In the particular instance mentioned, the temperature of the atmosphere was found to be 44°. I might further ask some of your scientific readers, that, admitting the above, would the lowness of the temperature be likely to increase the power of the phenomenon?

C. G. B.

CEMENT *v.* LIME.

SIR,—In Mr. G. R. Redgrave's interesting and enthusiastic paper "On the Use of Cements," printed in your number of the 27th ult., he gives a "statement of approximate cost of mortars" by Mr. Colson, showing results greatly in favour of cement mortars. The price of grey lime is there put at 14s. 6d. per cubic yard Now, our price for the best old Dorking greystone lime is 8s. per cubic yard, and the carriage to London is 1s. 3d., making 9s. 3d., to which about 56 per cent. must be added to bring it up to the approximation. It is true Mr. Colson points out such estimates must be received with caution, because of difference of locality; but surely no better place could be chosen than the great brick city chiefly affected by Mr. Redgrave's argument. In like manner the sand appears to be estimated at too low a figure, 2s. 9d.; that is to say, if a sharp, large-grained sand is meant, such as that found in the well-known pit on this estate, which would cost nearly double the money.

As Mr. Redgrave is firmly convinced that lime as now employed will shortly become obsolete, allow me to add that, without employing agents or travellers, and with simply an advertisement in the *Builder* to remind folks of our existence, the output from these works for 1880 will exceed that of any preceding year.

The season for transformation-scenes is at hand; but the idea of our dear old London exchanging her dingy bricks for monolithic concrete, with the beautiful appearance of stucco, even coloured stucco, does not present itself to my mind as "a joy for ever."

ALFRED BISHOP, Sec.,
Brockham Brick Company.

WHY WORK IS INFERIOR.

SIR,—The admirable article on the plumb-rule and spirit-level, in your issue for Nov. 20 (p. 606), merits the attention of masons, bricklayers, and carpenters. These instruments are the most important used in building construction, and there are many workmen, as you state, in each of the trades named, that do not understand the application of the plumb-rule and spirit-level in the most efficient manner to building-construction. Many, however, who do understand the necessity for their careful application in the construction of buildings, are not allowed by their employers sufficient time to use them so as to obtain accuracy.

In the present state of the building trade, the workman knows that his employer often considers levelling and plumbing mere waste of time, and the man who is most careful in these matters is frequently discharged in preference to an inferior and careless workman who knows neither how to use efficiently either plumb-rule or spirit-level, nor the necessity of their application in keeping his work plumb and level. Many builders' foremen are selected more for their abilities in urging on the workmen than for the purpose of directing them how to do their work in a careful and proper manner; and the workmen under such foremen are well aware that the time they take to do their work is noted in preference to any scamping they may do, or even mistakes they may make, as mistakes are frequently allowed to remain unaltered even in exposed parts, and treated as of little consequence. It would be difficult at present to find many buildings with the brickwork in level courses, the perpends carefully kept, much less true bond, masonry fixed in level courses and evenly bedded, and joinery carefully fixed level and plumb. I may note in addition to this, perhaps, the economy in mortar,—or, rather, what is in many cases called mortar,—and the care taken by the carpenter in the use of nails and screws; but there are other causes that affect this in addition to those already named. The present system of apprenticeship, or what is still worse, no apprenticeship in many cases, especially with bricklayers (who may, by the way, have served some time with the hod), is one. The apprentice is now instructed more with a view to piecework and quantity, than to be a careful and efficient workman,—as were those good and clever workmen in past ages, when men were respected for their skill by the employers whom they served, their abilities generally insuring them constant employment; whereas, at the present time, the workman who can do the most work, in what may be termed a reasonably scamping manner, is the most successful with many of the builders of the present time.

But probably the greatest evil of all is that of the owners of property and others who greatly encourage the entire system of constructing buildings in an inferior manner by their preference for the lowest tender, instead of giving a reasonable price to an honest and established builder or building firm that would employ efficient workmen of all trades under skilled foremen, and use sound materials throughout the structure that would be a credit to all concerned, and a gratification to the architect in seeing his plans carried out in a proper and efficient manner, and with the certainty that his client or clients would not, from the commencement of the occupation of the premises, be put to endless cost for repairs, or more serious consequences, as illness from defective drains, &c. The reader may picture the architect and his clerk of works in their efforts to maintain their credit in the construction of an important building with all this arrayed against them, and often in a most determined manner.

A CLERK OF WORKS.

HOW WE MAKE CONCRETE IN WESTMINSTER.

SIR,—Parliament-street is to have its wood pavement. The Institution of Civil Engineers is round the corner. The Whitehall Club is in the centre of it. Engineers abound in the neighbourhood, and look out of the club windows, presumably to see that the work in progress is being carried out satisfactorily, and in due accord with the most approved practice and theory. At the end of the last session we had at the Institution of Civil Engineers papers read to us and discussed before us relating to the most advanced means of using Portland cement, and in making concrete. Oh! architects, surveyors, contractors, everybody but engineers, come to Parliament-street, and see how we, the engineers, carry out in practice what we teach in our Institution.

Some short time back Parliament-street was "up" for repairs to gas or water mains. The trench was duly filled up, and the traffic again for a short time went along Parliament-street. Then in comes the contractor to lay the "improved" wood paving; and his mode of proceeding, so far as can be ascertained by a casual observer, is as follows:—the trench over the gas or water main is again opened, and the macadam of the whole street picked up to a depth of about 18 in. The trench is then filled up with a remarkably well-made concrete, composed of Thames ballast and Portland cement, in the proportions of about five or six to one. Let us hope that, in justice, the contractor, who may have, at some future day, to get at these pipes, will be informed of the material which covers them. Dynamite at least will be required to get through that 3 ft. of concrete.

The trench having been filled up, the ground is levelled and prepared to receive the concrete foundations for the wood paving. The concrete is composed of the old macadam mixed with a small quantity of Portland cement. So far as could be seen, it seemed about a yard of macadam to about a bushel of cement. The two were mixed together on a wooden platform, and several canfuls of generally extremely dirty water poured over it; it was then stirred up again, put into barrows and wheeled into position, and knocked down with the back of a spade to about 1½ in. thick, and as near level as the rough nature of the compound would allow.

It may fairly be expected that in the course of time this mass of dirt and granite will be about as hard, or somewhat less so, than the macadam that previously formed the roadway.

The surface of this concrete not being, presumably, sufficiently level to lay the wood upon, about half an inch of cement and sand is, after a few days, gauged up and laid over the whole surface; this is carefully cambered off to the desired curve, and the wooden blocks are laid thereon.

It may fairly be expected that, in the course (say) of a few months, this veneer of sand and cement will have returned to the granular condition in which it was only a few days back. Whether or no in that condition it will support the roadway level I am unable to say, not being a road contractor; but I sincerely trust, for the sake of the ratepayers, that there is a maintenance clause in the contract.

WESTMINSTER.

BARRACKS.

SIR,—Kindly allow me space to say, with reference to Major Seddon's letter in your impression of Saturday last,—

1st. That I was most careful to disclaim, explicitly, any personal connexion with the subject of my paper.

2nd. That I was equally careful to give the whole credit of the designs, &c., to Major Seddon and his assistants.

The "Transactions," when published, will give the paper in full, and show how clearly the above points were brought out. Meanwhile, I am not responsible for the incomplete newspaper reports of which Major Seddon, not unreasonably complains.

E. INGRESS BELL.

*** Why should Major Seddon, or any one else, complain? The reports were simply abstracts of the paper, referring to the more useful points of the discourse.

FRENCH BARRACKS.

Sir,—In reference to the subject of the improved construction of barracks, recommended by Mr. Bell at the meeting of the Royal Institute of British Architects, I should suggest that a visit might be paid next to the model barracks lately erected by the French Government for their forces. They are well worthy of an inspection by the sanitarian, architect, and military officer, as they are intended to embody in their plan and construction all necessities required by modern science. After seeing some of them, particularly at Tours, I described their character to a meeting of the Medico-Chirurgical Society of Edinburgh in the winter of last year. Some of the salient aspects of their design seem to point to economy of construction as to material and expense; the avoidance of complicated machinery in ventilation, drainage, warming, and sewerage, is also very apparent to the visitor. The canteens, kitchens, latrines and urinals, stabling, storerooms, and artificers' and artisans' shops, are all placed round the outside walls. The blocks for men's barracks are placed in the middle of the square enclosed by them, and are of four stories in height, comprising the regimental offices in the lower one, the effective men's rooms in the two middle ones, and the casualties in the topmost story. There are complete guard-rooms, cells, and prison, only a casualty hospital; but the real novelty of the whole plan is that of the transport regimental department, comprising stabling, forage, and harness rooms, and wagon-sheds.

W. V. Black.

LONDON FOR AMERICANS.

At the inaugural meeting of the Topographical Society of London, already mentioned by us, Mr. Henry Stevens (of Vermont), F.S.A., in proposing a vote of thanks to the chairman, said,—As an American, and he feared he was the only one there, he wanted to pat this young Society on the shoulder, and say in American language, "Go ahead." Americans were anxiously looking to Londoners to turn up the early history of America; for their ancestors all migrated from England, and a great many from London. There were movements now going on for the purpose of discovering American memorials in London. For instance, they are erecting a monument to Sir Walter Raleigh, the founder of Virginia. They also wished to restore a monument in a neighbouring church to Captain John Smith, the author of the "History of Virginia." But, perhaps, one of the most interesting monuments in London for an American was the Bank of England; for in a little garden in the centre was buried Thomas Hariot, the tutor and friend of Sir Walter Raleigh,—a man appointed by Raleigh and also by Queen Elizabeth to go out to Virginia in the first expedition under Sir Richard Grenville, his report being made in 1588. He was one of the most celebrated of England's mathematicians of any period. He was consulted by all scholars; he was a frequent correspondent of Kepler; and was, perhaps, the inventor of the telescope,—at any rate, he brought out a telescope in London in the same month that Galileo did in Italy, and it was now a disputed point whether he was not the real inventor. He was buried in 1621, in a church close by, and a monument to his memory was placed there by his great friend and patron, the Duke of Northumberland. In 1832 that church was wanted for the Bank of England. The little churchyard, however, was not destroyed, but built round, and now that little garden was the only memorial they had of this great man. Here it was proposed to re-erect the original monument, or something of the kind. There were hundreds of other spots in London which were interesting to Americans far more than they could be to Londoners, and he had no doubt that this Society would receive much encouragement from America.

A Hardening Liquid.—Correspondents say that Dr. Gehring, at Landshut, in Bavaria, by means of an enamelling liquid, renders any species of stone or cement harder than granite, and gives it the absolute appearance of any other mineral that may be desired. The process, the writer goes on to say, admits of being applied to metal, which is completely protected from rust.

THE MAYOR OF LOUTH, LINCOLNSHIRE.

We might well have added to the notice on p. 651 of our last number that the architect of St. Swithin's Church, Lincoln, of which we then gave an illustration, — Mr. James Fowler, F.R.I.B.A.,—is now, for the third time within seven years, mayor of his town. All our readers know that the talents and tact of the student whose name was appended to many good drawings in Bowman & Crowther's "Churches of the Middle Ages" years ago, have won for him a general recognition; and will not regret to know also that he is evidently not without honour in his own country.

SEWERAGE AND DRAINAGE WORKS.

Newbury.—A ratepayer of Newbury having made complaint to the Local Government Board that the Urban Sanitary Authority here had made default in providing the borough with sufficient sewers, Mr. J. T. Harrison, one of the inspectors of the Board, held an inquiry into the subject on the 16th ult. On behalf of the complainant, it was stated that there had been a great deal of sickness, including malarious fever, in the town, which contains some 12,000 inhabitants; that the drains empty themselves into the Kennet and Avon Canal,—which is half canal, half river, and a very sluggish stream; and that some of the sewers (particularly one in Gas House-lane) were on a dead level, and were consequently nothing but elongated cesspools. It appears that three years ago the subject engaged the attention of the local authority, and at that time plans for the proper drainage of the borough were prepared by Mr. James Lemon, C.E., but nothing has yet been done towards carrying them into effect. The evidence given by Mr. Benjamin Sargent, borough surveyor, was to a great extent corroborative of the statements made on behalf of the complainant, while Dr. Woodforde, the medical officer of health, gave evidence not only as to the defective condition of the drainage of the borough, but as to the bad quality of the water. Alderman Adey deposed to the steps which the Council had recently taken in reference to the drainage question. The committee, who had visited various towns, had recommended the sodium process as adopted at Taunton. The system was one of filtration in tanks. The committee were in favour of a modification of the system in force at Aylesbury and Taunton. The process was to filter the sewage, which ultimately went into the river. The Inspector said that was a system which the Local Government Board would not sanction. The Board would be very much to blame if they allowed the sewage water to flow into the river, unless thoroughly purified, as it would become the drinking-water for other places, including Reading. Ultimately the local authority undertook to submit to the Local Government Board, by Lady Day next, a modified scheme for the treatment and disposal of the sewage, and the inquiry terminated.——At a meeting of the Urban Sanitary Authority on the 25th ult. it was resolved to offer a premium of 100*l.* for the best plan for the drainage of the borough, and 50*l.* to the engineer sending in the second best plan.

Lichfield.—Mr. Taylor, an inspector of the Local Government Board, has held an inquiry at Lichfield with regard to an application by the Town Council for sanction to borrow an additional 8,000*l.* for the carrying out of the sewerage works. The city treasurer submitted a financial statement, which showed that the total amount already borrowed for sewerage purposes amounted to 21,125*l.* 13s. 10d., out of which 18,999*l.* 1s. 5d. had been expended, leaving a balance of 2,126*l.* 12s. 5d. The surveyor gave an estimate showing the items embraced in the additional 8,000*l.*, among them being 3,200*l.* for the purchase of the reversion of the sewage farm from the Ecclesiastical Commissioners; balance due to contractors, 2,000*l.*; extra work and sewage-pipes, 2,750*l.*; surveyor and clerk of the works, 800*l.*; probabilities, 1,376*l.* The estimated total cost of the sewerage works was 29,000*l.*

Lincoln.—Public attention in Lincoln has on several occasions been called to a nuisance existing on what was at one time a favourite suburban walk—the Monks'-road. This nuisance has resulted from the drainage of the County Hospital being allowed to run down Clay-lane and so into the dyke on the north side of the road in question. The effluvia from this dyke has been so noxious, especially in dull and rainy weather, as to virtually close the road to all but those whose business compelled them to use it. Complaints thereof having reached the Hon. W. F. B. Massey-Mainwaring, owner of the land in the immediate neighbourhood, that gentleman requested the engineer (Mr. S. K. Page) of the Native Guano Company, who deal with the Aylesbury sewage by what is known as the "A B C" process, to visit Lincoln for the purpose of demonstrating by a series of actual experiments how easy it would be to successfully deal with the nuisance. Temporary tanks were erected in a field on the east side of Clay-lane, and here for some days the experiments have been carried out, with (according to the *Lincolnshire Chronicle*) perfect success.

PROPOSED SANITARY WORKS.

Workington.—The Workington Local Board has applied to the Local Government Board for permission to spend 3,000*l.* for works of water supply; 300*l.* for sewerage works, and 3,000*l.* for works of water supply outside the Board's district.

Cockermouth.—Captain R. C. T. Hildyard, late of the Royal Engineers, and an inspector of the Local Government Board, has held an inquiry here as to the application of the Cockermouth Local Board for permission to borrow 1,500*l.* for works of sewerage, water supply, &c. The area of the Local Board's district is 2,424 acres, and the population in 1871 was 5,115. The works are to be carried out from plans by Mr. Pickering, the engineer to the Board; 800*l.* of the proposed expenditure is to be spent in flagging the footpaths of some of the streets with white Lazonby stone.

CHURCH-BUILDING NEWS.

Broad Hinton.—The parish church of St. Peter, Broad Hinton, has just been reopened, after restoration, which has consisted principally in rebuilding the chancel and east walls of the nave, with the addition of an organ-chamber, the erection of a new chancel arch, and removal of the old one to the organ-chamber, and the repair and strengthening of the tower. In connexion with this latter work, it may be mentioned that the pier of the tall and handsome tower arch was found to be bulging inwards to the extent of 9 in. from the perpendicular, about 10 ft. from the floor, and rapidly giving way. The tower was shored up with timber under the direction of the architect, Mr. Ponting, the base removed, concrete laid on the solid rock, and new foundations built 4 ft. 9 in. below the surface. Scaffolding still remains on the exterior of the tower, the casing being now under repair, and new pinnacles are being provided. The reredos is of Beer stone, with a cross of alabaster, filled in with tiling of a mosaic character. The re-table is of red Mansfield stone. The chancel steps and pavement are newly laid with Minton's tiles. The east window, by Clayton & Bell, has been enlarged by the addition of a copy of Leonardo da Vinci's "Last Supper." Two north windows in the chancel, and the east window of the organ-chamber, are by Mr. Alexander Gibbs, two of these,—that of St. John the Baptist and St. Cecilia,—having been erected to the memory of the present clerk's father (a former parish clerk) at the expense of Mr. Wm. Eatwell, of London. The dole window is filled with stained glass by Hardman & Co., Birmingham, the subject being St. Nicholas, from a picture by Botticelli. The cost of the works is estimated at about 2,000*l.* The builder is Mr. Barrett, of Swindon.

Tedworth.—The new church at Tedworth, near Marlborough, Wilts, erected at the sole cost of Sir John Kelk, to take the place of the old parish church at South Tedworth, was consecrated on the 9th ult. The plans were prepared by the late Mr. J. Johnson, architect, of London, who died before the work was commenced; but Mr. Gordon, son of the Hon. and Rev. Canon Gordon, of Salisbury, has taken up the work, and carried it to completion. The exterior walls of the church are built of Bargate rag, with Bath stone dressings. The high-pitched roof is covered with bands of plain and ornamental tiles. This is surmounted by a spire, 120 ft. in height, built entirely of Bath stone on the pier of the west end, between the two west windows, gabled out by means of arches into a circular turret. The old burial-ground is retained around the old parish church, which

will henceforth he nsed as a mortuary-chapel, and consequently there was no consecration or provision made for funernls in the churchyard. The spire hears within it,—ia an open turret rendering them visible from helow,—six hemispherical hells. The east window (a three-light one) is filled with stained glass, hy Messrs. Heaton, Butler, & Bayne. The centre light depicts the Crncifixion, the figures heing nearly life-size. The reredos has heen sculptured hy Messrs. Farmer & Brindley, and represents the Road to Calvary. The sacrnrium is paved with marble mosaic, hy Messrs. Burke. The chancel is similarly paved. The oak stalls and reading-desk are of varnished oak, ornamented hy carved poppy-heads. The chancel ceiling is moulded, panelled, nnd decorated hy Messrs. Heaton & Butler. On the north side of the chancel is the organ-chamher; on the south side is Sir John Kelk's chapel. Both of these are divided from the aisles hy carved oak trncery screens, and separated from the chancel hy carved tracery screens of stone, with Devonshire marhle columns with carved capitals. The whole of the interior is huilt with Caen stone ashlar. The cost has heen 12,000*l*. Messrs. Dove, Bros., were the hnilders, and Mr. Hamlin acted as clerk of the works.

Wingfield.—The parish church of Wingfield, nesr Harleston, Suffolk, was re-opened on the 16th nlt., after restoration. The church contains three fine altar-tombs, one of them heing that of Michael de la Pole, second Earl of Suffolk. Another is that of John de la Pole, second Dnke of Suffolk. The third tomb, hitherto believed in the locality to he that of William de la Pole, fourth Earl and first Duke of Suffolk, is believed hy Mr. Phipson and other nrchæologists to be that of Sir John Wingfield. Some twelve or fourteen years since the chancel was restored hy the Ecclesiastical Commissioners, and at that time the roofs of the nnve nnd of the north aisle were also restored hy suhscription, hut when the present vicar, the Rev. W. Salter Price, hecame incumhent in 1877, he found much which needed to he done to put the church in good order. The south aisle roof was rotten and nnsafe, and the hrick floors were green from damp and age. With the generous help of Lord Waveney, who is now the owner of Wingfield Castle, nnd other liheral contributors, a fnnd was raised to defray the cost of restoration, and the roof of the south aisle was completely renewed and re-leaded, and this part of the church heing first done, it was boarded off, and service has heen held in the south aisle and chancel for some time past. The whole of the walls throughout the church have been re-plastered, and the stonework in the piers and arches of the nave has heen repaired and renewed where necessary. The unsightly old pews were removed, and the floor having heen raised 3 in., the nave and aisles have heen fitted with oak henches, the heads of the henches in the nave heing elegantly carved. The old pulpit, which had heen made up of part of the woodwork of the old rood-screen, though the carving has heen hidden hehind a profuse coat of paint, has heen remodelled. The old carved tracery of the panels has heen retained, and other panels in corresponding style supplied. The removal of the west gallery hns opened np the tower arch. The total cost of the work was 1,078*l*. The work has heen undertaken, nnder the direction of Mr. R. M. Phipson aa architect, solely hy Mr. G. Grimwood, of Weyhread, and the carving and other such work has heen entirely done hy Suffolk craftsmen.

Stow-cum-Quy.—On Sunday, the 22nd ult., the old parish church of Stow-cum-Quy, near Cambridge, waa re-opened, after complete restoration, under the direction of Mr. William White, F.S.A. The following legend, inscribed on a hand of stone in the north aisle, tells its own story as to the work, which has been carried out in a simple hnt thoroughly substantial manner:—

"This stone was placed as a record of the restoration of the parish church in the month of November in the year of our Lord God, 1880, and in memory of Clement Francis, of the town of Cambridge and of Quy Hall, in this county, by whom the good work was originated, and, with the willing help of others, was carried on. It had been in his heart to rebuild this House of God as a thank-offering for many blessings received during the course of a prosperous life. He died March 7th, 1880, aged 64, not having been permitted to see the full accomplishment of his desire, which was happily completed by Sarah Francis who for thirty and two years had been his loving and devoted wife."

The roof was found to he in an almost dangerous state; the ends of all the main timhers heing completely rotten. These have been pieced without removal. If once removed their replacement would have heen impossihle. The whole of the fittings are of oak. A few repairs were done many years ago by the now aged rector, who has held the living fifty-five years, non-resident, there heing no parsonage-house. The chancel has been thoroughly restored, with a grant in aid from the Ecclesiastical Commissioners. Some interesting arches carried on angels have heen opened out in the two side walls, — one containing a window, another forming n recess in which are remains of decorative colouring. A few remains of decorative colour nave been discovered also on the walls of the nave. These have been preserved, though not sufficiently clear to he deciphered. The upper stage of the tower also has been rehuilt in stone and flint. This had been removed some eighty years ago and replaced with timher framing, filled in with brick and a sham parapet. Some rather interesting parapets of brick, often found in the eastern counties, were necessarily removed from the clearstory, and could not he replaced.

STAINED GLASS.

Hurstmonceaux, Sussex. — The old parish church here has just had placed in it a three-light stained-glass window, the gift of Mrs. Hooper Greenaway, the subject running through the three openings heing "Christ the Comforter." A brass plate nnderneath the window records the gift, which is a memorial to the widowed lady's children. The artists are Messrs. Gihhs & Howard, of London; who have also in hand n memorial window to the late Lieut. Hamilton, who fell at Cahul last year, in defence of the Residency, under Major Cavagnari.

East Garston.—The east window here has been filled with stained glass. The church heing dedicated to All Saints, the most suitable suhject was thought to he, "Our Lord in Glory welcoming the Saints into Heaven." After much thought it was decided to place the chosen subject in the hands of Messrs. Lavers, Barraud, & Westlake, who hnve carried it ont in a very satisfactory mnnner. It includes a large numher of figures. Along the hase of the window is the inscription, "To the honour of God and in memory of All the Saints this window is dedicated by Martha Gray (horn Palmer), aged 91."

PROVINCIAL NEWS.

Huddersfield.—On the 17th nlt., Mr. Joseph Orossland, J.P., the president of the Hudders-field Banking Company, laid the foundation-stone of some new hank premises at the corner of Cloth Hall-street and New-street, Hudders-field. The intended building will he about 85 ft. long hy 47 ft. wide, covering a superficial area of about 440 square yards; it will have three fronts,—to New-street, Cloth Hall-street, and Chancery-lane. The first and second floors of the huilding will he arranged for suites of offices, with strong-rooms, &c., and will hnve access from a wide stone staircase opening into Cloth Hall-street. The contracts entered into up to the present time amount to ahout 17,000*l*. Messrs. Ratcliffe & Sons are the masons employed; Mr. James Christie, the carpenter; Messrs. Goodwin & Sons, slaters; Mr. Geo. Garton, plumher; Messrs. G. & F. Scholfield, smiths; Mr. W. E. Jowett, plasterer; Mr. S. Kendal, painter; and Messrs. Thornton, hot-water engineers, all of Huddersfield. The fire-proofing will be done hy Messrs. Dennett & Co., of Nottingham and London; the strong-room hy Messrs. Taylor & Sons, of Marsden; and the carving hy Mr. Harry Hems, of Exeter. The huilding is heing erected from the designs and under the superintendence of Mr. Edward Hughes, of Huddersfield.

Warrington.—On the 13th nlt. Lord Winmarleigh opened the extensive new offices and works which have just heen erected for the *Warrington Guardian*. The new huildinga are in the most central part of Warrington, adjoining the Post Office, and in front of the Town Hall. They measure externally close upon 200 ft. in length, and 100 ft. in width, are divided into three hays, and are lighted hy windows in the sides, gables, lantern windows, and skylights. A feature in the huilding is the nse of glazed white bricks in the inside, interspersed with diapers of hlue, and cornices of red, which give the whole huilding a hright character. The vitrified surfaces of the walls will render cleanliness permanent, and make whitewashing unnecessary. Sixteen iron columns support the roof, and divide what may he called the nave from the side aisles. Along the timbers supporting the roof of the nave, which is considerahly higher than the roofs of the aisles, the history of the *Guardian* from its commencement is given in gold old English letters, forming a striking ornamental frieze, divided into sections hy the county and city shields of the places or persons named. The huildings have heen erected for Messrs. Mackie, Brewtnall & Co. (limited), hy Messrs. John Collin & Son, huilders, from plans hy Mr. Thomas Beesley, architect, Warrington, nnd form what is no doubt one of the most complete provincial newspaper offices in existence.

Salford.—The Salford District Town-hall and Markets Committee, in a report just made to the Corporation, state that the contemplated extension of the Town-hall on the west side, for the purpose of affording more cell and other accommodation for the police department, is to he commenced forthwith, a contract having heen entered into for the work. This extension, when completed, will exhanst the whole of the available space afforded hy the present Town-hall site.

Teignmouth.—The Teignmouth Local Board having proposed to expend 6,000*l*. in erecting a market and Board offices, on the 26th nlt. Mr. Smith, inspector of the Local Government Board, held an inquiry, when it was stated that the unsuitahility of the present market had caused a decline of husiness, hut the tolls would pay the cost of a new market. Opposition was made to the scheme on the ground that the town was already 27,000*l*. in debt, and that the rates amounted to 5*s*. in the pound, hesides which there were water and sewage schemes on foot, which would cost ahout 12,000*l*. In reply it was stated that the Board rates were only half the sum mentioned, and in proof of the necessity for new offices it was pointed out that the snrveyor's office wns in a hay-loft, hut as this was over a placeloccnpied hy mnnnre-wagons, the chairman of the Board had declined to meet the snrveyor there, and as a compromise they met to discharge the Board's husiness in a disused mortnary (!)

Dorchester.—It is intended to proceed at once with the erection of a museum and library, also a school of art and accessory huildings, for Dorsetshire. About 3,000*l*. have heen suhscribed. Mr. G. R. Crickmay, of Weymouth, is the architect, and the tenders for the work are to he sent in hy the 20th of this month!

Kidderminster.—The Government have decided to erect a new General Post-office here, hnt local opinion is not unanimous as to the hest site. One party is in favour of retaining the present site in Church-street, while another seeks to remove it to Exchange-street. Deputations representing hoth sets of people have waited on Mr. Fawcett, the Postmaster-General, who has deferred his decision.

SCHOOL-BOARD SCHOOLS.

London.—On the 3rd of March last, the London Board accepted the tender of Messrs. Sheffield & Prehble, amounting to 9,873*l*., with the addition of 500*l*. for provisions, for the erection of a school for 1,200 children on the site in Farrance-street, Limehouse (Tower Hamlets). The contractors have since become hankrupt, and the Board accordingly invited fresh tenders for the completion of the school, and have accepted the lowest tender, that of Messrs. Hook & Oldrey, of Cowley Whnrf, Kensal-road, W., amounting to 8,534*l*., with the nddition of 500*l*. for provisions. As a snm of 1,600*l*. has heen paid to the original contractors for work already done, the total cost of the school will thns amount to 10,634*l*. The accommodation as recognised hy the Department is for 1,188 children. Cost of site (area 16,100 square feet), 6,602*l*. 19*s*. 2*d*. Total cost per head (inclusive of 1,600*l*. already paid), 8*l*. 19*s*. On the 12th of May last the Board instructed the Works Committee to hring np a scheme for the provision of a swimming-hath for the use of the hoya on hoard the training ship *Shaftesbury*, and to propose a tender for acceptance. The committee accordingly ohtained tenders for a hath 125 ft. long hy 45 ft. wide; hut as the lowest tender amounted to 1,047*l*., various alterations were made in the plans with a view to reduce the cost, and fresh tenders were then ohtained. As these tenders were still somewhat higher than had heen anticipated, the committee ohtained estimates of the saving which would he effected hy reducing

For the erection of Board schools, in three departments, for 1,000 children, situate in Cannon-street, Hanley, for the Hanley School Board. Mr. W. A. Keates, architect. Quantities supplied:—

Bennett, Rugby	£8,500	0	0
Gibson, Burslem	7,575	0	0
Tracey, Stafford	6,936	0	0
Inskip, Longton	6,793	0	0
Bentley	6,580	0	0
Cook, Burslem	6,330	0	0
Grosvenor, Tunstall	6,095	0	0
Gallimore, Newcastle	5,995	0	0
Barlow, Stoke	5,990	0	0
Ellis,* Hanley	5,799	0	0

* Accepted subject to certain reductions.

For alterations and bar fittings at the Blue Anchor, 67, Whitechapel-road, for Messrs. A. & J. Billinghurst. Mr. C. A. Legg, architect. Quantities by Mr. W. Hawker:—

Gill	£584	0	0
F. & F. J. Wood	553	0	0
Whyard	507	0	0
Aney	495	0	0
Walker	489	10	0
Parrish (accepted)	459	0	0

For additions to Ashton Gate Board Schools, Bristol, for the Bristol School Board. Mr. Stuart Colman, architect:—

Bennett	£632	14	0
Hodges	598	7	0
Pugsley	596	0	0
Hayes	590	5	0
Wilkins & Sons	590	0	0
Bastow	589	0	0
Searle & Son	589	0	0
Humphreys	559	0	0
Cowlin & Son	547	0	0
Veals	543	0	0
Crocker	541	10	0
Veals	529	0	0
Church	529	0	0
Crick	525	0	0
Banner	520	0	0
Lewis & Edbrook	514	0	0
Beaven	508	0	0
Coslea	498	0	0
Hatherley (accepted)	497	0	0

For farm-house to be built at Oghourne, Wilts, for Mr J. A. Buckeridge:—

Wiltshire, Swindon	£337	0	0
Hoskings, Hungerford	330	0	0
Elliott, Newbury	330	0	0
Gale, Ogbourne	325	12	0
Benner, Highworth (accepted)	238	10	0

For a Congregational church, Turnham Green. Mr. T. L. Banks, architect. Quantities by Mr. J. Sargeant:—

	Church.		Removal of Old Building.
Patman & Fotheringham	£3,963	.....	£120
Nye	3,790	.....	94
Sharpe & Mills	3,635	.....	100
Morter	3,585	.....	125
Colls & Son	3,549	.....	140
Adamson	3,436	.....	127
Toms	3,435	.....	75
Bransden	3,081	.....	72

For a residence at Streatham Hill, for Mr. T. L. Corbett. Mr. T. Lewis Banks, architect. Quantities by Mr. J. Sargeant:—

	House.		Fernery.
Morter	£4,136	.....	£99
Sharpe & Mills	4,115	.....	114
Toms	3,970	.....	105
McLachlan & Sons	3,784	.....	100
Patman & Fotheringham	3,783	.....	98
Downs	3,679	.....	78

For alterations at the Clarence, West Kensington, for Mr. Manley. Mr. H. J. Newton, architect:—

Minchin	£307	0	0
Taylor	227	0	0
Lanhle	220	0	0
Godden	210	0	0
Wagner	195	0	0
For New Counter.			
Warne	167	0	0
Skinner (too late)	166	10	0
Heath	163	0	0

For the erection of back addition to Leyden House, Christchurch-road, Streatham, for Mr. Edward Homersham. Mr. A. Johnson, architect:—

Knight & Richardson*, Sydenham	£130	0	0

*Accepted.

For erecting two new class-rooms at St. Gabriel's Schools, Easton, Bristol. Messrs. J. W. Trew & Sons, architects. Quantities by Mr. W. Munro, Bristol:—

Stock	£425	8	8
Dubin	402	10	0
Pugsley	398	0	0
Pitt	390	0	0
Forse & Ashley	384	16	0
Kidner	384	10	0
James	383	0	0
Summerville	380	0	0
Crick	376	0	0
Banner	360	0	0
Veals	349	0	0
Cowlin	348	10	0
Hill	345	0	0
Humphries	345	0	0
Davis	343	0	0
Hatherley	343	0	0
Saise & Son	342	10	0
Church	339	0	0
Williams	337	0	0
Williams & Prosser (too late)	329	0	0
Hodges (accepted)	324	18	0

For alterations and additions to Cox & Semadeni's Patisserie Suisse, High-street, Southampton. Mr. A. Martin, architect:—

Howland (accepted)	£183	10	0

For laying main drains, and making embankments on their sewage farm at Flixton, for the Barton Rural Sanitary Authority. Mr. J. Price, engineer. Quantities supplied by the engineer:—

Worthington, Manchester	£459	0	0
Jackson, Walkden	260	0	0
Marsland, Broughton, Manchester	251	17	8
Rayner, Bootle, Liverpool	213	14	0
Claridge, Shaw Heath, Stockport	212	14	2
Harrison, Salford	187	16	9
Turner & Sons, Warrington (accepd)	183	3	6

Warming and Ventilation.

*By a French Author.**

THE chapter in M. Planat's work which deals with hot-water heating at low pressure does not call for any special remark, except in regard to the "Chauffage Mixte," contrived by M. Grouville, and used at present only in one or two large hospitals in France. This is an arrangement whereby each floor or each set of rooms has a separate system of hot-water circulation from its own reservoir, but the whole of the hot-water reservoirs are heated by steam-pipes from one general boiler in the basement, which form a coil in each reservoir. The capability of steam to carry its heat for a considerable distance in pipes is thus utilised to bring a centre of heat to each floor, while the whole can be worked from one fire with the best economy of labour and fuel. The service of baths, &c., with hot-water, is fully illustrated. In the chapter treating of hot-water heating at high pressure, M. Gandillot's method of combining warming with ventilation in large apartments is worth mention. He forms the pipes into a coil at each corner of the room, in a chamber which draws in air from the exterior and passes it, warmed, up the centre of the coil into the room; around this chamber is an outer one, the space between the inner and outer coverings, which of course is more or less warm, communicating with openings in the floor or wainscot through which an *extract* current is formed. Thus the heat of the same coil of pipes is made both to draw in and warm fresh air and extract vitiated air. The contrivance is admirably compact and useful, if it really acts as theoretically intended. Unfortunately, that "if" is always suggesting itself in these matters. Warming by gas receives separate consideration, but we do not find any allusion to a method of applying gas where a gentle heat is required, just sufficient to take the chill off the temperature of an apartment, of which we certainly think something might be made,—that is, to employ gas in very small jets and with slow combustion to impart heat to fire-clay or terra-cotta. This use of gas was suggested a good while ago by a correspondent in our columns, and an instance of its employment cited. We have never ourselves witnessed any experiment with it. It has the advantage, or should have, of using the heat of gas in such a way as to produce the minimum of noxious result from combustion, at the expense, of course, of requiring a little time for the collection of heat in the fire-clay, and thus losing part of the special convenience of gas-warming,—its capability of instant application.

In concluding this part of the subject, M. Planat compares and sums up the advantages of various methods of warming. These must be regarded from various points of view: economy of construction and maintenance; power of assisting ventilation; uniformity of temperature when that is required; and power to change or regulate it easily according to circumstances. The most elementary form of warming is where the products of combustion, as in gas and fires, are merely turned out into the air of the apartment which is to be warmed. Gas has the great advantage of being instantaneously applied or cut off, and this is the one advantage it has; which operates largely, however, under certain circumstances. Open fireplaces are the least economical and the most feeble in result in comparison with the material consumed, of any; yet it may be said that there is no way of warming a room so agreeable, or more convenient, when it is a matter of consequence that each room should have its own independent source of warmth. And this independence is regarded as of much importance in Europe, though the author notes that in America there is an increasing favour shown towards schemes for general heating of a whole house, or even a group of houses. With all that can be said against the open fire, we do not believe any means of warming will ever be so agreeable or so generally liked. The open fire is like the chimney-pot hat; every one abuses it and yet no one likes to part with it. The open fireplace has also the advantage of furnishing a strong ventilating current, which, however, is very unequal unless the fire is constantly attended to and kept at about the same point, and is sometimes even an inconvenience in producing draughts, which draughts, from the position of the fireplace, usually pass along the floor exactly where one wishes it to be warm (an inconvenience we are practically experiencing at the moment of writing this with the back to an open fire), while the really warm air of the room is all at the top. In fact, there is no doubt the open fire is an uncivilised relic of barbarous and pre-scientific times; but, like some other relics of barbarism, it is undeniably picturesque.

Stoves, the author considers, are, when furnished with no special supply of ventilation, very economical and very unhealthy. Their special economy being to burn slowly, they, on that very account, do little to make a ventilation, as a fire does, and should always have a special "*prise d'air*" provided. We do not even agree with M. Planat in saying that it is only in very large public halls that stoves without a special air-supply should be tolerated. However large a public hall may be when full of people, it requires special air-supply as much as, or more than, any other kind of building, and every means possible for keeping the air in a state of flow should be provided. Let any one who doubts this go and sit, for instance, in the balcony at St. James's Hall on a full "Monday Popular" night, and experience the kind of atmosphere in which we are condemned to sit on such occasions in what passes for a first-class hall of entertainment.

In the case of an open fire, the air drawn into the room passes out naturally through the chimney; in the case of a stove with an "*appel d'air*," it either finds its way out through the interstices of the windows and door, through which it would be drawn inward by the open fire, or it escapes by apertures purposely made. The flow of air is thus the reverse way to what it is in an open fire. The air in the room is thus in a state of slight compression,—a state which in itself puts a limit to the inflow of air drawn by the stove, which thus is very inferior, as a self-acting ventilator, to the open fire. Complete ventilation in such a case can only be regarded as secure by the help of some means of artificially promoting the extraction of air, which is not always to be easily or economically managed.

M. Planat is decidedly adverse to the plan of warming our apartments through floor openings; the column of heated air entering vertically, ascends, he suggests, to the ceiling without mixing nearly so much with the air of the room as when the heated air is discharged from the sides and at some little height from the floor; and another practical objection is that an opening in the floor receives a great deal of dust, especially when the room is swept, which is then dislodged and sent up into the room when the current of warm air is in full operation.

Heating by steam M. Planat strongly recommends for heating operations on a large scale, as being capable of conveying its heat a long distance without sensible loss; owing to this latter quality, it can be worked from a furnace outside the walls of the building, and thus removes almost all possibility of danger from fire, and is therefore peculiarly valuable as a means of heating museums, or buildings where important documents are stored. The steam system, on a large scale, however, is liable to be inconveniently complicated in working, and requires a good deal of attention. It has the important advantage over stoves and *calorifères* that it never becomes so heated as to render the air unwholesome. Nearly all that can be said in favour of steam can be repeated in favour of hot-water heating, with the addition that it is more easily manageable when in operation. In regard to the expense of working steam and hot-water heating some observations were made by General Morin and others, the result of which was that the two systems were in that respect pretty nearly balanced. Warming by gas, as before suggested, can only be advantageous under very special circumstances; when there is but a very small space to be warmed, and

* See p. 663, *ante*.

when the warmth is required only at varying and intermittent periods; under any other circumstances gas is one of the least economical or agreeable methods of warming.

There remains, however, the "mixed system," which, as appears from M. Planat's observations, is only of very recent introduction in France, and which he believes has not been introduced in this country as yet. Our author sums up so decidedly in its favour as a system for warming large buildings that it is worth while to quote his remarks:—

"In this combination of steam, water, and hot air, it has been attempted to combine the advantages of all the three systems, and eliminate the inconvenience of each. The system is employed only to transport the heat developed in the ordinary boiler; but it provides also a motor power for all the accessory mechanism, without any necessity for a special boiler for this purpose, as in the case of heating by water. All the complication resulting from the employment of steam for direct heating is suppressed, and all the apparatus for the production of heat is below, in one story, and under the immediate control of the engineers. The water which directly heats the rooms receives its heat from the steam by means of a simple coil; its temperature and its effect in warming the air are the more easy to manage since they are directly influenced only by the steam. The advantages of water-heating,—low temperature, regularity, conservation of heat, &c.,—are thus maintained. Lastly, the hot air has only to accomplish a short journey, as the steam has made the greater part of the transit. At the same time all possible inconvenience from the escape of steam or hot water in the rooms is avoided. It appears, then, this system presents a great total of advantages; it is only to be objected that it is a little complicated."

The complication is apparently, however, in the fixing, not in the working; and, for an important building on a large scale, the objection is hardly worth taking into account.

The consideration of the subject of ventilation is one of the best parts of M. Planat's book; it is treated in a very practical and comparatively concise manner, and not so overloaded with formulas and computations as some other portions of the work. The author directs himself especially to considering the conditions under which ventilation has to be carried on under varying circumstances of atmosphere and inhabitation. In winter the action of the fire or other methods of artificial heating naturally acts to produce an influx of air; but there is no such influence in summer. Most dwellings have no method of ventilation in summer except that of opening windows, which may give rise to inconvenient draughts even in warm weather, and which at night becomes "dangerous." This last opinion is no doubt generally acted upon, though, in our opinion, most people entertain a most exaggerated idea as to the danger or inconvenience of open windows in sleeping-rooms; and, in fact, the danger to health from the close unventilated rooms in which the great majority of persons are content to sleep is a much more real and serious one. Many people have accustomed themselves so completely to the idea of closed-up rooms at night, even in the warmest weather, that if they find a window slightly open in their bedrooms they imagine a draught where there is none except what would do them good rather than harm. Any danger they may be under of catching cold from an open window at night is no doubt much promoted by adopting the constant habit of closely-shut rooms for sleeping in; those who are subject to "catching cold" being usually those who have rendered themselves peculiarly sensitive to such attacks by always bottling themselves up from the air; and then the inconvenience and annoyance of catching cold is easily felt and estimated, whereas the slowly deleterious effects of regularly spending several hours out of the twenty-four in a room closely shut up from change of air are not so readily appreciated by those who do not think about the matter. This is not to say that we should not be better for a special means of ventilation for sleeping-rooms, apart from windows, even in summer; but that until such means are established as a habitual adjunct to a dwelling-house, people will consult their own health much better by getting rid of their superstitious fear of open windows. To return to M. Planat: in regard to the admission of air either by inlets connected with the heating apparatus, or by special inlets apart from it, he recommends that these should always be as large as can conveniently be, in order to admit a sufficiency of air at the least possible rate of travelling,—a small inlet, under the same relative conditions of atmospheric pressure within and without, producing, of course, a much quicker in-draught. On this account especially is it desirable that the number and positions of air-supply entrances should be decided on by the architect from the first in contriving the plans: a remark which seems almost a satire on the practical architecture of the day; for how often, in dwelling-houses at any rate, is any such provision exercised? And yet the necessity for it might be thought to be one of the first principles of practical house architecture. One statement in regard to a supposed practice in English house-building is amusing, whichever way we take it, viz.:—that "In England the influx of fresh air is often provided for through the interstices of flooring-boards with open joints, which are covered with a carpet to better disperse the laminæ of air." This is said so seriously that we cannot determine whether it is a piece of conscious or unconscious satire.

The practical conclusion of our author, however, is in favour of special inlets for the introduction of fresh air, so designed and placed as to admit a sufficient body of air slowly, and without direct draughts. In the case of the exit of the air the draught may be stronger and quicker without entailing any inconvenience on the inhabitants of the room. An influx of air at too great velocity maintains itself as a special current for some distance into the interior air of the apartment, and becomes an annoyance to any one who may be so placed as to come in contact with it. A withdrawal or extract tube, however, at one point in the apartment, acts upon the body of air contained in it equably, without setting up a special suction in any one line or direction; and the evacuation is likely to be more effective in keeping up a ventilating movement of the air the quicker and stronger it is. In short, the theory of effective and agreeable ventilation of an inhabited room is a large but slow influx of fresh air, from various quarters if necessary, and a single but strong current of extraction at one point. We may have many inlets without weakening or confusing the flow of air for ventilation; in general, we can only have one outlet or extract, which must be proportionally strong and rapid in order to control and keep in action the flow of air through the inlets. More than one extract, unless in an apartment so large that practically two systems of ventilation may exist at opposite ends of it, is only likely to break up the movement of the air, and make the weaker extract act in opposition to the stronger one, and become an extra inlet, with the additional disadvantage of forming an inward draught in the apartment. The admitted air may be cooler than that in the apartment under certain circumstances: in hot weather it is sure to be warmer, in cold weather it will be so much colder as to require warming in its passage; but the extract-flue must always be warmer than the apartment, or there can be no certainty, or even probability, of its acting as an extract, except with very doubtful and intermittent effect. In regard to this question of the reciprocal operation of the inlets and the extract, one sentence in the chapter we are considering is either incorrect in printing or wrong in fact:—"Aux points où l'air est extrait de la salle, il est bon de réduire la vitesse plus encore que dans les conduite, pour éviter les courante d'air nuisibles aux personnes placées près des bouches d'évacuation." This is manifestly absurd, as in that case the extract would not act at all; and as the writer immediately afterwards observes that the draught towards the extract has far less operation in inconveniencing any one than the draught inward from the inlets, it is fair to presume that there is some misprint in the text.

In regard to the extraction of air from a room artificially heated, some pages illustrated by small diagrams are devoted to showing that the extraction of the air should always be in the lower and not in the higher part of the room, whatever method of warming is used to set up a current. To extract from the higher part of the room is merely to extract all the warmed air, which rises to the top of the room, instead of assisting it to circulate through the room. All the conclusions and examples on this point seem quite sound and reasonable, except in regard to No. 4 diagram, which shows a room warmed by a central stove with an opening at each side near the floor for exit, rather than extraction, in this case. The warmed air heated by the stove is to rise to the top of the room and thereby induce a down-current, which is to escape by the two exits below. This looks very neat and symmetrical in a diagram, but we do not believe it would act; one of the lower openings would become an inlet. Otherwise this portion of M. Planat's suggestion is worth study, and is very plainly and clearly put. Then we have separate chapters on winter and summer ventilation, by way of emphasising for the reader the fact that the conditions are quite different at the two seasons, wherever the temperature is so different that fires are used in winter and not in summer. For winter ventilation the author suggests a central upcast shaft with a current set up by a fire burning in it. Gas, of course, could be used for this purpose, but would be more expensive, and perhaps would gain very little in regard to convenience in the majority of cases, where ventilation was required to be constantly kept up. The application of this shaft system is treated in three different ways,—"*Appel à niveau*," where the extract from each apartment opens at once into the upcast flue on the same level as that at which it leaves the room; "*appel par le haut*," where the heat is supplied at the upper portion of the building and the extracts from the several rooms rise to that point; and "*appel par le bas*," where the heat is supplied at the base of the extracting-shaft, and the extract from each apartment is carried down to the bottom of the building and there turned into the upcast-shaft. In all three cases, in accordance with the principles before expressed, the extract from the separate apartments is from the lower portion of each apartment. We must leave the reader to follow out M. Planat's *pros* and *cons.* in regard to these methods. We have no manner of doubt that the "*appel par le bas*" would prove the most effective in practice, under proper conditions of working, but it would probably require a somewhat stronger heat in the upcast-shaft to ensure the requisite drawing power. For summer ventilation the author appears to think that the same system would answer without the artificial heating, on the principle that the outer air is in that case warmer than the air in the apartments. We should have some doubt of the "*appel par le bas*" answering in that case, however, and there would certainly be many days in an English summer in which the respective interior and exterior proportions of temperature would be such as to invert the current. On such occasions, of course, there would need to be a return to the winter system of artificially warming the extract-shaft. There are, however, one or two English inventions for generating an up-draught by the mere action of the atmosphere on a "cowl" of peculiar construction, which have been found to answer their purpose well. The concluding chapter is devoted to mechanical ventilation, giving a good many diagrams of apparatus for producing it. In summing up the advantages of the several systems, the author is decidedly in favour of mechanical extraction whenever the building is of sufficient size and importance to justify the expense, which must usually be greater than that of ventilation by warming, except in special cases in which motive power is easily available from some source existing for other purposes in the building. As he observes, we cannot in any other way have so complete and uniform control of the currents of air as in regulating them by mechanism, the action of which can be varied at pleasure and adapted to all the different conditions of heat and barometrical pressure.

In spite of a certain amount of pedantry and an unnecessary and often tedious elaboration, the book published by M. Planat is certainly a most important contribution to the literature of warming and ventilation, and is worth the attention of all who are specially interested in the subject.

Salford Baths and Wash-houses.—The General Baths Committee of the Salford Corporation, in their annual report, just presented, state that the first summer season during which the new baths have been open has been very successful, the total number of bathers being 58,844.

A GREAT FRENCH EXPLORER.

THE recent death of the eminent French archæologist, M. de Sauley, whose name will ever be connected with the valuable collection of Judaic remains he brought to France, and which now reposes in the museum of the Louvre, recalls many memories,—memories of that valiant band of seekers into the history of the past which is daily, page by page, being written by their patient hands. Little by little the history that seemed but a short time since so barren teems with life; quietly the researches of the archæologists people the silent streets of cycle-buried cities, the untrodden high-roads of bygone civilisation.

Of this valiant band was M. de Saulcy, and in the ranks of the army of archæologists his loss will be keenly felt. The day happily has come, however, when even such a gap can be filled in, and many an eager volunteer will be found ready to spring into the place, to lead forward the attack on Antiquity's silent strongholds. From every country these volunteers pour in, as they have done, indeed, within the comparatively few years that the common cause has been proclaimed, from England and from France, from Italy and from Germany, eager to help each other. In this army the list of those also who have already fallen is a long one; all have died sturdily, and not till they had fought the good fight to the uttermost of their powers did they sheath the weapons of their onset.

Very recently an interesting work has appeared in Paris, in which the debt that the world owes to the memory of one foremost among these warriors, Botta, has been gracefully paid.* Botta was an officer of high standing in that army of which we have spoken: his efforts led in a new direction, and, side by side with a brother soldier, Layard, they were crowned with a success that astonished and benefited the world. The sudden evocation of a civilisation, the remembrance of which was kept alive in faded traditions, themselves of no small antiquity, was a pleasurable surprise to the learned world of a generation ago. We of the present day, rendered *blasé* on the matter of discoveries, living as we do when telegraphy, when the electric light, the practical application of steam, the telephone, the microphone, the doctrine of selection, and what not, have come one after another to inure us to receive with perfect composure the relation of anything that but a short time since would have appeared positively wild, can form little or no conception of the effect first produced when the discoveries of Botta and Layard startled the European world of art and letters.

The name of the discoverer of Nineveh has, since that day, become familiar as a household word in every cultured circle, nor is the world likely to forget the services that Botta rendered. But the early life of the archæologist, that preceding the great event with which his name is so indissolubly connected, is less known. It has now been agreeably evoked in the work which Botta's old friend, M. Paul Levavasseur, has edited, and to which he has added an interesting notice of the life and more particularly of the character of Botta.

In 1837, the discoverer of the ruins of Nineveh had been charged by the Museum of Natural History with the pleasant task of an exploration in Arabia, the object of which was to complete the collections made there by Niebuhr. Botta had not at this time acquired his future celebrity. He was a learned naturalist, an excellent Orientalist, who spoke Arab like his mother tongue, and, what is more, the possessor of a mind above common prejudices. At the moment at which he was sent on this mission, his task was not alone to herbalise in Arabia, but to make diligent observations. The French were allies of Mehemet-Ali, and, therefore, to some extent supporters of his policy. Mehemet dreamed of extending his rule over Yemen, and his relations with the Cheikhs of that country it was advisable to watch. In addition, Botta was curious to study in its cradle the Arab nation, of which little else was known than its nomad existence; everything, therefore, combined to add an interest to Botta's journey, and this interest it may fairly be stated remains attached, after forty-three years have passed, to the relation he has left.

What, however, is more interesting than the journey is the traveller himself. Botta was a modest man, who mixed very little in the world, and who, therefore, was personally little known. His name is familiar to many from the fact that his father, Charles Botta, was the author of an excellent history of the Independence of the United States, as also of a history of Italy; but his own reputation he made by the discovery of the ruins of Nineveh. Botta became the founder of Assyriology, and by his researches transformed an almost conjectural branch of history into a positive science. As an archæologist and a scholar, his renown needs no additional remark.

By the few who still survive, that recall the *salon* of Mme. de Mirbel,—we are taken back to the days when the *salon* still existed in Paris,—Botta's place in the little circle will be remembered. Silent and meditative, apparently noticed by none, and yet his presence felt by all, he would sit in the evenings stretched on a sofa in the darkest corner of the room, rolling between his fingers, in Oriental fashion, an interminable chaplet. Evening after evening would pass without his proffering a syllable; his repose was respected like that of a child or of an invalid. Botta was, indeed, both; the baneful habit of opium-smoking, contracted in the East, had undermined his health, while his nature was essentially that of the child, and his timidity, with ladies especially, he never overcame. Mme. de Mirbel was indeed, perhaps, the only woman who ever succeeded in overcoming this, and then alone by the aid of stratagem. In the first place, she was no longer young when Botta knew her, and her tact was of the most refined nature. She waited, before speaking to the *savant*, until the circle had been reduced to two or three intimate friends; in addition, she had established between him and her *femme de chambre*, who was ugly and old, the most confidential relations on all domestic affairs. It was Pauline who ruled the servants of M. Botta; Pauline who settled with the tradespeople; Pauline who superintended the packing of his trunks when he was about to travel; and Pauline it was, above all, who protected the purse of the worthy Botta from pillage. No man was ever simpler in his habits and requirements, but none, on the other hand, was more generous or lavish in his expenditure. It was by dozens that he ordered his boots from his bootmaker. The tradesmen were enchanted to have a customer who was perfectly indifferent to the reception of all their shop-worn or out-of-fashion stock, a good faith equally abused by the eating-house keepers, who would send in fabulous bills for dinners never consumed. Botta, who was never rich, could ill stand such expenses; but through the kindness and affection of Mme. de Mirbel he was saved the distraction so fatal to his pursuits. The affection of Mme. de Mirbel was that of a second mother; she recognised the delicate character of this rare nature, and with a woman's heart protected it; it was her action that placed him in the way that led to his great discoveries; her protection and her counsels obtained his entrance into the Foreign Office; and it was during his stay at Mousoul, where he was named consul, that a good fortune visited him such as the wildest treasure-seeker could never have foreseen.

M. Levavasseur publishes a letter of Botta's, which is interesting, as showing the commencement of those researches which were to lead later on to such astounding results:—

"My successes in antiquities will surprise many scholars. I have unearthed a whole monument on which there are an enormous number of cuneiform inscriptions and historic bas-reliefs. It contains a whole history. If we succeed in being able to read this writing what things we shall learn! I continue, but it ruins me. There is a village built on the monument, and to unearth it I have to purchase and demolish the houses. They do not cost very dear, it is true; ten to twelve francs each; but the diggers cost more,—five francs a day, at least, in all. It is more than I can afford, and I ask the assistance of the Government. In the meantime, and before the decision arrives, which may be long, you must help me. The honour of France is at stake, for the English are ready to succeed me if I interrupt, and it would be a pity to abandon to them the most important discovery that has been made for a long time. I cannot at present afford the leisure to give you any details on my monument; but if you wish to know what it is, ask M. Mohl to come and see you and show you my descriptions and drawings. . . . . Adieu, my dear friend. P. E. BOTTA."

When, in 1848, M. de Lamartine sent him out as consul to Jerusalem, it was a considerate attention on the part of a poet for a brother in culture, for there existed between Botta and the mystic city not a small degree of harmony. Botta's devotion was of no ordinary nature; to the simple faith of the child he added what is a rarer quality, even in divine affection,—disinterestedness. His good deeds were never selfishly actuated. His house was ever open to the pilgrims; a cordial, though simple, hospitality received them. Speaking of his old friend Botta not long since,* M. Villamus expressed how often he had been surprised to know in what manner Botta was able to afford such incessant largesses. As recompense for his discoveries, the French Government had presented him with a national gift of 60,000 francs, and this was all that Botta ever possessed; nor can this sum have remained long in his hands. His income can never have exceeded the modest sum of 500*l.* to 600*l.* a year, and yet he kept in the East open table, and money ran like water through his fingers. M. Villamus tells us further some curious tales characteristic of Botta. One day Botta asked his friend to send him some beer to complete a medical prescription which had been made out for his cook; two barrels was the quantity considered necessary for this object. On another occasion M. Villamus was with Botta when he was purchasing clothes, and not unnaturally expressed his astonishment at seeing his friend buy twenty pairs of pantaloons. "I shall distribute them," replied Botta, "to those about me." Some years later, when he was French consul-general at Tripoli, a friend asked him at table the colour of the ribbon of a certain order,—one of the most highly-valued in Europe. "I do not know," replied Botta. "How!" cried his chancellor; "why, sir, you have the order." "You are wrong, my friend; I do not think I have it." "But, sir, I myself opened the letter containing the brevet and the insignia, and placed them into your hands." "If that be the case," replied Botta, "you will find the ribbon then, I suppose, in the drawer with the others."

In spite of a feeble constitution and of an even excessive nervous delicacy, his irritation never betrayed itself. Above all, he was profoundly religious, and not with that narrow-mindedness the result of a dogmatic belief. His respect for religious believers came from his heart, whether they were Christian, Buddhist, Mussulmans, or what not.

After an active existence, in the first place as a naturalist, and subsequently as an antiquary, Botta, settled in the desert post of Tripoli, slept away his latter years. Opium is a dangerous friend, which attaches itself only too securely to those who court its fatal influence, and Botta's life may be said to have been little more than one long dream, from which he awoke only to do some good deed of charity. His chancellor and his dragoman watched over him as they would have done over a child. Always dying, and yet alive, his trust was fixed on Providence. All advancement or change in the service of the Foreign Office was positively painful to him. "I only desire one thing," he wrote, "that God shall give me my order of retirement, and men shall think no more of me." But this modest wish was not carried out. The time came when Botta, having long passed the limit of age, was able to enjoy the ease of retirement; but what for others would have been a revival of life was for him to be fatal. The sun of the East was alone able to warm this exhausted frame. No family tie called him to France. His father was dead, his mother he had never seen, of his kind friends Mme. de Mirbel was no more; one alone remained,—one, faithful in death, and who has seen through the press the unpublished work of his old friend. Botta returned, however, like a dutiful son, to his mother country, and it was near St. Germain, in the little village of Achère, that he patiently waited his end. On March 29th, 1870, death came to release him, hearing off his gentle soul as the angel reaper in the poet's familiar lines.

The religious faith that breathes throughout his whole career consoled his later years. M. Levavasseur tells us that not least among the few troubles of his last solitude was the thought that the little parish of Achère possessed no regular vicar. On Sunday only an aged priest of more than eighty, but still robust, came several leagues on foot to perform the simple mass in the village church. This priest had himself travelled not a little as a missionary, and Botta anticipated his Sunday visits with a pleasure more than common. "To his (Botta's) funeral came," tells us M. Levavasseur, "all the inhabitants of Achère,—who have not yet forgotten his familiar face in his too short passage among them,—the heads of the consular service, some plenipotentiary ministers, and not a few distinguished savants. A voice retraced the life

* Relation d'un Voyage dans l'Yemen, entrepris en 1837 pour le Muséum d'Histoire naturelle de Paris, par Paul Emile Botta. Précédée d'une Notice sur l'Auteur par Ch. Levavasseur, ancien député. Paris, 1880. 8vo.

* *Revue Politique et Littéraire*, Oct. 9, 1880.

of the deceased; it was that of the old priest of St. Germain, who seemed to have forgotten his long walk of the morning, so firm and round was his tone. I was deeply touched as I listened to this noble and courageous old priest, and I asked myself more than once, by what mysterious coincidence it happened that in this little village church there should be present a priest who himself had journeyed far, and who was now called upon to make a funeral address over another traveller, who, during his life, had honoured France by his learned discoveries, and religion by a sincere and enlightened faith."

Those who will be induced to read the "Relation of a Journey in the Yemen" will find in its pages a faithful portrait of the author himself. The style is simple, the judgments intelligent and benevolent, in true accord with Botta's character. He loved the Arabs, that strange people that have taken so large a share in the progress of humanity. The two portions of Arabia, Northern and deserted Arabia, and Arabia Felix, the Yemen, are occupied by two very different populations. It is in the latter that can best be studied that great people who so many centuries ago civilised Spain and Portugal, and which influenced far more than is generally imagined the manners of Europe.

A STUDY OF THE MEDICEAN VENUS.

"Cleomenes, the son of Apollodorus, the Athenian, made me," is the record on the plinth of the far-famed statue who holds her court in the Tribune of the Uffizi Palace in Florence, without paying the homage of a visit to whom no tour in Italy is complete. As at other shrines, the adoration of her devotees varies both in quality and quantity, and some have even ventured to undervalue her charms; but as for some centuries she has continued to hold her pride of place among the relics of ancient art, a renown so enduring is not likely to exist without some good foundation.

She is, without doubt indeed, a beautiful work of art, and she is of beautiful Parian marble; but when and where she had her birth, ancient record sayeth not; and even Pausanias is silent, not only as regards herself, but even in respect to the very name of her sculptor, Cleomenes, which appears on the marble plinth beneath her feet, but not in the list which he gives of ancient statuaries.

Thus some have questioned the verity of the Greek inscription, and have favoured the idea of attributing her creation to Alcamenes or to Praxiteles, just because they deemed that so fair a daughter ought to have a renowned father. Discordantly, however, with these suggestions occurs the fact that there is no description extant of any work by Alcamenes that in any respect agrees with this statue; nor either does it correspond in character or treatment with any production by Praxiteles that we have remaining to us.

The fame of the perished Aphrodite of Cnidos, by the latter artist, has directed many thoughts to him as the possible author also of her of Florence, or at any rate to the idea that it probably must have been at least a near copy of that marvel of the ancient world. There appears, however, to be no sound foundation nor feasible plea for this theory, except that the position of the left hand is similar. The Aphrodite of Cnidos looked towards the right, and not over the left shoulder, as she of Florence does, and held up with her right hand a fall of drapery which descended to a vase by her right foot, instead of that hand and arm crossing and half concealing her bosom, as it does with her of the Uffizi Gallery; so that the attitude of the two statues must have been quite distinct.

Further than this, those who have surveyed with a careful and deliberate eye the especial graces of pose which Praxiteles peculiarly loved, cannot justly trace them in this work. A luxurious sway at the hips was in great favour and estimation with him; and, in as far as we can judge, was a particular attribute in the works of that great sculptor. It is to be seen accordingly in his Apollo Sauroctonos, his Faun resting on a tree, and markedly is this tendency of his art also illustrated in the lately-discovered mutilated statue of the Hermes of Olympia, by him, of which, as we mentioned some months ago, a cast has been received from Germany by the British Museum; where it may be consulted at leisure. Also on a well-known Imperial coin of Cnidos occurs a representation, somewhat freely translated, no doubt, of this celebrated Aphrodite of Praxiteles, the tutelar deity of the place, in which a similar inclination at the hips is to be recognised; but nothing of this is perceptible in the Medicean Venus.

On the contrary, the graces of this figure, which are, indeed, many, are attained without this lateral sweep of line of the body and lower limbs. They are peculiarly her own, and are not acquired in this manner. She rests, principally on one leg, it is true, but with very little sway at the hips. Her body, although inclined forwards, as regarded from a side point of view, is little otherwise than equally balanced in the front aspect, and the charm of the lines of her attitude, which are admirable, is obtained by other means.

These remarks are addressed to dissipate the idea of the Medicean Aphrodite being in any degree a copy of her perished sister of Cnidos; and to submit, on the other hand, that the two Venuses, Aphrodites, or Divine daughters of the sea-foam, hewn and wrought, both of them, from Parian marble, were, in other respects, pretty much as distinct as two ideals of the sculptural poses of gentle female beauty could well be; the one point of resemblance, which Ovid alludes to in his well-known couplet, being alone visible.

The fact that ancient annals are dumb in respect of the name of the sculptor which appears on the base of the Uffizi Aphrodite, suggests a likelihood that he did not execute many statues. Perhaps even he never did but this one great work,—his tribute to Venus,—to be by her alone immortalised! This appears to derive support from the consideration that, as far as data exist, the style and quality of form and composition of the Medicean Aphrodite are unlike those of any other existing work of ancient art. The Apollino has been said to resemble it, but this has been set forth on feeble grounds, such as may suffice in superficial criticism, but will not bring conviction to a careful student of art. Both these ancient works are statues of great refinement of form, but there the likeness ends. There is not in the Apollino that rich luxury of surface which the Italians term *Morbidezza*, that is possessed by the other statue, nor does there exist in him the lavish harmony of line and composition, in every view, that is a characteristic of the sweetly coquettish goddess that bends and shrinks, and embraces herself with her own arms in the Palazzo Uffizi of the City of Flowers. The Apollino is a graceful youth of a feminine style of beauty, but is of another family from the Venus.

In the position of the arms and hands before the figure, concealing the person, other statues of the goddess, in general action, resemble her, but in their air and quality they are different, and in several instances appear more modest because less conscious. It must be acknowledged that the Uffizi Aphrodite appears aware that she has placed herself in a most becoming attitude, and that she looks as if she had posed herself before a mirror so satisfactorily to herself that she was calling on all beholders to come and admire her studied graces. Her artist also has so fully carried out this undulating sentiment of line and figure in the whole work, that even the adjuncts of support in the marble of the dolphin at her feet, and the *amorini* riding on it, partake of the same character, and are so disposed as to harmonise in all respects with the limbs, insomuch that, in a merely decorative point of view, the *tout ensemble* is a triumph of ornament, just as fully as if it were constituted but of flowers, or of purely conventional forms, instead of its being a representation of a beautiful woman, instinct with animation, hewn from the solid marble, with only such supports left as were requisite to sustain it.

An excellent delicacy of personal presence is remarkable in this statue, but, as is usual with ancient classic works, this quality was not sought by making the extremities small. The sculptors of old, indeed, appear to have had some reluctance to employ this facile mode of obtaining *finesse*, and strove for elegance of proportion rather by refinement of contours than by smallness of parts.

This remark does not apply, of course, legitimately, in this statue, to any portion of it that is not original, and therefore not to the hands, which are restorations; but in respect to the feet, these are certainly not by any means small. The statue represents a woman who, if she stood up to her very utmost height, would scarcely reach 5 ft. 2 in., while living women are to be found in England much taller in stature than this, with feet no bigger, nor indeed even so large. These feet, however, which are original, have apparently supplied the measure of length for the restored lower arms. It is a standard of much value and of ready application in sculpture, and one that has been relied on, among others, by the great Thorwaldsen, that the length from the elbow to the wrist-bone, should coincide with that of the foot from the heel to the tip of the longest toe. This seems to have been known by, and adhered to, by the restorer of the arms of Uffizi Aphrodite, and the feet being of full-size and length, this has been the cause of the lower arms of the restoration being, perhaps, a little long, although this is not striking because of the bent position of the arms.

The statue was in a sadly mutilated state when it was found, having been broken at the middle of the body, at the thighs, the knees, and the ankles, and at the right arm, close up to the shoulder; the whole of that arm having been lost, and just below the elbow of the left arm, that lower portion having also perished; so that, for the arms now on the figure we are almost wholly indebted to the skill of the restorer, so that we have reason to be thankful that the marble creation is presented to us now in so fair a guise as it is.

On a critical examination, however, it cannot escape observation that the restored portions, although apparently correct in disposition, are not in detail so natural as the rest of the figure, although they deserve a high meed of comparative praise for the cleverness with which they are wrought, and the evidently sincere aspirations of the restorer. Impressed by the excellence of the torso and lower limbs, he applied himself to seek a similar perfection of grace and delicacy in the upper limbs, and has in degree sacrificed truth to sweep of line, especially in the right arm, in which he has somewhat bent both bones of the lower arm to meet his views. Both wrists, also, show signs of this yearning for flow of line; but the mark has been somewhat overshot.

There is little doubt that the *soupçon* of affectation which exists in this statue is much due to the conventional character of these restored parts. Had the hands and arms been more natural and more in accordance with the treatment of the rest of the figure, a simpler and more classic effect would have been produced. It may be remarked, however, *en passant*, that they present a notable instance of the force of precedent, even when it is not well founded, as although these arms and hands have no original authority, being but restorations of the lost parts, yet having been so long closely associated with this beautiful ancient statue, they have had a strong influence on these portions of the female form in modern sculpture, in inducing an over-degree of bending of the lower arm; and nowhere is this more perceptible than in some of the works of the great Italian sculptor Canova.

It is apparent, also, that the restored fingers are too slender to accord with the original toes; for in Nature the upper and lower extremities are usually in harmony. Probably the original hands were less like those which have been restored than to that well-known example of "The Roman Lady's Hand," so-called, which has the appearance of having been moulded and cast from Nature, and which has also been romantically attributed to that arch *empoisonneuse*, the Marquise Brinvilliers, the fingers of which in that case may have mixed her deadly potions; and also to the beautiful Princesse Pauline. In this elegant hand the fingers are plumper than those restored to the Medicean Venus, and the wrist is less forced in line than her wrists, which have a certain artificial character, which, although they must be allowed to be graceful, are yet thus, from the above cause, scarcely satisfactory.

As the whole statue was, doubtless, originally in one piece of marble, very noteworthy is the excellence of the workmanship of the portions of the bosom and torso immediately behind, and close to, the hands. This proximity must have been very embarrassing in the execution of the work, and yet perfection of contour and surface has been attained notwithstanding.

One may be allowed to wonder whether the inside of the original hands, so little removed from the body, were worked out with equal completeness, as the slenderness of their detached fingers and their consequent fragility in marble must have added to the difficulty of their execution. Of course, this was easy enough

to do in the restorations, as these were worked separate and away from the figure, and afterwards affixed. It is evident, however, that whatever have been the modern improvements in the working of metals, the tools of the ancient sculptors were of an excellent description, of which, indeed, the clean undercuttings of the highly-wrought draperies of the Parthenaio marbles are sufficient evidence. Thus, also, in situations so difficult to get at as the undersurfaces of hands of this Venus, tools were, no doubt, especially fashioned and bent for the purpose.

Much as this interesting and celebrated statue is prized, she is not well placed in the Tribune of the Uffizi Palace. Fine works of the sister art are associated with her in the same room, which are the frequent subjects of study and of copying by artists whose easels not unfrequently interfere with her being seen freely and to advantage from the best points of view. Most surely she is worthy of an apartment to herself, and should have a little temple or "Ædicula" solely dedicated to her, in the City of Flowers, such as whilom her perished sister is recorded to have possessed in the town of Cnidos.

Far different have been the fate of these two Aphrodites. She of Cnidos,—we know who made her,—Praxiteles, in the fourth century before our era,—held court in that city for a long period; after which, on the spoliation of her native grove and habitation, it has been supposed that she was taken to Rome; whence subsequently she was removed to Constantinople, where eventually she perished in the fire of the Laurian palace. In respect to her of Florence, we know not the period of her birth, but at present she is in safety in that lovely city which is her modern home. She, however, also was the subject of spoliation in the time of the first Napoleon, and went to Paris for a while, from which adventure, however, she returned, without injury, to her former place of rest. So much have we of her latest history, but as to where and when she was originally made seems shrouded in oblivion.

Although there appears not to be any case made out sufficient to invalidate the simple Greek inscription which appears on her base, namely, that she was the work of "Cleomenes, the son of Apollodorus, the Athenian," it by no means follows that she was made at Athens. Several of our finest ancient statues extant were the work of Greeks living in Rome during the Empire, and it may not improbably be that she was one of these; for, at any rate, there is no record of her as having been brought from Greece.

The Romans disdained the grasp of any weapon save the sword or spear, and the chisel was not for the hand of the conquerors of the world. When Imperial Rome desired statues, her patricians did not apply to a fellow-citizen to furnish them, but to some Greek dependent or slave, whose intellect, however, might be far above that of his ruler and master. In following this view, there appears no reason to attribute falsity to the inscription under the statue, or to doubt the truth of its record that it was the work of a Greek of Athenian parentage; but it is somewhat remarkable and singular that the nose of this charming figure should be more Roman than Grecian: at least it is in degree aquiline, and thus a feature which no other Greek female statue possesses. This might have been adopted by Cleomenes, either under order from his superior, or by his own predilection, from some Roman maiden of blue blood, or even from a *piquante* and graceful model from the Campagna. However this may be, it is one of the points in which she differs from other Aphrodites.

In respect to the uncertainty which rests upon her in regard to the date and site of her birth, on the one hand it may be said that the exquisite and much sought marble of Paros of which she is executed was early exhausted from the quarries of that island, and this might favour placing her period not later than the most palmy time of Greek art; while, on the other side, it may be shown that there is nothing conclusive in this, as many blocks of this beautiful marble were doubtless preserved as portions of architecture, or by other means, up to the date of Imperial Rome, which were available for such a small compact statue as she is. Also it is to the point of her period of birth not being early that the name of her author does not appear on the roll of the sculptors of ancient Greece.

No light, either, is thrown on this obscurity by any ray to be elicited from the discovery of this statue in the time of the Renaissance, as an almost equal want of information attaches to the time and place of this event. She is reported to have been found somewhere near Rome, broken into thirteen pieces, in the fifteenth century, but she did not adorn the Villa Medici until the sixteenth, and was transferred to Florence not before the latter part of the seventeenth, retaining as an affix to her title the name of the family to whom she had previously belonged.

That she is the perfection of female beauty is open to grave doubt; but in regard to her being a most beautiful, graceful, and refined work of art, there is none. It has been objected to her that her head is very small for a living woman. Intelligently regarded, however, it is evident that if it were made larger the proportion and grace of the figure would be injured. Rather thus, with due consideration, and without effort, we may justly adopt the view, not that the head is unduly small for the figure, but that the whole figure was advisedly executed on a slightly reduced scale, so as to give delicacy to the larger nude surfaces of the body.

Burke, in his "Essay on the Sublime and Beautiful," entitles one of his sections "Beautiful objects small," and affirms that, "attending to their quantity, beautiful objects are comparatively small." "I am told," he adds in another place, "that in most languages the objects of love are spoken of under diminutive epithets, and this is so in all languages of which I have any knowledge." He might have added as an example of the application of a diminutive, the frequent use of the word "Signorina" in Italy as an address of gentle respect to a lady. And this title might well be applied to the Florentian Aphrodite as a term of admiring endearment, appropriate to one who is a true Signorina among statues. It may be noticed also that a similar slight reduction from the exact scale of female life has been occasionally adopted, even in portraiture, by the most famous painters.

This view of the subject may well afford a certain satisfaction in contemplating this beautiful statue, namely, that her head does not necessarily represent one that is too small for intellect, but rather that the proportions of the whole figure have been somewhat reduced with the object of thereby obtaining superior refinement. Under this view she is to be considered as slightly diminished in scale from life; and if not of the highest order of beauty, she is none the less, perhaps, for that, a marvellously-attractive creature.

Scarcely may she rank as an Olympian goddess of the most elevated level of Homeric poetry, nor of the loftiest period of Greek sculpture, such as Phidias or Praxiteles might have produced, but we may still well cherish the conviction that she was the creation of a consummate Athenian artist, although in response, not improbably, to the behest of a Roman Mæcenas.

THE TWO WATER-COLOUR EXHIBITIONS.

THE Society of Painters in Water-Colours, and its younger rival the Institute of Painters in Water-Colours, as usual opened their private views on the same day, Saturday last, to wit. It would be much more convenient for those who like to attend private views if the two societies would avoid this, and open on different days; and it would probably be better for both of them as far as regards the sale of drawings.

The winter exhibitions of both societies are very good. The "Society," *par excellence*, has almost dropped the pretence of making the winter show a "sketch and study" exhibition, it practically becomes very nearly a second annual exhibition; but there remains still the advantage that a member can send a sketch or sketches, if he has any that commend themselves to his judgment as worth exhibition, without in any way prejudicing himself; and of this advantage some few members avail themselves. At the Institute the "sketch and study" theory is more frankly adopted, and a good many of the contributions come confessedly under this head, more so even than usual, in this year's exhibition.

The Institute shows a very interesting collection, with much less than usual of the mere drawing-master's drawings, against which we have often protested. It is partly from this fact that a certain contrast between the prevalent styles of the two exhibitions seems more than usually brought out this year. The Institute, in its best contributions, is the home of the school which aims at broad and powerful effects; the Society rather represents the refinement of manipulation of modern water-colour. The best landscapes shown at the Institute keep up for the most part the traditions of the days of David Cox, and give us effects obtained by broad washes and powerful touches rather than by minute finish. Mr. Syer's large "View near Wells" is a representative specimen of this school of landscape; a little too rough, perhaps, in its middle distance, but powerful in its foreground, and fresh and bright in its open-air effect. Mr. Collier, who is usually the main pillar of the Institute in this style of landscape painting, only sends some small and comparatively unimportant works this year, of which, however, his "Snowstorm over Carnedd David" is remarkable, and should not be overlooked. Mr. Orrock's "Summer Day on the Yorkshire Moors" is another work remarkable for its true qualities of water-colour effect, and the success with which it represents gradations of distance and aërial effect. "A Cornish Bulwark," by Mr. Philp, is a fine study of cliff, with the sea washing far below. Another remarkable drawing of a similar class is Mr. Aumonier's "A Bit of the Yorkshire Cliffs"; in this case the cliffs are seen from below, with a foreground of vegetation,—very powerfully treated,—and a number of seagulls flying out of the picture, so to speak, towards the spectator, put in with great force and relief. Mr. Harry Johnson's "Wyndcliff, on the Wye," is a fine drawing, with a fortunate combination, in the middle distance, of freedom of style with very tender and delicate effect. Among landscapes of more delicate finish, and perhaps rather more conventional effect, are one or two of Mr. Vacher's Egyptian drawings, especially the "Palace of Rameses III., with the upper portion of the yellow-tinted ruins in warm sunset light. Mr. Houston's "Stonehenge" (by moonlight), is a remarkably careful study of moonlight effect, and the old pre-historic stones, too, are very carefully drawn, and their character well shown. "After Sundown, Lucerne," by Mr. W. L. Thomas, is a fine piece of evening effect, in which nature is perhaps a little helped by art. Mr. Boughton's "Autumn Ramble by the Spey" is charming both in regard to the landscape and the figure which forms the centre of it; in feeling, tone, and composition, this is quite a perfect little picture. Two or three rather finished sketches, by Sir Coutts Lindsay, "The Harbour Fife," and "Desenzano, Lake of Garda," are so admirable in their combination of freedom with fidelity as to make us wish their author had done, or at all events exhibited, more work of this type. Lady Lindsay's "Souvenir," close by, the head of an Italian girl, is also excellent.

Figure subjects are usually rather prominent at the Institute, but less so than usual on this occasion. Mr. Linton confines himself to the single figures which may be termed studies of costume and colour rather than figure studies; they represent two apparently fine young women very much dressed, dressed up to the eyes, almost, under the titles of "Autumn" and "Winter"; the latter, with the rich amber dress and crimson scarf, is a very fine piece of colour, and exhibits that combination of high finish with dignity and largeness of style which usually mark everything from Mr. Linton's pencil. A kindred subject in its nature is the clever and delicately-studied drawing by Miss Gow, "Beggar my Neighbours," representing two little girls at a game of cards, a sofa and other accessories introduced; the children are nice in character, but the real interest of the drawing is as a study of browns and lighter but kindred tones in a combination peculiarly refined and agreeable to the eye. Mr. Edwin Bale's two drawings of a little Oriental-looking child with a brass pitcher, seem painted very much for the sake of the brass pitcher, which is the best thing, at all events, in each drawing. Mr. G. Clausen, whose name we have observed as generally connected with drawings which seemed rather to fall short of their apparent aim, has made a striking success in his small but very powerful and pathetic drawing "Waiting for the Ferry"; in the foreground a strong, sturdy woman, in sabots, stands fixedly waiting for the boat, which is just descried under the dusk of the opposite bank; on the bank some figures are relieved against the evening sky, which is partly reflected in the river. There is nothing unusual in the motive of the drawing, but it is very remarkable

for its power and its complete unity of effect and expression; it is like a picturesque moment snatched out of actual life and fixed on paper, in a style of handling which gives us all the essential poetry of the scene without any disturbing details. Mr. Hugh Carter's landscape and figure subjects are so palpably suggested by Israels, without the pathos of Israels, as to produce rather a sense of annoyance. Mr. Beavis's "Sand-cart, Pyrénées Orientales," is a good work, and a picture with two figures, by Mr. Towneley Green,—an old man and a young girl,—under the title "The Grindstone," should be carefully looked at; the two faces are most beautifully and minutely studied in character, expression, and modelling. The small room contains some very good studies in black and white by Mr. Walter Wilson (who also has among the coloured drawings some original studies of shipping), Mr. Lionel Smythe, Mr. Tenniel (*Punch* cartoons), and others.

The remarks which we made last week as to the too great frequency of exhibitions can hardly apply, it must be admitted, to the Society of Water-Colours, for the extra exhibition in winter is quite as good as the principal one in spring. Two of the lady contributors, Mrs. Allingham and Mrs. Angell, show an astonishing power of keeping up both the quantity and quality of their work in each of these semi-annual exhibitions. The former is quite up to her usual standard; the latter has surpassed herself,—in the matter of flower-painting, at least; her "Chrysanthemums" could not be praised too highly. The beauty of Mrs. Allingham's little idyllic pieces lies not only in the delicate finish of the figures and the landscape taken separately, but in the combined expression of both, the landscape and the figure appearing always such a complete and united whole. If we compare the Society, as a whole, with the Institute, there is in the main a decided difference of aim; the best works in landscape at the Institute are nearly always those which aim at the representation of the simple facts and feeling of nature in the manner to which water-colour best lends itself (only unfortunately such works are often far too small a proportion of the whole number); in the Society a considerable portion of the best landscapes are among those which aim at giving some special and poetic interpretation to nature, or at representing some peculiar effect by peculiar means. And thus there seems to be formed almost unconsciously a peculiar prevalent tone in the Society's exhibitions, in which strong and bold effects are the exception, and delicacy of treatment is the object. Thus such a landscape is Mr. North's "Autumn," which is like a dream of a landscape rather than like one of open day and common air, would be quite killed on the Institute walls. Where it is, it is in keeping with the general key of the place. The general level of intellectual interest is unquestionably, and has been for some time back, decidedly higher at the Society than at the Institute; nevertheless, we think the best of the Institute productions belong to a more healthy and genuine school than many of those very delicate and poetic, but occasionally somewhat unreal, landscapes which we see on the Society's walls. There is no doubt, however, that the present winter's exhibition in Pall Mall East is a remarkable one for the amount of fine work which it includes, of which we cannot profess to mention any but a very small part. Mr. Walter Field has been doing Henley in one or two drawings which happily combine topographical accuracy with effect. A comparatively new contributor, Mr. T. J. Watson (not to be confounded with Mr. J. D. Watson), from whom we from the first expected a good deal, keeps rising, and his "In a Wood" and "Sketch on the South Coast" are fine things, the latter literally a sketch, though very bold and on a large scale. Mr. Thorne Waite also contributes a large and powerful out-door sketch at "Parham Park." Mr. Walter Duncan has not returned to the poetic class of subject which he at first promised us, but his prosaic figures in "The Novel" and "With Wind and Stream" are as good as anything of the kind could be; the former especially, a drawing of a girl sitting sideways in a large chair and absorbed in a book: it is remarkable, though a small work with only the simplest subject, for a largeness and vigour of style which give it high interest. But we are anxiously looking for some more serious effort from this artist. Mr. Marshall, one of the recent members, has a beautiful work, "November's Hail-cloud drifts away," a very finely-composed landscape. Mr. J. D. Watson's corners of places with single figures, character figures, as one may say, are, as usual, interesting and various. Mr. G. K. Johnson's little girl standing on tiptoe to examine "A Sunflower" we like much better than his grown-up young women, who are nearly always (as in "Lilium Auratum") characterless and uninteresting. Mr. Matthew Hale seems to develop some new qualities in this exhibition; he has several admirable sketches, among which "A Lonely Moor" is exceedingly powerful and poetic. Mr. Henry Wallis shows his versatility remarkably in two works, one "In the Uffizi Gallery," an interior study, with the well-known seated figure pulling a thorn from its foot in the immediate foreground; the other, "A Study," a wild scene in a forest where trees have been overthrown, apparently by a storm. Other well-known contributors, Mr. Naftel, Mr. Davidson, Mr. Albert Goodwin, Mr. Tom Lloyd, Mr. Carl Haag, &c., are represented. A word is due to Mr. Parker's admirable studies of picturesque bits of old towns, especially "Place St. Yves, Vitré." Neither Mr. Alfred Hunt nor Mr. Boyce has been able to exhibit, their non-appearance leaving certainly "a gap in our great feast."

A special feature is the collection of some of the works of the late Mr. Dodgson; among others, a large and rather idealised but very fine view of St. Paul's from the river, which we do not remember to have seen before. On the whole, it may be doubted whether Dodgson's works are not likely to be more esteemed when seen separately. His style was a beautiful one, and it was of his own making, but his range was limited, and this fact becomes the more apparent when a good many of his drawings are brought together. Some of them, however, are, as far as they go, perfect works of water-colour, in regard to feeling for nature, rich tone and colour, and purity of style.

WILKIE'S "READING THE WILL."

ENGLISH ART ABROAD.

There appeared some excuse in 1854, when we first visited the Pinakothek at Munich, for finding in the section devoted to modern art but one English and no single French picture, because at that time the New Pinakothek, the work of the architect Voit, had been completed little more than a year, and the pictures which more or less adorned the architect's work might not have exactly found their proper destinations; but on revisiting the famous, and it must be owned greatly over-rated collection, it is somewhat disappointing to see that no additions have been made, or no attempt to support by adequate surroundings the one English picture, the famous "Reading of the Will," the exquisite work of Wilkie. We remember perfectly, on suddenly coming upon this picture, experiencing probably something like the sensation which more recently our countrymen have so often enjoyed in Australia at the discovery of a nugget, after labouring for a long time unsuccessfully in their field of operations.

It has been often remarked that there are painters who owe much of their popularity and distinguished name to the careful and skilful work of the engraver, and doubtless, in not a few cases, such is the fact; but perfectly as the works of Wilkie have been engraved in England, the fame of the engraver has in most instances been enhanced by the association of his work and name with the thoroughly intelligent and beautiful art of the great Scotch painter. It must be conceded that after 1821, when Wilkie painted his "Reading the Gazette of the Battle of Waterloo," a perfect style had reached its culminating point, and from our remembrance of the condition of the Duke of Wellington's picture when last we saw it, it has stood the effect of time very much better, notwithstanding the supposed deteriorating nature of a London atmosphere, than the "Reading of the Will," painted but one year earlier, although it has reposed for so long a time in the clear, high position on which Munich stands. But, alas! the "Reading of the Will" has been in the hands of "the competent restorer," and those terrible cracks that result from the use of asphaltum, or some equally dangerous transparent colour, and which fascinated so fatally our painters of the beginning of this century, and which, when we first saw the "Reading of the Will," twenty-six years ago, had already made a fearful progress throughout the surface of the picture, have now all been reduced to an equal surface, it is true, but there remains something more than a suspicion that the noble picture has been sadly injured.

There are certain galleries and collections of pictures in Europe that have gained, it must be owned, a not altogether well-deserved popularity, owing, perhaps, in many instances, to something euphonious or "catching" in their names; and amongst these both the New and the Old Pinakothek of Munich must certainly be placed.

RAILWAY SERVANTS, THE PUBLIC, AND THE BOARD OF TRADE.

There are sounds in the air which betoken the danger of a railway collision of a serious kind. It is a long time since the facts which tend to the production of this collision have been known to men familiar with the subject. Not a few of them have, from time to time, been pointed out in our own pages. But the deputation of railway guards, signalmen, and engine-drivers, representing the Amalgamated Society of Railway Servants, which waited on the President of the Board of Trade on the 2nd of December, has had the effect of putting the danger referred to in a stronger light. The collision of which we speak is not between one train, or one engine, and another, but between the Directors of the Railway Companies of the United Kingdom and the executive Government of the country.

The object of the deputation was to urge upon the Government the necessity of further legislation for the prevention of railway accidents. On this subject there is no class of men to whose experience more value is to be attached than to that of the operative servants of the railway companies. The force of this remark will be at once seen by referring to the general reports to the Board of Trade on railway accidents. Taking the year 1878, to which an unusual degree of safety has been credited, 1,032 persons were killed, and 3,513 injured, on the railways of the United Kingdom. Of these, 160 persons killed, and 1,307 persons injured, were passengers; and 452 killed, and 1,951 injured, were officers or servants of the railways. In this year the number of passenger journeys (exclusive of those of season-ticket holders), was 562,732,890; a figure which is swelled to more than 670,000,000 of journeys if the season-ticket holders are taken into account. If we suppose that each passenger took on the average two journeys a week, we should have a total of some 6,600,000 individuals, amongst whom the above-named 160 deaths and 1,307 serious injuries would have to be distributed, giving in round numbers one death in 40,000, and one injury in 5,000, passengers, allowing each of them 100 journeys in the year. The number of railway servants is not stated in the Government returns. It has been estimated at 300,000; and if we suppose that to be anywhere near the mark, there will have been one death out of every 666, and one accident, of sufficient gravity to attract the notice of the Board of Trade, out of every 153, servants employed by the companies. We have not seen the subject put in this light before. In fact, as far as we are aware, there exist no data affording absolute information on the subject. The Board of Trade Report, which glories in the fact that in 1878 only one fatal injury occurred to a passenger, from causes beyond his own control, out of 23,540,000 passenger journeys, gives a calculation which is, to a certain extent, highly reassuring to the public. But it selects the rarest of all accidents, and refers these to the largest number of journeys, so that the ratio by no means represents the safety of a traveller, but only his safety in one individual journey. On the other hand, as to the proportion of injuries among the railway servants, the report is not only absolutely silent, but it does not furnish the means of ascertaining the proportion. It states the deaths and accidents reported, but it does not show the danger-rate, or state the number of persons among whom those injuries have been distributed. If this were done, the horror of the public would be great. It should be observed that even if the number of railway servants attains half a million (which, we think, must be very far in excess of the reality), the proportion would still be as high as one death out of every 1,106, and one reported injury out of every 255, servants,

in the course of a single year. It cannot be said that this is a satisfactory state of affairs.

Mr. Evans, the secretary of the Amalgamated Society, urged that immediate effect should be given by the Legislature to the recommendations of the Royal Commission on Railway Accidents; that discretionary power should be given to the Board of Trade, under review by a new appellate tribunal; and that all companies should be required by law to provide all trains, goods and passenger, with sufficient brake power to stop them within 500 yards. We cannot but regret that a deputation with which our sympathy is so strong should have been so ill-advised as to suggest remedies which are so crude in their conception. If the deputation had developed the considerations which we have above indicated, and shown what was the death-rate and what the injury rate among that picked and highly deserving body of public servants in whose hands the safety of the travelling public lies, and had asked for a public inquiry into the causes of this danger, and the means, of a more thorough kind than those attempted by the Commission of 1877, that might be adopted to avoid them, they would have had the public with them altogether. But in suggesting details of legislation the deputation went *ultra crepidam*, with the usual result. Mr. Chamberlain pointed to the Report of the Accidents Commission to the effect that they were "not prepared to recommend such an interference with railways as would impair in any way the responsibility of the companies for injury or loss of life caused by accident on their lines." To place the proposed discretionary powers in the hands of the Board of Trade would be to take the most objectionable part of the plan for transferring the management of railways to the Government, without gaining any of the advantages of such a transfer. And the proposed spectacle of the Board of Trade contending with the companies before a new tribunal would be one hardly reconcileable with the dignity or utility of the Government of any civilised State.

Again, while we are fully of opinion that trains are now frequently unprovided with sufficient brake-power, we have the firm conviction that the efficiency of very powerful brakes in producing absolute safety has been much over-rated; and that the new sources of danger which arise from the use of such brakes have been wholly left out of sight. If we look on the series of disasters that occurred some few weeks ago, we find that at least as much danger was caused by reliance on these brakes as was prevented by their adoption; while it was only the presence of mind of a guard (of whose reward by the company we have not heard) that prevented a calamity more frightful than any yet recorded from automatic action of a self-acting brake at the wrong time. It is both idle and mischievous to take up a cry as to one out of many precautions, as if that was all that is required.

Mr. Chamberlain, however, took the bull by the horns, when he said that "if the companies will set their backs to the wall and defy public opinion, there will be no alternative but for the Government to lay a statement of the case before Parliament, point out how ridiculous is the position of the Board of Trade, and ask for such further powers as may be necessary!" There is no doubt that in the matter of railway inspection, (just as is the case in that of sanitary inspection), the absolute want of initiative power on the part of the Government is a great public evil.

The recent number of *Fraser's Magazine* contains, under the head of "The Problem of Railway Safety," remarks on this subject which deserve attentive perusal. The refusal of the directors of the English lines to supply the information of which the Board of Trade reports have been so long vainly declaring the need, is contrasted with the procedure of the French and the Belgian Legislatures, and with the full and detailed official information given by the Commissioners of the Railways of New South Wales. The direct relation between the variation of speeds (as between different trains), and both the earnings and the safety of the lines, are pointed out. And it is shown that, if it can pay the great trunk lines to carry minerals at rates of freight kept down by the competition of seaborne coal, it would pay them no less to carry passengers at one-sixth of a penny per mile.

The great thing that we now wish to show is, that the interests of the railway servants are identical with those of the travelling public. As to this, we think there can be no contention. Further, it is our opinion that the interests of those two great classes of persons are identical with those of the railway companies themselves, intelligently considered. And we therefore anticipate that if the companies continue, as the President of the Board of Trade said, to set their backs against the wall, collision with Parliament and with public opinion will come, sooner or later, and the later the worse for all parties.

THE CONVERTIBILITY OF THE IMPONDERABLE FORCES.

THE PHOTOPHONE.

THE lecture of Professor Graham Bell, which we announced in our number for the 27th ult., and of which we gave some anticipation in an article on "Noises" in the same number, was delivered at the Society of Arts on the 1st current. Our readers cannot be unaware of the fact that the last forty-five years have witnessed the successive discovery and application of a number of different methods for appreciating and utilising vibrations so small that "to any thick vision they are indiscernible." The first occasion, so far as our personal knowledge of the matter goes back, on which it was sought to apply to the service of daily life the results of the scientific probings of the phenomena of vibration, was in 1835, when Mr. Robert Stephenson was making what was called the Euston Extension of the London and Birmingham Railway; that is to say, the line from the Camden Station to Euston-square. The inclines on this line are what was then considered very steep. There is one gradient of one in seventy-five, and one, if memory serves, of one in sixty-six. To draw the trains up these inclines it was considered that it was necessary to use stationary power; and winding-engines with large drums were erected at the Camden Station, while sheaves were laid in the middle of each track of way to carry the rope of four miles long. The question of how to give to the engine-man at Camden a signal from the station-master at Euston much exercised the mind of Mr. Stephenson during the construction of the line; and Professor Wheatstone was one of the men of science whose co-operation was requested. The first experiments of Wheatstone were made with a view to the conduction of the vibrations of sound. Among other experiments, a wire was led from the sounding-board of a piano for some distance, and connected with the resonance-box of a violin. When the piano was played, the violin gave forth the tune, and that in the notes of the original instrument rather than in its own. Then followed the application of the electric current to the transmission, not of sound, but of motor vibrations, leading to the admirable results of the various electric telegraphs, the construction of submarine cables, and finally the creation of a new alphabet, the Morse code, which has already attained an unrivalled excellence, although the printing tapes used still admit of great improvement and simplification. For some forty-two years the attention of physicists was chiefly directed to the improvement of the mode of transmitting vibrations that would produce motion at a distance,—telemotors, in fact,—although in such minute doses as only to be available for signals. But even in this work, the introduction of the imponderable index of a ray of reflected light, the invention of Sir W. Thomson, was needed to afford a mechanism sufficiently delicate to be acted on by the small force transmitted through a long cable.

Some two years ago, the attention of telegraphists reverted to the original aim of Mr. Robert Stephenson, the transmission of sound, and since that time a whole continent of vibratory facts has been explored,—explored so far as to lead us to believe that we are yet only on the confines of discovery. The telephone was lectured on by Professor Graham Bell at the Society of Arts in 1878. By this instrument the vibrations impressed by the human voice on a disc placed at one end of the line of electric connexion are audibly thrown out as repeated by a corresponding disc at the other end. Then came the phonograph of Edison, by which the effects of the vibrations were so impressed on a yielding metallic surface that the sounds which made the dents could be reproduced from those same dents at will,—a wonderful invention, the full utility of which is yet by no means realised. Then came the microphone of Professor Hughes, in which, by taking advantage of the different vibratory elasticity of different bodies, a series of sounds committed to the magic custody of the transmitting wire can be magnified, even as visible objects are magnified by the microscope. The last invention, the photophone, seems to sum up the labours of the previously-named discoveries. It grasps Sir W. Thomson's imponderable lever; it utilises Wheatstone's insulated wires; it uses the telephone and the microphone ideas; and it crowns the whole by taking advantage of the discoveries of Baron Berzelius and Mr. Willoughby Smith as to the special electric qualities of the rare and newly-discovered metal, selenium, in its two allotropic forms. So sensitive is this metal to the influence of light that its power of electric transmission varies, with incalculable delicacy, according to the incidence of light on its surface. Thus if a plate of selenium is made to act as the receiving surface of a telephone, the sound received by this plate, or rather absorbed by it, will vary according to the light which falls upon it at the time of reception. That modification is effected by the use of a mirror, placed near the mouth of the speaker, the light from which is collected by a parabolic reflector, and sent through the selenium cell into the telephonic circuit.

We hope that a full and illustrated account of this last physical triumph will be published. It often occurs that the most brilliant inventions, like new-born infants, sleep much and for a long time after their birth. Some of the inventions to which we have referred have seemed to slumber in this way. How soon the photophone will find its place in the great order of vibratory movements, utilised for the service of man, it is impossible even to guess. All that we can see clearly is that we are collecting the elements of a new physical science and industry of which it is impossible to imagine the range or the limit. What Grove did in opening men's minds as to the co-relation of the physical forces, Graham Bell, Edison, Hughes, Sir W. Thomson, and others are doing for what used to be called the imponderables. We hardly like to use the term "conversion of motion into electric tension," but such, at all events, is the phenomenal explanation of the electric light. Now, the extreme delicacy of the relation of the vibrations of light and of sound has received a most unexpected illustration. And the result is that we are reconsidering our conception of the nature of solid matter. We have had to throw overboard the ideas formerly implied by the words solid and material. We form some faint idea how intimately heat enters into the constitution of matter; how light and heat and sound are, so to speak, allotropic forms of the same energy. All this is only paving the way for that transmission of electric force, not in doses that can move a needle, but in hundreds and thousands of horse-power, of which Sir W. Thomson and Dr. Siemens have given us such magnificent (though somewhat contradictory) forecasts. Instead of limiting our inquiries into the subject of "Heat, a mode of motion," we shall have to study the relation of vibration to physical condition, or of "motion, a mode of matter," or "matter, a mode of life."

THE STAFF OF LIFE.

ALL persons who lay to heart the welfare of the industrial classes, to say nothing of their own, ought to take interest in that question as to the best mode of bread-making, to which just now public attention is being pointedly directed.

For ourselves, our readers may do us the justice to remember, the subject has not the charm of novelty. The costly waste with which the Wiltshire agricultural peasant lays out the greater part of his weekly earnings in white bread, eaten hot from the oven,—which the Scotch would term "fizzenless,"—has before now been lamented in our pages. It is with great satisfaction that we see earnest attention directed to the subject. The first wish that we have to express in the matter is, that the reformers, with whom we have so much sympathy, should not ride their hobby to death, and throw away the real advantage of their position by claiming further advantages, which may be regarded as only imaginary.

Nothing, we are convinced, stands more in the way of any necessary and well-considered improvement than the excess of zeal on the part of its advocates. We were about to write igno-

rant zeal, but it will be more correct to say zeal partially instructed. A thing may be freshly proved to a certain mind to be an evil; but the probability is, that it has been long known to be, more or less, an evil. The zealous man sets his lance in rest and rushes to the charge. The wise man pauses to inquire how it was that the evil became rampant. Some reason must exist. And it is only by the detection of the *raison d'être* of the evil which it is wished to obviate that any steps that are adequate for the purpose are likely to be taken. Thus, it is not enough to say,—"White bread is costly and less nutritious than brown bread." That is no new discovery. Those persons who wish to utilise it have first to explain to themselves how it is that that costly artificial product,—the baker's loaf,—has established itself as so universal an institution in this part of Great Britain.

The ground taken by recent lecturers on the subject is that of chemical analysis. Of the extraordinary value of that method of putting nature to the torture we should be the last persons to speak with anything approaching to disrespect. The progress of exact knowledge in chemistry we regard as amongst the greatest triumphs yet attained by human genius. But nature must not be examined under torture alone. Especially as to those more subtle of her products which are beyond the direct cognisance of the chemist, must we be content to listen to her unconstrained utterances; at all events, in control of the results of the analyst.

Now, we are told that one shilling's worth of wheat meal bread will form a substantial meal for nine people, and that it contains forty per cent. more nourishment than an equal weight of white bread, which will cost much more. That is a proper subject of investigation; and, moreover, one in which personal experience is not absent to qualify the judgment. But when the lecturer goes on to say that it contains three times more flesh-forming material, seventy times more heat-forming material, and three times more bone-forming material than one shilling's worth of beef, it seems to us that the argument breaks down. It deals with the test-tube and scales instead of with the human stomach and the phenomena of consciousness. Take a working-man exercising the harder kind of labour, that is to say, a public writer, an architect in full work, or a busy barrister, either in the discharge of his daily toil, or when he is seeking new health on a Scotch moor or an Alpine pass. Place before him for breakfast a meal loaf, as good as the Bread Reform League have got to offer, and a pat of butter, with tea or coffee. He asks for a small bit of beef steak or a hot mutton chop, with perhaps a glass of ale. You meet this request with a pamphlet containing statements such as that bit of information about seventy times more heat-giving substance. He says, "As to all that I can say nothing. I know the difference that the little bit of hot meat makes to my comfort all day, and I leave analysis to chemists." Personal experience leads us to sympathise with the working-man in question. And to such, and thus to the great majority of those who influence the less-educated classes, the efforts of the bread-reformers assume a sort of fantastic, unreal aspect from the over-statement arising from relying on chemical analysis alone.

While we wish more power to the elbow of the Bread Reform League, we speak simply in support of the view that English people can, if they will, have much more nutritious bread than they usually eat, at a considerably lower price. We do not, however, think fit to join in a cry against the bakers. It is quite true that, from time to time, the want of conformity between the price of wheat and that of bread attracts angry animadversion, which, after a while, either produces its effect, or from some other reason sinks into silence. Nor do we in any way agree with those who cry out for legislation on the matter. We are of that ancient, unpopular, but robust school which holds that people ought to exhaust the means at their own command before they go to others to help them. In this case of bread, as in most others, it is the consumer who dominates the producer. The consumer elects what bread he will eat, and if the peasant who earns nine shillings a week insists on eating, and on giving his children to eat, the whitest bread that is made, but out of the oven, with, if he can by any means compass it, a bit of butter spread on the smoking slice, it is not by Act of Parliament that the wasteful and pernicious taste will be eradicated. Neither will it be by lectures. Example will, in such a case, go farther than precept. We are not undervaluing the importance of sound chemical knowledge as to the value of food. We think that if the Bread Reform League will study the files of the *Builder*, they will find very much of what is now being announced as new to have been stated very plainly in them. But all means of publicity are good for the purpose. Our annual consumption of wheat is now about 20,500,000 quarters, which is worth on an average some 54,000,000*l.* Of this, 32,000,000*l.* is allotted to home produce, and 22,000,000*l.* to importation. How much of this is lost to human consumption by our eating fine flour bread instead of meal bread, it will be an instructive sum to work out. As between wheaten and oaten bread, the proportion of nourishment is very much greater in the latter. Wheat contains 146 parts of flesh-forming material to 698 parts of carbon, or heat-forming material. Oats yield the proportion of 17 to 664. But beans, be it remembered, yield 240 parts of flesh-forming substance to 577 parts of heat-giving. The value of the bean as an accessory, where rice (with its low proportion of 65 flesh-forming to 795 heat-giving element) is the staple grain, is practically well known in India. And in Southern Italy, where the best white bread in the world is made from the superb Carozelle wheat of the Apulian plains, the peasantry may be said to live for at least two months out of twelve on beans.

It appears to us that for this matter of bread reform an ounce of practice will be worth a pound of theory. The first thing to do is to show that meal bread may be made not only economical, but palatable. The idea of the grinding of the wheat by a steel mill seems to us a very good one; and that the more so because it is not intimated that the inventor of the mill seeks to make undue capital out of his invention. How much of the discomfort produced by some kinds of meal may be due to the local nature of the millstones, is an interesting subject for inquiry. In his well-sung journey to Brindisi, Horace complains of the "stony" character of the bread of Canosa. "*Nam Canusi lapidosus.*" At the present day the traveller over the same route will do well to take care of his teeth. The bread of Canosa is still full of a grit which can hardly be produced by the fine corn of the district. Not that it is necessary to supply from mechanical sources a kind of impurity which is only too much to be regretted in some vegetable grains. In Australia, a plant of the family *Marsileaceæ* covers the ground, in some places, with its little black spores, about the size of sweet-peas. The albuminous matter contained in these spores makes a nutritious food, when properly prepared. As a porridge or stir-about, it is said to be delicious. But the skin of the pores is so irritating to the stomach, that, if it is not carefully removed from the meal, the food, though still palatable, becomes poison. It causes such disturbance in the digestive functions that one of the most famous explorers of that region, the man who first went through Australia from north to south, perished of absolute starvation, though never failing to eat daily meals. He had not the means of removing the husk, and, in the absence of other food, absolutely perished of hunger.

We had written thus far when we read, to our great satisfaction, two letters which have anticipated, in the most accurate manner, the recommendations which we were about to offer to the League. One of them is from Miss Yates, a member of the Ladies' Sanitary Association; the other from Dr. Bartlett, who spoke on the subject at the recent meeting at the Town-hall, Kensington. We were about to suggest that the first step to be taken for the practical furthering of the object in question would be to supply to the public such a sample bread as should avoid the objections raised, as above hinted, at such a price as would allow a living profit to a baker who could command a fair amount of custom. We are told that the Bread Reform League has now a list of nearly 100 shops where the bakers are willing to sell, at the same price as white bread, wheat-meal bread, made from meal ground in a steel mill. This is a step in the right direction. We may observe that, if all said be true, the meal bread ought to be cheaper than the white bread,—but let that alone for the present. Stern and sad experience leads us to caution the committee against relying on "lists of shops." To do justice to an important movement of this nature, it will be necessary that there should be a constant, unobtrusive, vigilant visitation of these shops. Some one fit for the task must look in from time to time and buy a loaf. He will have to note how often the shopkeeper "happens to be out of" meal bread; whether from having "already sold that day's supply," or from some mysterious failure in the mill, or the oven, or part of the machinery in the production. We shall be agreeably surprised if these hitches are not found to be more frequent than was at all anticipated. Next, our suggested visitor must take the pains to take his loaf home, and to eat it, or at least to eat enough to enable him to judge whether it is the real article, or some more lucrative imitation of it. If this he done, and if, with some care to suit the public palate, such meal bread as we know can be made be regularly supplied to the public at the price which accurately corresponds to the cost of production, plus a fair tradesman's profit, there will be a standing ground for the lecturer or the public writer; and we may hope to see the steady but certain introduction of a better and cheaper kind of bread.

THE SANITARY CONDITION OF UPPER-CLASS LODGING-HOUSES.

There can be no question that those who have for years been urging that more attention should be paid to the sanitary condition of our dwellings are at length beginning to see their efforts bearing some fruit. The more intelligent householders are showing some signs of an appreciation of the value of a good sanitary condition of a dwelling, though we fear that it will be a long time before the proper appreciation of this matter is taken hold of by the large mass of the population. There is, however, one class of dwellings which as yet is, it may be said, wholly uninfluenced by sanitary improvements. These are what we have termed in the heading to this article,—upper-class lodging-houses. These lodging-houses are most numerous in our large towns. London contains by far the greatest number, which are inhabited by all kinds of persons,—young noblemen, young barristers, young merchants, and every kind and manner of professional or non-professional person. In the larger towns, such as Liverpool and Manchester, they are chiefly occupied by young men engaged in the business of the place. And we venture to affirm, without fear of contradiction, that an examination of the numberless houses used as lodging-houses would show them to be in a very backward sanitary state. Can this be wondered at when the matter is considered for a moment? The ordinary lodging-house keeper is, no doubt, a very respectable person. In the best class of London lodging-houses the proprietor is usually a retired domestic servant, very respectful and civil, with no mean idea of the desirability of comfort, with a dislike of ventilation, and absolutely ignorant of the value of a good healthy house. In the large towns in England the proprietor is less often an old domestic servant; he is very often,—if a man,—a clerk, or is engaged in some lower kind of business occupation, whilst his wife attends to the house. But, again, he is a person with small appreciation of the necessity of a healthy house. In London most of the proprietors hold their houses on seven, fourteen, or twenty-one years' leases, and under the usual London system,—one which sets a premium on doing as little as possible to make a house healthy,—the tenant must bear the cost of any improvements which he makes. The natural consequence is, that in addition to ignorance of sanitary matters, there also exists a desire not to spend money upon anything which shall in any way diminish the profits to be taken from lodgers. This is perfectly natural. Lodging-house keepers work hard and do not make much money. They have rent, wages, and other expenses to provide for, and may not always obtain the tenants to pay for the outgoings, or to bring in the margin of profit. They are under fear of no authority to rummage into their pipes or drains or closets. The tenants, taken as a whole, consist of young men who have not yet given much thought about sanitary matters. As long as the cooking is fair, the rooms pretty warm in winter, and not overpoweringly hot in summer, they are content with their quarters. The larger portion of the day is spent in some other place, and it is

the evenings and nights which see them mostly at home. If sewer-air happens to make its way into their rooms and causes them to feel ill in consequence, they will say they are "seedy"; will lay it down to a hot theatre, had wine, or some cause quite different from the true one; and if healthy and strong, will very likely throw off the sickness. In many cases, too, the lodgers remain no very long time in the house; if they find the smells disagreeable they perhaps change, and change in all probability from Scylla to Charybdis. And so the time goes on, and the drainage and ventilation remain unimproved and a constant source of danger to the inmates of the house.

If we take, for example, an ordinary good lodging-house in Liverpool which possesses a bath-room, we shall in most cases find that a water-closet is in the bath-room, or, if it is not, that the waste-pipes of the bath directly communicate with the soil-pipe. This is only one instance of an unwholesome condition of a house, which is liable to breed disease and consequent illness. If we penetrate into the lower regions we shall find sinks, and drains, and traps which would set the mind of a sanitary reformer a-thinking on the uselessness of his endeavours. And all these defective drainage arrangements are the more dangerous in lodging-houses, because, as a rule, they are not counteracted by the open windows, good fires, open chimneys when no fires are burning, and general cleanliness, which a lady who is mistress of a house takes care to see exist. It must, in fact, be a matter of almost common knowledge to an observant man that the sanitary condition of lodging-houses is not what it should be. And let it be remembered that we are now treating not of lodging-houses for workmen, but of lodging-houses for the upper classes, who are, as a rule, engaged in some business or profession, and who, generally, are part of the rising generation of Englishmen, and we much doubt whether any improvement can be looked for for a long time. There is one reform which might do something, but which would be much opposed. That reform is the inspection of every lodging-house in a town by a competent inspector. The ordinary Englishman hates anything like inspection; the inspector is a man to be abborred, and we feel quite certain that any such reform would be greatly opposed. It would be opposed both by lessors and lessees or yearly tenants. It would be wholly unfair to make tenants (we are putting lodgers now aside for the moment) pay the cost of structural repairs, such as new drainage, alteration of sinks and closets, and ventilation of drains, and in London the ordinary landlord will not, if he can help it, do anything for a tenant. Therefore, to make any such reform just, it would be necessary to make the cost of such repairs a burden upon the landlord,—at any rate, to some extent; and, therefore, as we say, there would be two classes in opposition to such a reform. That any change for the better can for long years take place without a compulsory inspection of lodging-houses from time to time, we feel sure cannot be expected even by the most sanguine reformer; and, at the same time, there can be no question that the sanitary condition of upper-class lodging-houses is a subject which deserves very careful consideration, to settle the measures which should be taken to improve such condition.

THE CAFÉS OF MUNICH.

Whatever may be said for or against the views of a great part of the public with regard to the question of temperance, there can be no doubt that the movement in favour of what has been called coffee-taverns is exceedingly active, and to a very large portion of the population of our great cities these coffee-taverns must have come to supply a long-felt want; it is not too much to say that we may view them as one of the most beneficial of our adaptations from foreign ways. In the case of our coffee-taverns, adaptations they certainly can only be termed, for they differ singularly both from the ideal and the reality of the foreign *café*. But there are *cafés* and *cafés*, as any one familiar with the Continent knows, and the full-blown *café* of the Paris boulevard, the now adopted model of such institutions throughout the world, differs as strangely from the characteristic and dark little *café* of a Venetian bye-street as must the seventeenth-century Grecian Coffee-house in Devereux-court,—whose model, by the way, would be taken from this latter,—from the most recently-built *café* in the Avenue de l'Opéra.

The *café* is an institution which takes in the life of the Continental far more the place of the English club than is usually supposed, and he begins his acquaintance with its pleasures at an age when the club is, for ten years at least, shut to the Englishman. It is no new theory that it is in great part owing to this early training that the Continental acquires that familiarity with life and the world, and ease in manner, which in the present day are more than ever considered essential. The ways and habits of the mug-house must infallibly give way, and the coffee-tavern, it is not unjustly hoped, will tend greatly to aid in refining the habits of a large number of the inhabitants of our cities. In foreign *cafés*, side by side with the most ceremonious and formal of military martinets, the most punctilious and severe priestly or scholarly manners, will be seen the free-mannered *bourgeois*, the comfortable *boursier*, the radiant student, or the humble shopkeeper.

The *cafés* of all foreign towns offer their peculiar features of interest, and as snob have always afforded writers gifted with the happy power of "touching off character" ample field for the exercise of their peculiar abilities. One may be excused, therefore, in writing from Munich, in feeling that the *cafés* of the Bavarian capital offer some character by which they merit notice; their peculiar comfort, and the exceptionally generous consideration to what might be termed the literary accommodation, form a feature which, at a moment when there is a movement in favour of the spread of the consumption of coffee at home, is particularly worth note. When these same *cafés* assume the proportions of important architectural features of the city,—features in the decoration of which the wealth of the capitalist has been expended in the employment of art which falls little short of the art of the best days of decorative painting,—they present another claim to our notice.

The subject is not an uninteresting one to treat, as all who have visited Bavaria will concede that not least among the impressions they may have borne away, even of a short stay in King Louis's capital, was that connected with the numerous *cafés* scattered over the town. With the thorough-paced Parisian *café* we have all long since become familiar; nor is it, perhaps, going too far to say that with an increasing amount of familiarity has come its proverbial accompaniment. The Parisian *café* has ceased to be what it was; it has ceased, in fact, to be a *café*, and since it has lost this great feature it no longer possesses the charm that made it in the past the resort of the choice spirits of letters and of art; nor has the Parisian *café* any longer that fascination for the stranger,—we speak from an English point of view,—that once prevailed. In Munich the traditions still exist of the old days of the *cafés*. There we find much of the old comfort, and that absence of the too-clearly-expressed modern feeling of one's room being worth more than one's company; there one is induced, and, indeed, invited, to stay, by the accommodation afforded, by the smallness of the outlay, by a welcome from the proprietor or proprietors,—no syren-like *dame du comptoir*,—and by what appeals to the Anglo-Saxon peculiarly, a large supply of journals; German (of which there are several dozen ranged round the room) and foreign, always an English daily paper to tell one of the doings at home; the *Illustrated London News*, or its equally popular sister, and the ever-familiar face of Dicky Doyle's dear old *Punch* and his dumb companion, with all the picture papers from Leipzig, from Vienna, and from Paris, while further amusement is supplied by billiards, and cards, and chess, which replace in Germany the fast-dying science of dominoes in the Paris *cafés*, and, what is by no means the least uninteresting or unpleasant feature of all, a service of bright, intelligent, almost, perhaps, too well-looking girls, whose rapid movements and attention to the wants of the frequenters are a constant source of delight to the stranger, as well as evidently of amusement and pleasure to the native *habitués*.

Most of the *cafés* at Munich, and there are not a few, are arranged on this principle, though, as may be imagined, throughout the town the age of the different establishments affects not a little the interior style and decoration, but each as the date approaches more nearly the present day is more gorgeously decorated than the last. Among the more recently built no restriction seems to have been placed on the architect in his design, exteriorly and interiorly. It would seem as if we were indulging in an extravagant dream of splendour were we to describe fully one of the most recently completed of these establishments, for here is employed the largest and noblest style of modern Italian architecture in solid stone-work, enriched interiorly with carving and gold, and the walls and ceilings of the rooms are adorned with highly decorative paintings, executed by artists who are all but famous in the history of modern art.

It is not a little characteristic, and a point to which perhaps till now we have not drawn sufficient attention, that in each and all of these establishments, coffee, the genuine extract, not a decoction of the Mocha berry, is supplied at an excessively modest rate (2½d.), and forms the speciality, the only deviation from this rule consisting in the very small consumption of mild liqueurs in the regulation liqueur-glass. It is easy to trace the influence of Venetia in the large glass of pure water,—drawn from the continually flowing fountain in the middle of the room,—which is immediately brought one on entering, though it is more German to have supplied at all hours of the day coffee with milk in it, together with the three regulation lumps of sugar in lieu of the little cup of *caffè nero*, and the measure of pounded sugar, of Italy.

In many parts of the world there must be artists, especially musicians, architects, painters and sculptors, and decorators of all kinds, literary men and scholars, and teachers in many ways, who look back to the pleasant hours they have passed in the *cafés* of Munich with affectionate interest; and how often must even the casual visitor to this part of the world remember the courteous welcome that is always so liberally given both by the host and hostess. Whatever may be the system by which these establishments are made profitable investments (and this is difficult to understand), it is quite certain that they are capable of affording to any observant person an admirable lesson of the advantages to be derived from the strictest economy in every detail of their management, and the most careful desire to supply the clients with the utmost possible return for their outlay.

EATON HALL.

We publish in our present number a double-page illustration of Eaton Hall, near Chester, the seat of his Grace the Duke of Westminster, and a plan of the ground floor. Our view is taken from the south-west, and includes the main building and the chapel. The illustration sufficiently sets forth the character of as much of the exterior as it comprises, the style being Early Pointed, freely treated. We shall, however, call attention to some of the features on the east of the garden front. On this side of the house is the Grosvenor wing, containing the suite of family apartments, connected with the main building at the north-east angle by a vaulted corridor over a bridge. Between the Grosvenor wing and the main building stands the north wing, which sets back, and is lower than either, forming an important connecting-link in the general view. Behind the north wing rise the clock-tower and the chapel-turret, so that from certain points of view in the garden the Grosvenor wing stands as a central feature; on its right the main building, while on its left the stables and other inferior parts of this immense establishment stretch into the woods for a considerable distance, the chapel-tower forming, even from this side, the culminating feature.

The main entrance is by the *porte cochère*, which forms a conspicuous feature in our engraving, and which leads, by a flight of steps, and beneath a lofty doorway of alabaster, into the hall. This consists of a large square apartment, 32 ft. by 32 ft., extending through two stories of the building, with lateral extensions towards the north and south, which are only separated from it by two large arches, and are but one story in height. A double arcade at the further or eastern end leads to the saloon. The floor of the hall is a sumptuous one, of "opus Alexandrinum," in an elaborate arrangement of porphyry, serpentine, *giallo antico*, and Parian marbles.

The ceiling is of panelled wainscot, and the lower part of the walls is lined with

alabaster and Genoa green marble, while seats of red granite are ranged between the arches and the east and west walls on either side, and cover the arrangements for heating the apartment. The chimneypieces are principally of alabaster; that in the northern bay has a long sculptured panel, in the centre of which King Richard II. is represented delivering his famous judgment as to the right of Scrope or Grosvenor to bear the arms *azure*, a bend *or*. The *personæ* on either hand of the king are all of historic interest, and are recognisable by their semblance to known authorities, or by their armorial bearings, amongst them being John of Gaunt (the king's uncle), Geoffrey Chaucer, Hotspur, the clergy and notables of Cheshire, &c. The chimneypiece in the northern extension has a similar sculptured panel. In the centre is King William I. bestowing the sword of Chester upon Hugh Lupus, the present duke's namesake and ancestor; the groups on either hand displaying family or local incidents of historic importance.

The grand corridor, which passes between the eastern end of the hall and the saloon, leads towards the south to the great drawing-room and the library, and northward stretches right away, though diminished in width, throughout the whole length of the building to the cross corridor, connecting the chapel with the bridge which leads to the Grosvenor wing. The northern portion has a groined ceiling.

The library occupies nearly the whole of the south front, and is 90 ft. by 30 ft. It has a deep bay in the ground-story of the tower, which is conspicuous in our view, and two large bay-windows, which are also to be seen in the engraving. Two angle bays at the west end further diversify the plan. It is fitted with walnut. At the east end stands the organ, in a richly-carved case, and the bookcases extend round the walls of the room. The various panels, friezes, and cornices are brilliant with inlay of mother-of-pearl and boxwood. The chimney-pieces are on the north side, and are of walnut, and they are enriched with carving and the inlay of pearl and box. The upper portions of them project, and are supported by caryatides representing the relation of all ranks to a library,—royalty, the church, chivalry, minstrelsy, husbandry, &c., being represented. The hexagonal panel in the centre contains in the one a clock and in the other an anemometer. The ceiling consists of walnut-cased beams and plaster panels, highly enriched with foliage, &c. The windows will be filled with heraldic stained glass. Over the entrance to the library is the "Caxton Memorial" which was illustrated in our volume for 1877, p. 687. The floor is to be of oak parquet.

The great drawing-room, 45 ft. by 36 ft., communicates with the grand corridor on the west, the garden, porch, lobby, and library on the south, and ante-room on the north. At the east it has one large recess, in which we understand will be placed Mr. Thornycroft's "Artemis," exhibited this year in the Royal Academy. The old plaster groined ceiling is retained, with certain modifications, and has been re-decorated. The chimneypiece is one of various marbles, purchased by the Duke while in Italy.

The ante-drawing-room adjoining has also its old ceiling, which has been decorated afresh. This room will be celebrated for its twelve panels of birds painted by Mr. H. S. Marks, R.A. The saloon has a high wainscot dado, and the walls above are painted also by Marks, illustrating the "Canterbury Pilgrims." The chimneypiece is of alabaster, and the central panel contains a procession of world-famous lovers, from Antony and Cleopatra to Raffaelle and the Fornarina. The smaller panels in this and the other chimneypieces before described contain allegorical figures, which have all some reference to the principal subjects, *e.g.*, Truth, Valour, Constancy, Love, &c. The ceiling is groined, and of wainscot. It is of very elaborate design, and is to be decorated with colours and gilding.

We now come to the ante-dining-room, with its walnut dado, in the panels of which family portraits by Gainsborough, Millais, &c., are framed. As in the drawing-room, the old plaster ceiling is retained, and has been re-decorated.

The great dining-room is of the same shape and size as the drawing-room. It is being fitted up with all-becoming magnificence in walnut. At the north end is the sideboard recess, which has a groined walnut ceiling, and a serving-room adjoins. To the west of the dining-room, and on either side of the corridor, are the billiard and smoking rooms. They are treated similarly, and have wainscoted dados, with dark oak panels. The ceilings are also of wainscot, and the walls are hung with stamped leather. The floors are of parquet.

The grand staircase is enclosed in walls of Grinsbill stone, with bands of Robin Hood and Forest of Dean. The steps are of Portland, and the balustrade of alabaster, carried on small shafts of various granites, in pairs. The ceiling is of oak, and is supported by massively-framed principals, filled in with tracery. At the second-floor level a bridge is thrown across for the use of the servants. The corridors in the east side are glazed with tinted quarry glass, and those on the west side with clear plate, so as to command a view of the park and the Welsh mountains. This staircase leads to the state apartments, which are on the first floor.

We have now described the principal apartments in the main building, and proceed to the north wing, the Grosvenor wing, the stables, &c.

In the north wing is the magnificent kitchen, lined with terra cotta, and a groined ceiling filled in with the same material. The Grosvenor wing is in itself a large house, and much space might be occupied with a description of it. It has a central hall, round which the principal apartments are ranged, and which is lighted by a centre light. From this hall, the principal staircase rises, and at the first-floor level a gallery is carried round it which gives access to the various rooms. The floor is of coloured mosaic, and the ceiling is decorated with heraldry. The apartments on the ground-floor generally have parquet floors and wainscot fittings and dados, and ceilings of plaster panelling in geometric patterns, enriched with colour. The duchess's room is panelled with views of Cliveden, Trentham, and Dunrobin, by O'Connor. The chapel was fully described in this journal in 1879, when an illustration of the exterior of it was given (p. 888). The stables, which in many respects are as well worth a visit as anything at Eaton, stretch away further still to the north, and are arranged round a large court-yard, in the middle of which is an ornamental basin with a central equestrian group, by Mr. J. E. Boehm, A.R.A. Beyond the stables are the coachmen's cottages, and the establishment is completed by the gas-house, water-works, and laundry, still further away by the side of the Dee. Large tanks in the library and chapel towers (the latter in reserve) supply water for the hydraulic lifts and in case of fire. On the west side of the house is the Belgrave Avenue, which is about two miles long, and on the east side the corridors of the grand suite of entertaining-rooms command an extensive view of the terraces, the river Dee, and in the distance the Peckforton Hills and Beeston Castle.

SCIENTIFIC AND ARTISTIC ASPECTS OF POTTERY AND PORCELAIN.*

The third of Professor Church's series of Cantor Lectures on "Some Points of Contact between the Scientific and Artistic Aspects of Pottery and Porcelain," was delivered on Monday evening last, when the division of the subject dealt with was "Stoneware and other Wares glazed with Salt." The lecturer said that the stonewares to which he wished more particularly to allude were those which had been chiefly made in Germany and in Staffordshire, and at Lambeth and Fulham, and which were for the most part glazed with salt. With regard to the body, or paste, of these wares, it might be said generally that stoneware led up from earthenware, through the beautiful jasper ware of Wedgwood, to hard porcelain. What was the structure of the ordinary stoneware and of the jasper ware first of all made,—and, indeed, invented,—by Wedgwood? It was essentially a fire-clay or china-clay, made less plastic, or less greasy, as the French would say, by the addition of silica in some form or other, generally in the form of fine sand or ground flint, which took away to a great extent its "soapy" feel when it was moist, and gave it a greater degree of hardness when fired in the kiln. At the same time, however, the addition of silicious material to the clay imparted a certain degree of brittleness, which, in so far as it went, was one drawback of stoneware. At the same time, the addition of silica imparted to the product a peculiar and characteristic property which stoneware did not share with any other kind of pottery. If a piece of stoneware were examined under the microscope, it would be seen to consist, first of all, of a great mass of small particles of clay, not very much altered by firing; and the six-sided outlines of the crystalline fragments of the mineral which formed the chief constituent of the clay, and the little angular fragments of the sand or flint, could be seen. But there was something which held all these fragments and particles together, viz, the glassy material which was formed at a high temperature in the kiln by the action of a minute quantity of alkaline matter which existed in the clay and united with the silica, forming a hard silicate of potash or soda, and lime. The lecturer then entered into the subject of clay analyses, pointing out that Stourbridge fire-clay, which contained only ½ per cent. of alkaline matter, was the least fusible of all clays, and hence its practical value in the industrial arts. Watcombe clay contained about 7 per cent. of alkaline matter, and Poole or Dorset clay 4 per cent. All clays were not equally adapted for stoneware, those with the larger percentages of alkaline matter being too fusible. The contraction of the clay in the kiln was a very serious matter, various clays contracting in very different degrees. In the Jermyn-street Museum there would be found a beautiful series of specimens of the different clays, arranged geologically, which could be used for potting purposes, each clay being represented by experimental slabs of the same size burnt and unburnt, so as to show the amount of contraction. Mr. George Moore, who made the experiments, presented the specimens to the Museum of Practical Geology, and had contributed to the catalogue of the pottery exhibited there an elaborate series of tables showing the results he arrived at. Stourbridge clay would contract only from 1 to 2 per cent., while other clays would contract from 18 to 20 per cent., or about one-fifth of their whole bulk. As to the progress of the manufacture of the body of stoneware in this country, the lecturer observed that Simeon Shaw, whose valuable book,—not to be trusted in every particular,—was published in 1829, said that at first the Staffordshire potters used a mixture (for stoneware glazed with salt) of brick, clay, and sand. They subsequently used a clayey marl and a grey clay from the coal measures mixed with clean sand. Shaw stated that to each bushel of salt thrown into the kiln for glazing, some manufacturers added one pint of red lead. Another manufacturer effected an improvement in the body of the ware by introducing ground flint into the clay, and his successor introduced another improvement by thoroughly washing the clay to get rid of ochreous and other matter. Wedgwood, in making the body of his jasper ware, instead of mixing sand with his pipe-clay and china-clay, used sulphate of baryta (heavy spar), which was opaque, or nearly so, when finely ground. There was a great deal of difference in the Wedgwood ware made during Josiah Wedgwood's lifetime and that made subsequently, and any one studying the porous open texture of the body of modern Wedgwood ware must, he thought, attribute it to the less careful uniformity in the grinding of the materials. Referring to some stoneware jugs exhibited, the lecturer said they presented some peculiarities which would at first sight lead one to suppose that they were English. They were globular in form, with straight necks, and were well potted and glazed with salt. They generally bore as a monogram either "G. R." or "A. R.," and, more rarely, "W. R.," but they all bore indications of being of an earlier period than that of George I. Many persons had accepted the notion that "G. R." stood for "Gulielmus Rex," and that the jugs were really of the time of William and Mary. The specimens exhibited were not, he thought, English, but were, no doubt, made for the English market about the end of the seventeenth century. Similar jugs, but inferior in material, shape, and finish, were made by Dwight, of Fulham, about the same time. As to "Bellarmines," some of them made at Fulham by Dwight were as good as any made in this country. Having referred to the development of stoneware in Staffordshire (where he believed it was no longer produced), the lecturer referred to Continental productions, and finally referred to modern stoneware as produced by Messrs. Doulton and Messrs. Stiff at Lambeth.

Wyman & Sons, Printers, 74 Queen St.

EATON HALL, CHESTER.—Mr.

Waterhouse, A.R.A., Architect.

ARCHITECTURAL ASSOCIATION.

At the ordinary fortnightly meeting of this Association on Friday, the 3rd inst., Mr. Ernest C. Lee, president, in the chair, about thirty gentlemen were nominated for election as members.

Mr. R. Phené Spiers said:—I desire, by leave of the meeting, to say a few words as to

The Origin of the Architectural Association.

The precise date of the origin of the Architectural Association has so often been mooted in committee when a new "Brown Book" was being collated, that I have thought the matter sufficiently interesting to note down a few facts concerning it, especially as it was alluded to in the President's address this year, and as I am able to present the Association with what may be called the first "Brown Book" in existence. The society from which the Association sprang was called the "Association of Architectural Draughtsman." It was instituted on the 1st of September, 1842, and its objects, five in number, are set forth in the prospectus attached hereto. In this paper the rooms are stated to be at 33, Southampton-street, Strand. In the *Builder* of July 15, 1843, however, a notice is given of the society, wherein it states that the members meet on the first and third Wednesday in every month at the *Café Royal*, 42, Castle-street, Holborn; and a letter to the editor of that paper from Mr. J. K. Colling, who appears to have been one of the most active members of the society, states,—

"Sir,—It may not be known to you that a society exists called the British Association of Architectural Draughtsmen, having for its object, by union and co-operation, the providing with employment those of its members who may require it. For this purpose a register is kept of those unemployed, and which is available to architects who require assistants; also, each member of the society furnishes quarterly a drawing of some executed architectural subject, which drawings are kept in the portfolio of the society, and not only form the means of collecting vast professional information, but a sure guide to architects by which to judge of the ability of the assistants they may select. Connected with the society we have also established a benevolent fund, for assisting those of our body who, through misfortune or ill-health, may require it."

Mr. Colling then goes on to say that he has much pleasure in forwarding a drawing for publication, and hopes to be able to supply others. This drawing, of the chancel-window of the church at Little Maplestead, was published,* being, however, the first and last of the series. On the 2nd of September in the same year some one writes to the *Builder* to suggest a more extended plan, and asks why original drawings should not also be sent in. Nothing more is heard of the society till February 3rd, 1847, when Professor (then Mr.) Kerr, reads a paper on "Architectural Education" at the rooms in Southampton-street, Strand. This paper was a very important one, and led to the immediate formation of the Architectural Association, which sprang phœnix-like out of the embers of the decaying Association of Architectural Draughtsmen. The next notice I find in the *Fine Arts Journal*, in which it appears that a meeting was held on the 3rd of March, to put into operation one of Mr. Kerr's proposals, viz., to embody "a school of design," and it was then stated that the object of Mr. Kerr's paper, and from which this scheme (the formation of a school of design) emanated, was to form a society upon an enlarged scale, with a comparatively trifling subscription, which would induce every student of the art to avail himself of its privileges. Some amended rules were read out and approved of, and a number of new names were proposed for membership. A sub-committee of the old society was then appointed to meet a deputation of the newly-proposed members, and to arrange at once upon the actual working of the new schools. The next notice is on the 5th of May of the same year, when a paper was read by Mr. Colling before the already-formed society, still meeting in Sonthampton-street. On the 7th of July, 1847, a paper on "Architectural Style" was read by Mr. Kerr, who had been elected president; and on October 8th, the first *conversazione* was held at the new rooms in Lyon's Inn Hall, at which over a hundred persons were present, when the president, Mr. Kerr, delivered his opening address.† It then numbered eighty new members. The Association remained there till April, 1859, when it removed to its present quarters in Conduit-street.

* See *Builder*, vol. i. (1843), p. 275.

† A report of the speeches will be found in the *Builder* of that year. The assistance rendered by the *Builder* in the formation of the Association has been referred to more than once.

The following is a copy of the prospectus of the Association of Architectural Draughtsmen (instituted on the 1st of September, 1842):—

"This Association has for its chief object facility of communication between its members and all others of the architectural profession. The means employed to effect this, and no less the advancement of members in their art, are,—

I. The establishment of a registry of draughtsmen unemployed, and of architects requiring their assistance.

It is needless to dilate upon the advantages of this compared with any system which either makes a profit upon the remuneration of the draughtsman or depresses it without benefit to the architect.

II. The collection of drawings of existing subjects (by quarterly subscription), the first of which returns to the contributor's possession upon the production of the ninth, and so on in the order of contribution.

The drawings are open to public inspection on the undermentioned evenings of meeting, and serve the architect in forming his judgment upon the abilities of the member with whom he contemplates engagement.

III. Publication, in lithography, of such of the drawings as are suitable, each member being entitled to a copy of all published during his membership.

IV. Meetings held on the first and third Wednesday evenings in each month throughout the year, for the purposes of conversation and reading of papers upon professional topics.

V. A Book Club, for the purchase and circulation of professional works.

It should be observed that the Association has formed the nucleus of a benevolent fund, an object deserving of the liberal consideration of the wealthier members of the profession. Subscription to this is optional with members of the Association.

The Association commemorates the anniversary of its formation by a dinner to the town members at Freemasons' Tavern.

Members of the profession are respectfully invited to visit the meetings. Those intending to join are requested to communicate with the secretary at the rooms of the Association, 33, Southampton-street, Strand.

E. C. SAYER, Hon. Sec."

[*Copy of Card.*]

"ASSOCIATION OF ARCHITECTURAL DRAUGHTSMEN,
33, Southampton-street, Strand.

This Association facilitates communication between architects requiring assistance, and draughtsmen unemployed; either in permanent or temporary engagements, it offers advantages peculiar to itself.

It abstains from all interference with or profit upon the terms, so that the architect derives the full benefit of their amount, in receiving the best assistance they can command.

Its regulations are calculated to secure in its members respectability of conduct as well as to improve their talents. Quarterly drawings are required of them, which remain with the Association, and are open to professional inspection on the evenings of the first and third Wednesdays of each month throughout the year.

Note.—If no member should be disengaged who is qualified to answer any application for assistance made to the secretary, the Association will advertise for it, thereby saving the architect expense and trouble.

Communications, &c., addressed to the secretary, at the rooms of the Association, 33, Southampton-street, Strand, will receive prompt attention.

E. C. SAYER, Hon. Sec."

Thanks having been given to Mr. Spiers for his communication,

Mr. W. Hilton Nash read a paper on "The Architects of the Italian Renaissance." This we print elsewhere.

Mr. H. L. Florence, in proposing a vote of thanks to Mr. Nash for his paper, said that the examples which had been mentioned in it were certainly typical of the schools treated of, but the author had not given any particulars of the distinguishing characteristics of those schools. Now, those who had seen the buildings in question would have understood the reasons which gave to each style its peculiarities and the characteristics of the artist himself, because many of the buildings referred to were not by architects alone,—and the circumstance that they were by men who were designers in other arts, painters and sculptors,—materially influenced some of the buildings. With regard to Michelangelo, many of his works, especially the Farnese Palace, were well worthy of study, but they exemplified much that had better be avoided than copied. Of course, the great ideas which he had, such as were realised in his domes and other structures, were to be admired, but the admiration could not be extended to the details of execution.

Mr. Hugh Stannus, in seconding the motion, observed that Mr. Nash had incidentally referred in his paper to the varying conditions under which architecture was practised. He had spoken of the princely patronage that the old architects received during the two centuries dealt with in the paper, and had by implication suggested that the architects of the present day lacked the princely pay, and that therefore they were not able to do such good things. He (Mr. Stannus), however, did not think that architects had any reason to complain of, either as to the patronage or pay accorded to them in the present day. There were princely patrons now as there were of old time, and the remuneration of architects was reasonably good. In his opinion, one great reason why the architecture of the present time could not compare with that of some previous epochs was that the architects themselves were so greedy that they took too many jobs, and some of them, when occasion offered, sought to obtain and did obtain important works in styles in which they were not reputed to excel. So far from seeking work in a style alien to that in which they worked, the older men would have refused it when offered to them; and any one who read the pages of Vasari would find that there were not wanting instances in which architects of established reputation showed a considerate feeling for the youngermen. At the present time the younger men in the architectural profession were starving, while all the pluralists, who would take any number of commissions that they could not possibly attend to, flourished. The reason why modern architecture could not compare with the old work was simply that modern architects themselves could not compare with the architects of old. With regard to Raffaelle, Michelangelo, and Leonardo da Vinci, he thought it was to be just as much regretted that they had ever laid their hands upon architecture as it was to be regretted that Sir Christopher Wren had been called upon to build the towers of Westminster Abbey. Raffaelle, Michelangelo, and Leonardo da Vinci did not understand architecture, and thought it consisted in sticking columns and pilasters on to building. Mr. Nash had not alluded to what Sir Charles Barry did at the College of Surgeons in Lincoln's Inn Fields. There was to be seen a façade without an order, and it was one of the finest façades in London. His façade of the Travellers' Club was also very good. With regard to Palladio, architects ought to be grateful to him, not for what he built, but for his book. His buildings were very bad, and in many points of grammar would not be at all creditable to one of the Association's students in the Class of Design. The great debt of gratitude which architects owed to Palladio was for the publication of his book,—a book which had done more, perhaps, than any other to popularise and to systematise the study of architecture.

Mr. R. Phené Spiers said that Mr. Nash had appeared to regard it as a misfortune that the present generation possessed no painters of distinction, nor, indeed, any painters at all, who had carried out architectural works. But in his (Mr. Spiers's) opinion, if we in the present generation found ourselves placed in the same position as the people of Italy in the fifteenth century, there were several of our most distinguished painters who would be called upon, by reason of their talents and position, to design important buildings, just as painters and sculptors were called upon at one time to design buildings in Italy. The President of the Royal Academy (Sir Frederick Leighton) had perhaps a greater knowledge of Greek architecture (so far as its general artistic spirit as distinguished, perhaps, from its practical conditions, was concerned) than any architect now living; and no one could vie with Mr. Alma Tadema in his knowledge of Roman and Pompeian work. There was not the least doubt that if Mr. Alma Tadema were to be called upon to design buildings of that character, he would produce works of great beauty and merit. There were, he need not say, several instances of men who had begun life as architects, and afterwards turned to painting, as, for example, Mr. W. W. Deane, who was a distinguished member of the Society of Painters in Water-Colours, generally giving his attention, however, to architectural subjects. It was said that he was what was called a "disappointed" architect. He was one of the best designers of his day, and used to colour drawings for other architects. His original designs were such as would have brought him credit and honour had they been put into execution, but he could get no practice, and therefore left the profession. There was undoubtedly a very large number of young men who had abilities fitting them to be excellent architects, who joined the ranks of the painters. If they had seen any chance of getting a practice, they would have become architects. It would therefore probably be an easy thing to find several painters who would be capable of becoming excellent architects. Of course it should not be forgotten that many of the distinguished masters of the Italian school were not only great painters and sculptors, but great mathematicians and men of science. Leonardo da Vinci was an example of this in Italy, while in England we had Sir Christopher Wren, who at a very early age made an import-

ant astronomical discovery, and at the age of twenty-five was Professor of Astronomy at Oxford. He afterwards travelled in Italy, and later on produced the wonderfully-varied and numerous spires and towers of the London churches. Many of the distinguished architects of Italy devoted some years at the outset of their career to the study of mathematics and science. They then turned their attention to art, practising the drawing of the figure and probably modelling their figures before painting them,—a practice followed in the present day by Sir Frederick Leighton. Later on, when they had made their reputation either as painters or sculptors, they were called upon to carry out buildings. Such a system of training for architects, however, was impossible under present-day conditions, and any one who allowed himself to reach the age of forty before he took up architecture, would be unable to make himself acquainted with all the details of modern practice. Nearly all the chief architects of France had to go through, in their early training, severe mathematical courses, and if, having entered the École des Beaux Arts, they obtained the Grand Prix, they went to Rome, returning at the age of from thirty-two to thirty-five, without having acquired any practical knowledge as to the strength or properties of materials, or as to the details of construction. If appointed to some public or Government building, their practical knowledge was so deficient that they had to trust almost entirely to their inspectors. Some of them, it was true, had the courage, at that time of life, to turn their attention to the study of the nature and properties of building materials, but others confined their thoughts entirely to design. In England we had no architect who would be content to take the extraordinary position which the late M. Duc occupied for so long with respect to the Palais de Justice, to which building he devoted the whole of his architectural life. Of course, under such circumstances an architect was able to give more thought and care to his building, but it was not, he thought, a system which would find favour in England.

Mr. Nash having briefly replied, the proceedings terminated.

THE ARCHITECTS OF THE ITALIAN RENAISSANCE.*

It is almost impossible, within the limits of a short paper, to do justice to the number of illustrious names which crowd upon us at this epoch, and we can, therefore, only dwell briefly on the lives of the architects of the fifteenth and sixteenth centuries, and the motives which actuated these men to produce works which daily increase in interest, and compel us to offer our tribute of respect to the energy of mind and purity of thought as exhibited in them. Although many may take exception to the over-elaboration of detail, and to the naturalistic treatment of ornament in Late Renaissance works, yet we may discover in nearly all instances a freedom of design which, in earlier times, and especially during the Middle Ages, was often cramped and fettered by ideas which emanated from the seclusion of the cloister and the austerity of monastic life.

The architecture of the Italian Renaissance may be roughly divided into four schools,—the Florentine, the Roman, the Venetian, and, lastly, the Baroque school.

To the first belong the palaces of the Medici, the Pitti and the Strozzi at Florence, both having in them traces of Mediævalism and predominating strength. The house of the Florentine noble was literally his castle; the dark portal, and massive walls pierced with narrow openings, and the rugged rustication of the walls, all point to the troublous times in which these nobles lived.

The Roman style is less massive in treatment, and ornament is introduced less sparingly; a more refined taste was being developed, as evidenced in the works of Fontana, Sangallo, Bramante, and Michelangelo,—such as the Farnese Palace, the Palace of St. John Lateran, and the numerous villas with which the environs of Rome are studded. As to the churches of the Roman style, that of St. Peter's gives the keynote to all the others, and as almost all the first architects of the two centuries we are considering were engaged upon it, we may see in it the embodiment of this style.

The Venetian school is characterised by greater lightness and elegance, and includes among its ranks such men as San Michele, Palladio, and Sansovino; and the library of St. Mark at Venice, by the latter architect, forms a typical example of this school.

The Baroque style, introduced by Maderna, Borromini, and others, marked the decline of Renaissance art; its effects were, nevertheless, novel and striking, but were wanting in dignity and repose, and figures in impossible attitudes clinging for dear life to broken pediments marked the degenerate taste which prevailed.

First among the architects of this century, when the first faint glimmer of the dawn of the Renaissance was stealing over the land of Italy, stands the name of *Filipo Brunelleschi*, son of Lippo Lapi (born 1377, died 1444), who, though educated for far different pursuits, at an early age brought his powers of mind to bear, first on geometry, then on Dante and his writings, and eventually applied himself wholly to architecture, and, by earnestly studying the ancient masters in Rome and elsewhere, became imbued with the true spirit of the antique, and revived the ancient orders of the Doric, Ionic, and Corinthian. The two greatest works of this architect were the Pitti Palace at Florence, and the cupola over the cathedral, Santa Maria dei Fiori, in the same city. The Pitti Palace has a rugged simplicity, which makes this building astonish us, rather by its broad treatment of masses than by any delicacy or refinement of detail. The entire building is covered with rustic work, the blocks of stone in the lower story and in the wall of the terrace flanking the courtyard being of such an enormous size that they look like the work of giants. Some idea of the large proportions of this building may be obtained from the entrance-doorways, which measure about 28 ft. in height by 14 ft. in width. But Brunelleschi did not live to complete his work, and only carried the building as high as the second story, and later on Ammanati added mouldings and triangular pediments to the windows, to the detriment of the original design, which, as has been before stated, owed its beauty in a great measure to its simplicity of treatment.

When Brunelleschi's grand conception of raising a dome over the church of Santa Maria dei Fiori at Florence was first promulgated, his project was hailed with derision, and to prove that he was capable of performing what he undertook to do, he had recourse to the trick afterwards practised by Columbus. When the persons who had been clamouring to see his design were assembled, he produced an egg, and asked each one present to make it stand upright on the table. All tried, but failed, when Brunelleschi, striking off the end, accomplished the feat. "We can do that also," exclaimed those assembled. "So you will say when you have seen my design," replied the architect. The height of the cupola from the ground to the summit of the cross is 385 ft. It consists of an outer and inner shell connected together at intervals by walls, and it is octangular on plan. Other cupolas had been constructed previously to this, as at St. Sophia's, Constantinople, St. Mark's at Venice, and the Baptistery at Pisa; but this one outrivalled them all, both in size and ingenuity of construction. Brunelleschi was great not only in civil and ecclesiastical, but also in military architecture, for he designed the fortresses of Vico Pisano, the old and new citadel at Pisa, and he also built fortifications on the Ponte Amare. He died respected and beloved, and was buried under the shadow of his great dome at Florence; posterity has, moreover, awarded him the highest honours, for to him we owe the re-establishment of pure architecture and manly design.

Leon Battista Alberti (born 1398, died 1472) was a nobleman by birth, and son of Lorenzo and nephew of Cardinal Alberto of the Alberti, a Florentine family. Educated with the greatest care, and having a knowledge of mathematics, painting, and sculpture, and possessing a natural taste for the fine arts, he was not long in deciding on the profession which would be most suitable to a man of such varied acquirements. The church of San Francesco at Rimini bears witness to his powers of design, and is perhaps the most talented of all his works. The interior is still in the Gothic style, but the whole of the exterior was remodelled from his designs, and embellished with choice marbles. At Florence Alberti built the circular chapel of the Annunziata, which is wanting in many of the graces distinguishing his other works. The semicircular arches being circular on plan, have, as is usual in such cases, a distorted appearance, which mars the effect of the composition. The principal façade of Santa Maria Novella is attributed to Alberti; but Milizia, in his "Lives of Celebrated Architects," states that it was probably built by Giovanni Bellini. His life was passed as a true nobleman's should be, in liberality and courteousness to all, and he died at an advanced age in his native land.

During the early part of the fifteenth century, when the revived art was only feeling its way, and had not obtained that firm footing on the soil of Italy that the following century established, the names of great architects were few in number, and the two whose lives we have just considered,—namely, Brunelleschi and Alberti,—were the guiding stars of this epoch. Nevertheless, other architects flourished, some of whose works were of no mean merit, and amongst these were *Michellozzo Michlozzi*, a Florentine and a pupil of the sculptor Donatello. This architect succeeded in making a design for the palace of Cosmo de Medici, by which he secured the patronage of that influential man, and superseded Brunelleschi, who had previously made a design which was considered too sumptuous. Michelozzo built the famous library of the Benedictines at San Giorgio, Venice, to which city Cosmo had been banished in 1433, and whither his architect followed, with a devotion rarely witnessed in modern times. He made designs for and built the palace of Cafaggiulo, in Mugello, by order of the Duke Cosmo; also an ingenious villa at Fiesole, near Florence, on the side of a hill, with large cellars and stables under part; also the palace of the Tornabnoni, now belonging to the Marquis Corsi. Michelozzo died at the age of sixty-eight, and was interred at the church of St. Mark, at Florence.

Giuliano da Majano was also a Florentine, being the son of a stonecutter residing near Fiesole. Having studied architecture, he had the good fortune to be patronised by King Alphonso at Naples, where he built the great palace at Poggio, which is an exact square on plan, and is chiefly noted for the clever arrangement of its staircases.

About the middle of the fifteenth century flourished the celebrated architect *Bramantino*, whose field of operations was chiefly in Milan and the surrounding district. He erected the Church of St. Satiro in that city, which has been much praised, more, however, on account of the sumptuousness of its decoration than for its beauty of design; for the numerous arcaded corridors, and the many statues with which it is adorned detract from the main features of the design, and render them somewhat confused. Bramante, of whom we shall speak later on, is said to have benefited by studying his works, and we see tokens of this in many buildings erected by him.

Giovanni del Pozo and *Francesco di Giorgio*, of Siena, rank among the lesser lights of this epoch. The latter, however, erected some very creditable buildings, chief among which is the famous palace of the Duke Frederigo Feltre, at Urbino.

The sister arts of painting and sculpture were frequently combined in these times with the more practical art of building, and the appellation of "painter and architect" was as common then as "architect and surveyor" is in the present day. The artistic ideas of the nineteenth-century architects are often deadened by the worry of business; and this is greatly to be deplored, for the real artist should be free from the petty cares and anxieties which engross the bustling matter-of-fact people of the present day.

A liberal emolument will not evoke talent; nevertheless, architects, to do their work truly and thoroughly, require to have sufficient means to enable them to drive away anxious thoughts for the morrow, and the ancient architects were undoubtedly treated in a more liberal manner than those of to-day, or they could never have bestowed that painstaking care on their buildings which is so frequently exhibited, since their whole time and thoughts were often confined to one building, while the multifarious duties of the nineteenth-century architect disqualify him from taking that high position which was so acquired by the architects of Renaissance.

Having now briefly considered the architects of the fifteenth century, we pass on to those of the sixteenth century.

When on some bright summer's night we gaze upon the cloudless heavens, and see there some grand constellation which rivets our attention, and

* A paper by Mr. W. Hilton Nash, read before the members of the Architectural Association on the 3rd inst.

become for a time almost forgetful of the lesser luminaries, so it is when we pass in review the architects of the sixteenth century. Their names stand out so boldly among the lesser lights of art that we are for a time unaware of the existence of preceding or posterior artists, and we cannot help asking ourselves the cause of this great uprising and rebirth of intellect at a period when all true art seemed lost in a hopeless chaos. This great awakening to the study of the beautiful and the true, was mainly attributable to the cultivated tastes and judicious patronage of the leading families in Italy. They were the great motive-power which set the machinery of art in motion, and evoked the slumbering talents of men capable of greatness in every department of art,—in painting and sculpture, in poetry, music, and architecture. Well might Michelangelo and other contemporary architects have said of the Cosmos and Leos of the Medici family, as Horace said of Mæcenas, "O et præsidium et dulce decus meum," for had it not been for this opulent and cultivated family, many a talented artist who now illumes the page of history would have died "unwept, unhonoured, and unsung." Art patronage, however, is not the prerogative of the many, but rather the privilege of the few; and, like other good things, it must be judiciously administered, or its effects will be more baneful than productive of good; for far greater detriment is done to art by the ignorant patron, who enriches those who unjustly deserve it, than by the man who, though appreciating talent, fails to render it its due reward.

Bramante d'Urbino, though born at the end of the fifteenth century at Castel Durante, is generally classed among the architects of the sixteenth century. His talents were directed at an early age to painting, but he quitted it for the sister art of architecture, having studied and measured the principal ancient buildings at Rome, and the remains of the villa Adriana at Tivoli. His chief patrons were the Cardinal Caraffa, the Popes Alexander VI. and Julius III., and the Duchess Eleonora Gongaza, the latter of whom commissioned Bramante to build a palace for herself and her husband, the Duke d'Urbino. The greatest work of this architect was undoubtedly the re-building of the Church of St. Peter at Rome. In this design he equalled, if he did not surpass, the ancients, in the massiveness and unity of treatment which pervades the whole edifice. Strongly impressed with the grand proportions of the Pantheon at Rome, which, no doubt, he had studied in the days of his pupilage, he founded his design on this model and made his cupola of similar dimensions, adding the four arms of the Latin cross, forming, when completed, a building of unequalled vastness and grandeur.

Bramante could boast of having Raffaelle for a pupil and Michelangelo for a friend and adviser, and the great sculptor states his opinion that "Bramante is superior to all others since the time of the ancients."

Shall we praise or blame Bramante for the revival of the use of plastering and stucco ornament? There is much to be said in favour of the way in which he employed it, namely, on a wooden foundation; but unfortunately it latterly fell on evil times, its true place and use being forgotten, and the stucco, instead of assisting to decorate the buildings served only to overburden them with vulgar ornament. This is specially noticeable at Vicenza, where Palladio, not having had funds sufficient to erect his sumptuous designs in stone, has had recourse to plastered columns on a brick core, and the effect of time on these buildings has made them look pitiable in the extreme, and has given occasion to architects of the opposite school to decry all architecture of the Palladian school as a sham.

The most beautiful erection by this architect is the palace of the Cancelleria at Rome. The windows on the "primo piano," or first floor, have served as models for countless others, but none have surpassed the original. The façade is constructed of blocks of travertine from the Colosseum, which, during this century, served as a sort of quarry for numerous Roman palaces.

The beautiful dome of the Church of Santa Maria delle Grazie, at Milan, is certainly the most satisfactory of any of Bramante's works, and, as Fergusson says, in his History of Modern Architecture, "Had the architects of the succeeding age been only content to work with the moderate amount of classical feeling found in this building, we should have had no cause to regret the loss of the Gothic style; but the temptation to employ great pilasters and pillars, whose real recommendation was that they covered the greatest amount of space with the least amount of thought, was more than human nature could resist, on the part, at least, of men who were more artists and amateurs than architects."

The dome of Santa Maria is 65 ft. in diameter, and is consequently one of the largest constructed by Bramante, that at the church at Lodi being 50 ft., and the dome of the little church of San Pietro, in Montorio, at Rome, being only 15 ft. in diameter.

Bramante died in the year 1514, at the age of seventy, and was buried in great state in the church of St. Peter, the grand work of his lifetime, and which, had it been executed as originally designed by him, would have been a church worthy of the golden age of Renaissance art.

The two brothers *Giuliano* and *Antonio di Sangallo* flourished about this time (1443-1517). They were sons of an architect, Giamberti, whose works have not been greatly praised, and, being educated as engravers, ultimately turned their attention to architecture. The principal works of Giuliano were the cupola of the church of the Madonna di Loretta, at Rome, built by order of Alexander VI., the fortifications of Ostia, the castle of Monteflascone, for the Duke of Valentino, and he latterly superintended the building of St. Peter's at Rome under Leo X. His disinterested motives, and his affection for his great patron Lorenzo de' Medici, are exemplified by the following story narrated by Milizia. After completing the fortifications of Ostia, he journeyed to Naples and presented a magnificent model to the king for some work at Castel Nuovo, which so pleased the monarch that he presented him with horses, clothes, and a silver cup containing one hundred ducats. Giuliano, however, refused to accept them, stating that he was still in the service of Lorenzo de' Medici, and the king, surprised at his noble independence, allowed him the choice of whatever pleased him, and he accordingly chose some fragments of antique sculpture, which he presented to his patron Lorenzo on his return to Florence. Antonio or Sangallo the younger has left many excellent works as evidence of his talent, and his designs for St. Peter's at Rome were replete with originality, and differed greatly from those of Bramante. The most ingenious work of this architect was the well at Orvietto, which is of great depth, and has two spiral staircases,—one inside the other,—descending to the well, so that one set of mules laden with waterskins might be descending while the other set were ascending. Sangallo began the Farnese Palace when Paul III. was cardinal, and when the building had reached the roof, the Pope, anxious to have a cornice which, in beauty and richness of design, should eclipse all former efforts, instituted a competition among all the able artists in Rome, but even the Pope's infallibility could not ensure a satisfactory termination to it, for the decision, as in nearly all modern competitions, was as absurd as it was unjust. Sangallo competed, but his design was set aside for one by Melighino, formerly the Pope's groom, and he was unable to restrain his righteous indignation at this unfairness, and explained to the Pope that this man was a mere mountebank of an architect. "We wish Melighino," said the Pope, "to be really an architect, and will therefore take care to provide for him." But the groom did not carry it out after all, and the execution of it was entrusted to Michelangelo.

Simone Pollainolo (born 1454, died 1509) was a Florentine by birth, but he visited Rome at an early age, and there acquired a strong passion for architecture. He superintended the erection of the Strozzi Palace at Florence, which was designed by Cronaca, and built the beautiful little church of San Francesco, on the hill of San Miniato at Florence, which has, however, been over-praised, on account of the notice taken of it by Michelangelo, who surnamed it "La Bella Villanella."

Sansovino (born 1460, died 1529) was the son of a peasant, and became famous in his early years for sculpture, but especially for the two tombs in the church of Santa Maria del Popolo at Rome, and afterwards became equally noted for his architectural works. He built the beautiful Capella del Sagremento at Florence, adjoining the church of San Spirito, and as the compartments of the vaulting were not placed centrally over the piers, his clients found great fault with him, but he brought ancient examples to justify his design, and so silenced all criticism. The west façade of the Duomo at Florence was then, as at the present day, unfinished, and Sansovino placed against it a false façade of wood, of admirable design; but as the design was of the Classic type, with Corinthian pilasters, it is, perhaps, well for the harmony of the edifice that it was never executed. Sansovino made a design for a magnificent church at Rome, his drawings being preferred before those of Raffaelle, Sangallo, and Peruzzi, but the execution eventually devolved upon Sangallo, who was a better constructor than his contemporary. The library of St. Mark, at Venice, has, however, immortalised his name, and the building has a rich Doric order on the ground-floor, with a graceful Ionic above. Venice has, more than any other Italian town, been richly embellished by this architect. Having resided nine years in Portugal, at the invitation of Leo X. he returned to his native land, laden with rich gifts, and eventually built himself a villa near his birthplace, Monte Sansovino, where he spent the remainder of his life.

We have now to consider the character of a man who combined all that was manly and noble with a delicacy and refinement of thought which have seldom been surpassed. *Leonardo da Vinci*, the great painter, sculptor, architect, and anatomist, who was skilful in music and poetry, and added to a beautiful exterior the charm of graceful manners, was born in the Castel da Vinci at Florence. We are not acquainted with many of his architectural works; nevertheless, it is evident from his writings that he had studied the subject, and he was employed by Ludovico Sforza to conduct the waters of the Adda to Milan, and he made the canal of Montesano navigable for 200 miles. It was his habit to write on whatever he executed, but as all his writing, like Hebrew, is from right to left, it is not easily deciphered. His ingenuity was marvellous, and when the king of France, Louis XII., visited Milan, he fashioned the model of a lion, which, when the king was seated in the great hall of the palace, moved towards him by the aid of machinery, and on arriving at the throne it suddenly stopped, tore open its breast with its claws, and displayed on its heart the royal arms of France. Jealousy for his contemporary, Michelangelo, caused him to quit Italy, and at the invitation of Francis I. to visit France, but he was taken mortally ill at Fontainebleau, and the king immediately set out to see him. On the arrival of the monarch, Leonardo endeavoured to rise to pay him homage, but the exertion hastened his death, and he expired in the king's arms.

Raffaelle d'Urbino (born in 1483, died 1520) was the son of Giovanni Sanzio, a painter of some note, but whose name was eclipsed by that of his illustrious son. One of the first works of Raffaelle was the façade of San Lorenzo at Florence, for Leo X., and the palace of the Pandolfini. The stables of Agostino Chigi, in the Strada Longara, Rome, were designed by him; and here we see the coupled pilasters which were a constant feature in Raffaelle's designs; but this building is too much broken up to have a wholly satisfactory effect. He was one of the architects of St. Peter's, and in his design divided the Latin cross into nave and aisles, with recessed chapels in each bay. The arms of the cross were semi-circular, and were ornamented with numerous columns and pilasters. The idea is said to have wanted grandeur, and, in fact, it required an almost superhuman genius to master all the difficulties which were connected with the construction of so vast a work. But although Raffaelle's architectural works were great, his powers of painting were far greater, and he was treated with every mark of reverence and respect, and after endeavouring to imitate Michelangelo in sculpture, in which, however, he failed, especially in the nude, he devoted his whole time to painting. He died at the early age of thirty-six, and was buried in great state at Rome, Cardinal Bembo writing his epitaph, which has been thus translated:—"To the memory of Raffaelle. Nature feared to be conquered by him while living, and to be annihilated at his death."

Let us now briefly consider the strange and varied life of *Baldassare Peruzzi* (born 1481, died 1536), who was the son of Antonio Peruzzi, a Florentine noble. The civil wars which were then raging in Italy caused his family to be left in great distress and poverty, and Peruzzi

accordingly journeyed to Rome, and devoted himself to painting and architecture. He, like his illustrious predecessors, was engaged in superintending the building of St. Peter's, and made some improvements on Bramante's original design. The peculiarity of this design was the semicircular termination to each arm of the cross, and the porches were also semicircular in plan, with three doorways in each, and the high altar was placed centrally. This arrangement has been much commended, and has been partly carried out, but the cupolas which covered the whole have not been executed. Peruzzi built, and afterwards decorated, the palace at Longara, now called the Farnesina, built originally for Agostino Chigi, and he has been especially praised for the ornamentation of the loggia, which is in such accurate perspective that Titian is said to have climbed up to ascertain whether the corbels were real or painted. At the sacking of Rome in 1527, when the Spanish soldiers were plundering the city, Peruzzi was seized, and, on account of his aristocratic person, was thought to be some Italian noble, but was freed on stating his profession,—not, however, before he had been barbarously treated by the soldiery, and he arrived eventually at Siena, naked and wounded, having been robbed of his clothes on the road. His stern refusal to enter the service of the Pope, who wished to employ him at the siege of Florence, shows that a spark of patriotism existed in him, and that the Papal rewards were incapable of corrupting him. Besides the Farnesina, already mentioned, Peruzzi built some other palaces in Rome, among which may be mentioned the Massimi palaces, and that which bears the name of the Ossoli family. It is stated that his extreme modesty prevented him from ever asking a reward for his labour, and he consequently died in poverty, his only support being his salary of 200 crowns as architect to St. Peter's. He lies buried in the Pantheon beside the illustrious Raffaelle, whose works he had studied, and in some instances surpassed.

The last three men whose lives we have been considering were almost as much painters as architects, and, in the case of Leonardo and Raffaelle more so, and it has been before remarked that this was not an uncommon occurrence in the fifteenth and sixteenth centuries. In the present day, however, we have no great artists who have attempted to combine the two. We frequently find an architect who devotes his leisure to painting, but where can we name a painter who has shown any aptitude for the nobler art of architecture, which not only requires an artist's eye to originate the design, but a constructor's skill to carry that design into effect, and employ the materials most suitable in each particular case?

It would be well if the importance of architecture were more fully appreciated, for nothing shows the character, the wealth, or poverty of a nation, more clearly than the style of its architecture. "I cannot touch the lute," said Themistocles, "but I can make a small town a large city": and were the aristocracy of England and the wealthy merchants of London to take that pride in architecture which prevailed among the nobility of the Italian States, and the princely merchants of Florence, we might then find more earnest desire on the part of our architects to execute their work with that painstaking care and devotedness of which we see so many proofs in bygone times.

We are now in the full tide of the Renaissance, and all Italy has felt the influence of this stirring up into artistic life, which awoke the latent energies of the sixteenth-century artists. The bright and comely flower of Renaissance art has been nurtured and cultivated by rich and poor alike; warmed by the sun of genius, and gladdened by the freshening dews of intellectual effort, the tender stem has grown vigorous and healthful, and although not possessing the same energy as the hardier plant of Gothic art which preceded it, but partaking more of the character of a hot-house plant, it has, nevertheless, a charm and gracefulness of which antecedent artistic efforts were often sadly destitute.

Michele Sanmichele (born 1484, died 1559) was the great military architect of this age. He was taught the elements of architecture by his father Giovanni and his uncle Bartolomeo, who were both architects. He was sent by Clement VII, after having completed his studies, to visit and report upon the fortresses in the Ecclesiastical States; and having accomplished this, he started again to inspect the fortifications of Venice, for the purpose of improving his knowledge of these subjects. Verona, the birthplace of San Michele, has been embellished more than any other Italian town by the works of this artist, and the bastions which he built to fortify the town were on an entirely new principle, which has been adopted and improved upon by Vauban and others; but it was this architect who in reality invented the triangular or pentangular bastion with plain fosses and flanks, which doubled the support, and thus entirely superseded the ancient square and circular bastions. His fortifications at Venice were on an enormous scale, and those who were envious of his popularity suggested that the firing of the heavy artillery required for the defence would reduce his forts to ruins, and Sanmichele accordingly ordered the largest guns procurable to be brought and placed in the forts and all to be fired simultaneously. Many of the timid inhabitants fled when notice was given of his intention, and a terrific firing took place; but after it had ceased, not a crack or fissure was discovered in the fortress, and the fears of the multitude were converted into exuberant joy. He built the Porta Nuova, the Porta del Pallio, and the Porta San Zenone at Verona, and also the exquisite Pellegrini chapel, a work of small dimensions, but of the highest excellence. The stone of which it is built is found in the quarries of Verona, and is called "Bronzina," as when working it sounds metallic like bronze. He built five palaces at Verona, of which the Palazzo Pompei is the most harmonious in design, possessing a dignity of repose which is one of the essential elements of a Classic composition.

The universal genius of *Michelangelo* (born 1474, died 1564) cast such a refulgence over the tracts of Renaissance art, in painting, sculpture, and architecture, that all other artists seem lost for a time in the vigour and grandeur of the work of this great man. He did not devote himself vigorously to architecture till he was forty years of age, and his masters were his own talents, aided by his observations of ancient edifices. Two of his earliest works were the Medicean Library at Florence, and the second Sacristy at San Lorenzo, which is undoubtedly one of his finest designs. Michelangelo also made designs for several gates at Rome, but the only one which he erected was the Porta Numentana, or Porta Pia, as it was named, after Pope Pius IV., during whose pontificate it was built. He designed the Strozzi Chapel at Florence, and made many other designs for churches, few of which, however, have been preserved; and it was his constant habit to destroy any drawings which did not justly convey to paper the grand conceptions of his mind. His work at St. Peter's at Rome gives evidence of the sound knowledge of construction which he possessed, but his ornaments and mouldings are none of the purest, being frequently so whimsical as to border on ugliness; and he used sometimes to confess, perhaps only from modesty, however, that he knew nothing of architecture. It is well known that when pressed by Pope Paul III. to accept the office of architect to St. Peter's, he agreed to take it on condition that he received no salary, stating he did so "for the love of God."

Galeazzo Alessi (born 1500, died 1572), having studied mathematics, and shown an aptitude for mechanics when a youth, after perfecting himself in these subjects repaired to Rome, to be under the tuition of Michelangelo. His works in Genoa were very numerous, including the Palazzo Spinola, in the Strada Nuova; a handsome palace in the Porta Romana, for Signor Laoli; and the villas for Count Pallavacini, above Zerbius, and Signor Giustiniani, in Alharo. His church on the Carignano Hill, at Genoa, is sufficient in itself to make his name illustrious.

We now have to consider the lives of the two last great architects of the Renaissance, Vignola and Palladio. The former, whose real name was Giacomo Barozzi, was the son of Clementi Barozzi, a Milanese gentleman (born 1507, died 1573). He studied painting at Bologna, but eventually applied his mind to architecture, and produced a treatise in his later days, the outcome of his early studies in Rome, which has done more to perpetuate his name than all his works in stone and marble. He built many churches in Rome, and was employed by Pope Julius III. and the Cardinal Alessandro Farnese, who engaged him partly in the erection of the Farnese Palace. The celebrated Caprarola Palace, however, gained him the greatest encomiums, and eclipsed all his former efforts in ecclesiastical architecture. After the death of Michelangelo, Vignola was appointed architect of St. Peter's, and erected two cupolas on either side. His fertile invention often led him into extravagances, and induced him to depart from the correct forms and outlines of the ancients.

Palladio may be considered as the last great architect of the Renaissance. His finest ecclesiastical work is the church of the Redeutore at Venice; but the work which has brought most renown to his name is the Basilica or Town-hall at Vicenza. In this city Palladio reigns supreme. Whichever way we turn we meet with his works, many of them finely conceived, but executed in plastered brick, so that their true grandeur cannot be justly estimated. The peculiarity of his style were lofty columns running through two stories, pedestals without panels or raised mouldings, simple architraves, doors, windows, and niches of simple design, and crowned with unbroken pediments. The *Quarterly Review* and many amateur critics have endeavoured to prove that Palladio's architecture was false in principle, since the internal arrangements did not always accord with the external effect; but we must remember that Renaissance architecture never aimed at this, external symmetry being its chief characteristic, while Gothic architecture had for its primary object the exposing of the bones and muscles of the structure to which it was applied. For the beauty of Palladio's architecture we must look to his façades, which are bold and imposing.

In the latter days of the Renaissance the art which had once adorned churches and palaces confined itself almost entirely to the interior decoration of the dwellings of the nobility, and the Baroque style succeeded the bright and cheerful efforts of the earlier designers. This universal decadence was the precursor of utter annihilation of all genuine æstheticism, and with the close of the sixteenth century the curtain fell on all true art.

I do not pretend in this short paper to have exhausted the subject with which I am dealing. There are many architects of this age whose works it has been impossible even to touch upon; my object has been rather to turn the current of your thoughts in the direction of pure Italian architecture, so that each one of us may for himself, if he so desire, enlarge the subject, and contemplate with fervid admiration, as I have done, the beauties of this noble style.

ST. LEONARD'S TOWER, WEST MALLING.

Sir,—To the short but valuable account of St. Leonard's Tower, West Malling, given by "G. T. C." in the *Builder*, November 27, I am desirous to add, with your permission, a few additional notes. That in architectural interest it comes up to, and quite deserves, every single word which Mr. J. H. Parker, C.B., has written regarding it, is most unquestionable; for few other specimens of this period probably throw more light on the state of building art, directly after the Conquest, than does it and the two other *early* works of Gundulph, in its near neighbourhood,—namely, "Gundulph's Tower" at Rochester Cathedral, and that portion of the wall of Rochester Castle, which is his work (that next the river); the whole three presenting curious variations of construction which induce me (though undoubtedly inclined to pay the very highest deference to the opinion of such a veteran and able authority as Mr. J. H. Parker) to believe the earliest in date of the three to be "Gundulph's Tower," *now* of the cathedral, but then merely built on the town wall, and originally intended as a protection to the members of his new monastic establishment, their valuables and documents, prior altogether to the reconstruction of his cathedral.

The quoins of the St. Leonard's Tower, supposed by "G. T. C." to be of some "local ragstone," are there (as in all his other works) of *tufa*. The bishop nowhere, I believe, uses any other material for dressings unless in the case of his monolithic columns, with their caps and bases, in the crypt of his cathedral (which material he seems to have brought from Northamptonshire by water). The singular plan of producing "weatherings" by simply setting back the courses, is another of his peculiarities here produced, as "G. T. C." states, by two recessions, but at "Gundulph's Tower" by merely one; as I take it, a further mark of its priority of date and rudeness of execution.

The further fashion of his work in rising

from the ground (or, at least, footings) without any plinth, takes place even in the remains of his cathedral, as does also the square order devoid of mouldings, save only a label,—a rule which, with him, seems invariable.

I am not altogether clear as to "G. T. C.'s" intention where, in describing the "abbey" church at Malling, he refers to its west end. No part of this is of Gundulph's date, though its transept is, and eastern parts were. The west end is later than the period of the bishop's death, and was itself, in its lower part, much tampered with at the end of the eighteenth century (see Hasted (?) or Thorpe). A careful study of the peculiarities of construction presented in the rubble walling of the two towers, that of St. Leonard's and the "Gundulph Tower" of the cathedral at Rochester, reveals variations in the herring-bone work used, and in the items of bonding, tending, equally with the simpler recessing of pilaster "weatherings," to prove that the last named is the earlier in date. On the whole, considering, indeed, that the bishop had a palace or residence in Rochester itself, it seems not unreasonable to believe that the new monastic establishment would take precedence over any of his country seats. In his work at Rochester Castle *wall* (the keep is none of his, of course, nor is there reason to believe he built there any, nor could he likely to desire such a next-door neighbour if it could possibly be avoided). He has introduced what is a most unusual method of construction. On the Cliff, buttresses, no doubt, would he of little use outside, and if placed inside, would he in the way. He has, therefore, introduced a sort of *better* rag ashlaring pillars, if it can be so called, formed at certain distances in the solid walling, *flush with its ordinary face.* Whether similar work exists outward I know not; but at that point of his wall next Rochester Bridge its destruction presents a section by which it is seen to present the square set-backs, which was his plan of producing "weatherings," as stated above.

In regard to the St. Leonard's Tower, while adding the conjecture that the top room may have been most likely the private chapel of Bishop Gundulph, and that I very much doubt if any other defences of the bishop's time on the spot were of more than wood only, I would join with your able correspondent, "G. T. C.," in urging the wish that that excellent society, the Kent Archæological, should at least give one *careful* illustration of the construction of, say, the north front. Or better, perhaps, for the benefit of mankind in general, that some one would carefully draw it, with parts of the rag ashlar, to a larger scale, and send it for publication in your valuable journal; for, in spite of the wide facilities for good and cheap illustration which now exist, one often sighs for the want of that wealth of illustration on such practical details for which the world had to thank the works which will hand down the name of Mr. J. H. Parker to all posterity, and are still the text-books to which we refer.

J. T. I.

MACHINERY AND APPLIANCES AT THE SMITHFIELD CLUB SHOW.

THERE is, as usual, a good display of agricultural machinery and implements, roots, and seeds, at the eighty-third annual Cattle Show of the Smithfield Club, in the Agricultural Hall and its adjuncts. The principal contributors of purely agricultural machinery are such well-known firms as Aveling & Porter, Rochester; Clayton & Shuttleworth, Lincoln; John Fowler & Co., Leeds; Richard Garrett & Sons, Leiston; Richard Hornsby & Sons, Grantham: J. & F. Howard, Bedford; Marshall, Sons, & Co., Gainsborough; Messrs. Ord & Maddison, of Darlington (who exhibit the "Koldmoos" weed-eradicator,—an ingenious machine); Ransomes, Sims, & Head, Ipswich; Rohey & Co., Lincoln; and Ruston, Proctor, & Co., Lincoln. Most of these exhibitors, and many others, show a large variety of portable and other engines available for purposes other than agricultural, but none of them calling for any special notice. The heavier exhibits are as usual arranged under the galleries, and among them we need only mention Messrs. Aveling & Porter's well-known traction engines (Stand 15), Messrs. Clayton & Shuttleworth's 10-h.p. fixed engine (Stand 8), very well finished, and simple in action; Messrs. John Fowler & Co.'s (Stand 7) single-tipping wagon, suitable for contractors' use, and their 10-h.p. patent compound "Yorkshire" engine. Messrs. Barrows & Stewart, of Banbury (Stand 5), show some good portable engines. The Bristol Wagon Works Company (Stand 19) have a goodly show of carts and wagons for agricultural purposes; and Messrs. Hayes & Son, of Stamford and Peterborough, exhibit their "Royal Society" tip-wagon, which would appear to be as well suited for scavenging as for agricultural purposes. Messrs. Crosskill & Sons, of Beverley, also make a good display of excellently-built carts and wagons. The great bulk of the exhibits is contained in the spacious galleries, but out of the mass we can only mention those which come within or are closely connected with our own special province. Messrs. Bayliss, Jones, & Bayliss, of Wolverhampton (Stand 123), exhibit a variety of iron hurdles and fencing, including the "Victoria" rivetless hurdle, in which the ends of the horizontal bars are turned down and brought back again through the uprights, and then clenched. Mr. John Bellamy, of Millwall (Stand 84), exhibits wrought-iron water-tanks, corn-bins, troughs, &c.; and Messrs. Burney & Co., of Millwall Docks (Stand 72), have a display of similar goods, wrought and galvanised. Messrs. Croggon & Co., of Upper Thames-street (Stand 86), are exhibitors of galvanised iron tanks, corn-bins, wire netting, &c. Messrs. Hill & Smith, of Brierley Hill (Stand 158), exhibit iron fencing, including Gillett's patent rivetless hurdle, the horizontal bars being secured in the uprights or standards by hydraulic compression whilst the iron is cold. Mr. J. C. Humphreys, of Knightsbridge (Stand 97), exhibits models of galvanised iron buildings for agricultural purposes. Messrs. F. Morton & Co., of Liverpool, have a good display of galvanised corrugated iron roofing and wire fencing, the former shown in its application as a covering for ricks, &c. Messrs. Penney & Co., of Lincoln (Stand 32), exhibit flat and rotary screens for gravel, lime, &c. The St. Panoras Iron Works Company (Stand 100) have a good display of iron cow-stall fittings, piggeries, &c. Messrs. J. & B. Sainty, of Wisbech (Stand 126), exhibit their new patent "Universal" fencing, which possesses several good points. The wrought-iron standards are very light, yet require no fixing in the ground, standing as they do on a broad base. The horizontal bars, of wood, can be quickly inserted or removed, so that the fence is easily portable. Messrs. R. Waygood & Co., of Falmouth-road, Great Dover-street (Stand 194), exhibit some good horizontal steam-engines, and a new gas-engine (Robson's patent) manufactured by them.

Not included in the official catalogue of the Smithfield Club Show are a large number of exhibits, most of which do not come within the purview of agriculture, and these are arranged in the arcade by which the show is entered from Islington-green, and in St. Mary's Hall. In the arcade entrance, Messrs. F. W. Reynolds & Co., of Acorn Works, Blackfriars-road, exhibit a small but representative collection of their many well-known wood-working machines, including the "Eclipse" mortiser. Messrs. F. Rosher & Co., of Upper Ground-street, exhibit stable bricks, terra-cotta and stoneware garden edging, &c. Messrs. Tracey & Sons, of Ilford, show their system of glazing without putty, and their metallic tubular sash-bar. Messrs. Wurr & Lewis, of Laurence Pountney-lane, are exhibitors of hand-sawing and other wood-working machines.

In St. Mary's Hall there is a heterogeneous collection of articles, including perfumery, marking-ink, and stencil-plates, the thousand-and-one "notions" (American and English) in regard to domestic appliances, and such other things as those with the mention of which we conclude this notice. Messrs. Robert Boyle & Sons, of Holborn-viaduct, exhibit their air-pump ventilators and a new chimney-cowl for preventing smoky chimneys. Messrs. Ewart & Son, of Euston-road, exhibit their "Empress" ventilators and "smoke-cures," together with bath-heating apparatus and a large zinc dormer. Messrs. Jones & Willis, of Euston-road, show their "Hesperns" lamps. Messrs. Charles Powis & Co., of Gracechurch-street, are exhibitors of sawing-machinery, and Messrs. Pfeil & Co., of St. John-street-road, and Messrs. Selig, Sonnenthal, & Co., of Queen Victoria-street, show engineers' tools and specimens of iron of different brands. Messrs. Hamilton & Co., of Leadenhall House, exhibit their pavement-lights. Messrs. S. & E. Ransome & Co., of Essex-street, Strand, show a variety of small domestic appliances. The Sun Auto-Pneumatic Lighting and Heating Company exhibit their portable gas apparatus. Messrs. John Tomlin & Co., of Capland-street, Lisson-grove, exhibit a new mode of shoeing horses with a view to "roughing" in frosty weather. It should be added that the whole of the piggeries and other parts of the Show are disinfected, apparently with perfect success, by the Sanitas Company's products.

IN THE ENGLISH SECTION OF THE MELBOURNE EXHIBITION.

Mr. George Jennings.—An especially fine and exceedingly large display of baths, lavatories, and general sanitary appliances is sent by Mr. G. Jennings, Lambeth, London, for whom Messrs. Alston & Brown, Melbourne, are agents. There is shown a beautifully fitted-up lavatory, for gentlemen's residences, first-class hotels, &c. It combines all the essentials of compactness, with elegance and convenience. In addition there are less expensive appliances of a similar character, and every household convenience which can be mentioned. The local papers say, "We can quite believe the statement of the official catalogue, that Mr. Jennings's display has taken the highest award at every exhibition."

Messrs. George Wright & Co.—The above well-known stove-grate makers, of Burton Weir Works, Rotherham, and Queen Victoria-street, London, exhibit a few specimens of their manufactures in the shape of open fire-grates, fenders, fire-iron rests, &c. This firm earned its reputation as inventors and sole manufacturers of the English stove, the "Bivalve," which is an improvement on the Stevens principle. Of this class is their drawing-room stove (No. 555), which is a good illustration of artistic grace, while showing the rich effect that may be arrived at by combining in proper proportions ormolu and bright steel. No. 500 is also a drawing-room stove, and was, we understand, specially designed to exhibit the most beautiful of hand-painted panel tiles. Between the above stoves stands a massive dog-grate in the style of the Renaissance. The tile and slow-combustion grates, &c., suitable for general use, are, like all the work of this firm, simple in design and extremely neat in appearance.

Messrs. Arrowsmith & Co.—Interior decoration as an art has now reached great perfection among us. The firm of Messrs. A. J. Arrowsmith & Co., decorators and upholsterers, of 80, New Bond Street, London, has long been very favourably known in connexion with this subject. Especially have they become famous for the beauty and durability of their excellent patent solid parquet flooring, and their exhibits at Melbourne cannot fail to greatly conduce to their renown in the colonies. Their exhibit consists of the following objects:—Various specimens of solid parquet flooring, showing portions of floors laid for the Queen at Windsor Castle, and numerous public buildings and mansions; a very elaborate hand-carved staircase balustrade, in oak, polished; a very handsome bedroom suite in walnut and olive wood, inlaid brass finishings, &c.; a beautiful drawing-room cabinet in satin-wood, with hand-painted panels picked out in gold, in French style of Louis XVI.; dining-room suite,—light oak sideboard, bevel mirrors, carved panels, brass finishings; light oak chimney-piece, designed to harmonise, hand-painted tiles at the sides, marble linings, fender, dog-stove, &c., complete; light oak dinner-wagon table, side tables, chairs stuffed morocco. There are also several specimens of inlaid, carved, and parquet dados and wood panelling, and finally, there is a good selection of decorative drawings. The specialty of Messrs. Arrowsmith & Co.'s solid parquet flooring (patented) consists of being 1 in. thick, grooved and tongued together with marine glue, keyed at back, and traversed to a uniform thickness. For this ten prize medals have been awarded at the various exhibitions. We recommend colonists in London to pay a visit of inspection to the showrooms in New Bond-street.

The Worcester Royal Porcelain Company (Limited).—This old-established company have made a fine display of their productions, not specially got up for the Exhibition, but consisting for the most part of "every-day articles, neither expensive nor elaborate, but likely to be serviceable to the Australian colonist." The Royal Porcelain Works at Worcester were originally established in 1751 for the manu-

factnre of fine porcelain, and in 1789 they received the first Royal patent. Since then, in consequence of the great increase in business, the mannfactory has been much extended, and the variety of its prodnctions greatly increased, and in every respect it now stands second to none.

THE SEWERAGE WORKS FOR PETERBOROUGH.

The sewerage works now completed for the corporation of the city and borough of Peterborough involved the construction of thirteen miles of brick and pipe sewers, with the necessary manholes, ventilators, flushing arrangements, and penstocks; the construction of duplicate tanks for the straining of the sewage at the outfall, and two miles of concrete carriers; the preparation of 96 acres of land out of a farm of 300 acres purchased by the corporation for the utilisation of the sewage by irrigation; the erection of two pumping-stations, with the necessary machinery, and the erection of two cottages.

The sewage from all parts of the borough is brought together and discharged at one outfall. It is conveyed by the water-carriage method on the separate system. As about seven-eighths of the entire population of the borough dwell on the north side of the river Nene, it is consequently in this portion that the largest and most costly sewers are constructed; but the peculiar situation of the southern district renders the conveyance of the sewage to a suitable outfall a matter of considerable difficulty.

The borough on the south side of the river is drained by 3¼ miles of stoneware-pipe sewers, and the sewage brought to the river side, whence it is carried in an iron-pipe sewer under the river and across the wash-lands. After passing under the protecting bank of the north level, it is emptied into a tank sewer, devised for the reception of the sewage during the time the pumping engines are at rest. It then flows into the wells of the southern outfall pumping-station, and is put into the gravitation main close to the outfall.

The borough on the north side of the river is drained by nine miles and three-quarters of brick and pipe sewers. The northern arterial main is a brick sewer, egg-shaped in section, of 3 ft. by 2 ft. internal diameter, and 3,670 yards long. The main intercepting brick sewer is 1,235 yards long, and comprises 149 yards of 3 ft. by 2 ft. egg-shaped; 612 yards of 2 ft. 9 in. by 1 ft. 10 in., egg-shaped; and 474 yards of 2 ft. barrel sewers.

These sewers discharge into a barrel culvert, 3 ft. 4 in. in diameter, and 508 yards long, which empties into a penstock chamber, whence the sewage is taken by two 24-in. iron pipes, laid side by side, and for the most part in embankment to the straining-tanks at the outfall. The sewage from the districts north of the river flows directly on to the irrigation area by gravitation.

The geological formation through which the trenches were excavated includes principally members of the oolitic group, but in the south ward gravels of the post-tertiary period overlay the jurassic rocks. The thick beds of hard stone met with in nearly all parts of the north and east wards have caused the excavations to be difficult and costly; but the stone was utilised in the construction of the roads and the concrete carriers on the sewage farm.

The pumps by which the sewage at the southern outfall is lifted into the gravitation main are two duplicate three-throw lift-pumps, driven by two high-pressure non-condensing horizontal engines of six-horse power. The normal speed of the engines when working with a boiler pressure of 45 lb. is 100 revolutions a minute; and each pump working at twenty double strokes a minute will lift 400,000 gallons in twelve hours.

The sewage on arriving at the outfall is discharged into settling-tanks, built in duplicate, and provided with wrought-iron strainers. Passing thence, the liquid sewage is conveyed in a concrete carrier to the land prepared for irrigation. On arriving there the carrier divides into two smaller ones, from which the sewage is distributed over the irrigation area by land-carriers. The larger concrete carrier is 1,098 yards in length, and has a water-way of 6·5 superficial feet. The two smaller carriers are 2,159 yards long, and have a sectional area of 4·8 superficial feet. The irrigation-channels are 1 ft. wide at the top, 6 in. at the bottom, and 6 in. deep. All the carriers are laid in horizontal lengths, with sluices and drops at every change of level. The soil on the irrigation area is of a light alluvial character overlying silt, and has a natural filtration and drainage of 4 ft.

As the farm is situated near the Bedford Level, and within the protection bank of the North Level Commissioners, the effluent water is not allowed to be carried off by their drains, except in dry seasons, and must consequently be lifted over the north bank into the New Cut of the river Nene. This is effected by two 12 in. centrifugal pumps, driven by two 25-horse power high-pressure condensing engines. The normal speed of the engines is sixty revolutions per minute, with a boiler-pressure of 60 lb. The cylinders are 1 ft. 4 in. diameter, and the stroke 2 ft. The fly-wheels are 10 ft. in diameter, and weigh 2 tons. Each pump, when making 400 revolutions per minute, will deliver over the bank 1,600,000 gallons in six hours. The boilers are Galloway's patent, with shells 18 ft. long by 6 ft. diameter.

The works were designed and carried out by Mr. John Addy, C.E., of Peterborough, with Mr. John C. Gill, C.E., as resident engineer. The contractors for the buildings were Messrs. S. & W. Pattinson, of Ruskington, near Sleaford; and for the engines, pumps, boilers, and machinery, Messrs. Seekings & Ellery, of Gloucester. The works on the main drainage and irrigation farm were partly executed by Messrs. J. S. Cooke & Co., and partly by the Corporation.

LIVERPOOL ARCHITECTURAL SOCIETY.

The third meeting of this Society was held at the Royal Institution, Colquitt-street, on the 1st inst., the President (Mr. C. Aldridge, F.R.I.B.A.) in the chair, when a discussion took place with reference to "Some City Improvements."

Mr. Wm. Parslow, in opening the discussion, explained that the subject would probably induce the belief that it was his intention to propose some grand general scheme for street improvements, but such was not the case: his thoughts were of much smaller matters. He had seen and heard of so many accidents arising from carelessness in hoisting goods into warehouses in crowded business thoroughfares, such as North John-street, that he thought the corporation should take some decided step towards insisting upon proper protection being afforded the public. The next evil that suggested itself to him as requiring consideration was the danger to which wayfarers were subjected owing to there being no by-law compelling plumbers and slaters to provide against broken slates and other material falling from roofs under repair, and undoubtedly provision was necessary on all houses to prevent loose slates falling into the streets. There had been serious accidents recently from this cause, one ending fatally. There was great want of protection to life and property at the foot of Leece-street also, where there were accidents almost weekly from runaway horses; and last, but not least, there was no waiting-room and convenience accommodation for women in any part of the city; men had been fairly well cared for in this respect, but women had been entirely neglected. He thought that this subject should be taken up by the Corporation, and proper accommodation provided at different points; and if each were partly free, and a small charge made for the use of the remainder, the income would cover the cost of the whole.

In the course of the general discussion that followed, it was stated that a new Building Act was being compiled by the Corporation authorities, and the hope was expressed that the society and the Master Builders' Association would be invited to send representatives to act on the committee in whose hands the drafting of the Act lay, in order that the best information on all points might be obtained.

It was suggested that the question of warehouse-hoists, and protection to the eaves of roofs, might very well be dealt with in the new Act, together with the foundations of new buildings, with regard to which great laxity appeared to prevail with the authorities, instances being brought forward of large ponds in the outskirts of the city being entirely filled with refuse of the worst description, and houses being planted upon them directly the operation was completed.

The President explained that, in London, front walls were carried above the eaves to form parapets, which effectually prevented the fall of slates, &c., into the streets, and, at the same time, the gutters behind the same formed a safe means of escape from house to house, in case of fire.

Previously to the holding of the ordinary meeting there was a meeting of the class of design and construction in the small library, presided over by Mr. Aldridge, when thirteen designs for a "cemetery chapel" were handed in by students, several exhibiting considerable merit.

SOCIETY OF ENGINEERS.

At a meeting of the Society of Engineers, held December 6th, 1880, in the Society's Hall, Victoria-street, Westminster, — Mr. Joseph Bernays, president, in the chair,—a paper was read by Mr. Frank W. Grierson, member of the Physical Society, London, &c., "On the National Value of Cheap Patents," in which he showed that the stamp duties on a patent in this country lasting over fourteen years, are 175*l.*, while those on an American patent, lasting seventeen years, are only 7*l.* A table was given of the applications and grants of the British and American patent offices during the last ten years, from which it could be seen that our 50*l.* stamp duty at the third year kills 70 per cent. of the patents granted; and that our 100*l.* duty, at the seventh year, kills 20 per cent. more, leaving only 10 or 11 per cent. to complete the full term.

From a comparative table of average results for the last ten years it was seen that the applications for patents in the United States and Great Britain respectively are 19,770 and 4,496; and the grants are 13,355 and 2,980. The average cost to the inventor for one patent, including patent agent's charges, are there only 19*l.*, but here 190*l.* Only one patent is granted in this country to three that are granted in the States, after allowing for the difference in population; and the duties on one patent here would pay those on twenty-five there. We may, therefore, say fairly that the British inventor is handicapped at twenty-five to one in favour of the American; and it is to be remembered that in handicapping the inventor we handicap the nation.

LIABILITY OF BUILDING-OWNERS.—THE HAYMARKET ACCIDENT.

PERCIVAL *v.* HUGHES.

This was an action brought to recover damages for injuries alleged by plaintiff to have been caused to premises belonging to him through the defendant's negligence in re-building the adjoining house. It was tried at Westminster last week, in the Queen's Bench Division, before Mr. Justice Manisty and a special jury.

Mr. W. G. Harrison, Q.C., and Mr. M'Call, appeared for the plaintiff, and Mr. Philbrick, Q.C., and Mr. Kingsford for the defendant.

Mr. Harrison, in opening the case for the plaintiff, stated that his client was the owner of a house in Panton-street, Haymarket, adjoining the new building belonging to the defendant at the corner of the street, which, when roofed in and far advanced towards completion, fell with a crash in January, 1878, dragging down with it a house adjoining it (on the Haymarket side) and killing the occupier of that house,—Mr. Baron. In falling, the new building partially pulled over the party-wall dividing it from plaintiff's house, and the latter sustained certain damage to its structure and internal decorations. The learned counsel proceeded to explain, by means of photographs and plans, the appearances presented by the ruins after the accident, and after citing many of the statements made at the inquest * on the body of Mr. Baron, argued that the fall of the building was due to negligence on the part of the owner or his agents.

After considerable arguments between the counsel, his lordship expressed the opinion that it was unnecessary to go further into the case, and, in deference to this opinion, no witnesses were called on either side, although

Mr. Philbrick addressed the jury for the defendant, pointing out that he had employed an architect of considerable experience, Mr. W. Wimble, to prepare plans and specification, and

* Reported in *Builder* for 1878, pp. 227, 249—251 274—276.

to superintend the erection of the new building, and had employed a respectable and reputable firm of builders (Messrs. Newman & Mann) to carry ont the work. He contended that every and all the usual means had been taken calculated to ensure the safety of the adjoining properties, and that the accident was due, as stated hy witnesses at the inquest, to the cutting away of the lower part of Mr. Baron's party-wall, for the purpose of fitting a new staircase,—an act unauthorised by the defendant or his architect, or by the clerk of works representing the architect, and one for which the builders alone were responsible.

Mr. Justice Manisty said he was of opinion that there was no question in the case for the jury. He did not think the present case could be distinguished from that of Bower *v.* Peate (1 Q. B. Division, p. 321). There it was held "that a man who orders a work to ho executed on his own premises,—lawful in itself, hut from which, in the natural course of things, injurious consequences to his neighhour must be expected to arise, unless means are adopted by which they may he prevented, is hound to see to the doing of that which is necessary to prevent the mischief, and cannot relieve himself of his responsihility hy employing some one else to do what is necessary to prevent the act he had ordered to be done from becoming wrongful." He had no reason to suppose the decision in the case was likely not to he upheld, and therefore, taking the facts relied on by the defendant to be as stated, he should direct the jury to return a verdict for the plaintiff.

This having heen done,

His Lordship gave judgment for the plaintiff for such amount as might he agreed upon or ascertained to represent the damage he had sustained by the falling of the defendant's house.

ROMAN WORK IN ENGLAND.

BRITISH ARCHÆOLOGICAL ASSOCIATION.

THE second meeting of the session was held on Wednesday last. Mr. Thos. Morgan, F.S.A., in the chair. Mr. Gordon M. Hills exhibited a large collection of Romano-British fragments of pottery found at Manor Farm, Wanhorough Plain, Wilts, where foundations of buildings have been met with, and others are believed to exist. Mr. Hills described the position on the line of the thirteenth Iter of Antoninus, and suggested that it was the site of a lost Roman station, being where one may reasonahly be supposed to exist in relation to the next one on the line of road. Mr. Way exhihited some Roman coins recently found at Exeter; and the Rev. Mr. Maude a large series of foreign silver coins. Mr. Batcher produced a fragment of Roman Samian ware from the wall of London now opened at the back of America-square; and the chairman a perfect tile from the same place. It measures 17½ in. by 12¾ in., and is 2 in. thick. Mr. Loftus Brock exhibited a drawing of the wall, and, after a description of the discovery, pointed out its resemblance to the wall in the Tower of London, which was then described in a short paper. A vote of thanks was proposed and carred unanimously to Major-General Milman, C.B., Major of the Tower, her Majesty's Office of Works, and to Mr. J. Taylor, for their united efforts in having the fragment cleared for inspection in response to the wishes of the Association. The Rev. Dr. Hooppell then described at length the very remarkahle discoveries that have rewarded the exploration of the Roman station of Vinovium, the modern Binchester. This costly work has been undertaken hy Mr. J. Proud, of Bishop's Auckland, under Dr. Hooppell's directions. The external walls have been traced and found to be built on an earlier British wall. The plinth is chamfered similiar to the wall in America-square. A paved road, 30 ft. wide, extends through the station, and the walls of many private dwellings still remain, many of the doorways having bases of pillars in position. A large circular huilding was cleared out, and here and elsewhere the walls were found to he lined with hot-air flues of terra-cotta kept in position by T-irons. Traces of reconstruction were found in every direction, and a mutilated statue of Flora was found serving as a support to some paving. The lecture was illustrated by a series of large coloured drawings, which gave a clear idea of these important and extensive discoveries. A large portion of the station remains to be opened out, although so much has been done.

HOUSE-BUILDING AT LEWISHAM.

AT the last meeting of the Lewisham District Board of Works, attention was drawn hy one of the members to buildings going on in the neighhourhood. He stated that something like five-sixths of the more modern houses in the district were huilt on grass, and in many instances on absolute mud. Several other members of the Board also complained of the growing evil, various houses being named. After some discussion on the matter, letters were ordered to he written to the various district surveyors, calling their attention to these infringements of the Metropolitan Board's bye-laws, which order the foundations to he huilt on concrete. These directions of the Lewisham Board to the surveyors do not, however, appear to satisfy some of the residents, who wish more peremptory action to be taken against the offending builders. In a communication to the authorities, one of them states that he can vouch for the truth of the complaints which had been made to the Board, having seen many of the houses in question.

FROM SAVOY-STREET TO THE THAMES EMBANKMENT.

To the different streets leading from the Strand which have in succession been opened out for carriage-traffic on to the Thames Embankment, Savoy-street may now he added. Hitherto communication with the Strand from the bottom of Savoy-street, abutting on the Embankment, has been confined to a footpath, but the enclosed space at the lower end of Savoy-street, immediately under the buildings in Lancaster-place, has been thrown into the carriage-way, and is now being curbed, paved, and otherwise laid ont for vehicular traffic, by the Metropolitan Board of Works, with a spacious curbed footpath in the direction of Waterloo Bridge, forming a junction with that on the Embankment. The works are expected to be completed in a few days.

"SANITARY SCIENCE IN ITS RELATION TO CIVIL ARCHITECTURE."

SIR,—Out of the many similar difficulties with which architects have to deal, let me call attention to two little ones, both mentioned in Mr. E. C. Robins's interesting paper at the Royal Institute of British Architects on the 29th ult.

1. Is it quite settled that soil-pipes must never be put inside buildings? Again and again this is repeated till it seems almost criminal to listen to doubts ahont it. Yet I am assured that not unfrequently, in exposed situations,—after a severe winter has heen doing its worst,—soil-pipes have been taken indoors and kept there. In hitter cold a thin film of ice had formed itself on the inside of the pipe; no sun or warm wind came to thaw it; it was added to from time to time until nothing could pass through the pipe. Some of the best foremen urge this sort of argument with great force. Which is the worst?—to expect to find that such a pipe placed inside the building will some day be out of order, and will need repair, or to put it up and take it down at least once in every winter in the midst of intense frost? Every soil-pipe may very well be carried up, full size, above the roof, and fresh air be passed through it; but must an architect rush thus from one sort of peril into another? Does "should he" in Mr. Robins's,—"(3) The soil-pipe *should* he fixed outside the house," mean "must he"?—unless even mild persons are to talk of "gross ignorance and culpahle carelessness,"—and return verdicts of manslaughter as matters of course?

2. I should like to ask for the results of experience in the use of a soil-pipe with open ends,—as applied by Mr. Norman Shaw. Are there any instances of such pipes being in use for a good length of time without stoppage?—without the pipes becoming foul, and needing to be renewed?—without the grating at the ground level giving off very offensive smells? No true test of such a system has been made at the end of a couple of years. Many people hesitate still to think of using the system, believing that a complete renewal of the pipes must be inevitable after they have been in use a very few years; hut even these careful persons look with interest for information, and, indeed, seem to hope that their doubts may be gradually dissolved.

3. Has the last word been said about trapping sink wastes? Professor Corfield and Captain Galton, in the discussion at the Royal Institute of British Architects, went a certain length,—pointing out that mischief may come through waste-pipes which are not trapped at the top, even though the pipes convey nothing more suspicious than the water of London water companies. But, can the traps themselves be trusted? I do not simply mean that the water in the traps will be tainted by air in the foul pipes below them, but that the interiors of the traps will not escape from the influences which corrupt the pipes. An instance may be given from my own observation. A small lead-lined sink is placed in the corner of a cupboard in a room. A fixed brass grating in the bottom of the sink has below it 4½ in. of lead pipe,—that is, a dip-pipe entering a lead ⊃-trap,—dipping about 1½ in. below the water-line of the trap. The trap is a well-made (6 in. total depth) trap, with a brass screw-cap on the face of it. The 1-in. lead waste-pipe is carried about 10 ft. vertically, and discharges on another lead sink, on the story below. Here are no connexions with drains; nothing but water practically pure (no slops, &c.) is put down the sink; the inside of the trap is kept thoroughly clean,—yet a very strong smell has, I am told, at intervals made the room noisome. The short pipe from the sink to the trap seems to be the offending part. If there were a syphon-trap below the grating there would be a similar bit of pipe above the water-line. The substitution of a tight-fitting plug for the open grating may be a radical cure in this instance; but is there no detergent which would take all the evil out of the pipes, and leave all sweet, if applied say once a month? Most people treat lightly other people's experience; but are we to believe that butlers and servants generally are not so wrong after all in their belief, that very perfect sinks *will* smell at times, when they have been used for a while? Will somebody put the finishing-touch to the teaching about sink-pipes, which has afforded scope for a good deal of patient perseverance already? Till that is done, it is to be feared that good sanitation will still be sniffed at.

A.R.I.B.A.

MR. SAGE'S WORKMEN'S CLUB.

ON Friday evening, the 3rd inst., a Workmen's Club and Institute was very successfully inaugurated in connexion with Mr. F. Sage's shop-fitting establishment, at 80-84, Gray's-inn-road.

Impressed by the great inconvenience suffered by his *employés* in obtaining their meals at the very indifferent cook-shops, public-houses, &c., in the neighhourhood of his factory, Mr. Sage has placed a large room at their disposal, rent free, and also the materials for the fittings, such as tables, forms, shelving, &c., which have been manufactured by the members of the club in their spare time, and the result is a really comfortable apartment, capable of accommodating a very large company seated.

Four daily and two weekly papers are at present taken in. Additional literature will soon be provided, and a library is in course of formation.

The club is entirely self-supporting, by means of an entrance-free and small weekly subscription, and the members are amply repaid for these small disbursements by the daily saving in the cost of meals, the conspicuous cleanliness, and the quality of everything supplied, all stores being bought and examined by the committee of management.

The meeting on Friday was the occasion of a supper, a which Mr. Sage and some friends were entertained, to commemorate the opening of the club.

The stewards of Mr. Sage's club express themselves willing to render any assistance in their power to others who may wish to form similar institutions.

COMPETITIONS.

Tipton Gas Works.—The Tipton Local Board have awarded the first premium of 100*l.* to Mr. Proud, of Birmingham; and the second of 50*l.* to Messrs. Bromilow & Cheers, of London and Liverpool. Provision had to be made for an annual consumption of 60,000,000 cubic feet.

Wesleyan Middle School, Truro.—The directors of the Wesleyan Middle School, Truro, decided some time ago to erect new schools and master's house, providing for 100 boarders. In an open competition, Mr. Etwell, of Birmingham, obtained the first place. The designs submitted by Messrs. Bromilow & Cheers, of Liverpool and London, gained the second premium.

Board Schools, Isle of Man.—The design under the motto of "Simplex," for the Douglas (Isle of Man) Board Schools, submitted by

Messrs. Bromilow & Cheers, of Liverpool and London, has been awarded the first place, and those gentlemen have been appointed architects to the committee. Fifty architects entered the competition.

Burton-on-Trent Market.—Competitors are inquiring for the result of this competition, designs having been sent in some five months ago!

COMPENSATION CASES.

THE WIDENING OF LUDGATE-HILL.

The case of Smith *v.* The Corporation of the City of London was tried in the City Court of Sessions, before the Recorder (Sir Thomas Chambers, Q.C.) and a special jury.

The plaintiff was the owner of 33 and 35, Ludgate-hill, and in March last, having made preparations for the pulling down the old premises and erecting more commodious ones, he was served with an order by the Commissioners of City Sewers to put them back a considerable distance, under the powers of the Act of Parliament for the widening and improvement of the hill. The claim, which was for 16,007*l.*, was made up of various charges for loss of extent of premises, and the decreased rental consequent upon it. There were other claims for loss of profit on stock purchased in anticipation of the proposed enlarged premises, and for extra expense in building, the present smaller premises requiring a stronger wall to carry the weight of the rooms over them.

On the part of the Corporation it was contended that the claim was an excessive one, and should have been nearer 4,400*l.* than 16,007*l.*

The jury found for the claimant—damages, 9,691*l.*

In the case of Glover *v.* The Corporation of the City of London, which was also heard in the same Court, the plaintiff was the lessee of 15 and 17, Ludgate-hill, where he carried on the business of a ladies' and juvenile warehouse. He claimed 11,500*l.* in respect of having received similar notice to put back his premises, by reason of which he lost space, and the value of his leases was reduced.

The jury found for the claimant—damages, 6,330*l.*

CHARGE OF DEFRAUDING BUILDERS.

At the Guildhall Police Court, on the 7th, George Charles Adolphus Smith, of 11-4, Fenchurch-street, and 3, Downs-road, Clapton, colonial merchant, was summoned before Sir Thomas White for obtaining goods under false pretences. Mr. Besley prosecuted; Mr. Mead appeared for the defendant.

The case was only partially gone into, and as far as the evidence went it showed *primâ facie* that the defendant purchased some freehold land from the London Financial Association (Limited) in November, 1879. He afterwards entered into a contract with Messrs. Perry & Bartlett, builders, of Stratford, to build a house for him. They went on with the building, and after they had put about 2,300*l.* worth of material and labour on the ground and received 500*l.* on account, the defendant became bankrupt. It was then discovered that the defendant had made over the land to his wife in charge of trustees, and they claimed everything on the ground in right of the wife. Upon that Messrs. Perry & Co. prosecuted him for obtaining the goods by false pretences, and the allegation was that he held himself out as the freeholder, and by that means he induced the prosecutors to part with their goods, which they would not have done if they had known that the freehold of the land was vested in the wife. Mr. Perry was examined in full, and his cross-examination reserved. Mr. Vernon, the architect, was partially examined, and the case was adjourned.

THE MYSTERIES OF FIGURES.

Sir,—I was in company, a little while ago, when some one present requested another to write down any amount in figures. Then he desired that all the figures should be added together, and afterwards subtracted from the original quantity. This being done, the propounder of the "trick" (as it was termed) requested that all the figures,—of the remainder, except one, should be called out, and on this being done he immediately added the missing digit.

This was very mysterious to all present, especially as the propounder could have had no knowledge whatever of the figures set down by the other. We were afterwards enlightened a little on being told that it was done by adding up the figures mentally as they were being called, and "casting the nines" out of the result.

It seems to be a fact then, that on the figures representing any amount being added together, and their sum subtracted from the amount itself, the remainder will always be found to contain a certain number of "nines" exactly.

An example will show this clearly. Take 7,982,147 to be the amount, the sum of these numerals is 38, which, deducted from the original quantity, leaves a remainder of 7,982,109 = 36 = 9. Suppose we omit the figure 8, then the rest add up to 28 = 10 = 1. The 1 being left out, the rest will equal 35 = 8. It will be plain then that 8 and 1 are severally required to complete the "nine."

Most people are acquainted with the fact of this peculiar property of the 9 in proving all sorts of calculations, and for my part I consider it has some deep significance in the construction of our numerical tables.

I have never yet met with one who could tell me the *whys* and the *wherefores* of it, but I hope now to get an explanation of it through the publicity of this communication in the *Builder*.

J. H.

STRENGTHENING EMBANKMENTS.

Sir,—The Editor's note to a letter by "E." in the *Builder* of the 20th ult., reminds me of what I saw in Egypt a fortnight since, viz., the fellahs at work repairing the embankments which retain the waters of the Nile for irrigation purposes by means of vegetable growths. I refer particularly to the embankment which leads across to the Sakkara Pyramids, which is about 15 ft. wide at the top, and the sides slope at an angle of about 45°. It was then about 7 ft. or 8 ft. above the water, and as it leads to the desert, of course it is only a camel and donkey track, and being formed apparently entirely of alluvial deposit, if not attended to, the water soon makes inroads into its banks, and slips occur. The repairs were being done chiefly by mud, rushes, and occasional stakes. The stumps of a layer of rushes were first laid against the bank; then mud was pressed against it, and secured by the stakes; then another layer of staked rushes, and sometimes of palm-branches. There is, no doubt, great strength in such work. It makes a firm embankment to resist the inroads of the water, and consequently it is with considerable difficulty the mud is washed out,—not until the stakes or rushes rot, or the rats burrow into the banks; for when the waters of the Nile rise, thousands of rats are driven to the higher level. This mode of repairing embankments must of necessity be of very great antiquity; for the desert and almost naked plains offer no other means for repairing them.

H. H. Bridgman.

THE CAUSE OF BAD WORK.

Sir,—I can endorse every word of "A Clerk of Works'" admirable letter in the *Builder* of December 4th, after forty years' experience in London and the provinces, and two years in the United States of America. A great deal of scamped work is due to the system of letting-off work. If architects were to specify in their contracts that the work should not be sublet, and that it should be done by experienced workmen, there would be less scamping done. Take plastering, for instance. I do not believe there is a building to be found where plaster and Keene's cement are not mixed. It is the same with Parian cement; and in plenty of instances where it is above the ground level of large buildings, colouring material is put into the water that putty and plaster are gauged with to imitate Keene's cement.

A great deal of the scamped work is owing to architects specifying that the work must be done by a given time, or else the builder is liable to heavy penalties. That is a wrong system if you want good buildings; in fact, the whole building trade wants the broom of reform applied to it, as well as other institutions.

It would be a good thing, Mr. Editor, if you could devote a little space of your valuable journal for the ventilation of this and kindred subjects, under the heading of "Trade Grievances," week after week. I believe it would bring about a better feeling between employer and employed.

M. A. S., Plasterer.

LONG SUCTION PIPES.

Sir,—I should be much obliged if any of your correspondents would inform me to what distances (giving total height to which the water is raised) long suction-pipes have been found available for shallow wells. I should like to know the diameter of the suction-pipe and the power required to work the pump, *i.e.*, whether a child or woman using the ordinary lever-handle could overcome the friction; and I should be glad to know of any instances where a great length of suction has been found successful. What is the best practical work on hydraulic engineering, having especial regard to machines for raising water,—wheel, turbine, ram, &c.?

Surveyor.

The New General Post-Office, Manchester, which, according to the local press, has been much needed for the last twenty years, will, it is hoped, soon be commenced. It is stated that plans have already been prepared in the Office of Works.

CONCRETE IN PARLIAMENT-STREET.

Sir,—A letter in your paper of last Saturday, bearing the anonymous signature "Westminster," has misrepresented the composition of the concrete laid by this company in Parliament-street for the wood paving. As a fact, the concrete for the reception of the blocks was not, as represented in the letter, different in proportion from that used in covering the trenches, but of precisely the same proportion, viz., one to five.

The Portland cement was supplied by Messrs. White Brothers. The water poured on the concrete, and represented as "extremely dirty," was taken from the mains of the Chelsea Water Company, and is, therefore, I conclude, the water that the members of the Whitehall Club and the Institution of Civil Engineers have for drinking.

A. R. Grenfell,
Chairman of Improved Wood Pavement Company.

*** Our correspondent is a perfectly well-informed person on the subject, and we have no reason to doubt that he described correctly what he saw.

VARIORUM.

"Electric Light: Its Production and Use," by J. W. Urquhart, C.E.; edited by F. C. Webb, M.I.C.E. (Crosby Lockwood & Co.), gives plain directions for the working of batteries, lamps, and dynamo-electric machines. It may be recommended to those who wish to get clear ideas on the subject. The editor, to whom the book owes much, Mr. Frank Webb, will be agreeably remembered by many of our readers as a courteous official some years ago at the Royal Institute of British Architects. Mr. Webb is now connected with the Society of Telegraph Engineers, by whom his acquirements are duly appreciated. Mr. Urquhart's book is fully illustrated.——The new volume of the "British Almanac and Companion," now in its fifty-fourth year, presents a varied budget of articles in addition to the annual reviews of science, architecture, picture exhibitions, music, and metropolitan philanthropy, which have formed a marked improvement in its recent issues. The contents include:—"Weather Forecasting," by Robert H. Scott; "Sketch of the History of the Royal Observatory, Greenwich," by W. T. Lynn, B.A.; "Egypt in Liquidation," by J. Crowdy; "Proposed Ship Canal at Panama," and "Schemes for a Euphrates Railway," by G. Dodd; "Watchmaking by Machinery in England," by C. S. Murray; "The Food of the Poor," by W. E. A. Axon; "Parks, Gardens, and Open Spaces," by F. G. Heath; "London Hospitals and their Management," by the Editor (Mr. Charles Mackeson); "Bee Farming," by James F. Robinson. The Stationers' Company may fairly take credit for the contents of this useful volume.——The December part of "Cassell's Family Magazine" forms the commencement of a new volume, and affords the natural opportunity for new subscribers to commence taking it. Two interesting serial stories are commenced in it.

Miscellanea.

A Big Weathercock.—One of the largest linen-drapery establishments of Paris is constructing, near the Champ de Mars, where land is comparatively cheap, a vast building which will serve as coach-house and stables for the numerous horses and wagons belonging to the firm. There is nothing peculiar about these stables; the spirit of novelty and originality has manifested itself solely in the erection of a gigantic weathercock, which will be as remarkable in the artistic character and execution of its design as in its size. In height it will measure 26 ft., and its width no less than 13 ft. Nor will the design resemble that of ordinary weathercocks. It will consist of an heraldic lion rampant, holding up with its fore legs a gigantic initial; and the design of this monster has been entrusted to one of the most able heraldic engravers of Paris.

Proposed Infirmary for Kensington.—The Kensington guardians have decided on purchasing from the Vestry of St. Margaret and St. John the land adjoining the Kensington Infirmary and the buildings thereon, for 55,000*l.* The area is about 3¾ acres. The cost of adapting the premises, it is stated, will not be great.

A Mortuary for Kensington.—At a recent meeting of the Kensington Vestry, it was stated that the Guardians had refused to consent to a public mortuary being erected by the Vestry on their land at Notting-hill, and it was resolved to take steps for the purpose of constructing a mortuary in the parish churchyard, at the rear of the Town-hall, with the consent of the churchwardens.

The Love of Art the Love of Beauty.—On the occasion of distributing the prizes at the City School of Art, Skinner-street, Bishopsgate, Mr. Bryce, M.P., said,—"For those who lived by manual labour of the higher kinds nothing was more to be desired than that they should enjoy their work as an exercise of skill, calling out their faculties of invention and their dexterity of execution. The true spirit of the artist is the love of one's art, the desire to do work well for its own sake, and not merely because one is to be paid for it; and the more we can give to the artisan the character and feelings of the artist, the better and happier man he will be. There are many lines of life into which this kind of pleasure can hardly enter; but it is now absent from many others in which it might exist, and one of the chief services of art-schools is that they diffuse it, that they teach some workmen to design who could not have done so without training, while to a far larger number they give the power of appreciating and imitating or reproducing what is graceful and right, of feeling the harmony of colours and the elegance of form. And it was not only those directly occupied in production, workers in metal, or in earthenware, or in textile fabrics, to take the most important industries, who profited by a diffusion of knowledge of and taste for art, but through them the whole community. The true love of art, and not merely that love of fashion which often mistook itself for the love of art, was nothing less than the love of beauty. Material beauty, which came to us through the eyes, was of two kinds,—the beauty of Nature and the beauty of what man made for himself following or representing Nature. The latter was always accessible to us if we were trained to enjoy it, and, the more the taste for it is spread through the artisan class, so much the more rapidly would it leaven the whole population, and so much the commoner and easier to procure would artistic work become. We might just as well have beautiful things as ugly things before our eyes,—in our streets, hanging on our walls, standing on our breakfast-tables. Rich and rare they could not always be, but they need not be ugly; for plainness and simplicity are all the distance in the world from ugliness. The untrained eye may not always know the difference at first between a good wall-paper, for instance, and a bad one; but it soon gets to know, and the more it surrounds itself with pretty things the more it enjoys them.

Fogs and Mahogany.—After a paper on Fogs had been read at the Balloon Society the other night, Mr. W. H. Lefevre, C.E., the president of the society, said that he had conferred with Mr. Prim, the engineer of the Houses of Parliament. That gentleman said that the fog in the Houses of Parliament, which was occasionally found even when no fog existed outside, was due to the quantity of mahogany wood employed in the building. Mr. Lefevre gave an illustration of this phenomenon by lighting a cigarette and keeping the smoke over a table in the room. It was found that the smoke adhered to the surface of the table in a thin layer for about a minute. He claimed that, if a pipe was taken up to the top of Victoria Tower, the upper end would be above the fog, and that pure clear air could be brought down from that altitude for the ventilation of the House, and at the same time getting rid of the fog. Is it a fact that when London is in a fog the air is clear at the top of the Victoria Tower?

Artisans' Dwellings at Wolverhampton. At the Town-hall, Wolverhampton, on the 2nd inst., a county jury was sworn before Mr. M. F. Blakiston, the acting under-sheriff of the county of Stafford, to decide an appeal made by Messrs. Lowe & Jones, owners and mortgagees of property situate at Stafford and at Wolverhampton, and required by the corporation under the Artisans' Dwellings and Streets Improvement Scheme, against the award of Sir Henry Arthur Hunt, C.B., the arbitrator under the scheme, who assessed the compensation to be paid to the owners at 2,300*l.* After hearing evidence on both sides, the jury awarded the claimants a total sum of 2,600*l.*, with costs against the corporation.

Proposed Memorial to Caxton.—It is proposed to erect a memorial to William Caxton, England's first printer, in the shape of a stained-glass window in the church of St. Margaret, Westminster. A committee has been formed to carry out the object, with the Rev. Canon Farrar as chairman, Mr. G. A. Spottiswoode as treasurer, and Mr. A. Powell as secretary.

Overcrowding at Plymouth.—At a meeting of the Plymouth Mercantile Association last week, Mr. Pethick opened a discussion on the subject of providing improved dwellings for the poor. He adduced instances of shameful overcrowding, saying that in some instances eight or ten persons were living in one room, and in the case of the miserable hovels in which this state of things existed there was only one water-closet for the use of eight or ten families. Alderman Derry, who presided, referred to Mr. Cross's Artisans' Dwellings Act as unworkable, and added, "My own feeling is that we shall do nothing in this town until we get a special Act of Parliament. The state of things existing now in Looe-street, in this town, is most deplorable. There is one house at the bottom of Looe-street which contains sixty persons, with a water-closet 5 ft. 7 in. square, and all the persons in the house are obliged to go to that closet." (Mr. Pethick: 2 ft. broad and 5 ft. long.) The opinion was strongly expressed that the Sanitary Authority had not been doing its duty, and a resolution was passed directing the attention of the Town Council to the matter. Mr. Square, in the course of the discussion, referred to the financial difficulty involved in the asserted inability to erect workmen's dwellings to pay more than 3 or 4 per cent. Mr. Pethick (who is, if we mistake not, a well-known builder and contractor carrying on business in the town), in reply to that point, said,—"I may mention that I have two houses containing twenty-eight rooms, for which I receive 24*s.*,—less than 1*s.* a room,—and I say that others can be built inexpensively and substantially, and with due requirements, that may let in the same way and return 5 per cent.; and the rooms may be as they should be,—from 12 ft. to 14 ft. square, and not less than 9 ft. high." Quickly following on this discussion, a company has been formed in the town to erect dwellings for the poor. It should be added that the *Western Daily Mercury* has done good service in directing public attention to the matter.

Civil and Mechanical Engineers' Society. The opening meeting of this Society for Session 1880–81 was held on Thursday evening last in the Society's new rooms at 7, Westminster-chambers, when the President (Mr. H. Ellis Hill, A.-M.I.C.E.) delivered an inaugural address. The following is the syllabus of papers to be read during the session,—Dec. 23, "The Patent Laws and their Influence on Trade," by Mr. A. T. Walmisley; Jan. 6, 1881, "Account of Sombrero Island, West Indies, with description of submarine quarrying of phosphate of lime," by Mr. R. Harkness Twigg; Jan. 20, "Application of Hydraulic Machinery to Mines, Gasworks, Grain Warehouses, &c.," by Mr. J. Coates; Feb. 3, "Drainage and Embanking, with regard to River Outfalls," by Mr. W. C. Street; Feb. 17, "Water-bearing Strata of the Thames Basin," by Mr. A. F. E. Grant; March 3, "Steep Gradients *versus* Heavy Works," by Mr. J. B. Walton; March 17, "House Drainage and Sewerage," by Mr. R. E. Middleton; March 31, "Lifts for Warehouses, &c.," by Mr. G. J. Child; April 7, "Rainfall," by Mr. B. Hanghton; April 21, "Drainage of North Lincolnshire," by Mr. J. Henry Maughan. The annual meeting is fixed for May 5. Mr. G. A. Pryce Cuxson (of the firm of Maughan & Cuxson) has just taken the honorary secretaryship of the Society, which, we may add, has now been established twenty years.

St. Edmund the King and Martyr and St. Nicholas Acons, Lombard-street.—The extensive alterations and improvements that have been in progress in this church for some months past, under the superintendence of Mr. Butterfield, are now being rapidly completed, and the church will be re-opened for divine service on Christmas Eve. In addition to the repairs and decoration of the fabric, the organ is being greatly enlarged, and many modern improvements added to it, under the supervision of Professor Monk, of King's College.—*City Press.*

The Vacant District Surveyorship.—As usual when a vacancy occurs, there is a plethora of candidates for the office of district surveyor of Streatham and Brixton, rendered vacant by the death of Mr. John Mullins, the late surveyor. The number of candidates in the field is between twenty and thirty, including several Associates of the Royal Institute of British Architects. Mr. J. S. Quilter, the late deputy-surveyor, who is also one of the candidates, states in his address that, during the last three years, he has acted in that capacity.

London Fogs.—Mr. W. H. White, of the Institute of Architects, writes:—May I venture to inquire whether those lungs of the metropolis, the parks, may not, in some degree, be responsible for the fogs which periodically obscure parts of London? The fog of Thursday last is known to have prevailed principally in the northern, north-western, and western districts; at the termini of the North-Western and Midland Railways great inconvenience was felt. Now, on the afternoon of that day,—at about half-past four,—I passed through the Regent's Park, and there I observed over a vast space,—the circumference of which, I believe, is three miles,—a dense mass of bluish vapour rising apparently from the grass. In the midst of this vapour, a feeling of damp cold was experienced, with a tendency to cough, while beard and moustache were covered with globules of water. Objects at a few yards' distance could not be distinguished; both in the Euston-road and at Gloucester-gate the enclosure walls of different houses streamed with moisture. At a later hour,—at 11.30 p.m.,—I was in Portland-place, where foot-passengers clung to the area-railings as the only means available for directing their steps. Arrived, however, at Oxford-circus, the fog was less dense; at the eastern end of Oxford-street comparatively little existed. I traversed the slums of Soho, Covent-garden, and the Strand without any difficulty, and the city was free from fog. I would, therefore, humbly beg scientific men who are interested in this matter to visit the Regent's Park any day this winter between 4 and 5 p.m. I have been told that the drainage there is of an obsolete character, and from my experience of this and last year, when London has been visited with fog, the cloud has seemed to me to be thicker in Portland-place than in Oxford-street, or even the Strand.

Adulteration of Food in America.—Through the efforts of *The Sanitary Engineer*, the National Board of Trade, at their annual meeting in Washington last December, were induced to institute a competition for "the best Act or Acts, accompanied by an essay, designed to prevent injurious adulteration, and to regulate the sale of food, without imposing unnecessary burdens upon commerce." One thousand dollars were offered in prizes, which sum had been given to the Board for that purpose by Mr. F. B. Thurber, of New York. The committee of award have just made their report. In addition to awarding the prizes, the committee were required to prepare and submit to the Board of Trade a draft of a suitable National and State Bill designed to secure the results which the competition was instituted to accomplish. The committee have selected as the three most meritorious essays, with the accompanying Acts, numbering them consecutively in the order of merit as follows:—

1. The essay and acts having the motto "Aequo Animo."
2. The essay and acts having the motto "Sic utere tuo ut alienum non laedas."
3. The essay and acts having the motto "Overcome Evil with Good."

Upon opening the sealed envelopes, having corresponding mottoes, it is found that the authors of these essays are as follows, viz.:—

1. Motto "Aequo Animo," G. W. Wigner, F.C.S., London.
2. Motto "Sic utere tuo ut alienum non laedas," Vernon M. Davis, New York City, N.Y.
3. Motto "Overcome Evil with Good," William H. Newell, M.D., Jersey City Heights, New Jersey.

In addition to these essays, we recommend the printing of the essay having the motto "Cardinal Cajetan," whose author is O. W. Wight, M.D., Health Officer, Milwaukee, Wisconsin; and the remarks submitted under the motto "Work and Wait," by Albert B. Prescott, Ann Arbor, Michigan.

New Docks for Silloth.—It is stated to be the intention of the North British Railway Company to build a new dock at Silloth. A few days ago Mr. Thomas Meik, C.E., of Edinburgh, visited Silloth, in company with Mr. Charles Boyd, resident engineer to the company, for the purpose of reporting upon the proposed work. It is added that the new dock is to be about six acres in extent.

Measuring Tapes.—We have received several letters recommending this or that maker's tape; but these are all known to "Inquirer," and are fallible. We have not yet received a letter from any maker promising to try and do better. The want of thoroughly reliable and lasting tapes is admitted.

Light, Heat, and Ventilation.—An exhibition is announced of appliances for heating, lighting, and ventilation. It is to held at the Alexandra Palace, in the great central transept and adjoining halls, and will be opened from December 22nd to January 11th.

TENDERS

For the erection of two villa residences, Woodhouse-road, Mansfield, for Mr. G. Pickard. Mr. Thomas Hartas, architect. Quantities supplied:—

Fisher, Bros., Mansfield	£1,650	0	0
Roe, Alfreton	1,634	9	0
Alsop, Mansfield	1,602	11	6
Parsons, Mansfield	1,595	0	0
Vallance, Mansfield	1,595	0	0
Tinkler, Clay-cross	1,517	0	0
Bradder, Mansfield	1,448	0	0
Bell & Son, Nottingham	1,442	0	0
Maben & Fairington, Manchester	1,400	0	0
Greenwood, Mansfield (accepted)	1,323	0	0

For completing the Alexandra Mansions, Victoria-street, Westminster, for the Midland Land and Investment Corporation, Limited. Messrs. Bateman & Corser, architects:—

Francis	£18,230	0	0
Avias & Co.	17,647	0	0
Lathey Bros.	16,623	0	0
Colls & Sons	15,991	0	0
Martin & Co.	15,528	0	0
Longmire & Burge	15,352	0	0
Adamson & Son	14,400	0	0
Patrick & Son	14,317	0	0

For sanitary works, Cornhill. Mr. T. Mullett Ellis, architect:—

Beattie, Holden-terrace	£155	0	0

For decorative work, No. 3, Warwick-square, Pimlico, for Mr. Francis Mowatt. Mr. T. M. Ellis, architect:—Wilson, Sussex-street (accepted).

For building two houses and shops, Mile End-road, and altering stable premises adjoining. Mr. T. M. Ellis, architect:—

Hart (accepted)	£3,180	0	0

For two houses, Hampstead-heath. Mr. J. Milbourn, architect:—

Linsall	£2,100	0	0
Harper	2,490	0	0
Conder	1,960	0	0
Bishop	1,940	0	0
Cross	1,855	0	0
Ambley	1,815	0	0
Read	1,698	15	0

For alterations and repairs to houses, Stroud-green-road, for Mr. Earl. Mr. W. Smith, architect:—

Shurmur	£840	0	0
Steel Bros.	825	0	0
Harper	725	0	0
Larke	635	0	0
Mattock Bros.	595	0	0
Dunford & Langham	595	0	0
Stevens Bros.	539	0	0

For erecting villa residence, stables and fencing, at Winchmore-hill, for Mr. Sugden. Mr. W. Smith, architect:—

Steel Bros.	£2,093	0	0
Larke	1,990	0	0
Shurmur	1,950	0	0
Harper	1,939	0	0
Dunford & Langham	1,929	0	0
Pocock	1,763	0	0
Mattock Bros.	1,477	0	0
Wheeler	1,420	0	0

For the erection of greenhouse and pits in Venner-road, Sydenham. Mr. C. J. C. Pawley, architect:—

Hollidge & Stuart,* South Norwood	£210	0	0

* Accepted.

For the construction of sewers on the Aldrington Estate, near Brighton. Mr. Arthur Lewis, engineer. Quantities supplied:—

	Concrete.	Combined Brick and Concrete.
Crockett, London (add)	£230	£3,545
Oliver, Preston Park	3,371	3,371
Parsons & Sons, Hove	3,370	3,310
Marshall, Brighton	3,050	3,050
Norris, Hove	2,524	3,208
Hurst, Aldrington	2,950	3,020
Blaker,* Portslade (add)	528	2,978
Harrison,† Brighton	2,880	2,890

* Too late. † Accepted for brick and concrete.

For additions and alterations at 29, Gower-street. Mr. Thomas Newell, architect:—

Bush	£652	0	0
Perkins	650	0	0

For new schools at Glascoed, Monmouthshire, for the Llanbadoc, Monkswood, and Glascoed U. D. School Board. Mr. E. A. Lansdowne, architect, Newport, Monmouthshire:—

White, Abergavenny	£884	0	0
Davis & Jones, Newport	878	0	0
Davis & Thomson, Pontypool	844	0	0
Hatherley, Bristol	798	0	0
Linton, Newport	793	0	0
Thomas, Abergavenny	770	0	0
James & Son, Bridgend	700	0	0
Howard, Cardiff	698	0	0
Jones & Diment, Newport	690	0	0
Richards, Newport, Pontypool	663	0	0
Blackburne, Newport	649	0	0
Orphan, Newport	645	0	0
Davis, Usk	630	0	0
Burgoyne, Blaenavon	630	0	0
Jones & Son, Newport	629	10	0
Martin, Newport	610	0	0
Moulton & Brownscombe, Newport	585	0	0
Giles, Ewens Harold	578	0	0

For the new brewery buildings of ten quarters capacity, for Mr. J. Elworthy, Kettering, from drawings and specifications, Mr. Arthur Kinder, architect:—

Margetts	£940	0	0
Henson	927	0	0
Sharman	915	0	0
Barlow (accepted)	850	0	0

TO CORRESPONDENTS.

J. S. M. (shall have attention).—M. S. A. W. (we have already published the selected design).—M. A. S.—E. I. R.—W. C. T.—G. A. P.—C. G. B.—T. & P.—"Queen Anne."—A. L.—T. O.—W. B.—B. S.—J. & W.—E. & C.—J. M. C.—C. G. D.—E. S. & Co.—J. F.—J. & C. M.—J. H.—F. C. & Sons.—J. P.—E. & C.—C. T.—J. D.—T. M. E.—B. & C.—J. McG.—E. A. L.—G. T. C.—A. H.—T. R. S.—O. P.

Errata.—In the letter headed "Noises" (p. 679), the figure 44° should have been printed thus: −44° (*minus*, or 44 degrees below zero).—In the abstract of Mr. Robins's paper on "Sanitary Science," &c., printed on p. 686, the third principle summarised by Mr. Griffith should read,—"The soil-pipe should be 2xed outside the house," &c.

All statements of facts, lists of tenders, &c. must be accompanied by the name and address of the sender, not necessarily for publication.

We are compelled to decline pointing out books and giving addresses.

NOTE.—The responsibility of signed articles, and papers read at public meetings, rests, of course with the authors.

SPECIAL NOTICE.

Christmas Week.—*The* BUILDER *for the week ending December 25th will be published on* **Thursday, 23rd** *inst., at the usual hour.*

Advertisements for insertion in that issue must therefore reach the Office before Three o'clock P.M. *on* **Wednesday, 22nd** *inst.*

CHARGES FOR ADVERTISEMENTS.

SITUATIONS VACANT, PARTNERSHIPS, APPRENTICESHIPS TRADE, AND GENERAL ADVERTISEMENTS

Six lines (about fifty words) or under ..... 4s. 6d.
Each additional line (about ten words) ..... 0s. 6d.

Terms for series of Trade Advertisements, also for Special Advertisements on front page, Competitions, Contracts, Sales by Auction, &c. may be obtained on application to the Publisher.

SITUATIONS WANTED.

FOUR Lines (about THIRTY words) or under ..... 2s. 6d.
Each additional line (about ten words) ..... 0s. 6d.

REPLIES TO ADVERTISEMENTS.

Addressed Box ——, Office of "The Builder."

Cannot be forwarded, but *must* in all cases be *called for*, and the Office Receipt produced.

THE CHARGE FOR A BOX IS AS UNDER:—

For "Situations Wanted" Advertisements ..... 3d. per Week.
For all other Advertisements ..... 6d. per Week.

PREPAYMENT IS ABSOLUTELY NECESSARY.

*** Stamps *must not* be sent, but all small sums should be remitted by Cash in Registered Letter or by Money Order, payable at the Post-office, Ring-street, Covent-garden, W.C. to

DOUGLAS FOURDRINIER, Publisher,
Addressed to No. 46, Catherine-street, W.C.

Advertisements for the current week's issue must reach the office before THREE o'clock p.m. on THURSDAY.

The Publisher cannot be responsible for DRAWINGS, TESTIMONIALS, &c. left at the Office in reply to Advertisements, and strongly recommends that of the latter COPIES ONLY should be sent.

TERMS OF SUBSCRIPTION.

"THE BUILDER" is supplied *direct* from the Office to residents in any part of the United Kingdom at the rate of 13s. per annum, *prepaid*. Remittances payable as above.

The Builder.

Vol. XXXIX. No. 1976. Saturday, December 18, 1880.

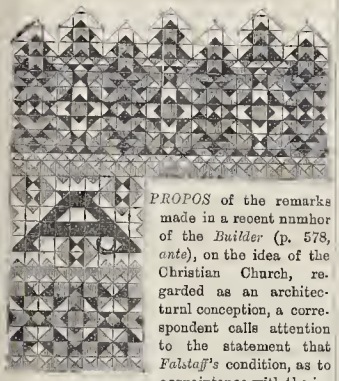
On Coloured Lights, as an Integral Part of Architectural Design.



PROPOS of the remarks made in a recent nnmhor of the *Builder* (p. 578, *ante*), on the idea of the Christian Church, regarded as an architecturnl conception, a correspondent calls attention to the statement that *Falstaff's* condition, as to acquaintance with the inside of a church, is far moro general than people are ready to admit, even in this church-going and church-building age. Nay, more, to the hoary reprohate "the inside of a church" was evidently something once seen, althongh hut dimly remembered. But the position of onr contrihutor is, that most of those whose ecclesiastical pilgrimages are confined within the shores of Great Britain never *have* actually seen the inside of a church, as it was conceived and wronght ont hy the great church-huilders of England, from the time of Edward (King and Confessor), down to the destructive reign of red-handed Harry Tudor.

The suggestion may he put in a humorons form; hut there is a meaning in it which deserves careful thought. Our own pages have not unfrequently contained articles on the snhject of illumination. The importance of that condition while viewing any work of art cannot he over-rated. Has a reader ever paid a visit to the National Gallery, or to any great collection of pictures, when they are half-hidden beneath the veil of a London fog? What becomes of brilliancy of touch, of purity of tone,—even of delicate grace of drawing,—under the disfiguring ahsence of light? In sculpture, the effect of lighting is far more important than in painting, for, in the latter, it is only dimness of effect that is produced hy want of light, while in sculpture positive distortion of the sculptor's idea is produced hy throwing the shadows the wrong way. That a piece of sculpture, whether in relief or in the round, should be entirely executed in ono light, and viewed, when finished, in that same light, is a *sine quâ non* of excellence. It is possible to make some exception to this rule in favour of what may be called chamher sculpture. Thus, the exqnisite proportion of the whole figure (except the head and restored hands) of the Venus dei Medici is so perfect that, like a living heautiful woman, she can hardly he viewed amiss, in any light or in any direction. It would he difficult to say which was the artist's point of view for this particular statne. Nor have its loving custodians heen ahle to solve the difficulty; so they have reflected the matchless curves by a girdle of radiating mirrors. Still, even the Venus, if lighted only hy a lamp plnced at her feet, wonld not maintain her fame. Again, in architecture, the effect hoth of outline and of shadow lines is so varied, owing to the incidence of the sun, and, again, the harmony of the colonr of a building so depends, hoth on its relation to other features of the landscape, and on the incidence of light, that the power of illumination in giving character to architecture is hardly less than in the case of sculpture.

Thus far, then, as to the incidence, and as to the quantity of light. But no less attention should he paid to its colonr. Colour is, as we know, the effect of certain conditions affecting either the transmission or the reflection of light. Our attention, since anything like a revival of art has taken place nmong ns, has been almost wholly devoted, as far as the effects of colour are concerned, to the action of reflection. The colonrs of a picture are reflected colonrs. But the great church-huilders to whom we have referred took the opposite view. They gave, so far as we can now gather from the relics of their finest works, hut little attention to reflected colour. Their chief reflecting surface was gold. But over gold or marhle, canopy and shrine, sculptured saint and carved foliage, a glow of rich harmonious light was thrown hy the glorious stained glass with which they filled their windows.

As to this, of conrse it may he said that the remark is hy no means perfectly novel. No donht that is so. But what we think *is* novel,—or at least has heen pretty generally neglected for three hnndred years and more,—is that the windows of onr churches grew np as integral parts of the structure, glass and all. It was not one man that hnilt, and left the painter and glazier to come after him and improve and ornament at pleasure. On the contrary, the glass-stainer grew in his art as the huilder did in his. The modification in the form, the proportion, and the distribution of the lights, that took place from the time when church windows were simply double splayed holes in the wall, too small to allow the hostile Dane to squeeze through, to that when the whole end of a church or side of a hnilding was one great frame filled with sparkling window jewelry, was accompanied hy modifications in the tints, the leading, and the pattern of the glass, which were accnrately proportioned to the conception of the framework of the window. Grave and solemn in hue, or hright and sparkling in lustre, the window was not an impertinence or an excrescence, hut an integral part of harmonious interior design.

Windows, no donht, when objects of beanty, are things to he looked at. But that was not the original aim or object of the window. One of the few huildings in which the idea of the original architect, in so far as it comprised the effect of the windows (though some restorations have since nnhappily] heen effected), may yet he observed, is the "Dome of the Rock," at Jerusalem. The glorions Saracenic stained glass yet remaining, to a great extent, in the windows of that huilding, forma an integrnl part of the structural effect. You do not go to look at the windows. The absence of figure subjects which here occnrs is in this respect a true architectnral feature. Yon are impressed hy the solemn air of the holy place; and how much of the impression is due to lofty height, or nohle proportion, and how much to the flood of toned light, you do not panse to inqnire.

If our old cathedrals and chnrches are regarded from this point of view, it is impossible to deny that very few of them have ever been seen by any of the present generation as they were intended to he seen hy the huilders. At York we have, perhaps, one of the most striking exceptions; and who that has worshipped there has failed to he struck hy the wonderfnl grandenr of York Minster? The beantiful group of five lancet windows, known as the Five Sisters, in the north transept, filled with glass covered with foliage, and displaying geometric forms, is of tho thirteenth century. In the vestihule of the chapter-house is to be found glass of the twelfth century. The east window of the choir and the west window of the nave date in the first decade of the fifteenth century. In the north choir aisle the glass in the Archhishop's window is not more than twenty-five years later. The sixteenth-century glass in the Jesse window, in the south choir aisle, is of the same date as the Perpendicnlar tracery of the window itself. To a very nnusual degree we can thus see York as it was seen by its huilders and early adorners, and we may refer those who donht the trnth of the remarks we have made to the test of the effect produced on the mind of a man of taste, or of religions sentiment, hy the interior of York.

If we look to snch examples as the oboir of the cathedral of Clermont, or the Sainte Chapelle at Paris (the visitor to the Sonth Kensington Museum may wonder at the sacrilege which has enahled him to form an opinion of the solemn grandeur of this work), we see examples of a very different employment of glass hy the architect from that whioh prevailed at York. At the Minster, if we are correct in our recollection, the windows of Thornton of Coventry, and other great window jewellers, were intended to light the church. In the French sanctnaries thia could hardly he said to be the case. Semi-lnminons pictures, the windows were rather architectural features than points of irradiation; and the worshippers mnst have depended in no small measure for their observance of the ritnal on the silver lamps that hnng from the roof, or on the candles on the altar. "A dim religious light," even at noon-day, is all that was transmitted by windows such as those of the chapel of St. Louis. Can there he a stronger contrast conceivable than that between the effect of glass

lika this, and that of some of the modern transparency painting that disfiguras both the cathedral of the metropolitan, and the cathedral of the metropolis?

Some illustration of the truth of these remarks may he obtained hy any of our readers who have the chance of paying a visit to the Church of St. Nicholas at Guildford. This huilding, the third which has been erected on the same ancient site, is an example of that ready response of the parishioners, and of the personal friends of the lamented founder, the late Rev. Dr. Monsell, to an appeal made by the latter, then rector of the parish, to which he was himself one of the most munificent respondents. St. Nicholas has an especial claim on the attention of the ecclesiastical architect, from the mode in which the More Chapel, the ancient cemetery of the family of which Sir Thomas More was a cadet, has been combined with the south aisle of the church; the small arcade which exposes the chapel to view heing filled with plate glass, so as to separate, from a sanitary point of viaw, the huildings whicb ara architecturally one. There are many points of interest, as well as one or two deserving of pointed criticism, in the architecture of St. Nicholas'; but the point which we hava now in view is the effect which has been produced in the interior by the successive filling up of the greater nnmber of the windows with stained glass. The windows of tha choir, or rather of the semi-octagonal apse which holds the communion-table, were the gift of the Monsell family. They have the disadvantage of being crowded with small figure subjects, poorly treated, and of containing a proportion of clear glass wholly inconsistent with the Early English form of the apertures. When tha church was first opened, the effect was anything hut satisfactory; and the want of harmony between glass and structure was after a time made more painful by the introduction of a reredos in gildcd wood, of which the less that is said the hetter. But after a time, tho west windows of the church were filled with stained g'ass of more appropriate design, as a memorial to Dr. Monsell. Then the south aisle windows were filled in the same way, as a memorial to the successor of Dr. Monsell in the living, the Rev. W. J. Few. And lastly, within the past week or two, the four windows of the north aisle have been filled with figure illustrations of the *Te Deum*, as a gift from a gentleman of the neighbourhood.

The point to which we now wish to call attention is the gradual change in the effect of the interior of the church produced hy these successive additions to its coloured shade. As each new series of windows has heen introduced, those previously inserted have become more admirable. The north aisle, the lowest part of tbe building, lying between a block which covers the very awkward entrance (the worst feature of the church) and the transept-like recess occnpied hy the organ, had a painfully mean look, whicb is removed by the effect of the windows. Nor is the improvement local alone. The harmony of the interior has become far more prononnced. Eaoh additional coloured light seems to have reflected something of its own richness on its neighhours. Even the unacceptable hits of white (or rather of transparent) glass in the choir windows are greatly toned down. And all that now absolutely pains the eye in transmission is the raw and badly-tinted light that comes through the circular window on the south side of the tower, and through the npper row of clearstory windows. These windows at present remain as they were originally filled with glass,—that is to say, in the mannor most detrimental to the general effect of the church, and most unpleasant to the eyes. They consist of transparent glass, a certain proportion of the panes heing of a greenish tint that increases the sickly tone of the brick-work lining of the interior.

The circular window is now about to he filled with stained glass hy subscription. If this prove as great an advance on the *Te Deum* windows as the latter are on the former stained glass, the church will he well worth a pilgrimage to visit. Then, too, if his visit he on Sunday, or on some holy eve, and if the rector occupy the pulpit, the visitor will hear such words as might have fallen from the lips of the greatest preachers of the English Church, when our language was that of Shakspeare, and the minds of men were aglow with the vivid growth of the Reformation. The only source of light remaining to disturb the general harmony, when the rose window is stained, will he the window of the More Chapel, in which the blank shields left by the glazier, fifty-four ont of sixty-six, ought to he filled with armorial bearings, and the before-noted clearstory windows (wa except, of course, the oak panelling and tabernacle work which is required for the lining of the apse). As to these, if they were filled with stained glass, the church would probably be too dark. But tha clear glass, and especially the green glass, should be removed, and its place supplied by dead white glass, as at York, with a small and lustrous quartette of window gems,—ruby, topaz, sapphire, and emerald,—in each light; just enough to show that rich colour was the tone of the illumination, although in this part of the buildiog hut a small quantity of colour was required. The problem of illumination and of effect combined wonld thus be solved.

In the four *Te Deum* windows there is much which reflects high credit on the artists. The two figures of St. Augustine and St. Nicholas, as representatives of "the Holy Church throughout all the world," are really noble. Starting from the west, the first three-light window contains the Apostles Peter and John, with an angel in the centre light,—and a very charming angel it is. With this exception, the celestial personages are less happy in their treatment than any other portion of the work. The second window contains the Prophets, Isaiah and Ezekiel, with Michael the Archangel in the midst. This latter figure leads one to ask,—how is it possible that artists who have evidently given so much thought to the subject should have dreamed of attempting any other representation of the Archangel than a reproduction of the St. Michael of Perugino, in the left hand compartment of that altar-piece in the National Gallery, which is nnmbered 288 in the catalogue? This fignra is nohle and imagioative, and at the same has a sort of Mediæval quaintness in force and general effect, which might be admirably rendered on glass, in which material the maintenance of a certain degree of conventionalism is, in our opinion, indispensable. St. Catherine and St. Stephen, in the third window, represent "the nohlo army of martyrs." Between them is a cherub, which is the same design as the seraph is the fourth window, with the exception that the colour differs, and that the seraph is objectionably besprinkled with human eyes. These, no doubt, are introduced to refer to the eyes mentioned in the vision of Ezekiel as being in the wings,—"their wings were full of eyes about them four." In the vision of St. John, the four living creatures were "full of eyes within"; but this description is materially different from that of the four-faced living creatures of Ezekiel, or the six-winged seraphim of Isaiah. It is a thousand pities, we think, that a symbolism which is not distinctly described, and to which pictorial art refuses to lend itself with any propriety, should here have been adopted. The windows are so good, the colour of the glass is so pure, much of the design is so admirable, and the example of the donor, Mr. Chester, is so mneh to be commended and imitated, that we are reluctant to speak ont ahout those celestial impersonations. But it is due to artists of merit to warn them against an attempt at evolving from their own imaginations representations of these mystio forms. We have pointed ont whence is to he derived an nnexceptionable pattern for the archangel. For the oherub we might point to St. Paul's Cathedral, and to the lovely choir of boy-angels, the work of Grinling Gibbons, that cluster in twos and threes, regarding invisible music-hooks, and nttering a perpetual *Sanctus* that finds an echo in the sculptor's ear. For the seraph some hint might have heen found in the Assyrian sculpture, where, indeed, the very name of cherub has been found associated with winged sphinxes. Or, if the artist had sought to embody the most lofty, because the least detailed, of the records given in Holy Writ of these celestial symbols, he would have found in the *petasus* and the *talaria* of the messenger of the gods an indication of the mode in which the greatest artists of the highest time of art rendered the idea, "with twain he covered his face, and with twain he covered his feet." The effect of the composition of these figures as they have been actually treated, is so disjointed that the idea of unity is almost lost.

We have dwelt at more length than we shonld otherwise have done on this series of windows because the mode in which the Church of St. Nicholas has heen successively adorned hy the piety and the munificence of so many donors, in so short a period of time, may he taken to mark almost a new era in the application of decoration to church architecture. That rich and appropriate decoration should be thus introduced is the desire of all true lovers of art, and, we think, of tha truest friends of the Church. But the more fully this is the case, the greater is the necessity to watch against the introduction, owing to the mistaken taste of any individual, of the grotesque, or even of the abominable. Among the latter may be mentioned certain dragons or other infernal monsters, the depiction of which on the walls of a rather notorious church will he fresh in the memory of many. From the sublime to the ridiculous we know the distance. About tbe same space separates the quaint from the odious. Whether it he desirable, even if possible, exactly to reprodnce ancient portraitures of saint or martyr, angel or cherub, may, perhaps, be questioned. Our own taste points most strongly to the use of such noble floriated or geometric patterns for window jewelry as those of the Dome of the Rock, or as the groundwork of the Brunel, Stephenson, and Locke windows in Westminster Abbey, in preference to figures. If figures must he had, we have, on the one hand, the patterns left of the early workers in glass, and, on the other hand, the limiting lines traced by the great Italian artists. We think that any worker on glass who would wish to leave such a name as, for example, that of Thornton of Coventry, should bear in mind that the imagination of a nineteenth-century artist is not strong enough to hring forth a new conception of an ancient symbol,—snch as that of chernh or seraph. The painter himself wonld here almost certainly fail; and the worker in glass labours under much greater difficulties than the painter. He has to work in honds. So working, a nobility and a grandeur are possible of a very high order. But they ara not to be attained by any attempt to overleap the bounds set by the leads of the casement, and the quality of glass. To paint a transparent picture may be magnificent, hut it is not window jewelry. It is not true architectural decoration. True window jewelry admits only of the colours of natural gems. They are also the colours of the herald, as well as those of astrology. The topaz, the ruby, the sapphire, the amethyst, and the emerald give or, gules, azure, purpure, and vert. Sable is given hy the leads, and the white glass should have the effect of pearl, which, in the hlazonry of gems, denotes argent. If we admit that dark-browns or semi-opaque purples may be introduced into windows,—which, if at all, is only allowable when the illuminated space is of very great area, as in the case of the south window of Westminster Hall,—Saint Augustine and Saint Nicholas, in tbe windows of the church we have named, may be pointed to as examples of what the workers of the present day can do in glass of which any church may be proud. All the more are we desirous that men who can turn out such thorough and noble work should not allow themselves to he seduced, under the plea of giving scope to the imagination, into the mechanical composition of impossible figures, which are neither reproductions of old glass, nor happy attempts at giving embodiment to poetio ideas.

A GRAMMAR OF JAPANESE ORNAMENT.

In the enthusiasm which has sprung up of late years for Japanese art, there has been for the most part little of critical judgment or moderation. It has been a kind of craze, under the influence of which many persons have devotedly imitated or collected everything Japanese they could lay their hands upon, and worshipped the collection with a blind and touching faith. The work put forth by Mr. Cutler * exhibits a different and much more moderate and critical spirit in dealing with the subject of Japanese art. It seems, indeed, to be the first systematic attempt to look for something like principle in the style of design characteristic of Japanese art; to consider in what lies the secret of its charm, and to criticise it in an independent spirit. The author modestly disavows any claim to the possession of literary ability; but his criticisms are expressed in sufficiently clear and readable language, and are in themselves often very sonnd and sensible.

With the short historical sketch we will not concern ourselves especially; the matter is to be found in much more detail elsewhere, and the author does not pretend to announce any new facts. In the following chapters on

* A Grammar of Japanese Ornament and Design. With Introduction, descriptive and analytical Text. By Thoma W. Cutler, F.R.I.B.A. London: B. T. Batsford. 1880.

architecture and sculpture the characteristics of these arts as practised by the Japanese are fairly estimated; in regard to the latter subject, the author raises the question whether it is through accident or want of power that in sculpture the human figure is never correctly rendered, but only in grotesque form; he concludes it could hardly be want of power, as an artist who could draw the feathers and claws of a bird in various attitudes could have learned to draw the human hand correctly. Undoubtedly he could; and our impression has always been that, like other races who have not arrived at the highest style of civilisation, the Japanese do not, or did not, care for the human figure. In character they may be said, compared with Europeans, to be rather like children, and their art has that comparatively child-like character which aims at what is pretty and fanciful and even funny, rather than at intellectual expression. They can use the human figure in satirical caricature with considerable effect, though even here it is sometimes difficult to distinguish between what is intentional caricature or oddity and what is merely defective drawing. But they did not study the human figure as they studied birds, beasts, and fishes. When the highly-interesting collection of Japanese carvings and drawings was exhibited at the Burlington Fine Art Club, we drew attention to the fact that while there were many careful studies of the limbs, plumage, &c., of birds,—and even the actual feathers were gummed to the paper for reference as models,—no one seemed to have had a single study of any part of the human figure, made for the purpose of study, to lend for exhibition. That fact, as we said at the time, was quite sufficient to explain why the same people drew birds well and figures badly. They took pains with the former, but they did not care about the latter.

The recollection of studies from birds with the specimens of plumage appended, which were to be seen in that same collection, leads us, however, to question the entire correctness of the statement in the chapter on painting, that the Japanese rarely, if ever, draw from nature. It was clear, from the Burlington Club Exhibition, that they sometimes study from nature very closely. But, for all that, we believe Mr. Cutler's general view to be correct, that the birds, fish, and plants introduced into or sometimes constituting Japanese decoration are rather the facile repetitions of well-known and long-established types than the result of any attempt to reproduce nature. As he points out, the birds and fish, even, are rarely anatomically correct, or resembling nature in detail; they are thoroughly natural only in the remarkably happy and effective manner in which action is shown in them, and which might result rather from the habit of observation by quick-eyed intelligence than from formal copying from life on the spot. The author's general estimate of the pictorial art of the Japanese, however, we hold to be quite correct, though it would startle the faithful among Japan-worshippers. It is simply that pictorial art, as we mean it, can hardly be said to exist in Japan; "ignorant of chiaroscuro, the play of shadows, and the relief which by their use one can give to objects, scenes, and landscapes, they paint all in flat tones as one paints a vase; it is not a picture which they execute on the sized silk, it is a decoration, and it is as a decorative process that painting in Japan must be considered." They have imposed on themselves a style copied from the Chinese; and "the merit of their art, if we may call it such, lies in their method, which, by repeated copying, gives them such accuracy, such perfect touch, and such mastery over the brush. They are feeble in conception, inimitable in execution; masters in the matter of taste, when the human figure is out of the question."

When we find a writer who has directed special attention and admiration to Japanese art, speaking of it in this judiciously critical tone, we may hope that we are about to see a more intelligent estimate of it succeed to the unreasoning and blind craze against which we have more than once protested; that we shall not always find people ready to demand that some jagged lines for rocks, and some curly lines for water, and some sprigs for trees, without any perspective, linear or aërial, shall be admired as a "landscape-painting," and placed in competition with, or even as superior to, the best European landscape-painting. We have actually heard such a claim made, and have seen some of these grotesque and childish attempts at the representation of landscape landed as evidence of the wonderful versatility of the Japanese, who could draw landscape and animals equally well. It may be hoped that even Japanese collectors are becoming a little more discriminating now, though it must be admitted that collectors as a class are hardly, perhaps, to be judged by the standard of rationality applied to mankind at large.

Mr. Cutler gives some brief chapters on the processes in ceramic ware, lacquer, metal-work, &c., which render the book more complete; and then we come to the æsthetic consideration of the subject. Some remarks in regard to the Japanese artist as a decorator are suggestive, and the brief description of the process of education of a Japanese designer helps to explain some of the peculiarities of their art:—

"A small manual of drawing, in which different designs are mapped out in squares, is placed in the hands of the student, who divides his drawing-paper into the same number of squares, which he is taught to fill up in their fixed order. When he has learned these by heart, designs of gradually-increasing difficulty are placed before him, and thus he learns by degrees to delineate flowers birds, landscapes, figures, and other objects in an artificial manner, without any reference to nature. One student may devote himself to birds and flowers, another may take up the subject of landscape, but in all cases the method pursued is the same, and thus the excellences and faults of the originals are perpetuated. Individual talent in draughtsmanship,—looking to originality of design,—can scarcely exist. The excellences of artists are therefore confined to the combination of conventional forms, and the delicacy or power of execution and colour, in which alone their fancy can have free play. These elegant stems, these feathery petals, are thus executed after a number of models prepared long beforehand, and which every painter possesses."

Admitting this description to be true (and we have no doubt it is) we are in a position to estimate Japanese art very differently from the view we might take of it if we regarded it as an art independently practised by individuals. Like so much of the best decoration in the world, it is, in fact, a kind of artistic school or habit of design, carried to great perfection of finish through the practice and teaching of many generations. In considering it as a style of art for study and emulation by European artists, therefore, we may reduce it to a comparatively few types, and we may then find room to consider whether, if we wish to reproduce for ourselves the effect of ornament of this type, we may not find a better and more living method of doing so, in ourselves adopting our own types and refining and finishing the execution of them to the highest point, and then applying our own details to the production of ornament on the same principle, but with novelty of detail. This would be more interesting and more likely to benefit and advance decorative design in new paths, than merely aiming at a mimicry of Japanese work. In analysing the elements of Japanese design, the author reduces them to certain leading groups. First we have diapers, frets, and medallions, not imitative of nature, and in some respects resembling forms that are found in Greek and Egyptian art. Next we have free-hand curve lines, made with single brush strokes; then a graduated series of studies from the bamboo, one of the most prominent and frequent objects in Japanese decoration. Following these are plates of studies in grasses, flowers, birds, and in clouds and water (so-called). These the author apparently regards as the typical divisions into which the materials of Japanese ornament fall. As to the principle of combination employed, Mr. Cutler defines it as "an avoidance of the appearance of symmetry while producing symmetrical effects, a suggestion rather than expression of proportion, an unobtrusive order, and in repetition of form an irregularity and changefulness, giving to it an unusual charm and freshness. A Japanese artist proceeding to decorate a given space would not mark out the centre and place his ornament there, nor would he divide it into equal parts, but he would most probably throw his design a little out of the centre, and cleverly balance the composition by a butterfly, a leaf, or even a spot of colour." This is perhaps about as much as can be definitely said as to the principle of Japanese design, which to superficial observers is marked apparently by want of principle and method, but which probably has so much of principle as is involved in the intentional avoidance of formality, together with the attempt to comply with the demands of symmetry (as one may say) unsymmetrically, and in a manner such as to produce the effect of a happy accident, a *contrived* accident. We believe that the highest class of decoration, that which has commanded the longest and most extended admiration, is that which is symmetrical and is precisely adapted to the space which it occupies. But we do not always want the highest or most serious class of art, either in decoration or in other forms of art; and when we are tired of the grave symmetry of the Greek, and the less grave symmetry of the Renaissance, ornament, the Japanese comes in like a child and arranges pretty things for our amusement, and seems ready to laugh with us over them. In that light, Japanese art is an exquisite element in the cycle of decorative arts, but it is not to be placed above, or on a level with, the graver, more precise, and more thoughtful ornament of the Greeks.

One other suggestion in the author's analytical chapter we may refer to. After observing that no doubt some of the Japanese work is intentionally conventional, he observes that it may be questioned "whether in their most successful work the artist is not decorative rather by accident than intent,—whether, in fact, he has not striven to produce a faithful and lifelike copy of Nature, and fallen just so far short of reaching a pictorial standard as to produce a decorative effect." This is exactly what we believe to be the case, not only in some of the Japanese work-but in many other schools; in the figure-subjects of Mediæval stained glass, for instance, where we have little doubt that the object was to produce as realistic an effect as was in the artist's power. The limitations which his powers and the exigencies of his material imposed on him led to the formation of a type of design exactly suited to the material and the circumstances, and which in succeeding times came to be regarded as representing the essential conditions of good design. A great deal of the apparently conventionalised art in the world was, we suspect, realistic art to its inventors.

It remains to say a word as to the illustrations to Mr. Cutler's book, which form by far the larger portion of it, but which, being all copies from Japanese originals, do not call for criticism on this occasion, except in regard to selection and execution. In both respects they rank very high. The selections include all the leading characteristics of Japanese ornament, conventional diaper, flower, bird, and fish subjects, designs for lacquer, &c. They are very well executed,—the majority in monochrome, a few in colour,—and do great credit to the publisher, as well as to the author's care and pains in their correct and finished execution. The book will be a useful as well as a very ornamental addition to any collector's, architect's, or decorator's library.

THE GEOLOGICAL EFFECTS OF HUMAN INDUSTRY.

THE unwonted activity which the long-observed depression of part of the surface of Cheshire has shown within the past week has been a source of danger and distress to not a few residents in that industrious county. Beneath the soil of Cheshire lie those treasures of salt on which, for the last 200 years, we have been drawing, as if they were inexhaustible. But it is not as matter of quantity alone that the labour of the salt-worker has been, in the most literal sense of the word, undermining that of the agriculturist. In rock-salt beds, as in coal beds, the miner is compelled, in self-protection, to leave pillars of the mineral that he extracts, or to supply their place by props of wood or of stone, lest the whole area of the roof of his workings should come down upon him. In abandoned workings this fall of roof is not uncommon, and a savage and squalid aspect is imparted to certain regions of "the Black Country," by reason of the descent of the earth from the very surface, to fill up the places left empty by the excavation of the thick coal-seams.

Two millions of tons of salt are now drawn annually from beneath the soil of Cheshire. As the bulk thus abstracted is about equal to twice that of the embankment across the valley of the Colne, near Watford, on the London and North-Western Railway, it is pretty clear that, sooner or later, the surface of the ground must sink. But it is not the miner, with pick and shovel, who is the real cause of the most pressing danger; it is the man who employs the apparently harmless instrumentality of the pump. Drawn up in the form of brine, the salt abstracted leaves space no less mischievous than that effected by the labour of the miner; and it has the further danger of being unknown in its

locality, as well as being unrelieved by any efforts to prop or to shore. A vast amount of solid matter is daily being removed in the form of brine, from which the water is afterwards evaporated to leave a deposit of salt. The water may be replaced from perennial supplies of rain; but the salt, once gone, is irreplaceable.

It is at Dunkirk, near Northwich, the capital of the salt-manufacturing district, that the more recent and most alarming subsidence of the ground has occurred. On the 4th inst. symptoms of unusual subsidence were observed over the site of an old and disused salt-mine, at Wilton, in the channel of a brook. A little later the movement became more active, and the accounts of the phenomena which took place recall the description of the Geysers of Iceland, or of the mud springs or mud volcanoes of volcanic districts. Water rose, as from a boiling cauldron, from the shafts of the old mine; and soft mud was thrown up for 7 ft. or 8 ft. into the air. A gradual settlement of the surface, through the whole day, produced this discharge from the shaft, which acted, not as a safety-valve, but after the fashion of those hydraulic standpipes with which the water companies have made us familiar. By dawn on the 5th of December the depression of the surface had so far advanced as to form the bed of a lake into which the water of Wincham Brook rushed like a torrent, furrowing a channel of 15 ft. in depth. As the water flowed in, the surface of the new lake rose and concealed the mischief below. About four p.m. another discharge took place from the old shaft, which can only be compared to that of an active volcano. Mud and stones were thrown up into the air to the height of 30 ft., and the surface of the earth sank another 5 ft. perpendicularly. With this movement the foundations of the neighbouring salt-works gave way, and the whole building soon after collapsed. A chimney, 90 ft. high, fell with a terrible crash. It soon became known that the Platt's Hill Rock Salt Mines, fifteen acres in extent, were flooded. The subsidence was still going on when this account was despatched. The level of the River Weaver has fallen a foot, and the brooks called the Twincham and the Flasher are still running into the new lake. The only consolation that is afforded to the sufferers is the fact that no lives have been lost. Thirty years ago a somewhat similar convulsion took place, and thirty lives were then sacrificed.

Small comfort as the reflection may afford to the sufferers, there is no doubt that this depression of the soil of Cheshire is a necessary consequence of the continuous abstraction of the salt. It is only a question of time when it may occur. The salt-miners, like the coal-miners, have to balance their accounts between wealth drawn from below and outlay caused on the surface of the soil. Even if permanent lakes are formed, they may have their utility. The great thing is so to watch the indications of movements of the kind as to prevent danger to human life. It is also obvious that none but strongly-framed wooden buildings, or iron buildings, should be erected in districts where the foundations may at any time give way.

There is, however, another consideration of great interest that is suggested by the accounts which we have above reproduced. The column of water thrown up from the old shaft is described as boiling. It is not said whether any observation was made of temperature, or whether the expression merely refers to the mixture of air, or to the violence of the eruption. But the close resemblance of the phenomena to those of a real volcanic eruption will strike all those who have witnessed the latter. If the water was actually warm, the heat may be accounted for on mechanical principles. The descent of such a body of earth must have developed a great degree of heat. The relation between gravity and heat is thus illustrated. We all know that if a mass of any solid matter falls from a great height, or is projected with great velocity (as the bolt of a gun), that the force of impact developes a high temperature. One description of bomb-shell is exploded merely by the heat developed by its concussion. But we have less acquaintance with the subject of the development of heat by pressure. This, however, we must expect sometimes to occur. And the point now before our consideration is,—to what extent may we consider that the heat that is found to increase as we descend below the surface of the earth is due to the pressure of the superincumbent mass?

We have long been accustomed to consider the earth as a body once heated to a molten state, and now gradually cooling. But we are not aware whether any physicist has attempted to investigate how far the terrestrial heat may be due to the active force of gravitation. One series of experiments made of late with reference to the heat of the St. Gothard Tunnel bears strongly on this view of the subject. If we look at the case of a permanent central fire, or source of heat, we should expect to find the terrestrial heat, as measured by the thermometer, proportioned to the distance from the earth's centre of gravity. Thus the surface-heat at the poles should be considerably greater than that at the equator. And thus a boring of 100 ft. or 200 ft. below the top of a lofty mountain should be much cooler than a boring of equal depth below the surface of a plain only slightly elevated above the level of the sea.

But such is not the law of the increase of terrestrial temperature. As far as it is yet known, it is distance, not from the earth's centre of gravity, but from its superficies, that determines the local heat. At 1,000 ft. below the summit of a hill 8,000 or 10,000 ft. high, the temperature is nearly the same as that at an equal depth below a maritime plain. It is to be observed that in sinking in a valley, the temperature increases somewhat faster than in sinking on a hill. But it is also the case that the pressure must be greater in the latter than in the former case. The latest ratio of increase of heat with depth taken from Alpine observations is 1° Fahrenheit for every 88·1 ft. of depth. We recommend the study of the relation between heat and weight to the careful attention of the physicist, and we shall be glad to publish any direct information as to the temperature of the water thrown up by the subsidence of land in Cheshire.

ROMAN REMAINS AT BRADING, ISLE OF WIGHT.

ROYAL INSTITUTE OF BRITISH ARCHITECTS.

At the fourth ordinary general meeting of this Institute for the present session, held on Monday evening last, Mr. John Whichcord, F.S.A., President, in the chair, a report of the Executive Committee (Mr. John E. Price, F.S.A., and Mr. F. G. Hilton Price, F.G.S.) for the Brading excavations was read by Mr. Hilton Price. The report described the position in which the remains have been found as a remarkably fine one, situate partly on the property of Lady Oglander and partly on that of Mrs. Munns. The first part of the remains was discovered by Captain Thorp, of Yarbridge, in April last. The present excavations originated in the finding on Mrs. Munn's property such indications of Roman buildings as offered encouragement for further investigation. While fixing hurdles upon this land, walls, roof-tiles, and traces of pavement were discovered, whereupon Captain Thorp devoted considerable energy and zeal to the more complete examination of the ground. It was subsequently suggested that, in order thoroughly to explore and ascertain the full extent and nature of the buildings, excavations should be commenced on the land belonging to Lady Oglander. With the introduction of their veteran colleague Mr. C. Roach Smith (himself a native of the island), and his relative Mr. F. Roach, of Arreton, Lady Oglander kindly accorded the Committee permission to excavate. The work commenced in August last. In the description of the various chambers (of which a plan was exhibited), the Committee had affixed to each a number by which it might *pro tem.* be known, as in the present state of the excavations they thought it premature to assign any particular name or use to the respective apartments.

Chamber No. 1 measured 18 ft. by 10 ft. 6 in.; the walls on the outside were 27 in. thick, the division walls between rooms No. 2 and No. 4 being 18 in. thick. There were five flue-tiles *in situ* in the chamber, on the east and south walls; the first one was 5 ft. 3 in. from the north-eastern corner; at 5 ft. 3 in. from the first was another; the next was 6 ft. further away; the next 4 ft. and the last 4 ft. 6 in. The flue tiles were 16 in. high and 4 in. broad. In the north-west corner, 2 ft. 6 in. from the wall, were the remains of an arch, composed of flat tiles, and the entrance was 2 ft. in width. There was no pavement in this apartment. In the chamber, fragments of black pottery, of New Forest ware; many broken flue tiles; some well-faced stones, some in the form of arch stones; iron spikes and small nails, roofing slabs made of Bembridge stone, with nails in them, and other articles, were met with.

Chamber No 2 was a square chamber measuring 20 ft., paved with grey marl tesseræ, and the walls were 2 ft. thick.

Chamber No. 3 measured 15 ft. 6 in. by 17 ft. 6 in.; the ornamental centre was 9 ft. by 10 ft. 6 in., and the margins of the pavement were chequered. In this room were found fragments of wall plaster with fresco, pieces of black pottery (Samian), broken flue tiles, and other things. Fully 20 ft. of the wall on the north-east corner were wanting. The pavement presented some novelties as regarded the subjects. It was square; on the western side were two gladiators—one with a trident, the other with a net—in combat. On the north side was a fox under a tree, probably intended for a vine. A building with a cupola completed that side. On the south side, in front of a pair of steps, was a man with the head and legs of a cock; on his right hand were two griffins. In the centre was the head of Bacchus or of a Bacchante, and similar figures occupied two of the angles.

Chamber No. 4, from the entrance to the arch on the south to the pier on the north side, was 11 ft. 8 in. by 10 ft. 6 in. in width. There was no pavement in it, but at the entrance to the arch a mass of plaster material, similar to that in which the tesseræ were laid, was found; when rubbed between the fingers it was quite soft, becoming hard upon exposure to the atmosphere. In the north corner of the room was a pier of masonry 2 ft. square and 2 ft. 6 in. high; upon the top of this the base of a pillar of greensand was found; a number of pieces of black pottery, flue tiles, an iron hinge, and a large number of stone roofing slabs and vitrified stones, were also here found.

Chamber No. 5 was a long narrow room, measuring 7 ft. 6 in. in width by 20 ft. in length, paved with inch grey marl tesseræ. The chamber communicated with No. 6 by means of a passage at the east end, 4 ft. 9 in. wide. The walls were about 18 in. thick. Many fragments of wall plaster with fresco were dug out of this chamber.

Chamber No. 6 appeared to be one long apartment, because the length from the border of the pavement described in room No. 3 to the margin of the representation of Orpheus, corresponded with the length of the other side of this mosaic to the wall of the Medusa room; these dimensions were 21 ft. 10 in. respectively. The representation on the floor of Orphens was 7 ft. 6 in. wide by 8 ft. 6 in. broad, with a well-executed border of the guilloche pattern 1 ft. wide. Orpheus was represented playing on his lyre, and wearing the Phrygian cap and flowing *pallium* or cloak; attracted by his music were animals and birds, suggesting the examples found at Woodchester, Winterton, Lincoln, and at other places. But the peculiarity of the pavement at Brading was the figure of a monkey placed near to the left shoulder of Orpheus; the monkey wore a red cap. The remainder of the chamber was paved in large red and white tesseræ in a chequered pattern. Beneath the pavement was a subway, which was covered with flat slabs of native tertiary limestone. It was 6 ft. 8 in. long, 2 ft. wide, and 3 ft. 2 in. deep; the stones forming it were of various dimensions, but corresponded in thickness, which was 8 in. The subway evidently had something to do with the heating apparatus for chambers Nos. 9 and 12, as both those chambers had suspended floors. The greater part of the wall on the eastern side of the chamber was wanting, and on the western side the wall was composed of rubble and irregularly-sized stones; just above the floor-line was a string-course of stone slabs, instead of bonding tiles. During the excavation of the chamber a considerable quantity of pottery, mostly coarse, of the variety known as Upchurch ware, was collected, but not sufficient to make up any vessel; also some pieces of a fine red ware, a sort of pseudo Samian, ornamented with incised figures of crescents, &c., of precisely the same kind as had been met with in Barge-yard, London, in Uriconium, and at Richborough. In this room and in No. 7 were a number of pieces of a large vessel, made of what resembled Portland cement, nearly ¾ in. in thickness, the inside being marked with the impress of the potter's fingers or thumbs all over. It was probably a mortarium. Some pieces of plaster with fresco upon them were picked up on the south side of the chamber, one piece 11 in. long by 6 in., representing a group of fruit in a circular medallion on straw-coloured

ground; another having a coloured bird of the parrot family, 10½ in. long, with a margin of red and white stripes 4 in. broad.

Chamber No. 7 was intersected by the boundary line dividing Lady Oglander's property from that of Mrs. Munns, and was 20 ft. square. It was paved in squares of red and white inch tesseræ, much injured by fire. The wall separating this chamber from No. 9 was much decayed, the mortar being quite rotten, but the marks of the foundation were plainly visible.

Chamber No. 8 was apparently a square, measuring about 20 ft. by 21 ft., containing no tesseræ nor concrete floor; near the hedge or boundary line was a circular structure, 4 ft. 6 in. in diameter, formed of slabs of Bembridge stone, and coated inside with salmon-coloured mortar. At the bottom were indications of fire, in such quantity as to suggest that the place was used as a furnace or oven. The committee had not been able to explore the whole of this structure, as it ran beneath the bank and hedge. The boundary-wall on the west side was nearly 3 ft. in thickness,—a circumstance which led the committee to think that it might have been an external wall, as its thickness was so much greater than that of other walls of the buildings. There was an opening into Chamber No. 10, 3 ft. 6 in. wide.

Chamber No. 9 was 19 ft. 9 in. square; the bordering was of the usual 1 in. red and white tesseræ; in the centre was a square measuring 5 ft. 10 in., enclosing a diamond-shaped figure, with a central medallion of parti-coloured tesseræ. There was a good deal of plaster or stucco still standing upon the walls to the north and west, displaying scroll patterns of dull colours much faded.

Chamber No. 10 measured 11 ft. 6 in. by 10 ft. 5 in.; the walls were 1 ft. 9 in. in thickness. It had a raised ledge or seat on the west side, 6 in. high by 1 ft. wide, covered over with red plaster, and on the north side was another similar ledge 2 ft. 6 in. wide. Upon the floor were, *in situ*, a considerable number of flat red tiles, 1 ft. 2½ in. by 11¾ in. No tesseræ were found upon this floor.

Chamber No. 11.—This was 15 ft. by 5 ft. The walls were from 1 ft. 6 in. by 1 ft. 9 in. high, and the chamber was paved with rough concrete.

Chamber No. 12 was the largest room yet met with on the site; its dimensions from east to west were 39 ft. 6 in. by 19 ft. in the western portion, and 15 ft. 6 in. in the eastern portion, and 11 ft. between the piers in the centre. The pavements in this chamber were remarkable. At the west end the mosaic pavement was almost square, its dimensions being 13 ft. 6 in. by 13 ft. 10 in., divided into compartments edged with the guilloche border in ¼-in. tesseræ of white, black, and red. The design might be described as in three divisions, with a central circular medallion also bordered by the guilloche, but the subject was destroyed; sufficient, however, remained to show that it contained a similar building to that already referred to as being found depicted in the pavement of Chamber No. 3. Upon either side were oblong panels containing mythological subjects, and at the corners were semicircles enclosed in compartments; these were occupied, with the exception of one which had perished, by busts in illustration of the Four Seasons,—the missing one from the north-west corner being probably Spring. The centre of the pavement was much injured, but sufficient remained to show that the central design was contained in a circular medallion, bordered with the guilloche pattern. Around the medallion were four oblong panels, placed between the angles containing the seasons. These probably represented mythological subjects, because in the one which was tolerably well preserved appeared figures which might be recognised as Persens and Andromeda. The eastern division of the chamber contained the largest and most important of the mosaics yet found. In the centre was a large medallion containing the head of Medusa, such as occurred both at Bignor and Bramdean. Springing from the centre were four compartments, arranged cross-wise; each of these was bordered by the guilloche pattern. At the angles north, south, east, and west were triangular compartments representing figures of bucolics blowing the *buccina*, or neat herd's horn; on their heads was the *petasus* of Mercury, and over their left shoulder was a *pallium*, or cloak. The whole of this apartment was bordered with inch red tesseræ, which contained a fret pattern laid in white, terminating at the head of the chamber in a figure of a *swastika*, or Vedic cross. The presence of this symbol upon Roman monuments had been noted upon remains previously discovered in Britain. A large quantity of plaster off the walls or ceiling was lying face downwards upon the pavement, and some of the colours on it were very bright, but none indicated any special design. There was a fair amount of plaster still adhering to the walls of the room, with fresco painting upon it representing scrolls in dull colours. The explorers also found some plaster roundels for inlaying in the wall.

Chamber No. 13 was a singular structure, consisting of rough stones, and measuring 7 ft. 9 in. long by 3 ft. 10 in. broad, and about 2 ft. deep, paved with large red tiles, similar to those found on the floor of Chamber No. 10. This structure extended on the east or seawards side, where the wall projected fully 18 in. It had been coated inside with salmon-tinted mortar, and on the east side of the compartment a wall had been inserted, which was found to be a continuation of the main wall running northwards. This addition was built of rougher masonry and common, badly-made mortar, indicating a later date. Various usages had been assigned to the chamber, amongst other suggestions being one that it was a bath; but as yet no indication of a pipe had been met with, which would probably have been the case had it been used for that purpose.

Chamber No. 14, which measured 15 ft. 4 in. by 10 ft. 2 in., had a concrete floor; the walls were low, and in certain parts the plaster still remained on the wall, which was of a dull blue colour, splashed with red and black in imitation of marble. The stucco which was dug up from off the floor, lying face downwards, as was the case throughout, was of very bright colours, but none of the fragments denoted any subjects.

Chamber No. 15 was a hypocaust, of great interest. The chamber measured 15 ft. 2 in. north and south, and 10 ft. 7 in. east and west. It contained fifty-four pillars of tiles arranged upon a floor of rough cobble stones; a large tile was placed upon the floor to carry the others, which were 8 in. square and 1 in. thick, with mortar joints 1 in. in thickness. These pillars were 2 ft. 6 in. in height, and consisted of about thirteen tiles each. On the east side of the wall were two flue-tiles *in situ*, 16 in. in length, joined together, thus making a flue of 32 in. leading to the upper portion of the room, and another on the north side. On the west side and in the southern corner was a neatly-turned arch of large flat tiles, with wide mortar joints; at the mouth of this arch a large stone of massive masonry was found placed across it. This arch might have led to the furnace on the outer side of the wall of the chamber.

Chamber No. 16 measured 17 ft. 3 in. long by 10 ft. 7 in. broad. The walls were covered originally with a red stucco, some of which still remained in patches; the floor was of concrete. A large number of flat roof slabs, 18 in. by 12 in., many with nails in them, were found amongst the *débris*, likewise a number of fragments of Durobrivian pottery, and two Samian bowls. Many worked stones were taken out of this chamber. A mortarium made of limestone, 2 in. in height and 6 in. in diameter, was found there; it had only one projection, which formed either a handle or an ornament, though it must originally have had three of them.

Chamber No. 17 was found to be 19 ft. 5 in. long from east to west, by 10 ft. 3 in. wide. The floor was composed of concrete, and the walls, which were now only about 2 ft. high, were covered with stucco, a small quantity of which still remained, the colour being a dull blue splashed with red and black. The chamber communicated with No. 18 by a stone step 1 ft. high and 2 ft. broad, situated about the middle of the wall. In the work of clearing out the fallen *débris*, several large nails or spikes varying in size from 10 in. to 13 in. were thrown out; in several instances these large spikes were removed from the tops of the walls, where they were lying in horizontal positions. The chamber was chiefly remarkable for the large quantity of window-glass it contained. The glass was of various colours, some bluish-green and some a drab colour; upon one side it was smooth and polished, while upon the other it was rough, like ground glass. The thickness of the largest pieces varied from one-eighth to a quarter of an inch. The largest piece of window-glass exhumed was 7¾ in. in length by 4 in. in width, of a brownish-white colour, and one-eighth of an inch in thickness, with a rounded selvage edge; the next largest fragment was a piece of green glass, which was three-sixteenths of an inch in thickness and 6 in. long by 3 in. in width. The explorers also met with bluish-green and yellowish-green glass, and one piece was a quarter of an inch thick near the selvage edge. One fragment had two outer edges rounded, and this might possibly afford a clue as to the manner in which the sheets were cast for fitting into the window-frames.

Chamber No. 18 measured 21 ft. 6 in. from north to south, and 18 ft. 6 in. from east to west; the floor was of concrete, with a red fillet round the margin of the wall. The stucco was still remaining in parts, and exhibited colouring of a dull blue ground, splashed with red and black in imitation of marbling, as was the case with chambers Nos. 17 and 14, and also at the Roman villa discovered at Aldborough, Yorkshire.

Chamber No. 19, which had not yet been excavated, measured 9 ft. by 10 ft. Walls had been traced for at least 100 ft. east of this chamber, disclosing many other apartments, but that area had yet to be systematically excavated. In conclusion, the Committee stated it to be their intention to recommence active operations early in the spring. By the time they were in a position to publish a second report they might be able, with the assistance of architects and antiquaries, to assign uses if not names for the various apartments.

The President, in inviting discussion, said he was sure that the meeting had heard with great satisfaction and interest the report which Mr. Hilton Price had read. He had much pleasure in introducing to the meeting another Mr. Price, a gentleman who, though not related to the reader of the paper, had been associated with him from the first in his researches. It was quite certain that the work could not be in better hands.

Mr. John E. Price, F.S.A., said it would have been apparent to all who had done him and his colleague the honour to listen to the report, that they had purposely abstained from making it other than a report to the Institute. The writers had felt that it was not within their province to go at length either into the topography of the district, or into the Roman occupation of the Isle of Wight. Perhaps the most interesting point of the whole matter was that the district near Brading should be found to abound in Roman remains. So little was known of the Roman occupation of the island, that the discovery of these remains at Brading was of exceptional interest. It was not until the present century that any trace of the Roman occupation of the island was discovered, although the information to be derived from ancient authors as to such occupation was very precise. Vespasian, in the reign of Claudius, was engaged in Germany with the Second Legion, when he was summoned by Claudius to go over and assist in the occupation of Britain; and it was on record that, after subduing Dorsetshire and Hampshire, he occupied the Isle of Wight. The committee hoped, therefore, that as the work proceeded they would succeed in finding some record of the Second Legion. Sir Henry Englefield, in his book, had stated that there was no trace of the Roman occupation to be found in the island; and it was not until 1859 that Mr. George Hillier was able to record the discovery of some Roman work in the grounds of the vicarage at Carisbrooke. With regard to the remains now laid bare at Brading, the executive committee were unable to identify the several chambers with the specific purposes for which they were used. In 1862, during the excavations for the Cowes and Newport Railway, some Roman remains were found; and in 1867 Mr. Roach Smith reported the discovery of further remains. In 1864 the discovery was made of some Roman buildings in Gurnard Bay, which curiously resembled those found at Brading. Among the things found in Gurnard Bay were merchants' marks made of lead and stamped with Roman devices, some coins of Vespasian, and others of the age of the Antonines. At Bonchurch, Shanklin, and Freshwater, Roman coins and other remains had been found. At high water Brading Haven had all the appearance of a lake. Many attempts had been made to reclaim that valuable tract of low-lying shore, but without avail. Captain Thorp was under the impression that he had discovered an ancient ford across it, and if so it would probably be found to have some con-

nexion with Centurion's Copse,—a name suggestive of military occupation. The remains at Brading were found in two fields, respectively known as the ten-acre field and the seven-acre field, both constituting such a slope of cultivated ground as would at once have commended itself to the attention of the Roman architects, whose text books contained important counsels as to the selection of sites. The walls found at Brading averaged from 3 ft. to 4 ft. high; there were none higher than 4 ft. The pavements found were constructed of tesseræ, made of native stones found on the spot,—taken from the sea-shore; and every kind of stone used for that purpose at Brading by the Romans could now be picked up in Sandown Bay or off Bembridge Ledge. With regard to the design of the pavements, too much stress was sometimes laid on the fancied motives of the *tesselarii* or makers of Roman tesselated pavements, and it was never safe to be too positive in assigning the subject of or in asserting a particular scene to be depicted on such pavements, because the men employed in the work seemed in many cases to have worked very much at random. But, nevertheless, the pavements found at Brading bore a significance that could not be mistaken, —the mythological character of their design could not be gainsaid. In conclusion, Mr. Price said the committee owed great thanks to Lady Oglander for the kind manner in which she had given permission to excavate on her land.

Major Leeds, the chairman of the committee, said that, as representing the persons locally interested in the remains, he was able to state that they were most anxious to render every possible help to architects and antiquaries who might desire to scientifically survey and explore the remains which had been found. Unfortunately there were difficulties involved in the fact that the remains had been found existing on two properties, but he hoped that arrangements would be made whereby the whole area of the buildings,—for he thought they must not merely consider the remains as simply those of a villa,—could be opened out at once. Lady Oglander was willing, and, indeed, desirous, to help in every possible way. Those locally interested felt that they owed great thanks to the Messrs. Price and to the learned societies who had assisted them, and they were very grateful to the Royal Institute of British Architects for placing their rooms at the disposal of the committee.

Mr. E. W. Brabrook, F.S.A., said that so much had been said with regard to the remains from an antiquarian point of view that he should be glad to hear what the members of the Royal Institute of British Architects had to say, and to reserve his remarks for a future occasion; for he trusted that it was not too late to hope that the matter would be fully discussed from an antiquarian point of view in another place. Messrs. Price were deserving of thanks for the manner in which they had conducted the excavations, one important lesson to be learnt from which was as to the necessity of pursuing them to the end. It appeared to him that there was a great deal more to be discovered at Brading, and it was to be hoped that the Messrs. Price would be assisted and encouraged in pursuing their explorations until they had ascertained the whole extent of the undiscovered remains which lay between what had been excavated and the seashore.

Dr. Lewis asked at what depth below the surface the Brading remains had been discovered, and as to the nature of the superincumbent soil. He and others who had had more or less experience in investigating Roman remains in this country knew that they were generally found a considerable number of feet below the surface,—from 16 ft. to 18 ft.

Mr. F. C. Penrose said that he had not pursued the subject of the domestic architecture of the Romans, and so could not enter into a detailed discussion of the paper. He would, therefore, confine his remarks to the marvellous specimens of glass which were exhibited as having been found at Brading. In Italy, as far as he remembered,—at Pompeii and elsewhere, window glass had not been found in connexion with Roman remains, doubtless because it was not needed in that climate. It had, in consequence, been tacitly assumed that the introduction of glass for windows was a mediæval or Gothic invention, and that the Roman occupants of Britain, and even the Normans, were unacquainted with glass in windows. In the pieces found at Brading, however, evidence was afforded of the use of glass in sheets of really respectable dimensions by the Romans in Britain. He should be glad to know from those who had followed up the subject of Roman antiquities in Britain whether glass had been found in other places. Some of the glass exhibited was very pellucid and of very fine colour. The remarkable preservation of the iron spikes and nails exhibited was very noteworthy.

Mr. G. H. Birch said it struck him that there was a great similarity between the remains found at Brading and those of the Roman villa at Lyme Regis.

Mr. T. Chatfeild Clarke and Mr. E. C. Robins having made a few remarks,

Mr. J. G. Waller, F.S.A., referred to the singular emblem known as the Swastika, mentioned in the report as having been found in the decorations of the Roman buildings at Brading. He said he believed he was the first person who gave it that name,—now forty years ago, getting his information about it from the papers of the Asiatic Society. The late Mr. Albert Way and himself had happened to light upon the English word for it in the same week. It occurred in one of the Harleian MSS. in the course of a few rough notes made by a gentleman for the execution of a window as a memorial of himself and his wife. The Swastika was a religious emblem amongst the Buddhists,—indeed, he believed it was the earliest religious symbol of which we had any evidence. Dr. Schliemann had found it in his excavations at Hissarlik, and had said a great deal about it, on the authority of a writer who was not to be too implicitly trusted. After all, very little was known about it, except that it was one of the most ancient, if not *the* most ancient, religious symbol of which there existed any sort of record.

Mr. Alma Tadema, R.A., said that Mr. Penrose would be interested in learning of the existence, in a museum in Rome, of two bronze frames, measuring about 2 ft. by 2 ft. 6 in., in one of which pieces of window-glass still remained. He was unable to enter more fully into the discussion, but he wished the excavators much luck.

Colonel Prendergast asked whether Mr. Price had come to any conclusion with regard to the cause of the destruction of the buildings at Brading? One curious fact was mentioned in the paper, viz., that all the plaster covered with fresco painting was found with its face downwards.

Mr. C. F. Hayward, F.S.A., with regard to the depth at which Roman remains were generally found, said that at Colchester Roman coins and other vestiges of the Roman occupation, such as ornerary urns, and even stone monuments, had been found very near the surface. Within the last few years there had been discovered there a figure of a centurion, in very high relief. The Roman walls found at Colchester were, it was to be observed, composed of a concrete made with septaria, dredged up at Harwich and in its vicinity. There was no stone whatever in the neighbourhood.

Mr. Nicholl asked whether the plaster or fine concrete floor mentioned as having been found at Brading was decorated with colour.

Mr. Hilton Price, in replying on the discussion, said that the remains at Brading were found at an average depth of 3 ft. or 4 ft.,—in some places at a rather less depth. The tops of the walls were about 18 in. beneath the surface of the ground. The pavements were about 3 ft. deep in parts,—in some places a little more. Mr. Penrose had asked whether window-glass had been found in connexion with Roman remains elsewhere in England. Yes: there were records of its having been found at Uriconium, and at one or two other places. Some of the fragments of window-glass found at Uriconium had mortar adhering to the outer edges, leading to the supposition that the glass was fixed into the window openings by means of mortar. Mr. Roach Smith, he should add, in a letter just written, stated that he had found window-glass in Roman remains at a great many places in England. As to the cause of the destruction of the buildings, there was, he thought, no doubt that they were pillaged after the Roman legion left the island, and were then destroyed by fire; for traces of fire were evident throughout, and many of the objects recovered were very much charred. The floors which were not covered with mosaic pavements were covered with a kind of fine concrete or plaster, but he could not say whether they had been decorated in colour. The plaster fillets round the walls were certainly coloured red, and splashed with black and other colours to resemble marble. One very curious point with regard to the glass, which had been analysed, was worth noting,—namely, that lead was wholly absent from it. The total dimensions of the buildings now uncovered were 200 ft. from north to south, and about the same distance from east to west.

The Chairman, in closing the discussion, said it might be expected, after receiving so interesting a communication as that which had been read, and especially as the meeting had the honour to be graced by the presence of so many ladies, that he should from that chair sum up the discussion. He should not attempt to do so, however, simply because any remarks emanating from him would be taken to represent the views of the body of the members. They as architects felt very great interest in discoveries of the kind described in the report, and they would endeavour, when the full facts were discovered,—as they could not be until the excavations were completed,—to pronounce upon the character of the buildings of which the remains had been described, and which buildings appeared to be only a fragment of a whole. It would be premature, with the comparatively limited discoveries which had been made, to attempt to pronounce definitely as to the uses and purposes of all the different apartments of which the remains had been found. It was better to take due time and care in arriving at conclusions. Many years ago now, when the first discoveries were made in Pompeii, there was issued one of the most charming books that had ever passed from the press. He alluded to Sir William Gell's work on Pompeii. Sir William was so fortunate as to be associated with a number of very eminent local antiquaries, and he was able, in the time he devoted to the preparation of his work, and by the care which he exercised in analysing the various discoveries from day to day, to propound theories and to indicate the uses to which the different apartments and buildings had been put. He believed that up to the present day the accuracy of the descriptions of Sir William Gell had never been challenged. Without attempting to compare the remains found at Brading with the imperial treasures found at Pompeii, he was bound to say that the character of the former seemed to be exceptionally important, regard being had to the size of the apartments and the character of the pavements and other objects disinterred. It was very probable, he thought, that further excavations would lead to infinitely greater results. It appeared to him that the work could not be in more diligent and careful hands than in those of the Messrs. Price, whom he assured that the Institute would receive with very great satisfaction any further facts that they might bring to light; and he hoped that when the matter was again discussed in that room, the members of the architectural profession would be in possession of sufficient data to enable them to speak authoritatively as to the plan and uses of the buildings. He concluded by formally moving a vote of thanks to Messrs. Price for their interesting communication.

This was carried by acclamation, and Mr. John E. Price having briefly responded, the proceedings terminated with the announcement that the next meeting would be held on Monday, January 3rd, 1881.

SPECIALISM IN THE BUILDING TRADE.

The tendency towards the acquisition of an exact knowledge of things, which is one of the prevailing characteristics of the present day, has already had the effect of altering the status and traditions not only of professions, but of trades as well. In the majority of employments, whether they embrace mental labour or handicraft, the ever-increasing call for division of labour has rendered specialism not only a prevailing feature of competition, but an almost necessary condition of success.

Whether or not this tendency is on the whole of advantage to the individual, as regards his power to grasp the general features of a problem connected with his particular profession, is a matter open to great doubt. Every now and then cases occur in which capitalists would be glad to have the advice and assistance of an "all-round man." Even in Medicine, where specialism may be looked upon as having to some extent found its level, and in which the divisions of labour are defined with considerable accuracy, there is often a difficulty on the part of a suffering layman as to whom he should

apply. The bodily organs are so interdependent upon each other that a specialist in derangements of one kind may possibly be found to treat his patient at the sacrifice of what the specialist in another department might consider to be essential to the recovery of health. It is not unfrequently one hears the remark,—"Ah! poor fellow, he went to the wrong man; if he had gone to so-and-so, he would, no doubt, have pulled him through." And this difficulty of whom to apply to is by no means confined to the profession of Medicine. We have already referred to the capitalist as being sometimes in a similar dilemma. Frequently the successful employment of money depends upon the solution of problems in which the judgment of a specialist is of little value. Cases occur in which investments that promised well at the outset are in imminent danger of missing the mark, on account of the unexpected appearance of difficulties that did not suggest themselves at the beginning. Hence, as in the case of men suffering from obscure ailments, it becomes necessary to inquire what kind of specialist should be employed, and often there is no answer to be obtained. Then it is that the "all-round man," who has been so nearly improved out of existence, is wanted, and cannot be discovered.

An engineer, like Smeaton, who could build a lighthouse or construct a windmill, would be a tolerably safe adviser in matters of engineering generally, but if he lived to-day he would have little chance of making a competence out of a reputation that embraced so wide a range of capacity. The occasions on which his advice would be paid for would be few and far between, unless he confined himself to some limited department of his profession, and his ability to advise his clients generally in matters requiring a strong grasp of the salient features of a difficulty would nowadays be scarcely a marketable commodity. Even if such another genius as George Stephenson were to arise amongst us, it would not be enough that he should confine himself to being a railway-engineer. We do not think we are far wrong in saying that if he were to choose the path that would bring him nowadays to the greatest amount of wealth, and even of reputation, it would be one that was narrowed to limits which were never even contemplated at the time he lived.

The consequence of an absence of any demand for the class of men of which Smeaton and George Stephenson were types, unless they consent to become specialists, has led very materially to a falling off in the supply. We know of cases in which the directors of great commercial enterprises have had to fall back upon the services of retired veterans who were trained under the broader system which is now practically extinct when they required the sort of advice which a specialist, by his very training, is frequently unable to give.

In the midst of all this general tendency towards specialism, which it is unnecessary to say is going on even more among trades than in professions, it is interesting to consider the case of one large industry which, in London at any rate, remains practically unaffected by it. We need hardly say that we refer to the building trade. As a short inquiry into the causes and conditions of this industrial anachronism cannot fail to be of interest to many of our readers, we make no apology for speaking of the matter at some little length.

Of course, we do not refer, in the remarks we are about to make, to those great contractors connected with the building trade who are in the habit of taking large contracts, and letting them out among specialists; nor to work in the hands of architects who insist upon its being subdivided among experts, as is invariably done in Scotland. It is the typical London builder of whom we wish to speak,—the man who calls himself a builder in the same way that a tailor or a bootmaker puts up his sign and looks for business, and yet who, unlike those tradesmen who stick to the specialty of cloth and leather, combines half a dozen trades in one by professing to overtake all the handicrafts that appertain to the construction of a dwelling-place. Viewed in this light, the builders we speak of may be looked upon as almost isolated examples of tradesmen who remain unaffected by the conditions which seem almost essential to success in every other industry we can think of. The men who build houses for the living are scarcely less affected by the prevailing system of division of labour, at least in London, than those who build houses for the dead. Masonry, bricklaying, plastering, painting, plumbing,—all are embraced under the superscription of a single signboard, and the advertisements in the newspapers from workmen in search of employment show how much the example of the masters has been followed by the men, and how important it is for a skilled tradesman to be what is known as a "handy man."

It is probably to this element of handiness that we owe the existence and continuance of the system. It is handy not only for the architect, but for the householder as well. As a rule, persons in London who wish to build a house fall in with the prevailing traditions of the building trade, and do not trouble themselves to consider the complexity of the appliances that are necessary in order to make it wholesome and comfortable. They do not think that it is necessary for them to have some guarantee that the different classes of work should be done by different classes of men. They do not notice that the system is directly opposed to the principles of specialism which have led to the perfecting and developing of other industries. The convenience of the prevailing method seems to cover its defects. It avoids trouble, and simplifies the business character of a building transaction. It concentrates the responsibilities of breach of contract or insufficiency of workmanship. It avoids the mutual recriminations of different tradesmen, and above all, it is the tradition of a highly conservative community.

In other parts of the country, notably in Scotland, division of labour has long been the rule, and not the exception. Nothing can strike the eye of a North British builder as a greater contrast between the system he has been accustomed to and the one prevalent in England than the simple record of one man's name in connexion with the construction of buildings in England. In Scotland one name would appear in connexion with the masonry, another with the plaster work, another with the painting, another with the plumber work, and so on. It is not, therefore, an unnatural question to ask, will the Scotch system, so consonant with the prevailing tendencies of the present day, spread to England, or will the present English system take root in Scotland?

As matters stand, there is much to be said on both sides. On the whole we believe it is generally admitted that the building in Scotland is superior to that in England. The system of land tenure, under which a man there builds for his remotest posterity without the fear of disturbance on the part of the superior, encourages the habit of constructing substantial houses. Saving in repairs is generally looked upon as more than a set-off against the additional outlay required for extra good workmanship and materials at the beginning. Moreover, there is a natural advantage over the great majority of building areas in England in the excellent quality and abundance of sandstone. Still, this does not by any means justify the supposition that there are not as good buildings in England as in Scotland, or that for one who is willing to give a good price, as thoroughly first-rate buildings cannot be had in London as elsewhere. We are rather inclined to go further, and say that the best workmanship in the world may be found in London. But having said this, we are by no means sure that we are justified in attributing the absence of specialism in the business of building contracts as the cause of the excellence referred to. We are inclined to think that in the majority of cases in which the credit of our national workmanship has been prominently maintained, the element of special contracts has prevailed; and we know very well how enormous is the amount of bad work done under the present mode.

Without going into the merits of the rival systems, it must be a subject of interest to many to inquire as to whether the plan at present in vogue in London is likely to last. Have the little Smeatons and George Stephensons of the building trade to continue, or are they to be swept away among the things of the past? Are people to continue to act with regard to their houses as their fathers were accustomed to do in matters affecting their health? Will they go on consulting the local builder about everything relating to their houses, from the drains to the gas-pipes, as the old-fashioned physician was consulted about everything connected with the ailments of his patients? or will specialism step in and change the aspect of the trade? Of the "handiness" of the present system there can be no manner of doubt. Even architects, whose business it is to know intimately the best method of doing every kind of work, are fain to confess to the great convenience of the prevailing system. The strange incongruities of a builder's yard have failed as yet to strike them as a great anachronism. Doubts have already been cast for some time on the advisability of being tempted to take the sign of a few pieces of wall-paper hung as a background to familiar sanitary appliances in the windows of the front shop as an indication that the general run of builders can be trusted in the matter of artistic decoration.

In this department a decided change has already taken place. The contract between the work of specialists in the province of house decoration and the notions of men whose attention is divided among half a dozen trades at once is already too great to admit of comparison. But we do not quote this case in disparagement of the typical builder, but only as an indication of how matters are likely to go with him. The convenience to architects and to the average householder of the present state of the trade is evident enough. The training of a really good builder in London is not unlike that of an old-fashioned journeyman engineer, who could turn his hand to everything, and whose rapid disappearance is generally deplored; but it seems to us impossible that he can long retain his present position. On the one hand the art of the decorator has gone into the hands of specialists, and, on the other, some architects seem already inclined (unfortunately for architects) to divide their work with the sanitary engineer, who, on his side, is beginning to demand the services of workmen who have been specially trained. Already, then, a process of disintegration is setting in, and in spite of much that is to be said for the present system and for the abilities of the men who are connected with it, there is every prospect of its being replaced by another that is more consonant with modern tendencies. For a long time the change may not appear on the surface. Builders will probably continue to carry out the entire contract of house-building, even after they have been forced into subdividing the work among subcontractors who are specialists. These specialists will no doubt sooner or later assert themselves, and just as we have come to have men celebrated in decoration, so, before long, we shall find other niches occupied by experts in the different branches of house-building, until perhaps before very long something approaching to the system in North Britain, and which formerly prevailed in England, has become almost universally prevalent.

THE PANAMA CANAL.

THE gigantic enterprise of M. de Lesseps, which seemed at one time a project impossible of realisation, is now actually taking form and position. Against every kind of moral and material difficulty, and through adverse opinion, M. de Lesseps has fought his way till the scheme of the Panama Canal is in train to become a *fait accompli*.

Before we come to the project itself, a few words about Panama from one who paid a short visit there may not be without interest, and serve to bring before the mind's eye a spot that will soon be the scene of one of the greatest engineering enterprises of any age or time.

"Twenty-four hours are more than enough," says this somewhat *blasé* traveller, "to know Panama. It is an indolent-looking spot, bathed by the waves of the Pacific, and yet seems by its geographical position destined to become the *entrepôt* of the commerce of the two hemispheres. Breezes are rare, so rare that the legend runs, Pizarro tacked about for sixty-six days before gaining the open sea. However, that may have been partly the fault of the ships in those days. The little islands one can see from Panama have a pretty appearance. One of them, Taboga, produces pineapples of the finest sort; further off you see the Archipelago of Pearls, but, notwithstanding the name, at the present time, not more than two or three pearls of any value are found in a year.

Panama is an old Spanish town, but it has become so cosmopolitan that the ramparts and churches alone reveal its origin. Almost every one there can speak Spanish, English, and French. Many of the churches are falling in ruins, but they are picturesque, and the crumbling ramparts serve as a promenade, where, at the end of the day, one tries to get a

hreath of fresh hreezy air after the intense heat is over. Panama has neither park nor theatre, nor any particular gaieties going on in the town, as it is merely a passage; and the passengers hardly leave the grand hotel during the three or four days they spend there, though English travellers always meet with great hospitality from one of the chief families of the place, the Messrs. Hurtado, whose father was for many years Minister Plenipotentiary at the Court of St. James's."

The railway which unites Panama to Colon traverses a forest principally of hrushwood. At some points the rails are literally on shifting and muddy ground, and travellers crossing these damp marshes often suffer from fever. The labour in laying down the rails was so excessive that, one morning, seven Chinamen, with that calm peculiar to the organisation of the children of the Celestial Empire, hanged themselves in company, on the same tree, sooner than continue their portion of the work. The railway-fare is very high, and the transit of merchandise ruinous. If once the canal is made through the isthmus, all this will change.

Colon (Aspinwall, Naos, Naoz, or Limon, for it owns all these names) is built on marshes. Every house seems to possess a little swamp before it, just as we would have a garden. However, the American quarter, built near the sea-shore, is more salubrious, as it receives the breezes from the north. The railway-station is adorned with a good statue of Christopher Columbus, the only monument one can cite; for if Panama is only a large hotel, Colon is only a railway-station.

One can understand from this description how, when French and English travellers desirous of attaining the coast of the Pacific have reached Panama, they have anathematised that tongue of earth, not twenty leagues in width, which has forced them to go hy Sonth America; thns adding 3,500 leagnes to their journey, and making it last three months longer, with all its added chances of disasters hoth to seamen and shipowners.

It was France who bestowed the first serious attentiou on this snhject, in 1843, when Mr. Garella, chief enginer of mines, was sent to Panama. He proposed to open a canal from the port of Panama to the Gulf of Limon, capahle of allowing a passage to the largest vessels. The difficulties the scheme of the Isthmus of Suez met with will make it nnderstood that this idea mst with but little support outside the engineering world; but the astouishing success of the communication between the Red Sea and the Mediterranean hrought the subject once more prominently hefore the public.

M. de Lesseps asked for an international congress, nnder the auspices of the French Geographical Society. Five great committees considered the question under every aspect, and the statistical committee decided that a tonnage of 5,000,000 wonld clear the canal.

On the report of these committees ths congress decided nnanimously that an inter-oceanic canal ought to be made at Panama, hetween the Bay of Colon and the Gulf of Panama. That this canal, of which the length is to he ahont forty-six miles (the Snez Canal is more than twice as long) is to be constructed without locks, and exclnsively fed hy the sea. It is to he without any sensible rapidity, and at the constant level of the sea in the hay, where it is not affected hy the influence of the tides. It is to he 72 ft. wide at the hottom, with ahont 27 ft. of water.

The canal wonld reduce the route from Havre to San Francisco to 3,300 leagnes, whereas at the present moment it is actually 6,500 leagues.

From New York to Valparaiso the diminution in distance wonld be 2,700 leagues. It is actnally 4,700 leagues hetween the United States and San Francisco. Six millions of tonnage, with a toll of 15 francs,—a figure which hardly equals the rate of the insurance paid hy the ships that go rnnd Cape Horn, whilst spending three months on a ronte that could he accomplished in two days,—would give an actnal revenne of 90 millions of francs.

The duration of the works is fixed at eight years, and this term could be abridged if, instead of 9,000, there were to he 12,000 workmen employed,—an angmentation to be taken into consideration, as it might he in the interest of constructors and shareholders. The enterprise is to he confided to Messrs. Couvrent & Hersent, who accept it at the terms of 512 millions of francs (say 20½ millions sterling), though the total estimate seems to make the cost appear some 50 millions of francs more. Messrs. Couvrent & Hersent were the contractors for the Suez Canal, and they have heen making fresh examinations, and have once more sounded, explored, and calculated. They affirm that 512 millions (francs) will suffice to dig ont on a line of 73 kilomètres the 75 million cnhic mètres of earth and rock from the hed of the canal, equalise the declivities and utilise the rubhish in the constrnction of a reservoir of a capacionsness of one milliard of cnhic mètres, and which is destined to retain the waters of the Chagres, that rise considerably in the rainy season.

To be more precise still, let us add that a dam will he constructed between two neighbouring peaks, and hold captive the waters of the river which flow throngh a cironit of mountains admirably disposed to form the hasin of a gigantic reservoir. The dam will be made at the foot of the hed of the Culæhra, so that the stone taken from the horing of the mountain will serve to constrnct the dam, which will he ahont 147 ft. in height.

There is much, also, to facilitate the ultimate success of the scheme in the fact that whereas at Suez there was the desert to conquer, at Panama there is water, a railway all along the line of the canal, ports, and steamhoats, which touch in large numhers at the port of Colon. The head-quarters of the Canal will be on the Atlantic, and three lines of French steamhoats will ply to Colon.

Such is the *ensemble* of the material elements. The financial may have some interest.

According to M. Levasseur, Memher of the Institnte and President of the Statistical Commission, the interoceanic transit wonld consist, almost immediately after the opening of the canal, of more than 7,000,000 of tons. Let us put it at what the company do, 6,000,000 tons. Lastly, it is hoped that the Panama Canal will he opened in 1886.

The capital (shares and honds) is not to exceed the sum of 600,000,000 francs. A good dividend is guarantsed while the works are going on.

The Suez Canal shares, issued at 20*l.*, are now worth 52*l.* However, it is as a great engineering work, not as a financial scheme, that we again draw attention to it.

A LINK TO JAMES BARRY.

The cleansing of Barry's remarkable works in the great room of the Society of Arts, the observations npon them in our own pages, and a recent eloquent lecture, have hronght him forcibly into notice. Turning over one of our early volumes just now (the fifth), we lighted npon a paragraph which reminded us of more than one conversation we had had, in our early days, with one who had known him well, and dwelt fondly on his memory, and this was Elizabeth Cockings, a servant in the house when Barry was painting his pictnres, and subsequently the Society's housekeeper, a post she retained up to the time of her death. According to her story, which we then recorded,* Barry often lived on bread alone; all his friends, with the exception of Edmnnd Burke, had given him up, hut in the eyes of Elizabeth he was ever a hero. There was James Barry—the stern, solitary, eccentric, and the then childish, playful girl of eighteen, who, as we gathered from her own statements to us, gazed complacently at these remarkable images, as they grew out of the mute canvas; and Barry may have painted some of his capricious female figures to astonish his yonng friend. She had many anecdotes showing the hent of his mind. A certain lord had lent him some costly work for reference, and as the artist had kept it some time, the owner wrote him a friendly letter, presenting him with the hook. This (poor, nndiplomatic) Barry repulsed as a downright insult! What was to he done with a man with such feelings in a commercial and higgling age? Then he wonld shnt himself np in his cheerless cold room, brooding over his own reflections, and then again darting forth and creating images which are becoming nnderstood. When, hy such behaviour, he baffled all his friends, none could approach him, save Elizabeth. Then she would take him his meals, deliver messages, and make his room as comfortable as his strict (and religionsly observed) orders would permit it to he. And then she had to hear his death, and the neglect of his memory which followed. Years rolled on. There were the paintings, though few looked at them. Bat time is a great justifier And then came Canova, and gazed long and intensely on the Apotheosis of man's history. This consoled Elizabeth's heart, who remained single all her life, living on the memory of a baseless dream.

* See vol. v., p. 59.

NEW RUSSIAN CHURCH, DRESDEN.

The new Russian church, erected at the end of the Reichsstrasse at Dresden, is from designs of the architect Harald Jalins von Bosse, of St. Petershurg, who has given to Dresden an addition to the series of remarkable buildngs within her walls. The comparatively large number of Russians of the Greek faith residing in the pleasant capital of the kingdom of Saxony have long felt the want of a church of their own, and when, a few years ago, a movement was set on foot for erecting a Russian chnrch or chapel, the project met at once with such liberal support that its realisation was not long delayed. The new temple has been raised entirely hy private subscriptions. A wealthy Russian-German, Alexander Wollner, at once presented a site; other Russian residents contributed handsome sums, the subscription list heing headed hy the Russian councillor, Simeon von Wikerlin, residing in Dresden, who gave 21,750*l.* of the 24,750*l.* required for the erection. The plan of the church follows closely that of Russian churches of the most flonrishing period of the Russo-Greek ecclesiastical style of architecture, as expressed in the finest churches of Moscow and Kieff. The church is not large, for it holds, in accordance with the limited requirements of its small congregation, only ahout 300 persons. It creates, placed among snrroundings of entirely different styles, a novel impression, with its towers and turrets, its bulbiform domelets, its shield-like gable-ends. The inner embellishment of the church by statnary, paintings, and general ornamentation has heen effected by Karl Weisshach, James Marshall, Becher, and other artists.

DECORATIVE SUGGESTIONS FROM NATURAL FORMS.—No. 8.

The suggestion for a pavement given in our present nnmber speaks for itself, and needs no comment.

COMPETITION: NEW SCHOOL OF ART, LIVERPOOL.

The Board of Directors have awarded the first premium of 100 guineas to the design marked "Fides," hy Mr. Thomas Cook, of Liverpool, and the second premium of 25*l.* to the design marked "Let there be Light," hy Mr. C. O. Ellison, of Liverpool. The directors have decided not to exhibit the designs submitted to them. In Mr. Cook's design, the entrance vestibule, 11 ft. wide, is placed in the centre of the front to Mount-street. On the ground-floor the accommodation comprises two elementary rooms, architectural, modelling, store, and attendants' rooms, also male and female lavatories and cloak-room; and on first-floor, two antique rooms, painting, life-class, and head-master's rooms. The building is designed in the Queen Anne style, and is proposed to he faced with Hollington stone, the estimated cost heing 10,600*l.**

Alleged Building Society Frauds.—Warrants were issued hy the stipendiary magistrate at Swansea, on the 10th, for the apprehension of the late treasurer and the secretary of the Second Swansea Equitable Benefit Building Society. Information was sworn hy the chairman, accountant, and directors, to the effect that the society was formed in 1872, and was conducted almost entirely hy the acoused, who acted also for the First Equitable Society. The hookkeeping was a sham, hut there was evidence of fraud in money and deeds, and the deficiency in hoth societies was about 12,000*l.* William Henry Jones, the secretary, is chief accountant in the borough treasurer's office, and also deacon of a Calvinistic Methodist chapel. He was apprehended, and subsequently admitted to hail in 400*l.* Herhert Jones, the treasurer, who was a hooksaller in the town, has been nnable to find hail.

* "Competitor" writes as to "rumours" of improper proceedings in this competition. There should be something more precise than rumours hefore charges are made.

VIEW OF THE LIBRARY IN SION HOUSE, SEAT OF THE

OF NORTHUMBERLAND.—Robert & James Adam, Architects.

DECORATIVE WORK OF THE BROTHERS ADAM.

Mr. Batsford knows which way the wind blows, and prepares for a *sale* accordingly; he sees that some of his customers are on the eve of going back to Adam, so calls in the aid of photography to supply them cheaply with materials for their journey. In plainer words, he has issued, under the title, "The Architecture, Decoration, and Furniture of Robert and James Adam, Architects," * a selection of twenty-six folio plates taken from their well-known but now scarce book, "Works in Architecture," published between 1778 and 1822. The new book includes a number of ceilings, chimneypieces, fittings, and pieces of furniture, besides views of two of the drawing-rooms in Earl Derby's house, Grosvenor-square; the library at Kenwood, residence of Lord Mansfield; the library in Sion House, the seat of the Duke of Northumberland; and other apartments. We are enabled to reproduce the view of the library in Sion House, which will serve as a specimen of the work and show how well it is done. It was a lucky thought, considering the temper of the times, and we have no doubt the publisher's enterprise will find a reward. We add a few brief notes as to the authors.

Robert Adam, who was the leading spirit of the firm, was born either in Kirkcaldy or Edinburgh, in 1728, and his father, if not an architect, designed two or three large buildings in Scotland. Robert went abroad to study; and, while his contemporaries, Jas. Stuart and Nicholas Revett, were measuring remains in Athens, Adam was measuring and drawing the now well-known and much-abused Palace of Diocletian at Spalatro, in Dalmatia, where he found the seeds of the style he afterwards produced. When settled in London, and in partnership with his brother, he executed a large number of buildings, public and private, some of which we have already named. Portland-place, Stratford-place, Hamilton-place, two sides of Fitzroy-square, and the buildings of the Adelphi, are also among their works, some of which, especially the last-named, were executed by them as speculative builders, and were not financially successful. We have no great admiration for their designs, but they were at any rate artists, had a distinctive style of their own, and certainly improved on the street architecture of their day. Robert Adam was at one time architect to the king, but gave up the appointment after a few years in order to go into Parliament, where he sat for the county of Kinross. He died in 1792 and left behind him the sweet savour of a kindly heart and high moral character. The brother died two years afterwards.

The selection made by Mr. Batsford is a very good one, and the original engravings are marvellously well reproduced.

NEW BOYS' SCHOOL, ARUNDEL.

We give this week an illustration of the above building, showing the back elevation and the covered playground underneath the school. In February last we gave an account of this building, and subsequently a view taken from the front in the London-road; it will, therefore, be unnecessary to recapitulate these particulars. The school was opened last Whitsuntide. The entire cost was defrayed by the Duke of Norfolk, Mr. Claridge, of Banbury, being the contractor; Mr. Heveningham, of Arundel, the clerk of works; and Messrs. J. A. Hansom & Son, of South Kensington, the architects.

The New Seed-Crushing Mills and Oil Refinery on the Boat Quay, King's Lynn, belonging to Messrs. Walker & Son, have just been opened, in addition to their Albert Oil Mills, by the side of the Dock. The buildings cover an area of nearly 4,000 square yards, and are fitted up with the newest and best-known machinery extant. The quantity of cake produced at Messrs. Walker's two mills amounts to 800 tons per week, with 200 tons of refined oil. The oil-mill machinery has been supplied by Witham & Sons, of Leeds (and is upon what is known as the Anglo-American system), and the engines are by Simpson & Co., of London. The buildings have been erected by Mr. W. H. Brown, of Lynn, from plans and under the superintendence of Messrs. Adams & Son, architects, of King's Lynn and Wisbech.

DWELLING-HOUSES: THEIR SITUATION AND CONSTRUCTION.*

THE PARKES MUSEUM OF HYGIENE.

In addressing you to-day upon the opening of a course of practical lectures on house building and situation, it is both my duty and pleasure to remind you of the provocative cause,—of the collection of interesting objects that form this museum.

The Parkes Museum of Hygiene is the result of a strong desire on the part of both the professional and personal friends of the late Dr. Parkes to found a memorial of such a character as to aid scientific investigation and practical study in the subject to which Dr. Parkes's life and work had been specially devoted. In determining what the museum should contain, the committee state in their first report that "They tried to limit their endeavours mainly to an attempt to illustrate, *visually*, the various subjects which are treated of in Dr. Parkes's comparative book on practical hygiene."

The articles exhibited are arranged in six groups, under the following headings, viz.:—

1. Engineering and local hygiene; 2. Architecture; 3. Furnishing; 4. Clothing; 5. Food; 6. Preservation and Relief; and, lastly, a library containing the most recent works on sanitary science.

You are all aware of the circumstances which have led the committee to inaugurate the course of lectures to members of building societies which I have the honour and pleasure to commence, with some remarks on the choice of a site for a house, and on the materials and general construction which should be employed to render any house not only commodious, but healthful.

The space in which the present museum is accommodated is, however, very limited, and I propose, therefore, in the first instance, to make some general remarks before I lead you to the objects themselves, so far as this institution supplies examples.

Dr. Corfield, who will address you on a future occasion, has already published a most useful and interesting little book, entitled "Dwelling Houses: their Sanitary Construction and Arrangement," and I should recommend any one desirous of possessing a better acquaintance with the subject than he is likely to carry away in his memory from anything I may say, to purchase that little book, which comprises a series of lectures commonly termed the "Cantor" Lectures, which were delivered by him before the Society of Arts, and which lectures were largely illustrated by specimens borrowed from this museum.

And now as to our subject.

SITUATION.

By "situation" I mean to imply that it is quite possible to have an excellent house, and yet to have an unhealthy dwelling, if care has not been taken in the choice of its site. And in choosing a site I take it for granted that your choice is comparatively limited, and that I am addressing those who do not contemplate living in the midst of a beautiful park, but whose business necessitates their living within a city, or in its near neighbourhood, or within easy access thereto.

1. *Aspect.*—The value of land in the suburbs of any great city limits the choice of aspect. The streets are usually arranged in such a manner that the most may be made of the ground, and in the selection of your site, or of your house if it is already built, be careful to see that the road runs pretty nearly north and south, so that your house may have its principal windows and doors facing east and west, and the street in front of you and the garden at the back of you will always partake of whatever southern sun our ungracious climate vouchsafes. If you select a corner site, you will have three sides of your house exposed to the wind and weather; take care to choose the southern corner, and you will save much fuel in the preservation of sufficient warmth within. The thin walls of small houses allow the wind to pass clean through them at the rate of several cubic feet per hour. In large detached houses it is usual to arrange the living-rooms on the south, east, and west sides, and the kitchen offices towards the north, with a shrubbery beyond and around to screen the offices; the larder and dairy always to face north, and the wine-cellar to be an internal chamber, to preserve an equable temperature throughout the year.

2. *Soil.*—The nature of the subsoil, or the stratification of the earth upon which the building stands, is the next important inquiry, but not second in importance. A damp site makes a damp house, not only by the surface dampness of the surrounding ground, but by the ground air which forces the moisture under and into the house, drawn forward by the means adopted for warming the interior, which, by lightening the weight of the internal air, makes a free passage for the damp ground air in the direction of the least resistance. There are two general divisions in classifying soils, the permeable and the impermeable; and in proportion as the site is free from moisture, in the same proportion is it fitter for residential occupation. But it does not follow that impermeable soils are the driest; on the contrary, it is usually the permeable.

Pervious soils are those like gravel, sand, and soft limestone, which allow of the free passage of water through them, and if there is nothing to obstruct its free passage, and the level of the water in the ground is sufficiently deep, the upper surface upon which the house is built is always dry and healthy. If, however, the gravel has no deep outlet for water which passes into it, owing to its being situated in a basin of impervious soil, so that the level of the water in the soil is brought very near the surface, then it is necessary to find an outlet for the accumulated water by artificial means, called land drainage.

Impervious Soils are those chiefly composed of the various clays, which do not allow the water to sink into their depths, but only suffer it to flow over their surface, and consequently the garden soil gets super-saturated; and if the land is level, the water is long in getting away, and the evaporation of the moisture in and upon the soil produces a humid damp atmosphere, very injurious to health, and requiring very careful surface-drainage to overcome.

The public roads, forecourts, and areas of houses in a town are usually so well drained that no evil comes from this source, as a rule, in front of the houses; but the back gardens are commonly neglected, and the basements suffer in proportion. It is obviously important to you as investors in house property, for income or for residential purposes, to look to the surface and subsoil drainage of the site of the house you buy or build, as the case may be. But this is not all. Suburban villas are not always built on natural soils. The brickmaker has sometimes preceded the builder on impervious soils, and the gravel and sand merchant has sometimes sunk great gravel-pits for the sale of gravel and sand, on pervious soils. And to bring the land to its uniform level, the well-known notice-board has been put up, inscribed "Rubbish may be shot here," which is only another phrase for "The Seeds of Disease sown here." Avoid such sites altogether. I could point you to many, but common sense is shocked at the folly,—shall I say the wickedness?—of raising human dwellings over such abominable deposits. Happily the Public Health Acts all over the country are gradually influencing the age; and the action of the Nuisances Removal Acts, Local Management and Building Acts, are all aiding the public in the acquisition of sounder and healthier dwellings. Instead of grudging the fees paid to district surveyors and local officers, it would be wiser to secure their influence and direction, and to support their authority.

CONSTRUCTION.

Having secured a fairly healthful site, let us next consider how to make the best use of it.

1. *Foundations.*—You will not often have the opportunity of building your house upon a rock, but let us see that it is not built on the sand, or, what is equivalent to it, upon soft loamy soil. Hard gravel or chalk is an excellent foundation, but usually the soil is treacherous, and if there is any doubt about it, do not spare a few yards of good concrete formed of one of ground-stone lime and six of good clean ballast, or hard-burnt clay broken up to pass through a ring 2 in. diameter. If there is water in the soil, use Portland cement instead of lime, in either case to be thrown into the trench from a height of, say, 6 ft. The concrete to be of sufficient thickness, not less than 12 in. thick for any wall, and usually 2 ft. thick; but it is rarely necessary to exceed 3 ft. in thickness; and always make the trenches 12 in. wider than the lowermost footings of the wall. Do not raise your

* By Mr. Edward C. Robins. The first of a course of lectures to members of building societies, delivered on Saturday, the 11th inst.

concrete above the level of the top of the trench, but fill in your trench with concrete, and form a layer of concrete from 4 in. to 6 in. thick over the whole surface of the basement, to keep back the ground-air and the moisture it brings with it. And a similar layer of concrete to be put under all paving external to the walls of the house. Bed the soil-drains in concrete to a fall of not less than 3 in. in 10 ft., and as much more as possible. The footings of all walls should be in single courses, and each should project 2½ in.; the lowermost footing should be twice the width of the wall resting upon the footings. The bricks used for the foundations should be sound, hard-burnt, grey stock bricks, or others equally hard, or harder, and the joints should be filled up solid with the mortar or cement used.

Damp Course.—Just above the level of the lowest floor of the house two courses of brickwork should be built in cement, and between them should be laid a double course of slates in cement, or a layer of asphalte not less than ¾ in. in thickness, as a damp course to prevent damp rising by capillary attraction in the walls themselves.

We will look at some of the contrivances in the museum for making damp courses of stoneware, and of utilising them as air-bricks for passing air from without to the spaces sometimes left under basement floors, and always required under joisted floors so as to give free access for the air to permeate every part of the space, which should never be less than 12 in. from the surface of the ground or concrete layer, to the underside of the joists of the floor over. Dry-rot will never appear where there is a free circulation of air; where it has appeared, it may be arrested by the introduction of a sufficient quantity of moving fresh air.

2. *Walls.*—The enclosing walls, of solid brickwork, of a building to be lived in, ought never to be less than 14 in., or a brick and a half, thick, though the Building Act allows them to be 9 in., or one brick thick for certain heights and lengths, and certain stories defined in the schedules appended to it. But a much drier wall would result from walls of the same thickness, but built hollow, and united by galvanised iron ties, one in every square yard. Walls built of cement concrete are both strong and dry. The materials used in the construction of walls are various, and thickness is not the only thing required.

Mr. Lascelles has constructed cottages with walls 1½ in. thick, and quite impervious to moisture, but then they are formed of hydraulic cement concrete slabs as hard as nether millstones, and not so porous. But bricks will always be most in requisition for house building in this country, except in the stone districts, where more or less porous freestone will be used for those parts that require to be worked with a tool, and the hard flinty rubble stones will depend chiefly on the imperviousness of the cementitious matter in which they are bedded for their soundness and resistance to the weather. The porousness of soft building stones may be overcome by various chemical solutions. The Indestructible Paint Company have provided one, two coats of which applied by a brush when the stone is dry will stop the pores and cause water to pass off it as water from a duck's back. I never use Bath stone externally without applying this solution.

With reference to bricks, it is all-important that they should be well burnt; the half-burnt bricks are not only very porous, but crumble away the first winter; they are called place bricks. Rubbers, or bricks required to be soft enough to cut to mouldings, or for ganged arches over openings, are necessarily pervious.

White gault bricks, wire-cut or pressed, make good face bricks, and the "pinks," as they are termed, are best to back them with, because they are of equal size. It is bad to face with a thick brick, and to back it with a thin brick, as it is obvious that the mortar joints in the one case must be thicker than the other, and cause unequal settlement. A quarter of an inch is as wide a joint as is desirable.

Red bricks are usually more porous than others; but there are good hard red bricks to be had.

Glazed bricks are very costly; but Candy's granite bricks from Chudleigh, in Devonshire, are like flint, and to be put into trucks for 37s. 6d.

The blue Staffordshire are like iron, and are commonly used for copings and curbs to railway platforms and kindred purposes.

All brick copings should be set in cement, with a double tile creasing projecting to throw the water off the wall.

It is an important axiom in building to put "voids over voids": it is the best construction, because it involves putting solids over solids, and so produces equality of settlement. It is economical, too; for if a solid wall comes over a bay-window, the chances are that the bressumer will be overweighted if no architect has been employed, and if it is not, the cost of the bressumer will be increased by the additional strength required to carry a wall where a window should have been; yet how common it is to see two windows on the upper floors situated wide apart, and a bay-window on the ground-floor, just under the pier between the upper windows.

The superincumbent brickwork over every opening should be sustained by discharging arches which should pitch on the brickwork, and not on the wooden lintel beneath it, which is placed there to fix the door and window frames, and to carry the filling-in between the arch and the lintel. *Rough lintels* of artificial stone, for use in place of timber for door and window openings, introduced by the late Matthew Allen, now made by Lascelles, are much in use by architects.

When openings are wide it is usual to distribute the weight of the piers upon the foundations between by means of invert arches. But what most disfigures buildings is the bad construction of the arches over the openings, more especially where they are covered with cement architraves and cornices; being out of sight, they are not formed as arches at all, but hold together by the tenacity of the cement only. It is better to employ half-brick rings, one over another as required, than to make false flat arches, and put false joints to make believe.

Mortar.—In the matter of mortar, it is needful to add a word of caution. Much of it is not mortar at all,—that is, lime and sand in the proportion of one of lime to two of river sand. The lime is of inferior quality, and in small quantity, and it is often mixed with loam, or street sweepings, or the *detritus* from sludge brought up from the main sewers, and sold at 6d. a yard to Jerry builders. Houses compacted together with materials so mixed,—full of impurities, such as decomposed or decomposing animal or vegetable matters,—cannot be healthy, and the smell that often comes from plaster with which interior walls are lined may be traced to this source. I have used at the Choir Schools of St. Andrew's, Wells-street, and elsewhere, selenitic mortar for the brickwork and for the plastering. It is a valuable substitute for the ordinary mortar and plaster, at nearly the same cost, and it sets hard like cement. Care must be taken in the mixing, or it blows in the setting, or sets with a curious array of pinholes.

Chimneys.—In the construction of chimney-breasts, it is often the case that the breasts are not built up solid, but have large cavities left, and the flues are built on no principle, with wide and open jaws below and a small pot above. It is desirable that the flues should be as straight as possible, for the sake of preserving a good draught upward; but it is often important to prevent down-draught by sloping a portion of its length, with a seat for the air to beat against to break its descending force. All flues should be quickly gathered over the mouth of the fireplace, and should be lined with plaster, or be formed with terra cotta, though the use of the latter, by giving too little hold for the soot, occasions its unexpected fall at inconvenient seasons. All hearths in upper floors should be supported on half-brick trimmer arches in cement, but sometimes these are omitted, and the centreing for the arch is latbed for plastering, and the stone hearths rest on the timbers of the floor. The arch, though butting against the trimmer, should have a deep skewback in the wall, so that if the trimmer were removed, the arch would stand alone when set. All trimmer joists should be at least ½ in. thicker than other joists. But besides solid or hollow walls of brick and stone, and cement-concrete walls of various kinds and thicknesses, there are other forms of enclosure which are to be commended as combining picturesque effect with weather-proof construction, and with a minimum thickness and weight of material. I allude to what is called half-timbered work. Of old, the upper stories of buildings were rarely built of such solid materials as the ground story; but stout angle-posts, filled in between with more or less substantial intermediate posts, called quarters, let into a plate below, and head and sill above, with intermediate braces, were all well knit together with oak or iron pins; and these timbers were, and still are, usually filled in with half brickwork, and rendered in lime and hair both inside and out: the inside was finished with fine plaster face for colour, paint, or paper, while the outside was either finished in rough cast plaster with pebble face, or was filleted with battens, and covered with vertical tiling of plain or ornamental design, well secured to the battens with two galvanised rails. The tile battens may be put on either before or after the plaster rendering. For sound-proof flooring and partitioning, and for a frost-proof covering to cisterns and pipes, nothing is better than slag felt.

The tiles used should be well burnt; pale red coloured tiles, like pale bricks, are but half-burnt, and are porous; but rich warm colours, with a bloom, are well burnt, and of indestructible durability. Such tiles used for covering roofs are at once the warmest of coverings in winter and the coolest in summer. Speaking of tiling and tile-work generally, great improvements have been made in ridging tiles. Cooper of Maidenhead, and others, produce very perfect work, and there is no better ridging than saddle-back tiles well set in lime and hair, carefully pointed in cement. The cresting, if any, should not be a separate part of the ridge fitted into a groove; it is better that the tile should be complete in one piece, with handsome hip-knots and finials finishing, also moulded in one piece. The simplest outlines are best. No pavement is better than the best Staffordshire red, black, and buff paving-tiles, and none are cheaper except Portland cement mixed (half and half). They should always be laid in concrete, worked to a smooth face to receive the tiles, bedded in mortar and pointed in cement, and if they are laid anglewise to set patterns the commonest floor is made interesting. The more beautiful colours and quality, delicate texture, and beauty of design, which distinguish Minton's, and Maw & Co.'s tiles, must be paid for if desired.

Floors.—But tiles, like stone and asphalte, both of which are valuable in their place for paving, are oftentimes too cold for the feet, for internal use, and wooden floors are preferred. To get a wooden floor, and yet one as solid as either of the rest, it is necessary to substitute 1½ in. to 2 in. thick wood blocks, about 6 in. long and 3 in. broad. These blocks, set to a herring-bone or other pattern, should be Barnettised to prevent dry-rot, and may be bedded in gauged lime-and-hair mortar, and the interstices filled in with Portland cement powder; then sweep the surface clean, and wash it down with water, which, setting the cement in the joints, makes a permanent floor, which may be polished. They are sometimes laid in asphalte, and are of various sizes. I exhibit a specimen of this kind of solid wood-block floor, sent by the manufacturer, Mr. Gregory, of Station Works, Clapham Junction. Mr. William White, an architect, was the inventor of this, which I believe to be the best kind of flooring for basements. You will observe that these blocks are dipped in pitch before laying, which is a further improvement. As the surveyor of the Berners Estate, Oxford-street, where I have some 600 houses under my care, I have had very great opportunities of observing the relative durability of houses, and my experience has taught me that the exclusion of moisture is the secret of perpetuity, as it is also the most important element in healthfulness.

Damp soils, damp walls, damp roofs,—these are the causes of premature decay. The area pavings allowed to be laid on the ground instead of on concrete, or bedded in mortar, perhaps, but not pointed in cement, the wet gets through and saturates the foundations, which may be built of absorbent bricks, and have (as the walls of old houses often have not) no footings, and, what is more common still, no concrete, but baulks of timber laid under them, which, rotting by the alternate wet and dry state to which they are subjected, their decay is revealed by the settlements which appear in the walls, which walls, having no damp course, have become by the attraction of the warmer air in the house, and what is called capillary attraction, saturated with damp several feet above the floor, which, if of wood, will in all probability have no space under the joists and no air-bricks in the outer walls to ventilate the same. The walls may be lined inside and out with plaster or cement badly made at the first, and receiving the moisture like a sponge, which is absorbed by

the bricks as it is forced through the walls by the winds or differences in the temperature of the air. But the walls may not be cemented or stuccoed on the outside, the bricks may be exposed, and the badly-burnt ones will scale off in flakes as the frost affects them; and even if the facing-bricks are good, the joints are defective, and the original pointing has fallen out, and where renewed, has been done without first well raking out the old decayed mortar, and so there was no hold for the new pointing, and it may be picked ont with the finger, and is ready to fall at any time, the result of which is that the wall has admitted the damp to such an extent that the walls have bulged and twisted and become detached from the cross or party walls and finally fallen into the street,—as the fronts of three houses in Newman-street, Oxford-street, did about ten years ago.

Then there is the roof: the parapets and chimney-stacks are crumbling to pieces and out of the perpendicular, and the owner would probably as soon think of pointing the joints of walls that could not be seen from the street as to wash his own body because it was hidden by his clothes. The continued neglect of such things brings its own punishment in the bill for dilapidations which comes with the termination of the lease, if not before.

But to return to the roof. It may once have been well tiled, or slated, or covered with lead, but it has been improperly repaired; and zinc has been substituted for lead internal gutters and iron external or eaves gutters, and cement filletings for lead flashings to walls and chimney-stacks. The zinc has decayed, never having been laid with proper fall or with proper rolls or 2 in. drips to shorten the length of the sheets used; but the sheets have been soldered to one another and the changes of temperature have twisted, and buckled, and torn the gutters and flats, which, if made of zinc at all, should have had free scope to shrink or swell, being put together by a system of overlapping joints, no solder or other immovable fastening being used at all: then the zinc is so thin, No. 12 instead of No. 15 being used as a rule. Use galvanised or Barfied iron in preference to plain cast or wrought iron, which will prevent corrosion, whether painted or not. Then the timbers of the roof have been much too slight and not properly braced together; the rafters have neither collar to cross-tie them, nor purlins to shorten their bearing, or these are too slight, or too far apart, and the roof sags, and the cement filleting, if it has not rotted, has become detached from the wall or the slates or both, and the damp trickles down inside, and the walls and ceilings attest the defective state of the roof, and its consequences.

Now, good construction in building houses is not to be understood without taking the pains to understand it, and the majority of Jerry builders, as they are called, make it a chief part of their business to learn how *not* to do it. And thus you see that the province of the architect is not to be despised. He it is who stands between the owner and the builder and arbitrates between them. He it is who not only designs the pretty façade archæologically correct in whatever style of architecture the fancy of his employer may desire, but he it is who writes the specification, describing every part of the building, determining every kind of material or sanitary appliance to be used, specifying everything of the strength required for its purpose and no more. He it is who brings his scientific as well as his technical knowledge to bear upon the attainment of the largest result for the least money compatible with sound construction and good sanitation. And not only is he all this, but he also takes upon himself the responsibility of seeing that his instructions are carried out by the builder employed, whether that builder is the lowest in a large competition of builders, or a person whom both employer and architect know to be a trustworthy tradesman, who knows his business and is willing to do it at reasonable prices. Such men are raror than they ought to be, but honesty is the best policy, and an architect who has reason to know his man and to trust him fully can make the fortune of any such person, and prevent the necessity of his stretching his conscience to do things which his poverty and not his will consents to.

There are lots of young educated architects anxious to make their way in the world to whom the smallest opportunity of distinguishing themselves is a pleasure. Such men are ready and willing to give their services with the earnestness of men of their class for the poor pittance of 5 per cent. on the cost of the building. Why deprive yourselves of the assistance of such men to save a penny and to spend a pound you know not how? Why not have the help of intelligent men, whose interest it is to get the work done in the best possible manner, as the best means of gaining the reputation which will ensure their future success as architects?

The mass of the buildings in London are not built by architects at all, and yet we often hear them blamed as if they were responsible for the miles of miserable dwellings with which this great city abounds.

I have spoken chiefly of what concerns the exterior fabric of a building, because keeping the weather out is easier than contrivances for overcoming the consequences of its having already got in. And in this connexion I ought to have mentioned the advantages derivable from the use of terra-cotta, instead of stone or cement, or even brick, dressings and cornices, &c. Good terra-cotta is comparatively indestructible, and if a pattern is given which is repeatable, it is cheaper than any other materials. If moulded bricks are used, let them be moulded and not rubbed if you wish them to last and keep the weather out. I need scarcely say that brick drains are now entirely exploded, and stoneware socket drains are everywhere substituted for house-drains. No soil-drain should be more than 6 in. in diameter or less than 4 in; 5 in. would be better than either. They should be set in puddled clay, and pointed in Portland cement, and laid in concrete. So far as they may have to pass under any part of the house, they should be perfectly straight, with openings at the back and front of the house for examination and cleansing. Every soil-drain should be ventilated before it is connected with the sewer, on the house side of the sewer. This cannot be too often repeated.

And now a very few words on the interior. Good joiner's work is the test of a good builder, some say; certainly, bad joiner's work is abominable. Good yellow deal or pitch-pine, free from sap or shakes, and obtained from Christiania, is as important a material for use in joiners' work, as is Baltic timber from Memel or Riga for carpenter's work. You may always know where timber comes from; there are trade-marks put at the end of every plank, and in "Spon's Builders' Pocket Memorandum Book" the corresponding letters are all given, along with all the rules which are necessary to be known in order to secure good building, and to know how to measure and value it when done. Do not be led away by pretty casements. Stick to the old rising sashes. Nothing is better for keeping out weather or for ventilating purposes. In my lecture on ventilation I shall have something more to say on this subject; in fact, I fear I must defer mention of many internal contrivances till I can consider them in connexion with their bearing on ventilation and hygienic considerations generally.

Do not strain after empty grandeur; do not covet heavy plaster cornices and central rose-flowers; do not insist on big architraves and other mouldings,—a bead or a splay is often quite as effective, and does not harbour so much dust and dirt; do not try to save by pinching the price given for ironmongery: a few shillings make all the difference between misery and comfort in the use of good locks and furniture and fastenings generally.

Do not put iron pulleys to sashes to get rusty, instead of brass, that will not rust; but do not despise lacquered ironwork,—it is stronger than brass, and does not tarnish by damp, and costs nothing to keep clean.

Have good sound flooring, 1¼ in. thick, for ground-floor rooms, and let them be tongued, and stain and varnish them for 1 ft. 6 in. or 2 ft. all round, and you will be able to carpet your house at half the cost, and have the pleasure of removing the carpets for cleaning as often as you please without trouble or injury to either floor or carpet. Exercise your common sense in building your house or in choosing your house, and before doing so buy Mr. Teale's book, illustrating the evils of bad plumbing, about which you will hear enough before these lectures are over. And inspect in this museum the disastrous consequence of neglecting this most important part of house sanitation.*

* At the close of the lecture Mr. Robins explained many of the articles exhibited in the museum. Mr. Rutherfurd, director of a building society, proposed a vote of thanks to Mr. Robins and the executive committee, and expressed a hope that, before long, the museum would be sufficiently well supported to enable the committee to arrange for the delivery of such lectures with better accommodation, so that a larger number might benefit from them. Mr. H. Rutt seconded, and the resolution was carried unanimously.

SANITARY ASSURANCE ASSOCIATION.

A MEETING of the members and subscribers of this Association,—convened to receive the report of the provisional committee appointed to consider the means of organising the society and of carrying on its work,—was held on Tuesday evening at the Langham Hotel, Sir Joseph Fayrer, M.D., in the chair.

Mr. Mark H. Judge, the surveyor *pro tem.*, read the report of the provisional committee, who stated their conviction that it was desirable, firstly, "to promote the establishment and maintenance of sanitary arrangements among all classes of the community, and in every household, so that the public health might be guarded and improved;" secondly, "to leave the execution of works recommended by their officers to such persons as the members or subscribers might themselves elect." The committee further reported that, having ascertained the views of persons prominently connected with sanitary questions, and others desirous of assisting the movement, they had come to the conclusion that the best means of organising the Association (the members not proposing to provide a capital divided into shares or otherwise) was by incorporation under the Act of 1867, 30 & 31 Vict. c. 131. By that statute, in order that an association, formed for any useful object which did not involve the division of profit, might be granted the privileges of the Act, the licence of the Board of Trade must be obtained, for which purpose a draft of the proposed Memorandum and Articles of Association must be previously submitted to the Board, and, if they were approved, a licence would be granted. Accordingly the committee now submitted the Memorandum and Articles of Association for the approval of the members and subscribers.

The Chairman then moved, "That the report of the provisional committee be received and adopted, and that the first executive council be now elected, with power to have the Association incorporated in accordance with the recommendations of the provisional committee, with such alterations and additions as they may consider necessary." In the course of his remarks, Sir Joseph Fayrer insisted on the necessity of such an association being formed, especially on account of the enormous and crowded population of London, where the death-rate, considering all the circumstances, was, he thought, marvellously low, although it could, no doubt, be materially reduced by due regard being paid to the sanitary condition of the houses of the people.

Professor Corfield seconded the motion, saying that he thought a workable scheme had been put forward by the provisional committee.

The motion was carried unanimously.

Mr. J. G. Romanes, F.R.S., moved the next resolution, to the effect that Sir Joseph Fayrer; Mr. George Aitchison, F.R.I.B.A.; Professor Corfield; Professor De Chaumont; Mr. Mark H. Judge; Professor T. Hayter Lewis; Mr. H. Rutherfurd, barrister-at-law; and Mr. T. Roger Smith, F.R.I.B.A., be the first executive council of the Association.

Dr. Poore seconded the motion, and observed that the Association had a vast field of work before it. Every medical man was aware of the prevalence of disease caused by unhealthy dwellings, and he hoped the time would come when what had been called "adulterated" houses would not pay for building,—and that time *would* come if people would refuse to live in houses which could not be certified as healthy. Not only the poor, but the rich, were deeply concerned in the matter, for many of the mansions of the rich were mere decorated and gilded pest-houses.

The resolution was adopted.

Professor Tyndall, in moving a vote of thanks to Sir Joseph Fayrer for presiding, said the Association was one which, if supported as it should be, was capable of conferring great benefit on the community.

The motion having been seconded by Mr. Rutherfurd, was adopted, and the proceedings terminated.

Mr. Inderwick on Tithes. — Mr. F. A. Inderwick, Q.C., M.P., addressed a meeting on Saturday last at Hastings, in connexion with the newly-formed East Sussex Branch of the Farmers' Alliance. The mayor (Mr. Alderman Gausden) presided, and about 100 farmers were in attendance. Mr. Inderwick explained the law relating to tithes, and stated he was preparing a Bill to be laid before the next session of Parliament on the subject. Tithes were the property of the nation, and not of the subject. Parliament, he said, had never hesitated to deal with tithes when it thought proper in the interest of the public. He proposed to make extraordinary tithes redeemable at a certain charge, and suggested a nine years' purchase. After much consideration he had come to the conclusion that a nine years' purchase was the proper amount. He had spoken to several members of Parliament on both sides of the House on the matter, and they had promised their hearty support to the principle of the Bill, though not fully concurring in some of its details.

THE ORIGIN OF THE ARCHITECTURAL ASSOCIATION.

Sir,—In the account of the origin of the Architectural Association, recently given by my friend Mr. Phené Spiers, what little I did in the matter is referred to so very kindly that I am prompted to add a little in the way of gossip to complete the picture of the birth of my favourite society.

The real origin of the movement is traceable to a letter which was published in the *Builder* about Christmas time, 1846, written by Mr. Charles Gray, who, if my memory serves me well, became afterwards the first honorary secretary of the Association, and whose name ought to be held in especial honour. Mr. Gray was then a pupil in an architect's office, and he complained boldly of the want of a proper system of professional education, proposing that if masters would not, or could not, teach their pupils, the pupils should attempt to obtain instruction elsewhere. This letter brought about a little consultation amongst a few young men, when it was discovered that a Society of Architects' Assistants existed, although in a condition of what I will call repose. Their number was small; but they were of the class of exceedingly respectable middle-aged married men, and therefore perhaps a trifle slow. Mr. James Wylson (long at the head of the office of Mr. Sydney Smirke) was their president, and Mr. Jayne their secretary; the other members were the two Messrs. Colling, Messrs. Drayton Wyatt, William Young, Sayer, and three or four more. Mr. Wylson had gone to Glasgow a year or two previously, but Mr. Jayne (whom I was glad to see evergreen the other day) received us with the utmost friendliness. We thought it might be advantageous to found our proposed society in some way upon the basis of this little club. The address on "Architectural Education" was, by permission, read at their place of meeting, Mr. Jayne's rooms, in Southampton-street. They themselves attended, and we mustered as many younger friends as we could. The result was a resolution to get up a society, not like theirs, a fraternity of the permanent assistant class, but an instruction-guild for architectural youth of an aspiring turn. Accordingly, *they joined us; we did not join them.* Having existed for only four years, and with such indifferent vitality, they had no traditions to surrender, and gave place loyally to our broader purpose. The Association of Architectural Draughtsmen confessed failure, and passed away; while the Architectural Association, full of hope, came into being. Lyons' Inn Hall (where the Globe Theatre now stands) was adventurously taken for the weekly meetings, and we resolved to make our appearance before the world with a special gathering. Two gentlemen of influence now appeared in the character of practical helpers, namely, Professor Donaldson and Mr. George Godwin. They came down to Lyon's Inn, listened to our speeches, gave us speeches in return, and from that day to this have never ceased to back up the Architectural Association. Pray, therefore, let not their agency be forgotten; nor that of Mr. Gray; nor that of the *Builder* journal. I may add that Professor Cockerell and Mr. Beresford Hope deserve the credit of having helped us also. They came down one night and condescended to hear a paper read; and, as it happened, we had a lively meeting in consequence of the great Amateur too flatly contradicting the great Academician. The amazement of the Professor was splendid. "Sir," he exclaimed, "I knew the gentleman's father! And he held different opinions."

Of the original "Draughtsmen," several became respected presidents of the Association,—Mr. James Colling, Mr. Drayton Wyatt, and I think, Mr. Young; but I need not say that adolescent architecture proper had no difficulty in producing presidents out of its own fertile resources.

The great distinction between the Draughtsmen and the Association was that the one was a small and unsuccessful benefit-club, and the other an important educational institution, calculated to accomplish any amount of usefulness the times may require. Robert Kerr.

Sir,—As my name has been mentioned by Mr. R. Phené Spiers, in connexion with the origin of the Architectural Association, I consider that it is only justly due to the memory of the late Mr. James Wyleon, whom we all liked and respected, to say that he was the sole originator of the "Association of Architectural Draughtsmen." I and others assisted him, but the idea originated with him. He drew up the first rules, and called together the first meeting, which was held at the coffee-house in Castle-street, Holborn. James K. Colling.

THE PUTNEY VESTRY AND THE PROPOSED NEW TRAMWAYS AND RAILWAYS IN THE PARISH.

The Putney local authorities have decided to oppose the proposed introduction of tramways into the parish, and have also concluded to resist the project of the Metropolitan District Railway to construct a new line across Putney Common. At a meeting of the Vestry which has just been held, the members unanimously expressed themselves as strongly opposed to tramways being brought into the parish, and the Putney members of the Wandsworth District Board of Works were instructed to oppose the tramway scheme at the Board. The memorial against the undertaking being permitted was agreed upon. The proposal of the Metropolitan District Railway to extend their line to Wimbledon by crossing Putney Common was also opposed at the meeting, and a resolution adopted to the effect that the Conservators be requested to oppose any encroachment on the Common. The proposed new bridge likewise formed a subject of discussion at the meeting, in the course of which it was incidentally stated that the new structure would be wider than Waterloo Bridge. A sketch showing how the High-street would be affected by the approach to the proposed bridge was ordered to be placed on the churchyard wall for the information of the parishioners.

BUILDING LAND AT WILLESDEN AND SNARESBROOK.

Several plots of building land in the neighbourhood of Willesden were sold last week by Mr. Belton. They included, amongst others, a number of plots on the Neasden Station estate, described as eligible for the erection of shops and the better class of houses. Some of the plots, having frontages to Neasden-lane, of 18 ft., were sold for 90*l.* each, whilst a number of others realised 110*l.* each. A plot, with a frontage to Vicarage-road of 17 ft. 6 in., was sold for 65*l.* It forms a portion of the property known as the Willesden Church Estate. Numerous plots in Willesden-lane and on the Willesden-green Estate were likewise offered. Various plots, having frontages to a new thoroughfare called Cobbold-road, of 15 ft., were sold at 35*l.* and 36*l.* each, and 40 other lots, having frontages of 16 ft., were sold for from 40*l.* to 45*l.* each. Five plots on the Willesden-green Estate, having frontages of 20 ft. to Willesden-lane, were sold for 90*l.* each.

Mr. F. M. Whittingham offered, at the Eagle Inn, Snaresbrook, twenty-eight lots, on an estate close to the Snaresbrook Railway station and to the Wanstead main road, and in the immediate neighbourhood of Epping Forest, several of the plots being described as eligible for the erection of first-class villas. It was stated that the property was offered free from all rights of the Conservators of Epping Forest, the rights having been purchased under an award made by the arbitrators under the Epping Forest Arbitration Act. A considerable number of the lots, which have frontages of 20 ft., and an average depth of 100 ft., were sold at the rate of 5*l.* 10*s.* per foot frontage, or about 110*l.* per plot.

WORK IN MOSAIC.

The apse of St. Peter's, Bayswater, has been decorated with an important work in Venetian mosaic. The subject is Leonardo da Vinci's "Last Supper," and the work has been executed by Messrs. Burke & Salviati. The treatment differs from the original in the arrangement of the background. Instead of showing the side of a square room in which the Last Supper took place, it has been arranged to suit the semi-circular surface of the apse, and its features are made to harmonise with the leading lines of the architecture in this part of the church. The copy for the mosaicists was made by Mr. A. Booker from the copy of Leonardo's work by his pupil Oggione, which is possessed by the Royal Academy. Oggione's copy is of the same size as the original, and was probably painted under the supervision of Da Vinci himself, and may therefore be relied on as expressing faithfully the spirit and the drawing of the original. The whole has been executed under the direction of Mr. Chas. Barry, from whose design the arrangement of the background was made. The cost, which is very considerable, will be borne by the widow and family of a late churchwarden, who took interest in the fabric of the church.

COMPENSATION CASES.

ARTISANS' DWELLINGS ACT.

At the meeting of the Metropolitan Board of Works held on the 10th inst., the solicitor read the following report:—

Artisans' and Labourers' Dwellings Improvement Act, 1875,—Goulston-street Scheme.—I have to report an important inquiry which took place at the Sheriffs' Court last Wednesday, on the appeal of the Board against the award of Mr. Hunter Rodwell. The subject matters of the claim were thirteen houses held on long lease in Castle-alley, High-street, Whitechapel; also a long leasehold interest in 8, 9, and 10, Inkhorn-court; and a copyhold of inheritance in six houses, 1 to 6, Inkhorn-court. It is impossible to speak too strongly of the disgraceful character of these premises, the approaches from High-street, Whitechapel, being some 3 ft. wide, and the courts being of wholly insufficient width for sanitary requirements, the houses also being in a wretched state of disrepair and dirt. The claimant is of the Jewish persuasion, who, no doubt, made his living by collecting the weekly rents of these houses and of other property of a similar kind in the neighbourhood. I ascertained that numerous notices under the Nuisances Removal Act had been served upon the claimant, and this was duly proved at the inquiry. Three claims were delivered amounting to 6,675*l.*, and the gross income derived from the property was, as put in evidence by the claimant, 617*l.* per annum. Mr. Rodwell's provisional award amounted to 3,100*l.*, but upon hearing the claimant's adviser before making the final award, he increased his award to 4,874*l.*, the valuation of the Board being 2,771*l.* The committee directed an appeal to be lodged against the final award. At the inquiry at the Sheriff's Court last Wednesday, Mr. Meadows White, Q.C., and Mr. Freeman appeared for the Board, and Mr. Willis, Q.C., and Mr. Muggeston for the claimant. I, of course, arranged that the jury should take a careful view of the premises, and it was clear throughout the inquiry that they took the strongest view against the claimant, and but for the summing-up of the Under-Sheriff, who called their attention to the fact that the Board itself had valued the property at 2,770*l.*, I have no doubt that the jury would have given a verdict for less than the Board's figures. They did, however, return a verdict for the exact amount given in evidence by the Board,—that is, 2,770*l.*, or 2,100*l.* less than Mr. Rodwell's final award. In addition to this, the claimant will pay his own costs, less 30*l.* certified by the Under-Sheriff as payable by the Board. This is another illustration of the extreme uncertainty of the verdicts of juries, as the committee may recollect about three weeks since property of the same character, almost adjoining this, and belonging to Mr. Thurgood, was the subject matter of an appeal against Mr. Rodwell's final award. The jury in that case, after a view, did not express any opinion as to the character of the property, and gave a verdict for 1,950*l.*, or 200*l.* only under Mr. Rodwell's award, and 700*l.* more than the Board's figures.

On Wednesday last Mr. Under-Sheriff Burchell presided over a special jury at the Middlesex Sheriff's Court in the appeal "Churchwardens of St. Luke's *v.* The Metropolitan Board of Works." Sir H. Hunt, the arbitrator, had made an award, and the churchwardens demanded a jury to assess the value of the property, consisting of a house on lease for eighteen years, and the reversionary interest. The contention was as to the reversion. The house was in Golden-lane, St. Luke's, and was required for artisans' dwellings. Evidence on both sides was given as to the reversionary interest, and the difference in the estimates of the surveyors was somewhat large. The jury, which consisted of only eight, no tales having been prayed, inspected the property, and the result was a verdict for 900*l.* As the amount exceeded the award the appellants had their costs allowed.

WOLVERHAMPTON STREET IMPROVEMENTS.

Mr. M. F. Blakiston, the acting under-sheriff of the county of Stafford, sat in the Sessions Court of the town-hall, Wolverhampton, two days last week, to hear an appeal of the trustees of the late John Savage Davenhill against the award of the arbitrator under the Improvement scheme in respect of property situated at the Queen-square end of Lichfield-street, which is required by the Corporation under the scheme for the purpose of the projected main street to replace Lichfield-street.

The property is a half-timbered house occupied by a relation of the late Mr. Davenhill.

Mr. Underhill (town clerk, appearing for the Corporation) said that as the property was not in the unhealthy area under the scheme, its purchase would come under the Lands Clauses Act, the provisions of which allowed that besides the actual value of property purchased, the owners should receive compensation to the extent of 10 per cent. on the intrinsic value for compulsory sale. The area of the

property was 132 square yards, which, at the very high figure of 10*l.* a square yard, would give 1,320*l.*, as the price of the land; or, putting it at the (for Wolverhampton) fabulous figure of 2*l.* a yard, would amount to 2,640*l.* I the place had to be rebuilt as it stood, it would not cost more than 1,200*l.*

The evidence of valuers was, as usual, very contradictory, those for the Corporation putting the total to be paid at between 4,000*l.* and 5,000*l.*, and those for the appellants at between 9,000*l.* and 10,000*l.*

The jury awarded 6,766*l.*

ARCHITECTS' ACTIONS.

HANCOCK *v.* BAKER AND SONS.

THIS was an action in the High Court of Justice, Common Pleas Division, before Mr. Justice Lopes, brought by Mr. W. St. John H. Hancock, an architect, of Furnival's Inn, to recover from Messrs. Baker & Sons, auctioneers, a sum of 66*l.* 10*s.* for professional services.

It appeared that defendants had originally been in communication with another gentleman respecting laying out an estate for selling in plots, and making roads thereon, who, before any work had been done, was obliged to retire from business, owing to illness. Mr. Hancock was asked to take up the work, and it appeared in evidence that he stated to Messrs. Baker & Sons that he would do so on his own account, to which, according to plaintiff's evidence, the defendants assented.

The work in question was done in 1877-8, covering nearly six months. Some months after the work had been done and the estate put up for sale, defendants, being asked for payment, denied their liability to pay plaintiff, stating that they had never employed him.

A great deal of correspondence was put in, and several witnesses examined, the hearing of the case occupying part of three days.

The jury had to decide as to whether the plaintiff (who did the work) was to receive pay, or the estate of the former surveyor (who was a bankrupt)? Was the statement of the plaintiff or that of the defendants to be relied upon?

On these questions the jury gave a verdict for plaintiff for the full amount claimed.

Mr. Bigham and Mr. Frank Safford, instructed by Mr. S. J. Debenham, of Lincoln's-inn-fields, were for the plaintiff, and Mr. Telfourd Salter, Q.C., and another learned gentlemen, instructed by Messrs. Blewitt & Tyler, were for the defendants.

WHAT PART OF A SHOP-FRONT BELONGS TO A SHOP?

HAYES *v.* CORDINGLEY.

THIS somewhat curious action was tried in the Exchequer Chamber about a week ago. The plaintiff, Mr. F. B. Hayes, an auctioneer and estate agent, has a lease of a shop on the ground story of No. 14, King-street West, Hammersmith; the shop being part of a larger shop, and described in the parcels as "all that portion of the shop now in the occupation of the said lessee containing the dimensions and abuttals more particularly delineated and set forth in the plan drawn in the margin hereof, and being a portion of the ground-floor of the premises aforesaid." The interior of the shop was tinted pink on the plan, but not anything beyond the exact internal area; the pink tint was not referred to in the body of the lease.

The defendant (the lessor) occupied the rest of the premises, including the upper floors, and the parties being recently on bad terms, he damaged the painting of the cornice and of the brattishing above it, as also of the centre pilaster, between the shop-fronts, and cut a door in a very rough way in the wooden stallboard under the shop-window, and used it for access to the basement story. The plaintiff brought his action for peaceable possession, and claimed some moderate damages. There was apparently no attempt to dispute the fact that there was an intention to annoy the plaintiff, and to damage the effect of his premises, for which a high rent was paid, the only question being, were the parts in question demised to the plaintiff or not? It was proved that, previously to the lease being granted, in November, 1876, the lessee had painted all the parts over which he now claimed control.

Mr. S. Flint Clarkson, architect and surveyor, gave evidence in support of the plaintiff, and was followed by Mr. Vickery. The jury returned a verdict for the plaintiff, damages 30*l.*

The evidence, and the summing up (of Mr. Justice Watkin Williams) go to establish,—(1), that a tint on any portion of a plan may be taken to have no signification whatever, unless it is specially referred to, and its meaning expressed in the body of the deed; (2), in the absence of stipulations to the contrary, the whole of a shop-front, including the entablature, will be demised with a shop. The cornice and cresting must be considered as connected with the rest, as the upper parts of a frame would be with the lower parts. In this case the ceiling of the ground-story reached only to the top of the fascia, but the whole of the upper part of the entablature is to be reckoned as part of the ground-story; (3), "occupation" may extend to the external surface of a structure. In this case, for instance, the lessee, having painted the woodwork under the stall-board (although it contained a glazed panel giving light into the basement) previously, without being interfered with, it was held that this surface was "in the occupation of the said lessee" at the granting of the lease.

THE MYSTERIES OF FIGURES.

THE following is a mathematical demonstration of the fact alluded to by your correspondent "J. H." We will first show that if the sum of the digits of any whole number greater than nine be subtracted from that number, the remainder will be divisible by nine.

Let N denote any whole number, and let p_1, p_2, p_3...p_n, represent the digits, beginning with that in the units place, and represent the base of the common scale of notation by $r=10$.

Then $N=p_1+p_2r+p_3r^2+\ldots\ldots p_nr^n$

Subtracting $(p_1+p_2+p_3+\ldots\ldots p_n)$ from both sides of the equation we have $N-(p_1+p_2+p_3+\ldots\ldots p_n)$

$$=p_2(r-1)+p_3(r^2-1)+\ldots\ldots p_n(r^n-1)$$
$$=p_2 9+p_3 99+p_4 999+\ldots\ldots \text{to } n \text{ terms.}$$

This equation is therefore divisible by 9, since every term on the right-hand side is divisible by 9. The above is therefore established.

We will now show that the sum of the digits of any whole number divided by 9 will leave the same remainder as the whole number divided by 9.

Adopting the same notation we have as before

$$N=p_1+p_2r+p_3r^2+\ldots\ldots p_nr^n$$
$$=p_1+p_2+p_3+\ldots\ldots p_n$$
$$+p_2(r-1)+p_3(r^2-1)+\ldots\ldots p_n(r^n-1)$$

therefore $\dfrac{N}{r-1}=\dfrac{p_1+p_2+p_3+\ldots\ldots p_n}{r-1}$

$$+p_2+p_3(r+1)+\ldots\ldots p_n\frac{r^n-1}{r-1}$$

But $\dfrac{r^n-1}{r-1}$ is an integer, whatever positive integer n may be; therefore $\dfrac{N}{r-1}=$ some integer $+\dfrac{p_1+p_2+p_3+\ldots\ldots p_n}{r-1}$

The second case is therefore established, since $r-1=9$.

Now, by the first case it was demonstrated that if the sum of the digits of any whole number greater than 9 be subtracted from that number, the remainder will be divisible by 9. Therefore by the last case the sum of the digits in the remainder will be divisible by 9. Should "J. H." be unable to follow the demonstration, then perhaps the last few lines will satisfy him. A reply to his letter, however, hardly seems complete without a rigid demonstration.

J. G. VINE.

SIR,—In reply to your correspondent, "J. H.", although I do not undertake to explain the *whys* and *wherefores* of the peculiar property of the figure 9 to which he draws attention, I beg to subjoin the following algebraical symbol for the "trick," which will make the peculiarity of the "9" element more apparent.

Suppose a, b, c, d, e, f, g, h, represent eight figures, the problem will become:—

$$10000000a+1000000b+100000c+10000d+1000e+100f+10g+h-(a+b+c+d+e+f+g+h)$$
$$=9999999a+999999b+99999c+9999d+999e+99f+9g-$$

where 9 is the common factor. H. L.

RADIATION AND CONDUCTION.

SIR,—At the Royal Institute of Architects' discussion, on the 29th of November, more than one speaker drew a distinction between radiated and conducted heat, expressing a decided preference for the former. Mr. Robins said that radiated heat passed through the air without heating it, warming the first obstacle to its passage. Captain D. Galton says, in his "Healthy Dwellings," that air cannot be heated by the radiant heat of an open fire. Now, our thermometers indicate the temperature of the air. The heat we require, say 60°, is got by contact of the air with the walls, furniture, &c.; therefore it seems to me that our desired air temperature is got by conduction when a fire is the means of warming. Are there, therefore, any solid grounds for the distinction which is drawn? Suppose a room to be warmed up to 60° by a supply of air, warmed by passing through a chamber kept to a temperature of 70° or 80°, why should it not be as satisfactory as the warmth got from an open fire? I admit that ordinarily a room warmed by hot air is not so agreeable as one warmed by an open fire, even when the ventilation is as good, which it rarely is; but this I attribute to the fact that hot air for warming rooms is almost always passed over highly heated surfaces, very generally moving slowly over parts of those surfaces, whereby particles of organic matter floating in the air get charred.

F. LLOYD.

SANITARY SCIENCE IN ITS RELATION TO CIVIL ARCHITECTURE.

SIR,—The letter from "A.R.I.B.A.," at page 709 of last week's *Builder*, shows that there is ample room for at least some of the members of the "R.I.B.A." getting better acquainted than they are with the science of practical plumbing, and especially in its relation to the proper position and fitting-up of the sanitary appliances of houses. All soil-pipes should be put up outside of the house, and if any soil-pipe in that position freezes up, that is the pnnishment for some sin, viz.,—the waste of water. I do not think that, as "A.R.I.B.A." supposes, films of ice forming in the interior of the soil-pipe when it is used are the cause of the freezing up, but, as I said, some water crane or valve leaking continually into the soil-pipe, and so wasting the water. I have put outside a number of soil-pipes that were formerly inside, and heard no complaint during the late severe frost of anything freezing up; nor did I last year either. And as to the ventilating traps at the foot of the soil-pipes, &c., and upon the drains, I do not remember of hearing of a single one freezing up, although about seven thousand are now in use.

I was rather astonished to read the statement of "A.R.I.B.A." that the waste-pipe from his sink is only 1 in. in diameter. In Scotland we generally use 2½ in. waste-pipes from sinks. The smell he speaks of may likely be owing to want of ventilation. He should consult either Mr. S. S. Hellyer's book, "The Plumber and Sanitary Houses," or my own work on "Plumbing and House Drainage," and he would then gain a better knowledge of the subject than his letter leads me to suppose he at present possesses.

In reference to Mr. Norman Shaw's published plan of fitting up soil-pipes, I beg to observe that it was very crude, and open to improvement in various respects; and unless he has lately issued an improved plan correcting himself, his first plan is not one to be copied, more especially as other more practical and better plans were and are in existence.

W. P. BUCHAN.

MEASURING TAPES.

SIR,—I should think that a good stout linen tape, passed through a solution of rubber, in order to render it waterproof, would answer. I do not, however, know of any firm making such, but would gladly purchase one so made. Linen hose so prepared will last for years.

J. C. M.

LINCRUSTA-WALTON.

WHEN this material was first introduced to the public, under the title "Muralis," or "The Sunbury Wall Decoration," we were able, without any hesitation, to point it out to our readers as a particularly good and available material, and we have no cause for changing our opinion in speaking of it under its new name, Lincrusta-Walton. Trade reasons have probably led to this change, but it is not wise for all that. Still it will come right in time. When a hard-working and long-popular member of the Lower House, let us say Mr. "Bob Lowe," consents to accept a peerage, he commits temporary suicide, and disappears from the outer world under a new name as entirely as if he no longer existed. In time, however, his personality asserts itself, and the same qualities bring Lord Sherbrooke equally to the front. As the Honble. Bardwell Slote, in the "Mighty Dollar," used to say, in reply to Mrs. Gen'l. Gilflory's preference for *pommie de terre* over potato,—"Fortunately, ma'am, the vegetable tastes the same in both languages," so we have no doubt Mr. Walton's material will be equally valued, whether called Linorusta or Muralis, because

it is a really good thing. It is in (low) relief, like wood-carving; it is waterproof and impermeable to moisture; can be washed with soap and water; and will not absorb infection. It has a comfortable appearance, can be adapted by architects to any style of building, and is applicable for dados, panels, cornices, friezes, borders, and folding screens. The company by whom it is supplied have just now issued a very pretty Pattern Book (7, Poultry), wherein, by means of the autotype process, as we suppose it to be, the patterns in stock are shown with marvellous fidelity and effect, the patterns themselves exhibiting so much good taste and skill in design and drawing as to make it obvious that intending users may safely place themselves in the hands of the company. Care is required in cutting and fixing the material. The latter is done with glue and paste, made (in the proportion of one-third of the former to two-thirds of the latter) as thick as it is possible to use it, and laid on lightly with a stiff brush. "Then take a piece of lincrusta and attach it to the wall under the cornice by means of gimp pins, and gradually press it to the wall, making the joint good until it reaches the bottom. In doing this, care should be taken to work from the centre outwards, so as to avoid the air getting under the piece and preventing adhesion." Very rich effects, we will add in conclusion, may be obtained by decorating the Lincrusta in colours.

CAN A BUILDER CHARGE FOR AN ESTIMATE?

Sir,—I should be glad if some of your correspondents would enlighten me as to the following, viz.:—

"An architect invites two or three builders of equal merit to tender for works in alterations and additions (700*l.*) where quantities are not supplied. On opening the tenders the difference is so trifling that the architect's client accepts one above the lowest, although the usual clause, 'the lowest or any tender not necessarily accepted,' is omitted to be mentioned."

In a case like the foregoing I certainly think a builder can send in a claim to the client of, say, two per cent. for the taking out of quantities and preparing of estimate.

If, in your next issue, some of your correspondents will give their opinion, and kindly state if such a case has been decided in a court of law, they will confer a favour on many builders. W. B.

VARIORUM.

A fifth edition of "The Proportions of the Human Figure," by the late Joseph Bonomi, just now published by Charles Robertson (Long Acre) contains a photograph and short memoir of the much-regretted author. It also includes a list of authorities on the subject. The scope of the work we have before now stated and commented on.——*Nature* of December 9th has an interesting article showing what has been done by science towards the prevention of the vine disease in France due to the *Phylloxera*. Two maps show the extent to which its ravages have spread.——With No. 3 of "Decoration" (Sampson Low) a decorative picture, "Karlavagh," designed by Mr. Moyr Smith, is presented.——Part 1 has been published of a new issue of Cassell's "Cookery," a very useful book of its kind. It will be completed in thirteen sixpenny parts.——The same firm have also commenced a new issue of the "Popular Educator."——The *Garden Oracle* for 1881, edited by Shirley Hibberd, maintains the reputation for usefulness acquired by previous issues. We give a quotation that may be useful as to an aquarium and fern-case combined:—"The whole of the rock-work should be built on a wooden floor, and when thoroughly set should be put into water and remain immersed for at least a month, to season it thoroughly; for new cement is poisonous to fishes, and therefore undue haste in this work tends of necessity to a break down. In stocking the tank you need not introduce any vegetation at all, but a clean bed of well-washed pebbles and a few fishes only. But if you wish to have a little vegetation at once plant a few tufts of Vallisneria only; if you introduce a variety of water-plants you will come to grief speedily. The whole affair ought to be in full working order a month or so before any fishes are put in, and during that time of probation the water should be changed twice a week at least. We now come to the subject of the fishes. These should be few and small, and of the most peaceable disposition. The lovely gold carp is the most suitable of all, but any other kinds of carp may be adopted. Minnows and bleak are suitable, but scarcely desirable, as they soon suffer if the water should be insufficiently oxygenated. Such interesting but delicate fishes as the eel, the stone loach, and the miller's thumb are really quite unfit for the purpose. The principal object is not to secure a zoological collection, but a beautiful object. The ferns will, of necessity, comprise such as thrive when constantly bathed with moisture, and the filmy ferns, such as *Trichomanes radicans* and *Hymenophyllum tunbridgense*, are the best. The small species of *Todea* will answer, as will also our pretty Britishers, the wallrue, *Asplenium ruta-muraria*, and the sea spleenwort, *A. marinum*.——The eighteenth annual issue of the *City Diary*, published at the office of the *City Press*, 154, Aldersgate-street, has just made its appearance. In it will be found, as before, a great deal of information respecting official life in the City, together with the customary matter of an almanack.——"The Golden Mark," the Christmas number of the *Quiver*, contains a large amount of good reading and illustrations for 6*d.*——The December number of Harper's *Monthly Magazine* for both quantity and quality is noticeable. It is now published by Sampson Low & Co.——"The Belgravia Annual" and "The Gentleman's Annual" (both published by Chatto & Windus) include many good stories of their kind.——According to the *British and Colonial Printer and Stationer*, "Cherry Ripe" the supplement to the Christmas number of the *Graphic*, was produced in fourteen printings at a speed slightly exceeding 800 sheets per hour, two on a sheet, and that no fewer than 400,000 copies have already been produced and sold.—The second volume of the *Antiquary*, edited by Mr. Edward Walford, M.A., which consists of the parts published between July and December, affords much interesting reading to those who find pleasure in the study of the past. The *Antiquary* supplies a want.

Miscellanea.

Wilmslow Sewerage.—The Wilmslow Local Board of Health have for several years past been trying to obtain a satisfactory scheme for the complete sewerage of their district, which includes the village of Wilmslow and the surrounding residential and agricultural district of 6,907 acres, with a present population of about 7,000. About eighteen months since the Board offered premiums of 100*l.*, 50*l.*, and 25*l.* for the best schemes for sewering and disposing of the sewage of the district. A large number of plans were sent in by engineers, and Mr. J. G. Lynde, C.E., formerly city surveyor, of Manchester, was called in to advise the Board as to the merits of the several schemes; and the Board subsequently awarded the first premium to Messrs. E. Corbett & Sons, of Manchester; the second premium to Messrs. Brierley & Holt, of Blackburn; and the third premium to Mr. Vawser, of Manchester. Messrs. E. Corbett & Sons' scheme is on the "separate system" for collecting only sewage in the new sewers, leaving the rainfall to be conveyed by existing drains, streams, &c. The scheme provides for a northern and a southern outfall of 15-in. glazed earthenware pipes, jointed watertight in cement, with branch sewers of 12-in. and 9-in. pipes. A sewage-farm of about 57 acres is proposed on or near Lindow Common (where deep sand is overlaid by peat of varying thickness). The sewage is to be raised from the two outfalls, a height of about 45 ft., to the farm, by means of Shone's patent sewage-ejectors, worked by compressed air from an engine at the farm. The estimated cost of the whole scheme is as follows:—19,095 yards of pipe-sewers and 170 manholes, 6,500*l.*; air-compressing engines, boilers, ejectors, rising-mains, air-pipes, and buildings, 4,250*l.*; sewage farm, farm buildings, drainage, &c., 4,800*l.* Total, 15,550*l.*

Silver Work.—Mr. J. W. Benson has had the honour of exhibiting for her Majesty's inspection a silver model made in imitation of the Albert Memorial for the late Siamese Embassy. It has now been shipped for Siam. It is a remarkable work, more than 7 ft. in height.

Window Cases for Queen Anne Houses.—"Can any be obtained?" says a correspondent. Yes, certainly! Messrs. Dick Radclyffe & Co., of High Holborn, have prepared some purposely, as our advertisement columns show.

Bells, Lincoln Cathedral.—On Saturday last the new clock and set of quarter bells provided for Lincoln Cathedral were formally opened by the Dean, in the presence of the members of the chapter, priest, and vicars, and other officials of the cathedral, as well as Messrs. N. Clayton and A. Shuttleworth, members of the celebrated firm of agricultural implement makers, the donors, in conjunction with Mrs. Seely, the wife of Mr. Charles Seely, M.P. for Lincoln, of the quarter bells. The new clock, which has been provided at the expense of the Dean and Chapter, takes the place of one by Thwaites, dated 1775, subsequently altered by Vulliamy. It has been constructed by Messrs. Potts & Sons, Leeds, under the superintendence of Sir Edmund Beckett. The bells, which are arranged for the well-known "Cambridge quarters," are from the foundry of Messrs. Taylor, Loughborough, the founders of the new peals of St. Paul's and Worcester cathedrals. They weigh respectively 27 cwt. 2 qr. 7 lb., 13 cwt. 0 qr. 14 lb., 12 cwt. 3 qr. 24 lb., and 11 cwt. 0 qr. 10 lb. The crowning-stone was laid of the newel of the spiral staircase of the south-western tower, thus formally signifying the completion of the work in which the Chapter has been for some years engaged, under the direction of Mr. J. L. Pearson, R.A., in tying together the magnificent western façade (which was bulging outwards to an alarming extent), rebuilding the lower part of the south-west tower (which had become so rent and shattered as to threaten imminent ruin), and strengthening the whole.

The Society of Engineers.—The twenty-sixth annual general meeting of the members of this Society was held on Monday evening last, the 13th inst. The retiring president (Mr. Joseph Bernays) occupied the chair. The following gentlemen were balloted for and duly elected as the council and officers for the ensuing year, viz.:—As president, Mr. Charles Horsley; as vice-presidents, Mr. J. Church, Mr. F. E. Duckham, and Mr. Arthur Rigg; as ordinary members of council, Mr. S. Cutler, Mr. C. Gandon, Mr. Perry F. Nursey, Mr. Thos. Porter, Mr. W. Schönheyder, Mr. R. Berridge, Mr. C. J. Light, and Mr. Henry Robinson, the three last-named gentlemen being new members of the council; as honorary secretary and treasurer, Mr. Alfred Williams; and as auditor, Mr. W. H. Bennett. The president announced that premiums of books had been awarded by the council to Mr. G. M. Ward for his paper on "The Utilisation of Coal Slack in the Manufacture of Coke for Smelting," and to Mr. W. Worby Beaumont for his paper on "Steel as a Structural Material." The annual dinner of the Society was held on Wednesday evening.

Proposed Tramway between Warwick and Leamington.—The Leamington and Warwick tramway extends along a route of about 5,377 lineal yards, and consists of about 4,859¾ lineal yards of single line, and 517 lineal yards of double line in crossings, passing-places, &c. The undertaking is now assuming a very practical and complete form; plans, sections, details of rails, crossings, specifications, and bills of quantities having been prepared by Mr. E. Pritchard, C.E., of Birmingham and London. In answer to an advertisement which appeared in the *Builder* and other newspapers, some time ago, about a dozen contractors have since inspected plans at Mr. Pritchard's offices, and the directors have since received tenders for the works. The new tramway will consist of a continuous iron sleeper, 90 lb. to the lineal yard, laid upon a bed of concrete, having a rolled steel rail 34 lb. to the yard let into the sleepers, and secured at intervals of 18 in. with wrought-iron pins, in the form of a wedge. No timber whatever will be used in the system.

Church Warming.—Mr. R. S. Dunbar, of the Thames Bank Iron Company, has warmed the Catholic Apostolic Church and the Cloisters, Gordon-square, by a system of hot-water boiler and pipes placed above the floor. This very large church has for a long time past been without any heating apparatus, but recently the committee called in the assistance of Mr. Dunbar, and the result, at the cost of 337*l.* 10*s.*, is said to be satisfactory.

The Abbey Church of Romsey, Hants, has just received the addition of a stained-glass window, representing Christ leading the Blind Man. It is in memory of Caroline Maria Noel, youngest daughter of the Hon. and Rev. Gerard T. Noel, and cousin of the present Earl of Gainsborough, and has been well executed by Messrs. Mayer & Co., of Munich and London.

The Re-valuation of the Metropolis.—The results of the re-valnation of the metropolis, a work which has oconpied the various districts during the year, have been reported to Mr. Jebb, the chief clerk of the Metropolitan Asylums Board, whioh is the authority nnder the Act (the Metropolis Valuation Act, 1869) to issne the return. This is the second quinquennial valnation. The metropolis shows a vastly increased value, owing, not only to the increase in the number of buildings, but to the rateable valne of houses having been raised by the local authorities. When, in 1871, the list was first issued, the gross value of the metropolis was 24,176,338*l.*, and the rateable value 19,900,072*l.* The returns now given in show a gross valne of 25,785,556*l.*, and a rateable value of 23,697,405*l.* These totals, however, do not include the City of London, whose rating authorities have not yet sent in their returns; nor Poplar, nor the Middle Temple. The gross value of the City of London is estimated at 3,953,707*l.*, and the rateable valne at 3,313,522*l.* The rateable value of Poplar is estimated at 311,895*l.*, on the gross of 423,796*l.* The Middle Temple is estimated as likely to give in its returns 10,929*l.* of rateable value on a gross of 13,144*l.*,—a total increase of 50,000*l.* on the three places. Hence the returns will be,—gross value, 33,176,203*l.*, and a rateable value of 27,833,751*l.*; an increase in the second quinquennial period of 5,079,391*l.* gross, and 4,679,112*l.* rateable; and a total increase in the ten years of 8,999,865*l.*, and 7,933,679*l.* The largest assessments of gross valne, next to the City, are Kensington, 1,969,501*l.*; St. Pancras, 1,828,828*l.*; Islington, 1,757,589*l.*; Marylebone, 1,659,874*l.*; St. George's (Hanover-square) Union, 2,728,318*l.*; and Lambeth, 1,577,631*l.*

A Verdict of a Penny a Month.—In the Warwick County Court, on Tuesday last, a case was heard before Sir Richard Harington, bart., judge, in which Messrs. Denston & Co., glass and lead merchants, Birmingham, were the plaintiffs, and William Roberts, builder, Leamington, the defendant. The action was brought to recover 14*l.* 13*s.* 3*d.* for goods sold and delivered. It appeared that the debtor some months ago filed a petition in the Warwick County Court, for the liquidation of his affairs by arrangement. The creditors agreed to accept a composition of 3*s.* in the pound, payable in a month, on the joint security of the debtor and of Mr. George Grove, ironmonger, Leamington. Mr. Grove in due time gave his own cheques for the amount to each creditor, and one for 2*l.* 4*s.* was accordingly forwarded to the plaintiff, who declined to accept it, as the offer was not strictly in accordance with the terms of the resolution. The judge made some comments on the proceedings, and gave a verdict for the plaintiff without costs, and one penny per month.

Parliament Street.—The site occupied by the two old houses with projecting shops situate 53A, to 54, Parliament-street, abutting in the rear on Cannon-row, and on the site of the Grand National Opera-house, has now again been disposed of by Mr. Robins, of Waterloo-place, Pall Mall. In 1874 the property was sold by auction to Mr. Mapleson for the purpose of forming a direct approach to the new Opera-house from Parliament-street, but the purchase was not completed. Its re-sale points to an immediate movement in connexion with the site of the Opera-house on the Embankment, while the demolition of these old houses, whose incongruity with their more modern surroundings is very remarkable, will considerably improve the appearance of this part of Parliament-street. We understand the price now paid is equivalent to 7*l.* per foot super.

District Surveyorships, Streatham.—At the meeting of the Metropolitan Board of Works on the 10th inst., it was agreed, on the recommendation of the Building Act Committee, that the district of Streatham and Brixton (part of Lambeth), vacant by the decease of Mr. John Mullins, be divided into two districts, to be designated East Streatham and Brixton (part of Lambeth), and West Streatham, respectively; and that the centre line of Brixton-hill, Streatham-hill, and Upper and Lower Streatham, do form the line of boundary between such districts. It was further agreed to proceed to the elections at the meeting of the Board this Friday, the 17th inst.

Patent Pendulum Pump.—The Bronze Medal of the Mining Institute of Cornwall has been awarded for the above pump to Mr. J. Stannah, engineer.

Ventilation of the School Board House.—At the weekly meeting of the School Board, on the 9th inst., Dr. Richardson was permitted, as a matter of emergency, to make a statement as to the ventilation of the Board-room, and the corridors and rooms adjoining. He said that he and the architect to the Board had, during the past three weeks, been looking into the arrangements for ventilation existing in connexion with the building in which the Board were in the habit of meeting. He had come to the conclusion that the ventilation of the Board-room was a matter of great emergency. The room in which the Board sat should be one they could occupy without dangerous results. Without desiring to cause any unnecessary alarm, he felt bound to say that the members incurred danger by sitting in this room. The architect was of opinion that the necessary alterstion in the ventilating arrangements might be made in a month or six weeks. That would involve the Board meeting in another room for some time, and it would also involve expense. In the opinion of the architect the expense would be about 300*l.* He (Dr. Richardson) imagined it would be more, but 300*l.* might be taken as about the cost. He, therefore, moved that it be referred to the Works Committee, to consider and draw up a proposal as to the warming and the ventilation of the Board-room, the landings adjoining, and the ladies' room. Mr. E. Buxton (vice-chairman of the Board) seconded the proposition. After some opposition from Mr. Bonnewell, who suggested that the lighting of the room should be also inquired into, the motion was carried unanimously.

South London Water Supply.—Notice is given of a Bill to be introduced into Parliament next session for the incorporation of a company to supply the southern districts of London with water to be obtained chiefly from springs in the neighbourhood of the Basingstoke Canal and other places on the borders of Hampshire and Surrey. Power is sought to transfer the undertaking to any trust that may be formed to control the water-supply of the metropolis. It is stated that from the sources specified in the notice about 13,000,000 million gallons daily could be obtained.

Street and Road Tramways.—A Parliamentary paper shows that there are in the United Kingdom 3,680 miles of street and road tramways open, from which (for passengers, parcels, mails, animals, goods, minerals, &c.) 1,312,933*l.* have been received, and upon which 1,113,094*l.* have been expended. This leaves a balance of receipts of 229,830*l.* The total number of passengers who have travelled on the tramways is given at 173,067,103; the mileage run at 23,842,000; the number of horses at 12,392, of locomotive engines at 17, and of cars at 1,619.

"Fogs and Mahogany."—Mr. W. J. Prim, Resident Engineer at the Houses of Parliament, writes to say that he never made the statement attributed to him by a speaker at a recent meeting (mentioned in our columns) "that the fog in the Houses of Parliament, which was occasionally found when no fog existed outside, was due to the quantity of mahogany wood employed in the building," for, as a matter of fact, oak is almost exclusively employed for the furniture and fittings in those buildings.

Female School of Art.—Her Majesty the Queen has again signified her approbation of the work of the Female School of Art, 43, Queen-square, Bloomsbury, by purchasing a life-study in water-colour. We understand that there will be some specimens of wood-carving by female students on view at the annual exhibition on the 22nd and 23rd inst.

Folklore of Old Japan.—At a meeting of the Birmingham Philosophical Institute, last week, Mr. Pfonndes read a paper on "The Cosmogony Legends, Witchcraft, Spirit Rapping, and other Superstitions of Japan." Native illustrations and photographs were exhibited by the lecturer.

Bribes.—More than one architect complains to us of a circular sent out by some "Sanitary Engineers" in the Blackfriars-road, offering to allow them 10 per cent. commission on all the said engineers' goods the architect may specify. Manufacturers ought to know by this time that such offers simply do them mischief.

The Strike at the Welsh granite quarries, South Carnarvonshire, terminated on the 13th inst., the men going in on the employers' terms. The cause of the dispute was the appointment of an English foreman, whose dismissal the men wanted.

Dryclough.—A new (R.C.) school-church, dedicated to SS. Aidan and Oswald, was opened on the 28th ult. at Dryclough, near Royton. The main room measures 66 ft. by 30 ft., and is approached by a porch containing the stairs of the gallery. A separate chancel, 18 ft. 6 in. by 15 ft., opens from the main room by means of large doors, 19 ft. by 6 ft. 9 in. each; and an infants' room, 30 ft. by 22 ft., having gallery accommodation for sixty children, is attached to the main building. The sacristy and class-room measures 18 ft. by 18 ft., and the boys' vestry 11 ft. by 11 ft. The accommodation for school-work is for 350 children, infants included, and for Divine service for about 500 worshippers. The rooms are all lofty, and have stained and varnished open-timbered roofing throughout; and, to enhance the comfort of the rooms, the roofs are boarded and covered with felting under the slates. The style is described as a free treatment of English Gothic. The windows are glazed with quarry lead lights. The altar is in carved oak, from a design supplied by the architect, and has been executed and fixed by a Dutch firm, Messrs. J. A. Orr, of Roermond. The building works were entrusted to the following local firms, viz.:—Brickwork, Mr. Thos. Whittaker; masonry, Messrs. J. Hirst & Sons and Mr. P. Walsh; joinery, Messrs. R. Hilton & Sons; plumbing, painting, and plastering, Mr. M. J. Hearne; slating, Mr. J. Bamford; and benching, Messrs. S. Ashton & Sons. The whole has been carried out from the designs and under the superintendence of Mr. Thomas Mitchell, architect, of Oldham. The cost will amount to about 2,200*l.*

Burnham Westgate.—St. Mary's Church, Burnham Westgate, Norfolk, has been reopened, after restoration. The chancel has been nearly rebuilt and provided with a new roof, Minton tile pavement, new window, carved oak seats, and other fittings. In the church the old chapel of St. John has been restored with new lead roof, well lighted, opened to the north aisle by a new archway, and fitted with open seats. The nave and aisles throughout are repaved with Minton tiles, and supplied with open seats of pitch-pine, a carved oak pulpit and reading-desk, and additional windows, with a thorough repair of all the stonework. The cost of the works has been about 750*l.*; some work still remaining to be done to the tower and porch is estimated to cost 120*l.* The restoration was under the direction of Mr. Phipson, architect, Norwich, and executed by Messrs. Daw, the builders; Mr. Alfred Beavor, stonemason; and Mr. W. Witton, plumber and glazier, all of Burnham.

The Builders' Ball.—The annual ball in aid of the funds of the Builders' Benevolent Institution is announced to take place on Thursday, January 27th. We trust that it may be as successful as the recent anniversary dinner proved to be. Those of our readers who are willing to do their part in attaining the desired end should communicate with Mr. F. W. Keeble, the honorary secretary for the Builders' Ball, 4, Vernon-place, Bloomsbury-square.

Royal Asylum of St. Anne's Society.—An Old Boys' Club in connexion with this noble charity is now organised. All Old Boys desirous of joining or aiding the movement are requested to communicate with Mr. John G. Adams, at 69, Cook's-road, Kennington Park, an ex-scholar, who has undertaken to receive all names.

TENDERS

For the erection of a new brewery (exclusive of offices and brewery plant) at Walham Green, for Messrs. Stansfeld & Co. Mr. William Bradford, architect and engineer. Messrs. J. & A. E. Bull, surveyors:—

Smith & Co.	£21,760 0 0
Lucas Bros.	21,528 0 0
Holland & Co.	21,374 0 0
Trollope & Son	21,048 0 0
Higgs & Hill	20,898 0 0
Bywaters*	20,210 0 0

* Accepted, subject to modification.

For the erection of warehouses and printing-offices, Shelton-street, Drury-lane, for Messrs. Henry Hansard & Son. Mr. Octavius Hansard, architect:—
Mitchell & Co. (accepted).

For the re-erection of premises, and dilapidations, No. 11, Berwick-street, Oxford-street, for Mr. Francis Pinn. Mr. John H. Swann, architect:—
Mitchell & Co. (accepted).

For a mission-house, Brunswick Park, East Barnet, for Mr. J. L. Wood. Mr. S. C. Capes, architect. Quantities not supplied:—
Garratt (accepted) £360 0 0

For shops, Peckham-road:—
Taylor & Parfitt (accepted) £2,835 0 0

For five houses and shops, Brixton-road, for Mr. Earle Bird. Messrs. Fowler & Hill, architects. Messrs. Fowler & Hugman, quantity surveyors:—

Hook & Oldrey	£3,841	0	0
Freight	8,600	0	0
Forrest	8,487	0	0

SPECIAL NOTICE.

Christmas Week.—*The* Builder *for the week ending December 25th will be published on* **Thursday, 23rd** *inst., at the usual hour.*

Advertisements for insertion in that issue must therefore reach the Office before Three o'clock P.M. *on* **Wednesday, 22nd** *inst.*

CHARGES FOR ADVERTISEMENTS.

SITUATIONS VACANT, PARTNERSHIPS, APPRENTICESHIPS TRADE, AND GENERAL ADVERTISEMENTS

Six lines (about fifty words) or under ..... 4s. 6d.
Each additional line (about ten words) ..... 0s. 6d.

Terms for series of Trade Advertisements, also for Special Advertisements on front page, Competitions, Contracts, Sales by Auction, &c. may be obtained on application to the Publisher.

SITUATIONS WANTED.

FOUR Lines (about THIRTY words) or under ..... 2s. 6d.
Each additional line (about ten words) ..... 0s. d.

REPLIES TO ADVERTISEMENTS,

Addressed Box ——, Office of "The Builder,"

Cannot be forwarded, but must in all cases be called for, and the Office Receipt produced.

THE CHARGE FOR A BOX IS AS UNDER:—

For "Situations Wanted" Advertisements ..... 3d. per Week.
For all other Advertisements ..... 6d. per Week.

PREPAYMENT IS ABSOLUTELY NECESSARY.

. Stamps *must not* be sent, but all small sums should be remitted by Cash in Registered Letter or by Money Order, payable the Post-office, King-street, Covent-garden, W.C. to

DOUGLAS FOURDRINIER, Publisher,
Addressed to No. 46, Catherine-street, W.C.

Advertisements for the current week's issue must reach the office before THREE o'clock p.m. on THURSDAY.

The Publisher cannot be responsible for DRAWINGS, TESTIMONIALS, &c. left at the Office in reply to Advertisements, and strongly recommends that of the latter COPIES ONLY should be sent.

TERMS OF SUBSCRIPTION.

"THE BUILDER" is supplied *direct* from the Office to residents in any part of the United Kingdom at the rate of 18s. per annum, *prepaid*. Remittances payable as above.

The Builder.

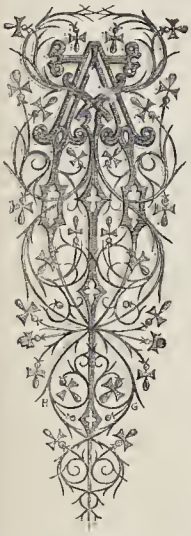
Roman Building in England and in Italy.



AN interesting description of the masonry of the portion of Roman wall lately discovered in the excavation for the Fenchurch-street Railway Station has been sent to the daily papers by the engineer of the Great Eastern Railway. The top of the portion discovered was about 9 ft. below the surface, and the bottom 9 ft. lower, giving a total of 18 ft., which very fairly corresponds to what we have before had occasion to mention as a rough scale for the accumulation of *débris* on town-sites, of about 1 ft. per hundred years. There are, however, several particulars of an unusually suggestive nature with regard to this wall. We need only slightly refer to its ponderous strength,—9 ft. in thickness at its foundations,—a strength which, before the invention of gunpowder, was enough to guarantee a long resistance to even a pertinacious attack.

But it was not on mass alone that the Roman builder depended for security. When we consider the details of the present portion of his structure, we shall see how much thought has been given to the production of stable and durable work. Of the character of the cement used we shall have a word or two to say, only now remarking that after a lapse of more than 1500 years the solidity of the work is such as to render its demolition,—even when attempted course by course,—a very serious affair. The courses of wall are, in the main, 6 in. courses of random rubble, in limestone and mortar. But the thickening of the wall, not being effected by batter, but by steps, involved the introduction of a material that would afford a more level surface than rubble for the offsets,—if we rightly understand Mr. Langley's expression, "projecting three inches." This material is afforded by what the account calls tiles, but which are really the Roman bricks, frequently found in ancient work in this country, and made and used to this day in Italy. These bricks are 17 in. long, 12 in. broad, and 1½ in. thick.

There can be no doubt that the Roman bricks were introduced in order to form plinths or level offsets, as three offsets on each side of the wall are thus finished. The value of the long flat form for bond is also to be remarked. The two upper layers, of three courses each, extended through the wall. The lowest layer, 18 in. above the foundation, was probably not far from the level of the soil. This course only extended 18 in. into the wall; the rubble being built on two layers of blocks of stone, each 9 in. deep, and about 2 ft. square. It will be very interesting to ascertain from what quarries the Romans brought the limestone to build the wall of London; and Mr. Langley will do good service to archæology, as well as to the kindred professions of the architect and of the engineer, if he will obtain an accurate analysis of the stone found, and aid in determining whence it was brought.

Under the stonework of the wall was a bed, composed of six layers of flint and clay, 2 ft. 6 in. deep. Whatever was the level of the soil, this, no doubt, must have been a sunk and buried foundation. There occurs a very remarkable parallel to the mode of preparing the foundation of the second city built on the site of Novum Ilium (*ante*, p. 663), in which cakes of clay were used as a sort of packing for the foundations. Between each course of flint in the London wall was a bed of clay about 1½ in. thick. This structure was carried down 3 ft. into a solid bed of gravel. It would seem as if the ancient builder was of opinion that, when protected from atmospheric effect, clay was reliable as a building material, and the existence of the wall confirms the truth of this opinion.

The Roman bricks are bright red, well burnt, and retain their form and sharp arrises. About the year 1844, during the construction of the railway from Gravesend to Rochester, specimens of Roman pottery were discovered, in which the bright red colour, and smooth, sharp surface, were like those of Samian ware. But the simplicity in form of some of the articles was such as to render it highly improbable that they had been imported. Like the bricks, they must, we should conceive, have been British-made. One of the Gravesend vessels, more like the saucer of a garden-pot than anything else, but smooth and bright, had the word GRACISCE on it in raised characters from an indented stamp. The Society of Antiquaries have not as yet explained this word. It seems to indicate the existence of some Roman earthenware manufactory in the valley of the Thames; and the red bricks in London wall seem to us to tell the same tale.

We now come to the question of the mortar. And here we would ask our readers to compare the perfect petrifaction of the lime used in the old Roman work in this country with the crumbling condition of the mortar in many of the ruins of 300 or 400 years later date. Who has not been struck with this in examining such a ruin as Kenilworth, or in making his way up the turret staircase of some long-deserted keep? If we compare the Roman mortar of the third or fourth century with the London mortar of to-day, what is the result? The architect shakes his head, but is unable to repress a smile at the question. "Yes," he says, "but look at the age of the one." Is that a satisfactory reply? We at once admit that a certain time is assignable during which well-prepared mortar gradually becomes more and more solid, more and more, to repeat the word purposely before used, petrified; but we do not think that, when a certain time has gone by, the process continues. Between a house of six weeks old and one of six years every one can perceive the difference. Go back to sixty years and you may, perhaps, say the same. From sixty to 600 we are not prepared to say what takes place. But as between, let us say 1,200 and 1,600 years, we do not think that at all events any solidifying process goes on. Things being alike,—that is to say, the mortar being as well made by the castle-builders of the twelfth or fourteenth century as by the wallers of the third or fourth century, we think that any difference in solidity could not be expected to be in favour of the latter.

We conclude, then, that the builders of the Roman wall of London made use of British materials, to which they applied the patient forethought and thorough integrity of execution that characterise Roman work. They dug the clay of the valley of the Thames, and instead of moulding it into thick blocks hard to bake, and next to impossible to bake thoroughly through, they moulded it into flat 1½ in. plates, on which the vitrifying process could have full effect, and which are almost, if not quite, as durable as firebrick. As to brick, then, there is no doubt. But how about the mortar? As to that, also, we have ourselves no difficulty. The Romans used British lime, whether burnt from the chalk from Gravesend or from some other and harder stone it is for the chemist to tell us; but they made it into mortar in the Roman method. What is that? a reader may ask. We have, we think, before now, mentioned in these columns what it was; but, if so, it may well bear to be repeated. It was the diametric opposite of the present English method. There are many builders and persons conversant with public works who can remember the immense care which Mr. Brunel bestowed upon his specifications, and the elaborate system of inspection by which he effected the practical application of his rules. No one, as far as our experience goes, in modern times, so laboured to secure the greatest excellence of work. It fact, it is well known that what Mr. Brunel called rubble would be called ashlar by some of his contemporaries, and that the rigidity with which his orders were carried out made it by 10 per cent. or 20 per cent. more costly to execute his designs than those of some of his brethren. Mortar, of course, exercised much of his care, and the mortar that he used was mixed hot from slaking the lime. If any remained to the next day, it was to be thrown away. Such was the specification; and although that was an extreme case, we apprehend that nine

builders out of ten would say, if it erred at all, it erred on the right side.

In Italy an opposite view is taken, and an opposite method is adopted. The first practical preparation for building in that country is to dig a large oblong square pit, into which the lime is thrown when burnt, and covered with water. It is thought desirable to throw in at once all the lime that will be required for the building, and the longer it is before it is used the better it is considered to be. It forms a dense paste, which is taken out with a spade and mixed with sand or pozzuolana as required. It is usual to keep it moist, but we have never heard of or seen any thrown aside for any cause at all. The magnificent character of the work done with this mortar is well known. The Italians of many districts are born masons. Where we should call in the carpenter, and rig up a shore, a centre, or a set of props, the Italian builder runs up a temporary wall. He saves the cost of wood, for he can use the stone over again; and his temporary work, if required, will last almost as long as his permanent work. In the cases, which are far from uncommon, of damage to building from earthquake, the wonderful celerity with which they are repaired is quite a phenomenon. Again, many of the Italian roofs are made of a species of mortar, a mixture of lime and clay, beaten for a week or ten days incessantly with clubs or mallets. The surface is quite water-tight, a condition by no means to be obtained by English mortar. Again, for plasters of all kinds, down to the smooth surface which lends itself to the rapid brush of the fresco-painter, the excellence of the Italian lime, notwithstanding the wide geological range from which the limestone is taken, is something that is unattainable in England. It is all very well to say that the genius of the English school does not tend to work in fresco; there is something more than that. The English artist has not the opportunity of exercising himself by that most artistic use of his implements.

We recently saw a very remarkable illustration of the difference effected in the same material, and that, too, a cement, by the mode of treatment. We know an artist of rare patience and skill in the restoration of broken china. We know of a dragon vase, once fractured into twenty-five pieces, and of a china plate, shivered into nearly forty bits, that are now on their owner's shelves, without any visible mark of a crack. The cement that was used is that known as the "Mend-all cement"; but, of course, the skill goes for much more than the choice of material.

The artist in question, however, has long been careful to procure the smallest possible bottles of the cement; and that for the following reason:—The material is prepared for use by dipping the bottle containing it in hot water. It then becomes fluid, and is easily applied to the edges to be joined, the fragments being themselves kept in hot water, and taken out and wiped before being cemented and put into place. If a large number of mends are made, and the whole affair gets out of shape,—which it is very difficult in that case to avoid,—the mended article is again put in very hot water, when it comes to pieces at once. Each piece has to be carefully wiped and re-cemented.

The objection to large bottles of cement is this,—hitherto a perfectly empirical one:—After the cement has been liquified and cooled a certain number of times, it becomes refractory. It no longer liquifies easily, if at all. It makes bad mends, or is altogether useless.

To this long-observed fact, a second observation has been added, within the last few days, which is highly significant. The bell of a "Queen's" reading-lamp, which had a large piece broken out of it some years ago, was mended by the artist in question, and has been in nightly use ever since. After the fashion of mended things, this glass shade has outlived its more robust brothers. But the line of junction was visible, and the repairer thought that it would be an improvement to wash the bell, remove the old cement, and re-cement it. The bell, however, thought otherwise. To the surprise of the operator it laughed at the hottest water, and absolutely refused to allow the crack to re-open, or the cement in any way to soften or dissolve.

This phenomenon is worthy of reflection. It is impossible to disconnect it from the behaviour of the cement in the bottle. The shade of a queen's lamp does not get so hot as to burn one's fingers, but it gets warm. The mended individual has thus been warmed and allowed to cool at least a thousand times. At what stage in the process the chemical change was complete it is impossible to tell. Very likely in twenty or thirty days. But slowly and gradually the cement has so parted with some element of solution as to vitrify, or, at all events, to unite itself with the glass in a union indissoluble by the agency of hot water, the original solvent of the preparation.

We cannot bake walls, unless it be by selecting very hot weather for their construction. On the other hand, we can avoid that soaking of the bricks, if rain happen to come on during the process of building, of which no notice is now usually taken. We know of one costly building, of which the colour is permanently and entirely ruined by this neglect. Our object is to induce the Royal Institute of British Architects, the Institution of Civil Engineers, or others whom it may concern, to investigate this important fact of the behaviour of lime or other cement. What is the effect of time on their cohesive force? Should time be allowed to elapse before the use, as is the case in Italy? Should it be combined with repeated rise and fall of temperature, as in the case of the Mond-all cement and of the lamp-glass that we have cited? Will an exposure of a certain duration to a steady heat have the same effect? And, if so, what heat, and for how long applied? These are questions of primary interest to the architect. Their solution may place a new material within his grasp. He may be enabled to rear those egg-shell domes which the imagination of Bulwer fashioned for the homes of the "Coming Race." We can never tell how far a new idea may carry us. We strongly suspect that the builders of the earliest bridge over the Tiber, or of the walls of Rome,—certainly that the builders of the Roman wall of London,—had a much clearer insight into the relation between the time spent in preparation and the permanent durability of work, than has any writer or lecturer on structures at the present day. We are not now speaking of those "Jerry builders" of whom a contemporary justly observed, *apropos* of this very discovery of a Roman relic, that the Romans would have thrown them from the Tarpeian rock. We are speaking of thoughtful and experienced men. We are quite sure that Isambard Kingdom Brunel, were he now alive, would respond to our words by an elaborate series of experiments; and that if the result confirmed the practice of the Italian builder, he would then and there have re-drawn his specifications. We know not on whom now to place confidence for an equally earnest and practical desire to reply to such a question, but we trust that each and all of our friends who have the opportunity will do their best to aid in the formulation of the answer.

THE ARCHITECTURAL PROFESSION IN ENGLAND AND GERMANY.

In the Prussian Parliament, about a year ago, Dr. Reichensperger made an attack on the system of education and State connexions of the architectural profession in Germany. There arose in consequence in the German press a controversy, to which we referred at length in the columns of the *Builder* at the time. Up to the present day the dispute has by no means been settled. On the contrary, it has broken out again with renewed vigour. The *Cologne Gazette* is again taking a leading part in the paper war, and has just published a general review of the present state of the question. While Dr. Reichensperger condemns the German practice, and holds up England as a model for Germany in regard to the education of architects and builders and their relations to the State, the *Cologne Gazette* contends that Germany has little or nothing to learn in the matter from this country. "In our articles on the subject," says the paper in question, "we adduced evidence based on the judgments of Englishmen that the system prevailing in their country in regard to the education of the building 'professions has for many years been found defective and unsatisfactory. The most competent authorities in the professional societies and journals of England have declared in favour of a change in imitation of foreign models. A continuance of the present state of things, it is considered, seriously threatens the reputation of the profession in England, and endangers the industrial interests of the country. We concluded that Dr. Reichensperger had spoken in the House of Deputies about things of which he was ignorant."

In a pamphlet he has just published under the title of "Parliamentary Utterances on Art and Art Industry, together with Comments thereupon," by Dr. A. Reichensperger, the author takes up his old position and defends it against the *Cologne Gazette*. In this publication he reproduces his speech of December 6th last year (filling five pages) and accompanies it with "glosses" or comments (filling twenty-six pages) in which he settles accounts with his opponents. His remarks are mainly devoted to former criticisms of the *Gazette* upon his theories. Dr. Reichensperger predicted that the Rhenish paper would ignore his latest utterances, but, so far from doing so, the *Gazette* enters into an examination of them at great length. The Prussian Deputy is accused of great ignorance of the subject on which he presumes to lay down the law. He is charged with dragging everything into the discussion,—the system of the technical high schools, the connexions of architects and builders with the State, their various official titles, the procedure in contracts and tenders, the preparation of estimates of cost, the practical erection of buildings, the correction and improvement of the navigation of rivers, the construction of bridges,—in fact, everything, "and something further besides." The way in which he deals with these matters is, according to his critic, calculated only to show his want of thorough acquaintance with his subject.

While Herr Reichensperger charges his Cologne critic with heaping on him "contemptible suspicions and coarse insults," the latter replies that the Doctor is angry at having his ignorance exposed, and the latter is charged with having, in his pamphlet, entirely failed to meet the arguments brought against him. The essence of the charge against the Deputy is, that he urges the Prussian Parliament to adopt certain English practices which are anything but worthy of recommendation. He professes to have thoroughly studied the position of architecture, architects, and builders in England, and states that the extensive apparatus of professional officials, such as exists in Prussia, is scarcely to be found in Britain. There the system of studying privately under the masters of the profession is in vogue, and this he recommends in preference to the system of state instruction followed in Germany. There are no State examinations as in the latter country. There is no great architectural institution similar to the "Bauakademie" in Berlin. And yet, urges Dr. Reichensperger, Germans are beaten by Englishmen in all departments of the field of architecture. It would, therefore, he contended, be worth while that the Prussian Government should cause a thorough inquiry to be made into the English system. He thought the result would be to convince Germans that they might shut up their state-endowed institutions, like the "Bauakademie," and throw the keys into the Spree.

With reference to these opinions of Dr. Reichensperger, the Cologne critic writes:—"Such a laudation of a system which in England itself has for years been generally acknowledged to be defective,—acknowledged, indeed, to be a *misère*,—a system which the most eminent authorities are most energetically endeavouring to improve, bears witness to a want of knowledge of the subject that is almost inexcusable, especially when the place where those opinions are delivered is taken into consideration. They are the less to be excused, as they will serve as a foil to other attacks on our own [Prussian] system, and our own architects, and their achievements."

The writer refers to a former article in the *Cologne Gazette* for an unbiassed description of the real state of things in England, and adds that his earlier remarks have been discussed by the English professional organs in a manner which deserves his most grateful acknowledgment. The most widely-circulated English technical journals had given their readers a *resumé* of his criticism; as, for instance, the *Builder* (March 13), &c., and afterwards some American organs. The English papers had understood how to go to the kernel of the matter, as the titles they had prefixed to their articles showed ("Technical Education of Architects in England and Germany," &c.). These articles, the German writer says, did not charge him with making any mistake, nor did they dispute his assertions respecting the English system. On the contrary, they so far agree with him that the system here required a thoroughgoing improvement. From the perception of the deficiencies of the

present system, the English will proceed to an attempt to remedy them. This, in the writer's opinion, is guaranteed by that most laudable absence of prejudice with which they have accepted the comments of foreign critics.

An interesting contribution to this question, continues the writer, is presented in the recent speech of the president of the largest English architectural association, the Royal Institute of British Architects. We have formerly explained that, in England, architecture has no connexion with the Government. State institutions, like our high schools for the education of technical men, do not there exist. On the other hand, the great technical societies step into the breach, and devote their energies to providing some portions of that higher instruction which, in other countries where self-government is less developed, it falls to the State to supply. Thus, the great London society above mentioned does what is in its power to make up for the deficiencies of the English system by providing a preparatory course of instruction for young architects after the Continental method.

How greatly assistance of this kind is needed appears from a remark of the president, Mr. J. Whichcord, in an address published in December last. He referred to a question mooted at the Institute in 1874, in a discussion respecting the defective preliminary training of English architects, when it was asked, "What measures should be taken by the Institute or otherwise in order to make certain that the young men who call themselves architects shall learn something more of architecture than they are in the habit of acquiring in the offices where they sit for a long time copying plans and drawings?" The reply to this question amounts to a strong condemnation of that English system of masters' schools so highly praised by Deputy Reichensperger. It will shortly be seen by the inauguration of a new practice in England. It is intended of institute that very system of examinations which Dr. Reichensperger so greatly despises. It has been resolved that from May, 1882, all students of architecture shall, before being admitted into the Institute, undergo an examination, the nature and extent of which the committee will prescribe.

In speaking of the position of architecture in England, we must, to our regret, once more refer to the results of the competition which took place in 1872 for plans for a new building for the German Parliament. In opposition to Dr. Reichensperger's statement, that "in every direction we (Germany) are beaten by Englishmen," we adduced this international competition to prove that in point of genuine and intrinsic worth German architecture was by no means inferior; and we showed that the English plan which gained the second prize showed various important defects. Herr Reichensperger is highly indignant at our remarks. He charges us not only with being untrustworthy in our facts, but also with casting "mean suspicions and contempt on the decision of the jury," and, indeed, with heaping coarse abuse on the design in question and on its authors. We confess that we are to some extent disconcerted at this want of caution on the part of Herr Reichensperger. We had given him credit for greater capacity for understanding architectural designs than he here seems to show, as the obvious defects of the plan in question are manifest to any non-professional observer. On the other hand, it is impossible to understand how a gentleman who himself belonged to the jury should know so little of the feeling in professional circles, and of their criticism upon the design, that he thinks our remarks are singular. We should hardly have trusted ourselves to utter such a judgment if we had been alone. But it is as we said. The award of a prize to the English project was publicly spoken of in professional circles as scandalous, but for this hard judgment substantial reasons were adduced. The *Deutsche Bau-Zeitung* made itself the vehicle for the prevailing feeling, and expressed itself to the following effect:—

"That the production of the two English architects, in regard to the first and most indispensable basis of every architectonic work,—the satisfaction of the practical requirements of the design,—leaves almost everything to be desired will have become clear to our readers even after a superficial study of the plan, and will have filled them with increasing astonishment. We do not say that all the apartments demanded in the programme are not there, with the dimensions required. But in what order are they arranged? The committee and sectional rooms, and the business apartments for the Federal Council, are scattered all about the house. The president's dwelling is distributed through four stories,—that of the director of the bureau through three. The refreshment department is in a story below the hall of session. The festival saloon and the offices lie isolated in the projecting wings, and are difficult of access from the rest of the building. Not a few of the corridors are dark or most scantily lighted. With still greater astonishment do we contemplate the way in which the plan fulfils the requirements of such a building, considered as a monumental edifice combining dignity with beauty. What is to be said when we find the transverse axis of the cupola in the front hall, which has required a gigantic expenditure of expedients to give it prominence in the external architecture, runs dead in the interior,—that is to say, debouches on the urinals? All the power of the architects, their entire thought and endeavour, have been exclusively directed to give external effect to their work,—to make it look as splendid and rich as possible; and the artistic feeling of us Germans turns away offended from so thoroughly hollow an effect, which, instead of suggesting sound thoughts, brings only a deluge of dazzling phrases, concealing behind them the most extreme poverty. If we may briefly state our judgment on the design, it is, that as a study in the decorative adaptation of the architectonic forms of the Transition style, and as a picturesque production, it is not uninteresting; but, on the other hand, it does not contribute a single element towards a real solution of the task,—the designing of a German Imperial House of Parliament."

So far the *Deutsche Bau-Zeitung*. The Cologne critic, in continuation, says that many persons wished to judge the plan less harshly, but they were influenced by the circumstance that the six architects who were on the jury participated in making the award, and concluded that they acquiesced in it as an act of international courtesy (!). The criticism above quoted, however, was the unvarnished opinion of German professional circles, and the journal in question, in afterwards discussing the competition, was able to state that it had heard not a single voice that had ventured to defend the award of a prize to this design. This has been left for Deputy Reichensperger to utter, and we beg him to inquire in professional circles and try to find a single professional man who would defend this defective project. Herr Reichensperger, in one of his glossee, says, "In my opinion it does not require a well-schooled so-called scientific education, in order to distinguish genuine splendour from a hypocritical tinsel gaudiness, and to judge whether a church or a public building answers its purpose, or whether a dwelling-house affords its occupiers, down to the servants, light, air, and as much comfort as possible." In the above case, however, he gives a very weak proof of the correctness of this "opinion" of his, and shows very clearly what happens without a "well-schooled education." He perhaps understands now why we have been silent about the names of the English authors of the plan, though, of course, as a purely matter-of-fact discussion about the superiority of English architects over German, names are altogether unimportant. Deputy Reichensperger has been decidedly unfortunate in his examples taken from England, and only shows the sort of thoroughness with which he has studied the state of things in that country. There is certainly no country in the world which sends so many technically-trained professional men, old and young, abroad as Germany, for the purpose of studying foreign productions; and every year a large number of such persons in pursuit of knowledge go to England,—the best proof of the esteem in which Germany holds the sister nation across the Channel in regard to certain departments of the technical arts. On the other hand, England is one of the last countries which is visited, whether by Germans or by other nations, for the purpose of studying architecture. Still less do people go there to learn what arrangements are deserving of imitation as models in reference to a preparatory training for this profession. In these two respects, however, the excellence of its architectural creations and the system of preparatory training for architects, Herr Reichensperger has unhesitatingly awarded the palm to England.

In conclusion, in order to obviate misconceptions, we wish to caution the reader against supposing that we considered our native system of architectural education, professional organisation, and productions as being all perfection. No one more than the professional man himself is convinced that in all these respects we are open to improvement, and that we ought to work hard to do away with the defects of the forced economy of past times, and to alter and perfect the organisations hitherto existing. This is not the place to pursue the present argument, or to suggest new ideas. We have here only to protest against the manner in which Herr Reichensperger criticises the architecture and architects of Germany, especially their relations to Government. His representations are calculated, unjustly, to spread the notion that there is "something rotten in the State" in regard to the profession in question. That against which we most particularly protest is his attempt to discredit the academical training of German architects and his advice "to throw the key of the Banakademie into the Spree." One who is capable of giving such advice ought to think ten times before venturing to utter a word about technical matters in a public assembly. For nothing evidences ignorance of the nature of modern technical art so clearly as such a want of appreciation of the daily increasing importance of science in every department of the arts.

SOME BILLS FOR THE WORKS AT BLENHEIM.

WE have printed the following bills for works done for the Duke of Marlborough at Blenheim Castle in the years 1709-10, under the direction of the architect, Sir John Vanbrugh, from the originals now in the possession of Mr. Stephen I. Tucker, Somerset Herald. Four of them are signed by Vanbrugh and receipted; the fifth is not signed by him, but is endorsed paid at London. In the third bill forty cards of kid's hair are priced at 6d. per card, but moneyed out as if at 6½d., viz., *li.* 1s. 8d. And in the last of the bills given it will be observed that a rod of brick work is described as containing 272 ft. *cube*. These bills will doubtless be interesting to some of our readers, as affording means of comparison in respect of prices. The troubles which befell Vanbrugh during the building of Blenheim through the inconsistency of Parliament, and the evil spirit of Sarah, Duchess of Marlborough, are well known. He says, in a letter to Jacob Tonson,—"I have the misfortune of losing, for I now see little hopes of ever getting it, near 2,000*l.*, due to me for many years' plague and trouble at Blenheim, which that *wicked woman* of Marlborough is so far from paying me, that the Duke, being sued by some of the workmen for work done there, she has tried to turn the due to them upon me, for which I think she ought to be hanged." The strange history of the building of Blenheim is told in D'Israeli's "Curiosities of Literature." A reason for Somerset Herald's regard for Vanbrugh's autograph may be found in the fact that he for a time held the office of Clarencieux King of Arms, an appointment which enabled Swift to insinuate that Vanbrugh's new title enabled him to "build houses" in more ways than one. Vanbrugh was always well abused, and Pope's spite has done as much to keep his name in memory as Blenheim or Castle Howard. He was a man of original genius, and even the bitter little poet of Twickenham admitted that he was "a man of wit and man of honour."

May, 1709.

To Robert Wetherilt, Plaisterer, for work done at the Maunor House in Woodstock park, for his Grace the Duke of Marlborough:—

	£.	s.	d.
ffor 401¼ yds. of Plain Ceiling.....at 6d. ℔ yd.	10	0	10
ffor 900 yds. of Rendering walls....at 4d. ℔ yd.	15	0	0
ffor 658 foot 7 in. Run of Small Molding 6 in. deep.....at 9d. ℔ ft. run	24	13	11
ffor 83 foot Run of Small Molding, 1½ in. deep .....at 2½d. ℔ ft. run	0	13	1
	£50	7	10

May, 1709.

To Mr Thos Joseph for Oak Timber, bought of him at New Ditch Quarter, in banger Walk, in Whittlewood forrest, Northampton Shire, for his Grace the Duke of Marlborough use at Blenheim Castle, Woodstock Parke:—

foot cubic	£.	s.	d.
For 570 of Oak Timber at 8d. per foot cubic.....	19	0	0

Measured and cast up ℔

This Bill according to ye prise above agreed on amounts to the sum of Nineteen Pounds.

Allow'd ℔ me, J. VANBRUGH.

Sept. 15th, 1709. Rec'd. of Mr. Henry Joynes the sum of Nineteen Pounds in full of the above bill.
£19 0 0 ℔ me, Thomas Joseph.

June, 1709.

To Roh[t] Wetherilt, Plaister[r], for Daye Worke ℔form'd att Blenheim Castle; in Stoping of windows, after y[e] Masons, in Atick Story, in Kitchine wing; and Botome after y[e] floors were layd there; in Stoping of y[e] Breatchee in Attick Story, in y[e] Maine Howse, y[t] y[e] Joyners made in puting up their Wainscott; for Takeing Downe y[e] Lathing of y[e] ont Roome next to y[e] Servante Hall; and two Groins in y[e] same paeeage; and for Stoping and Mending eorveral Johbe at y[e] High Lodge, &c., for y[e] Service of his Grace y[e] Duke of Marlhorough, in Woodstock Park:—

	£.	s.	d.
ffor A plaisterer 49 Days at 3s. ℔ Diem	07	07	00
ffor A Labourr 26½ Days at 2s. ℔ do.	02	13	00
ffor 40 Cards of Kid's Hare at 6d. ℔ Card	01	01	08

THE ARCHITECTURE OF MADEIRA.

It would hardly be eupposed that anything architecturally interesting is to he found on an Atlantic ieland 380 milee from the nearest mainland, Mogador, and more than 500 miles from St. Vincent, tho neareet architecturally civilised coaet. The island, in trnth, owee little to man's interference. Ite interest centres in the eublime grandenr of the central axis and the northern side of the ieland, which is intersected hy deep cañon-like gorgee, whose dark walls riee almost vertically for thousands of feet. All ie massive hasalt, built up of euccessive overflowe from a mighty central crater, so new geologically that the plants here and there enclosed and petrified are of existing island speciee, and the only record of changed conditione they anywhere entomh is a tiny coral reef. Alternating with the lava flows are layers and layers of earth hurned to a bright cherry red, and sheete of pumice-stone and ash. The possession of every ledge and every fissure ie disputed hy numerous kinds of laurel, giant trees which "ripen, fall, and cease."

Ferne clothe the moist ravinee. Woodwardia fronds cut to ehade my hammook measnred 9ft., and in remote glene the hright feathery fronde of Dicksonia, 12 ft. long, curve to the grouud, and delicately translucent ferne, elsewhere rare, twine round every stump and rock. The hack-bone of the ieland riees 6,500 ft. in wildly jagged peaks, in climbing which the sea horizon risee with you as it does in Teneriffe, taking on the appearance of a high hlne wall, and melting into sky a hundred milee away, while at other timee a white hillowy expanse of cloud stretchee beneath you.

The island was discovered in the reign of Edward III. The etory ie a romantic one, and often told, discredited, and lastly proved heyond all doubt. Lost eight of, it was re-discovered in 1414 again through accident, hy Zarco, and Trietam Van Teixeyra, two squiree to Prince Henry, the navigator. The spiritualities of the island were made over in perpetuity to the Order of Christ hy Don John I., and the papal confirmation granted in 1442. The carliest existing edifice, once a small chapel, now a coal-store on the western ontskirte of Funchal, is low, with sqnare windowe, and none hut the plainest buildings appear to have heen erected until almost the close of the fifteenth century.

Funchal, the chief town, reminds one in its situation, of Naples. There ie no harhour; vessels lying in the roadetead simply trust that the prevailing northerly winde will continne to hlow. The hills elope rapidly, and are studded with villas to a height of 2,000 ft., where these and vineyards give place to pine woods. In 1508 it was made a city, posseesing equal privilegee with Lishon; in 1514 a bishopric, and in 1539 an archhishoprio. The cathedral, commenced in 1485, and opened in 1514 under the auspices of a Captain-General surnamed "O Magnifico," is anything hnt of archiepiecopal dignity. A plain Italian Gothic huilding, with square whitened tower and glazed-tile epire, is only curious as heing Gothio in form with no trace of Gothic eentiment. Moorish influence ie apparent in the capitals; and the juniper-wood roof, as in other churchee in Madeira of the same period, is an interlaced, purely Moorish design. The altars and their furniture are unusually tawdry, and everything is meretricions except a finely-executed, hnt poorly-designed, wrought-iron grille. The more ancient eastern part of the city has twice heen almost swept away hy floods, hut a good example of the ancient architecture is still standing close to the western gate. A courtyard is overlooked hy windows of two lights, with semicircular heade to each, and divided hy a slender pillar, with foliated capital of peculiar design. The general appearance ie Lombardic, hnt a closer inepection reveals a thoroughly Spanish Renaissance character. At one end is a paradoxical triple-lancet window, like thirteenth-century work; and the ceilings, rafters, &c., are of the same Moorish design as the cathedral, and horrowed apparently from the church of St. Francie d'Assiei. Another house, repnted erroneously to he that of Columbus, has just been removed to make way for a so-called improvement. The windows had the same Lombardic donble-lighte, with the striking peculiarity that the eill, instead of heing level, drops to the centre mullion at an angle of 60°, the mouldinge of the jambs heing continued down the elope and stopping against the hase. Setting back from the front, there is a stone filling-in with a horizontal line continued about a foot above the commencement of the slope. The capital of the centre mullion and the two terminations, for they can scarcely he called caps, to the side-jambs, are sculptured with considerable spirit. The whole appearance is perfectly unique, and there is probahly no similar window on the European continent. The Custom House, almost on the heach, has a vaulted basement with pillars of octagonal plan, and capitale with a quatrefoil leaf on each face, curious as a rough reminiscence of the Spanish late fifteenth-century carving, where capitale are composed of three or four vine-leaves, and depend for their light and shade on the foliations of the leaves. Thece pillars support round arches, while the doorways are pointed. Exteriorly, four large gurgoyles are interesting. These are apparently of lead, and of the seventeenth century, two being grotesque monsters pointing muzzles of cannon; a third, the head and front of a game-cock; and the fourth, a frog-like monster. The most intereeting huilding ie a convent, on high ground, in which is Zarco's tomb. It has the same vaulting and architectectural features as the cathedral; hut the walle are completely lined with Hispano-Moreeque tiles, richly arabeeqned in hlue and orange-yellow. The tomh is a rough sarcophagus huilt into the wall and resting on Lombardic lions, with decipherable legends. The recess is arched and moulded in the Early English style, with Decorated tracery and capitale. The nnne attend mase hehind wronght-iron grilles. The later churches, two of the town gates, and a few pnhlic buildings, are of heavy Spanish-Jesuit style. At Santa Cruz, tho second town in the ieland, the principal square ie entirely surrounded with buildings of the fifteenth century, similar to those described above, and including a cathedral, hoepital, prieon, &c.

The streets in overy town are narrow, and paved with cobbles worn smooth hy sledges and bullock-wagons. The houses are rectangular, more often one-storied than two, hnt frequently carried up three or four additional floore in a square tower, in order to command views over the bay. The material nsed is rnbble, with angles of dressed drab lava, cleanly white-washed or tinted huff or roee, the dressings being painted a different colour or left the natural stone. The windows are fairly large, protected hy green jaloneiee. The roofe, tiled red or bnff, slope from each face at 25°, and project several feet over the streets, the hnff tiles and white mortar in which they are eet forming pretty overhanging cornices, which never seem to soil, and cast an agreeahle shade. The better honees have wrought-iron balconies of excellent workmanship and great diversity of design, and it is lamentahle to notice that these, one of the chief features, are heing replaced to some extent with common cast-iron from England. The basement windows are invariably protected hy maeive grillee, in which the bars are threaded through each other in the old way with as many as 200 interlacings to a moderate-eized window.

Take it altogether, no style could be more suited to the climate and support more effectually the theory of evolution in architecture, for it can olaim to he ae much evolved from the insular and sub-tropical conditions as the zoological featnres undoubtedly are. The dwellings are rendered more pleasing and

characteristic by clumps of banana, occasional date-palms, and trellised vine, and some enclose inner courts full of gardenia, stephanotns, and heavily-scented flowers. Three castles frown over the city, one in its centre, one above it, and one on a rock rising from the bay in front. They have sloping sides, technically known as "battered," pierced all over with mock casemates, and battlemented, and are stagy in appearance, and, of course, utterly useless for defensive purposes.

The commerce and enterprise of the place are English. Every ship in the harbour seems consigned to Blandy Brothers. The wine trade lies almost entirely in the hands of the great house of Cossart, Gordon, & Co., and other almost historic English names. The beautiful and well-kept villas in the outskirts are owned and were built by Englishmen, and the native press laments that the island is not under English rule. The only flourishing Portuguese building, a splendid hospital, and the gift of royalty, is directed by an English gentleman. Purely Portuguese undertakings are often ridiculous failures. A short road from the Custom-house to a small landing-stage, the Pontinha, was breached by the sea, and abandoned before half completed. A huge mill, covering an immense area, with machinery, costing 100,000 dollars, from St. Quentin, of power enough to crush in a week all the sugar-cane grown in the island in a year, has never even been opened. The finest building, a Franciscan Convent full of inlaid marbles, was pulled down, and the tombs of the old families violated, to make way for a Palais de Justice. The foundations were so Titanic that before they rose above the ground the whole available money was absorbed, and the building abandoned. After a long interval, this stony desert of building material and massive walls is to be converted into a botanical garden. As a preliminary, some magnificent palms, previously spared because the finest in the island, were felled. A large Lazaretto, built in separate blocks in a picturesque little bay, has just been condemned on the eve of opening, because too near the town, and the port is still without quarantine accommodation. A water-course pierced for miles through the rock, and found to run uphill, and a sea-wall, knocked down by the military to permit the retreat of troops from the beach in case of invasion, are other monuments of folly. On the other hand, the Government system of irrigation is beyond praise, and has involved in many cases enormously difficult engineering works; while the Portuguese system, which is to return to the island part of the taxation if required for public works, offers a direct premium to the Madeirese to embark upon any work, however unproductive, which will cause their own money to return to their own country. J. Starkie Gardner.

ARCHITECTURE AS INFLUENCED BY CUSTOM.

BY W. PETTIT GRIFFITH, F.S.A.

"From all arts and sciences whatsoever, there are drawn certain principles, rules, or natural conclusions, which if we shall apply ourselves with all care and diligence to examine and make use of, we shall undoubtedly find the benefit of, by the perfect accomplishment of whatsoever we take in hand."—Ferabt.

In treating of architecture, there is an important distinguishing feature much overlooked in the present age. Wren, in the "Parentalia," very pointedly alludes to it; he says that "there are two causes of beauty, natural and customary. Natural is from geometry, consisting in uniformity [that is, equality] and proportion. Customary is begotten by the use of our senses to those objects which are usually pleasing to us for other causes; as familiarity or particular inclination breeds a love to things not in themselves lovely. Here lies the great occasion of errors, here is tried the architect's judgment; but always the true test is natural or geometrical beauty."

It is not surprising that architecture is influenced by custom, as it prevails over everything:—

> "Custom, that does still dispense
> An universal influence;
> And make things right or wrong appear,
> Just as they do her liv'ry wear."

Reynolds observes that the prejudices in favour of the fashions and customs we have been accustomed to, and which are justly called a second nature, make it too often difficult to distinguish that which is natural from that which is the result of education.

In a paper entitled "On the Influence of Fashion in Architecture," read before the Liverpool Architectural Society in 1863,* I directed attention to the styles of architecture as reproduced at various epochs to suit the ever-varying taste of the public; but the object of the present paper is to point out the abuses which have been introduced into regular architecture, sanctioned by custom, although contrary to common sense and the original intentions of the early architects. Fashion in architecture refers to the reuse of existing styles (the idea of a new style having been shipwrecked long ago), and has no bearing upon architecture as perverted by custom. The latter, consequently, is by far the graver question of the two, as the creation of architecture has to be considered and not simply its modern use.

> "Custom, the world's great idol we adore;
> And, knowing this, we seek to know no more.
> What education did at first receive,
> Our ripen'd age confirms us to believe."
> Pomfret.

Although custom often constitutes a moral rule in cases where no legal dictum prevails, it does not always do so. For instance, it was the custom when Classic architecture was the fashion, to denounce the Gothic; hence, in 1724, Tickell, in alluding to Queen's College, Oxford, says:—

> 'Mark that old ruin, Gothic and uncouth,
> Where the Black Edward pass'd his beardless youth.'

Custom has introduced many abuses, contrary to reason and ancient rules, which for years have been rules of architecture, because

> "Some lucky licence answer to the full,
> Th' intent proposed, that licence is a rule."
> Pope.

These abuses should be carefully considered by all who desire to produce correct architecture; the more so, as time cannot render irregularities legitimate, nor can authority justify abuses of taste; for

> "Custom does not reason overrule."
> Rochester.

No errors, however ancient, or however countenanced by long practice, are fit objects of imitation. If rules were laid down for determining with precision what ancient monuments are of the true standard principle of correctness, they would greatly contribute to accelerate the progress of architecture; but, to ascertain such rules would require the qualifications of the philosopher, united with those of the architect. He whose mind is enlightened by these reasoning powers knows how to stamp a just value upon works of real merit, and to reject any excrescence that "old Time," as Milton says, "with his huge drag-net, has conveyed down to us along the stream of ages."

Some of these abuses have been pointed out by Vitruvius, Palladio, Perrault, Chambers, and others. Among them may be named the swelling of columns. Freart blames the practice of making "pillars swell in the middle, as if they were sick of some lympany or dropsy," and he justly remarks that it is contrary to the original and natural type in trees.

A column with straight lines would appear concave to the eye, consequently curved lines are requisite; but whether the curve should have the greatest diameter at the base or at about one-third up the column is a point for consideration. Vitruvius says that it is made in the middle of the column. This is absurd, as he has no authority for it. The curve should start with the greatest diameter at the base, unless there be any truth in the assertion that bodies must diminish as they recede from the eye. In this case, the greatest swell would be a certain distance up the column. Vitruvius perhaps took the idea of fixing the greatest swell in the middle of the column from his composing the Doric column upon the model of a man, the centre of the latter being his navel: of course there is no authority for anything of the kind.

Sculpturing modillions and dentils of pediments perpendicular to the horizon, and not to the slope line of the pediment, is erroneous; but custom has adopted this innovation. So, too, putting modillions on the four sides of a building, and in the horizontal cornice of the pediment; modillions being proper on those sides only where the rafters are set, whose ends they represent, and not in the cornice that runs under the pediment.

Making several breaks in the horizontal entablature or cornice of a pediment.

Breaking entablatures over columns and pilasters, particularly if there do not appear to be the same occasion for it as may be perceived in the triumphal arches at Rome, or other structures of a symbolical description, where the breaking of the entablature indicates the characteristic intention for which the columns were so introduced; namely, that of supporting emblems expressive of commemorable events, and in that instance not unappropriate.

Perrault says, neither ought we to make statues placed above larger than those set below, when they are of the same kind, that is, when both stand each in its own story or order. But, on the contrary, they ought always to be diminished, as the orders are, which are necessarily less than those below.

It is not only important, but necessary, to judge of the sizes of objects to be placed on lofty erections. It was remarked in "Roma Illustrata," 1721, and in 1806, by an architect who visited France and Italy, that the figures high up in the bas-reliefs of Trajan's column are somewhat larger than those below; the perspective reducing them to an equal size to the eye. By referring to Taylor & Cresy's Rome, it will be found that this assertion is not correct: the twenty-three blocks of white marble are all of the same size, and also the figures upon them.

We are informed by Vasari that towards the close of his life Michelangelo began to study his compositions in sculpture with more care, making models, not only for statues, but also for architectural ornaments, of the full size, which he used even to place at their proper height in order to judge of the true effect of the future work.

When two or more orders are employed, one above the other, in a building, the laws of solidity require that the strongest should be placed lowermost; the Tuscan to support the Doric; the Doric, the Ionic; the Ionic, the Corinthian; and the Corinthian, the Composite.

In England there are few examples of more than two stories of columns; in Italy and other parts of Europe are to be seen three and sometimes more; yet it is a practice by no means to be imitated. Palladio attempted it at the Carita in Venice; Sangallo, in the Farnese at Rome; Ammannati, in the Cortile of the Pitti at Florence; but all unsuccessfully.

Breaking of pediments, and leaving them open in the middle; pediments being intended to throw off the rain, and not to let it in.

Breaking the entablature and making the cornice of a pediment rise from the top of a column, pilaster, or pier.

Placing two or three pediments, one within another. The ancients, observes Chambers, always avoided introducing pediments of different sizes in the same composition.

Raising pediments on circular bodies.

Employing other forms of pediments than the triangular and round. Placing balustrades on the inclined cornices of pediments, balustrades being intended to enclose terraces and other heights to prevent accidents. Also intermitting the horizontal entablature of a pediment to make room for a niche.

Putting triglyphs in any other part than over the column. Enlarging the metopes. Putting dentils below the mutules, because the feet of common rafters cannot be below those of principal rafters. Adding dentils under modillions.

Projecting the cornice too much, so as to exceed reasonable utility, and thus appear unsafe to passers by.

Adding rustics to columns and pilasters, scored like loins of pork; making columns and pilasters penetrate each other; coupling of columns, condemned by Blondel and vindicated by Perrault.

Triangular, circular, and polygonal pedestals are objected to.

Chambers objects to adorning the pedestals or pilasters of attics with moulded panels, which look like joiner's work, and should therefore be avoided; neither should they have capitals, as is always the custom in France, which give them the idea of a clumsy, ill-proportioned composition.

In France, and in Sir John Vanbrugh's works, the horizontal joints of rustics only are marked, the vertical ones being entirely omitted. This has a bad effect, and makes the building look as if it were "composed of planks" rather than of stones. Palladio's method is preferable, who, in imitation of the ancients, always marked both the perpendicular and the horizontal joints.

* See the *Builder*, vol. xxi., p. 38.

In the Ionic capital, forming one volute parallel and the other oblique.

Placing the Attic base under the Doric column. Using pilasters instead of columns. The Araeostyle disposition of columns suggested by Perrault, and opposed by Blondel. Piling two or three orders of detached columns one above the other. Setting the Composite column over the Corinthian was not approved by the judicious.

Using cartouches instead of columns or pilasters, as they appear deformed to the intelligent eye.

Putting the cyma or cavetto for supports instead of the ovolo and talon. It may be tolerable to omit a usual member of architecture, but it is insufferable to put it in the wrong place.

The cyma and cavetto were correctly used by the ancients for finishings, and never where strength is required; the ovolo and talon, on the contrary, were always employed as supporters.

Palladio erred in employing the cavetto under the corona in three of his orders, and using the cyma as a supporting member.

Vignola ignorantly finished his Tuscan cornice with an ovolo.

Using frets or guilloches, decorated with leaves, ribands, and flowers, instead of balusters.

Placing a sepulchral or funereal pediment (such as is found on ancient tombs, cippi, and obituary tablets), upon the houses of the living, in defiance of every principle of truth, and in subversion of every rule of architecture.

The French architects, who "do all novelties," have adopted all innovations. The fact is, the French were ambitious of forming a new school; they were to invent new orders, which were to be exclusively French; and their buildings in the age of Louis XIV. exhibit examples in which all kinds of incongruous ornament are collected together without principle or meaning. The buildings in Paris are neither Greek nor Gothic, and in the highest degree irregular and formless. Of course, there are exceptions.

These foregoing cautions of the ancient architects form good lessons to modern practitioners, which they would do well to keep in their memories, in all compositions.

The criticisms on the several parts of a stone building, by comparison with a wooden prototype, are somewhat absurd, as that which was suitable and constructively necessary in the latter had no reference to the former.

From a careful study of the ancient regular architecture, as represented and misrepresented by the Italian and other architects, and of the buildings themselves, there need be no more talking about copying; each architect, if he will but devote the time and attention to the works of antiquity, can himself adopt from them his own proportions and details. First, by pruning and rejecting all extravagances, and licentiousness, flatness, and insipidity, disagreeable to the eye, and strictly copying such things as appear to be perfect, and carefully correcting others that seem in any degree faulty; and, secondly, by not accepting apparent beauties when not founded in reason; thirdly, by not retaining any modifications dictated by custom alone; and, fourthly, by availing himself of all real improvements which are easily perceivable by a judicious eye. Sir Joshua Reynolds admits, it is true, that the beauties and defects of the works of our predecessors may be pointed out; the principles on which their works are conducted may be explained; the great examples of ancient art may be spread out before them; but the most sumptuous entertainment is prepared in vain if the guests will not take the trouble of helping themselves.

It will be well for architects to consider these alleged abuses, as many of them have been introduced with reason and judgment, and with approbation.

It will be the more necessary to do so, when we consider the vague foundation on which the more refined parts of the art are built; Chambers says that it has "given rise to such a multiplicity of contradictory opinions, all of them supported by plausible arguments, that it is difficult to make a choice, or to distinguish the real from that which is merely specious. The connexions are frequently very distant, and it is necessary to trace a precept through all the combinations, that can possibly exist in every branch of the art, before its truth or fallacy can be determined."

Although Sir W. Chambers's judgment is to be generally admired, he errs in rejecting the Corinthian capital as a support to an entablature. He says, "There are many things which, though beautiful in the highest degree, yet, in their application, carry with them an evident absurdity; one instance whereof is the Corinthian capital, a form composed of a slight basket surrounded with leaves and flowers. Can anything be more unfit to support a heavy load of entablature, and such other weights as are usually placed upon it?"

Now the Corinthian capital having originated from a nurse placing a basket on a young girl's tomb is doubted, as the temple of Solomon gave the idea for putting leaves on a capital; be this as it may, its origin does not bear on the case, as the bell off the Corinthian capital is a carved solid, and the leaves are in relief on it. If the bell were an open basket, Chambers's criticism would have displayed more sense.

The golden mean as applied to the measure of moral rectitude may have much truth in it; but surely there is no mental energy displayed in seeking a mean in architectural proportions and works. This childish plan is often had recourse to by juries and arbitrators, who in cases of compensation take the highest claim on the one side, and the lowest claim on the other side, then add them together, and divide by two. Now, although a mean is obtained, affording sometimes a correct decision, still there is no science or mental energy displayed. To the men who create the extremes by their calculations, must be awarded the credit, and not to those who without brainwork adjust the conclusions.

To judge of the precise proportion awarded to the first man, and to each of all other forms at the Creation, is difficult, unless the golden mean be appealed to for a decision; and I think that, as far as living objects are concerned, a tolerably correct conclusion may by this means be obtained. To apply a mean to art objects is absurd, as buildings and their component parts are separately created. Perrault with great labour reduced the proportions of the various orders of architecture to a mean, and Paley in recent times applied a mean to the varieties of fonts.

The course recommended by Sir W. Chambers is far more scientific and practical than the mean between extremes as suggested by Perrault. The former enters with more judgment into the subject, and endeavours to correct deviations from the antique originals.

In employing regular architecture, nothing betrays the ignorance of an architect more than a violation of the ancient rules, or to introduce in his compositions the abuses which custom, contrary to reason and confirmed by time, has imposed upon us. Chambers has justly pointed out some of these irregularities in St. Peter's at Rome, St. Paul's Cathedral, and the Banqueting-house at Whitehall. Many of our more recent public buildings abound with unmeaning novelties. In the architectural world as in the political world, there should be a liberty definitely established.

In 1728 ancient architecture was as much neglected as at the present period; an architect of taste complained of the continual spring and circulation of follies, which are in a series of false appearances connected together, and disguised by artful softness of definition, and varieties of incoherent parts, consisting of no foundation but the emptiness and shadow of appearance; and this, and this only, being the grounds and practice of most of the productions of our moderns in building, architects seem to forget that beauty is founded on reason, irregularity on fancy,—

"Can beauty from deformity arise?"
Rusden.

The folly of permitting custom and fashion to prevail over the ancient rules was much deplored by Freart, who says, "Honest Vitruvius in his time well foresaw the ill consequence which those of the profession would introduce out of their love of novelty, which already began, it seems, to incline them to libertinism, and the rules of that art which ought to remain most sacred and inviolable; so that we must look on this as on a grey-headed evil, which grows worse and worse daily, and is become now almost incurable."

Instead of teaching anything new, the public require treatises to explode the errors which have been introduced by the admirers of novelty.

It is absurd for an architect to attempt to design without materials on which the mind may work, and from which invention must originate. "From mere nothing, nothing can proceed."

We should ever bear in mind the injunctions of the great masters, whose advice is always grounded upon theory and practice, and well considered. Of course they have faults, and those should be studied as well as their beauties. Variety and novelty are always valuable, provided that they are not introduced in opposition to precepts of art, and are sanctioned by reason. The more the student inquires into ancient architecture, the less will he be pleased with the new. He will derive more knowledge than the ancients because he has the advantage both of theirs and his own.

The Scriptures say we ought to "make a stand upon the ancient way, and then look about us, and discover what is the straight and right way, and so to walk in it." The predominancy of custom, remarks Bacon, is everywhere visible, insomuch as a man would wonder to hear men profess, protest, engage, give great words, and then do just as they have done before, as if they were dead images and engines, moved only by the wheels of custom.

The English architect is much indebted to Wren for his good sense and judgment in awarding the true test of beauty to nature or geometry. Of course, our Continental neighbours differ in opinion. Let us listen to Perrault,—"Neither," says he, "the imitation of nature, nor reason, nor good sense, are then the foundation of those beauties, which we fancy we see in the proportion, order, and disposition of the parts of a column; and it is impossible to assign any other cause of their agreeableness than custom."

However, notwithstanding this assertion, it has been shown that custom is not a principle or cause of true beauty. What arises from the manners and customs of particular nations can at best be but adventitious and local; and what is local cannot form a universal rule or principle; and since the principles of true beauty must be acknowledged as such by all men, therefore local custom cannot be a principle of real beauty.

I cannot do better than conclude with an admonition handed down to us by the great architect of St. Paul's Cathedral:—"An architect," says he, "ought to be jealous of novelties, in which fancy blinds the judgment; and to think his judges, as well as those that are to live five centuries after him, as those of his own time. That which is commendable now for novelty will not be a new invention to posterity, when his works are often imitated, and when it is unknown which was the original."

THE ARCHITECTURAL TREATMENT OF SMALL STAIRCASES.

At the ordinary fortnightly meeting of the Architectural Association, held on Friday, the 17th inst., Mr. Aston Webb, A.R.I.B.A., read a paper on this subject, as elsewhere mentioned. The following is the substance of it:—

There is no house so small or unpretending but that the staircase offers an opportunity of architectural treatment, and by a little care and good arrangement, and without adding to the cost, may give a suggestion of artistic feeling, and break the spell of that oppressive monotony which is the curse of so much of the general small-house architecture of the present day. The difference, also, between a well and badly planned house often lies in the staircase. Our client's property may, therefore, be seriously damaged in point of value by any omission on our part to arrive at the best staircase the circumstances will permit. One more word before entering on my subject,—namely, that I have purposely steered clear, as far as possible, of style and design in detail; for style, after all, is only the language in which an artist's thoughts are expressed, and the same beauty and feeling may be seen and felt, treated in various styles, just as ideas may be conveyed in various languages, though one style or language may often be better suited and appropriate than another to express those thoughts.

The subject naturally divides itself into three divisions:—1st. The position; 2ndly. The arrangement; 3rdly. The details of a staircase in a small house.

I.—*The Position of the Staircase in Relation to the House.*—This may be external or internal; but as I propose to deal more especially with staircases suitable to small house in this country, in the latter part of the nineteenth century, external staircases need not long engage our attention. No notice, however, of small staircases

could be deemed complete without mention of a few of these. Most of the remains of old English houses up to the close of the thirteenth century show signs of external staircases, leading to living-rooms on the first floor, which were, also, usually approached by a second staircase from the great hall, which usually up to that date was the full height of the house. The very beautiful external Norman staircase to the buildings attached to the cathedral at Canterbury is well known; but Italy, *par excellence*, is famous for these features, great and small. A very well-known one, and illustrated in our Association Sketch-book, is one at Spoleto. The position of a staircase in relation to the internal arrangements of a house is a very interesting and important question. Professor Kerr, in his book on the "Arrangements of a Gentleman's House," says "A staircase ought to be so placed as to afford direct passage for the ladies, particularly from the public-rooms, to the bedrooms." Mr. Stevenson says, "No rule as to the position can be laid down. It is usually in a conspicuous position; but when the hall is used as a sitting-room, it is better adapted for the purpose if the stair is shut off from it, at least by an open screen." Now the position of the staircase is so radical a factor in the planning of a house, that it is very important that we should have a clear and right view as to what is desired by those who are to occupy the house. Mr. Stevenson says, "it must vary in each house, and no doubt it will to some extent, though the principle aimed at will probably be the same." The same author says it is usually in a conspicuous position, also the fact, as we all know; but the question then comes in as to whether, in our present habits of life, this is desirable or not. Let us look back for a moment to the planning of our old English houses, for though our habits are much changed, and what has been can never be again, there is generally something to be learnt either to follow or avoid, and it helps to show the growth and principle on which our intricate plans of the present day are based. We shall find that up to the time of Queen Elizabeth, the houses were more or less fortified, and the staircases of stone, placed principally in turrets, an arrangement not likely again to come into general use, though at West Deane Rectory as early as the end of the thirteenth century, a newel staircase is still to be seen placed, as will be found almost invariably the case, in the corner and occupying no conspicuous position, though their existence was duly emphasised on the elevation. During the time of Queen Elizabeth, however, newel staircases came largely into use, with their straight flights and square landings; and during this time some of the finest staircases we have were put up, and many of our most thoroughly English houses were erected, the arrangements being distinctly to make the hall an apartment for general use, with the stairs leading merely from some retired corner to the rooms above, in most cases being absolutely concealed by a door; and Palladio, in his description of staircases, assumes as a matter of course that it will be so enclosed, but advising that the door should be in a conspicuous position, and in the best part of the house. Sometimes we find the stairs placed just off the hall in a lobby between the hall and one of the living-rooms, as at Wrotham-place, or, even still further away, as at Severn-end, Worcestershire (this house, by the way, is shown to visitors, and though very little known, is well worth a visit). In all these cases there is a separate staircase for servants, and the usual plan shows the hall dividing the family apartments from the servants', and connected over by the gallery. This arrangement assumed, of course, that all the reception-rooms were on the ground-floor, and the stairs led only to private rooms, and were therefore planned as private as possible. In larger Elizabethan houses, some of the principal rooms began to be placed on the first floor; here the staircase naturally became grander, but were on a scale beyond the limits of this paper. After this date, the Italian model came into vogue, where the staircase was placed in a central hall or cortile, or immediately leading off it, and this plan, with more or less modification, has continued to be largely adopted down to the present day. The Italian plan also often required the reception-rooms on a first-floor, and therefore led to a grander staircase. The demand in the present day, where the space can possibly be obtained, is decidedly in favour of all the reception-rooms being placed on the ground-floor, when the staircase should, therefore, as I consider, return to a less conspicuous position, its only object being means of access to bedrooms. The question, therefore, has to be considered as to the best position of the stairs, in a modern house, taking note of what has been done before, but not copying it, without regard to the altered requirements of the day. What I wish to lay before you is that privacy rather than conspicuity is to be aimed at in a staircase of a house of ordinary dimensions leading to bedrooms, and that with the reception-rooms on the ground-floor, the staircase is put to no use but private and domestic ones, and that where this privacy is observed, it is of advantage to all who use it, and more especially to the ladies of the household. You probably all know the story of the amateur architect who designed his own house, his great idea being a large central hall and staircase, with a gallery round on the first-floor, off which all the bedrooms opened; the consequence being when any occupant of these rooms went for a bath in the morning he was seen by the servants downstairs; and later on, when the servants were removing the slops from the rooms, they were, in their turn, seen by the guests and others from the hall below. The hall and staircase arrangement, a very common one, appears to me both wasteful and inconvenient. The staircase spoils the hall, and the hall spoils the staircase; that is to say, the hall is of no other purpose than for effect and show, it being impossible to use it as a sitting-room, and in my view, the stairs, being placed in the hall or general thoroughfare, are too public for the purposes they are intended. Another great objection, also, to this arrangement, is, that the hall has to be lighted from above only, and the proper ventilation of it becomes a matter of great difficulty, if not absolute impossibility. You will understand that I am speaking strictly of small staircases, that is, such as you will find in gentlemen's houses generally, and these remarks do not apply to houses where a portion of the building is occupied by State apartments, and where, therefore, a larger hall and staircase may be necessary for architectural propriety and to befit the apartments to which they lead. Of late years, on the other hand, the demand for cheap houses with large accommodation has led to an undue reduction in some cases in the size of the hall, where, in fact, you enter the front door, and the stairs are at your feet, and an array of little doors all round you, too suggestive of cheeseparing to be pleasant or desirable. My own idea for a country-house is a vestibule, with passage from same to servants' department as means of access for waiting at the door. The vestibule to lead into a hall, with a fireplace, of course carpeted and furnished with comfortable chairs and side-tables, and with the staircase screened off from one corner of it. In town-houses and restricted sites, the *position* of the staircase is hardly a matter of choice, and must necessarily come in the hall; but the same idea of privacy can be aimed at here also.

II. By *Arrangement*, I mean the number of flights, the landings, and their disposition. And here privacy should again be aimed at,—privacy, that is to say, from strangers coming to the entrance-door, and the simplest way of obtaining this is by reversing the flights so that you go up in the direction of the door rather than come down opposite to it, as is the common rule; the practice of making the staircase rise immediately opposite the entrance-door is objectionable. I have usually turned the stairs round the other way myself, and the only objection I have ever had raised was in the case of a pair of semi-detached houses, where the tenant told me his wife's friends "chaffed" her about the staircase being turned round the *wrong way*, and supposed it was because she was ashamed of her stair-carpets; and this opportunity for the display of the stair-carpet seems to be really one of the reasons for the common arrangement. On the other hand, I have more frequently found the tenants soon appreciated the advantages of the arrangement. In a town house, indeed, this seems absolutely the only relief from the stereotyped plan. There is one other plan of placing the staircase, in the centre of the house between the front and back rooms; but this involves top lighting, and means semi-darkness on the ground-floor, and is not desirable. A favourite arrangement in Queen Anne houses, where the stairs have to be arranged in the entrance opposite the door, is to turn the last four steps at right angles to staircase. This breaks the straight ladder-like flight in front of the door, but requires a wider hall than can usually be obtained. Having settled the position of the staircase in regard to the house, and the point on the ground-floor most convenient to rise from, the next question is the arrangement of the flights and landings, the first point to be kept in view being, of course, the main landing on the first floor, the object to be aimed at being to place this landing so that all the rooms on this floor open on to it without, in small houses such as we are speaking of, any corridors or passages. In a skilful plan there may be a good roomy entrance-hall on the ground-floor, where it is of use, and a very economically-disposed first-floor landing, though with the central top-lighted hall and staircase already mentioned this is not possible. Every one knows that long straight flights are to be avoided, eleven treads being about the extreme number in one flight, and also that square landings are desirable, though these should only be used sparingly, for too many square landings and short flights are more tiring and cumbersome, even, than over-long flights; but where this is impossible winders have to be introduced, and these need not necessarily interfere with the comfort of the stairs. There are winders *and* winders, and everything depends on the way in which these are arranged. It is common to find writers on this subject give a wholesome condemnation to winders, and to speak of them as makeshifts hardly to be tolerated. The most usual way is to form the square quarter-space, and then cut it up into three treads, by the easy process of an angle set-square of 30 and 60 degrees; this involves that the treads partake each of a triangular form, terminating in a point, and so are as dangerous and prolific of accident as can be, even though the treading-line, which is about 18 in. from the handrail, may be equal throughout. A portion of the staircase in Conduit-street leading up to the offices of the Association is a choice example of this arrangement. I do not know whether you recognise it; it is an example very well known as leading from this entrance-hall up to "the only lending-library in the profession"; it has a peculiar "refinement" in the width of the tread between the winders, being 12 in. instead of 10 in., like the others, and this, coming between the very narrow winders, makes it singularly awkward; but you can all judge by experience whether it is easy "going" or not. Now, with a well-hole of 12 in., as this has, it would surely be better to divide this among the winders than to give it to the one central step, and if arranged as on the plan shown, the "going" would have been comparatively good, for the rise and tread are easy in themselves; it is only the arrangement of the winders that makes it otherwise. Viollet-le-Duc, in his "How to Build a House," shows a stair with winders,—a very general practice in France. A very good example of a staircase plan, practically composed entirely of winders, has very kindly been lent to me by Mr. Lawrence Harvey, by whom it was recently designed for a house in Queen's Anne's Gate. I have dealt on this question of winders somewhat at length, as our practice in England is contrary to that more generally adopted on the Continent, and, I think, inferior. The objection to it, certainly, is an absence of landings for the aged and infirm to rest during the ascent; but I doubt whether they cannot stop almost equally well on any part of the stair as on a quarter-space landing, and unless the rooms are very lofty, the question really seldom arises at all. A continuous handrail with this arrangement is, of course, necessary, and this of itself helps to lead one in the direction of the stair. Another very important point to be remembered in the designing of the staircase is that it naturally acts as an upcast shaft to the house, and is, as it should be, its great ventilator. It is very essential, therefore, that it should have at least one outside wall with windows, for ventilation. Without this a house is always liable to a close and stuffy smell, and it must be remembered that where a w.c. or kitchen stairs are placed, as is often the case, under the principal stairs, special care must be taken, or the least smell from either will at once pervade the whole of the house. The aspect of the staircase windows can hardly be considered, as the stairs will naturally be placed where the aspect is least suitable for rooms. If you can get a sunny aspect, however, it is preferable. The landings of a staircase, where space will permit, should be wider than the stairs themselves, in order to allow of a stand of flowers or some china jars, or of a window-seat, which really would offer rest to the old and infirm using the stairs.

III. *Details.* — The rule for proportion of treads and risers need hardly be mentioned; but the aggregate of the tread and riser should always be about the same. Thus take 17 in. to be the recognised standard, then a riser of 7 in. would require a tread of 10 in., a rise of 6 in. one of 11 in., and so on. With regard to the width, this should never be less than 3 ft. in the clear, and if any of the reception-rooms are on the first-floor, the stairs should not be less than 4 ft. wide in the clear. Staircases in modern houses may be generally divided into those with well-holes, and without; the former are either newel staircases in which the handrails stop against the newels, or else have a continuous handrail,—probably the most dangerous arrangement where children are concerned, affording every facility for sliding down them and toppling over; where the rake becomes steeper, stairs without well-holes are either dog-legged staircases, or of the character shown in the example from Viollet-le-Duc, and these are generally used where space is limited. For internal domestic staircases wood is undoubtedly the best material. Stone may be used for the principal flight, its advantage being the quiet which is obtained. In Italy, and warmer climates than ours, stone staircases seem more appropriate. The soffit of wooden stairs is usually plastered, but the material is not really suitable, as the spring, which a good staircase should have to a slight extent, sooner or later cracks it at the junction of the flights with the landings. A deal panelled soffit would add but little to the cost, and, at the same time, gives character to the stair. The inclosure of the stairs by handrail and balusters needs no remark, beyond the fact that 2-in. balusters will always look better than 1 in., and that three to a step, as they used to be, is immeasurably superior to the two poor little inch-balusters generally seen. If only two are used, they should be of such a substance that there is not more than their own thickness between them. The wreathed mahogany handrail, with its elaborate scroll on the ground-floor, is very expensive, and should be perpetrated no longer; it has called forth many elaborate treatises on its setting-out, and many "staircase-hands" have made its perfection the aim of their lives; but beyond this there is little reason for adhering to it, except in the case where winders are introduced, where it becomes a necessity. A close or open string is very much a matter of taste and design, though perhaps the balance is in favour of an open string, and ladies will certainly be found generally to favour it, as having less corners difficult to sweep than a close one. A staircase should always look solid, with no stint of material, and while elaborate workmanship would be out of place on a small staircase such as I am speaking of, care should be taken that all the mouldings should be full and rather more massive than those in any other part of the house. The ladder-look of many stairs is, above all things, to be avoided. An old oak staircase, which has weathered almost black, with its heavy newels, handrail, and balusters, its solid oak steps, covered in the centre with a white drugget, has a quiet, homely, and inviting look, very different to the general toilsome-looking and uninviting ladders of the present day. With regard to its decoration, little need be said except, probably, the less the better. It is needless now to inveigh against block-marble paper, as architects, at any rate, have given up its use. A wooden-panelled dado, or a plain varnished and painted one, with a severe patterned paper, of not too dark a colour, is all that is required. Cornices on the landings are better omitted; but if a panelled soffit is adopted, a small cornice would probably finish this, and run round the landings also. Generally we may say, plain, honest, good construction is all that is required in a staircase. Ornamentation likely to arrest the attention is out of place; the same applying to the carpet, which should be quiet and unobtrusive in design, and indeed, if you are so fortunate as to be able to make the stairs of solid oak, nothing looks better on these than a clean white drugget.

Fire at a Builder's.—Last week a serious fire occurred on the premises of Messrs. Staines & Son, builders, Great Eastern-street, Shoreditch. The building, consisting of three floors, about 40 ft. by 20 ft., and used as workshops and stories, was nearly burnt out; and the stock comprised in the open yard in the rear severely damaged by fire. The building and contents were insured in the Phoenix Office.

ARCHITECTURAL ASSOCIATION.

At the ordinary fortnightly meeting of this Association on Friday, the 17th inst., Mr. Ernest C. Lee, President, in the chair, the following gentlemen were elected members, viz., Messrs. J. W. Cockrill, S. H. Maile, J. K. Cole, E. V. Grove, W. C. Jones, A. North, L. Littlewood, C. W. Jackson, S. A. Pentecost, A. E. Kingwell, W. Hodson, H. E. Trivett, E. G. Dawber, E. A. Mann, W. F. Sutton, S. P. Rees, F. P. Telfer, F. Radkin, A. C. Wissenden, J. Clinnie, S. A. Edwards, W. Weir, C. Mayne, H. Gordon, E. J. Pine, J. L. Robinson, W. J. Lauder, P. E. Mantell, and G. W. Hatcher.

The announcement made from the chair that Mr. Quilter, past-president of the Association, had been elected District Surveyor for East Streatham, was received with applause.

Mr. Aston Webb then read a paper on "The Architectural Treatment of Small Staircases," the substance of which we print in preceding columns.

The Chairman, in opening the discussion, said that the paper was one of thorough practical interest; for houses could hardly be built without staircases, although he knew of an instance in which it had been done,—greatly to the inconvenience of the inmates, however. He agreed with almost everything that had been said by Mr. Aston Webb as to the planning, arrangement, and decoration of staircases, but he could not hold with him in the matter of the white drugget, which he thought had a very unsatisfactory appearance. He liked to see stairs carpeted, and carpeted for their whole width, instead of leaving the usual margins, which were generally of dirty paint. Mr. Webb had not made any special mention of the external staircases which were to be found in Caen, going up to the first floor of the buildings. On the road to Ardennes almost every other house had an external staircase, some of them dating from the sixteenth century, and others from the fourteenth. In these houses the entrance to the ground-floor rooms was beneath the external staircase. One very noted external staircase was the one at Syracuse, of which a sketch by Mr. Charles Eastlake had been published in the Architectural Association Sketch-book. Architectnrally, such staircases admitted of very charming treatment indeed. No doubt most of the members of the Association were well acquainted with M. Viollet-le-Duc's chapter on "Escaliers." Prior to the fifteenth century, as Mr. Webb had stated, all staircases were practically in turrets or towers, as in the one given by Viollet-le-Duc of the old Louvre. There were numerous large staircases of that kind at Blois, and he presumed that almost every young architect who had travelled had measured up several of the old turret staircases of Normandy and other districts. He himself had met with a very interesting one in an old house in Orleans: it was a newel staircase, measuring not more than 3 ft. across, and was noteworthy on account of the manner in which the handrail and the newel interpenetrated. Mr. Webb had not particularly remarked the very small staircases which were to be found in many of the largest and most important houses built in the time of the Georges. At that period, people seemed to live almost exclusively for show. They had very grand reception-rooms, but directly they went up to their bedrooms they seemed to live in a hugger-mugger style. The staircase to the first-floor was very grand indeed, but the staircase to the upper floors was so very mean and small that any architect would be ashamed of putting it into a parsonage-house. The houses in Brook-street afforded an illustration of this. In an old country mansion dating from the Georgian period, which had lately been pulled down, the drawing-room was 40 ft. by 30 ft. by 19 ft. high, the dining-room being of similar proportions. The hall was 30 ft. by 20 ft., but the staircase that went out of it was only 3 ft. wide, with treads of 7½ in., and risers of 10½ in. This was an illustration of the manner in which people lived for outside show instead of for comfort and convenience. The staircases in the houses at Lancaster-gate seemed to hear out the views enunciated by Mr. Webb as to central staircases; for, except on quite bright days, gas had to be kept burning continually. A very fair illustration of the inconvenience of too many landings was afforded by the stairs up to the Esplanade at Richmond Hill, which consisted of an arrangement of four steps and a landing alternately repeated about ten times. If a person was at all in a hurry in ascending, he was most likely to fall up, and if in a hurry when descending, he was quite sure to fall down. One feature often found in the treatment of the angles of landings of staircases in old houses was, he thought, worth noting. Mr. Webb had stated that landings should be made fairly broad,—broader than the stairs themselves,—but he (the President) thought it would be a mistake to put seats on such landings; for it was very questionable whether any one would ever sit upon them. Flowers might, however, very well be placed there, and one good means of filling up the corners was adopted in the Georgian period, viz., angle cupboards with glazed doors, and containing shelves on which china was arranged. The effect of these was very charming.

Mr. Thomas Porter (who was very indistinctly heard) was understood to say that the subject was one of such an extensive character that he hardly knew what points to discuss. The paper was one which suggested a variety of practical considerations, some of which he would proceed to refer to. He thought there could be no rule laid down for the position of the staircase. The planning of houses was generally subject to the shape of the site and to other circumstances of a varied character, so that the position of the stairs must be left to the architect to determine in each individual case. He could not agree with the author of the paper in the *dictum* laid down that in small houses the staircase should be in as retired a position as possible. His own view would be to make it as handsome and as conspicuous a feature of the house as possible, consistent with the fitness of its surroundings. There was another reason why the staircase of a house should be in a conspicuous position, viz., that inasmuch as it was one of the secrets of planning a good staircase that the bedrooms should be entered direct from the landings,—or at least from lobbies opening on to the landings (so that there should be no waste room),—it was highly important that the staircase should be well lighted and ventilated, and the more conspicuous its position the more likely was it to fulfil these conditions. Windows were the best means of getting at once good light and ample ventilation. As to landings, nothing could be worse than having one step on them: it was sure to be a source of continual stumbling. As to the stairs themselves, there should be no discrepancy in the heights of the risers. A staircase in which this occurred was most unpleasant to those who used it, particularly when the top riser of a flight was of less height than that of those below it. If a comfortable staircase were needed, the risers must not be made too high or the treads too narrow. He did not think that Mr. Aston Webb's formula on that point was infallible. For instance, if a 9 in. tread were used, he (Mr. Porter) saw no reason why the riser should be 7 in. On the contrary, he thought that the height of the riser should never exceed 6 in. nor the treads, even in large houses, 11 in. As to the embellishment of small staircases, he thought it was usually the case that the ornamentation was far too elaborate and on too large and heavy a scale. Small staircases would not look well if fussy and overdone in their details. A 6 in. newel was all very well when the stairs were 4 ft. or 5 ft. wide, but in small houses, with stairs only 3 ft. 3 in. wide at the outside, 6 in. newels and 2 in. balusters would have an extremely awkward and heavy appearance. He advised the younger members of the profession not to take for granted all that was set forward as models for imitation, for he had lately seen a "prize design" for a small staircase in which the stairs were only 3 ft. wide, with 6 in. newels of a most elaborate character, while the balusters were of such dimensions that they must have been made out of 3 in. stuff; the material in which they were proposed to be executed was wood, but their forms were such as were proper to stone. The handrail was no less than 6 in. deep and 4 in. wide, and instead of being designed so that it could be laid hold of, it partook of the character of the coping of a Gothic gable. In regard to the wood used for balusters and other parts of staircases, it should be borne in mind that oak was capable of treatment with far finer mouldings than was the case with commoner woods. The height of the balusters and handrails was another important point. The rule laid down in books was that of the old-fashioned standard of allowing a height of 2 ft. 7 in. above the nosing of the step to the top of the handrail, but he ventured to recommend in small staircases a

height not exceeding 2 ft. 5 in.,—a dimension which was much more comfortable, especially to ladies, for 2 ft. 7 in. was a rather uncomfortable height for a bandrail for even tallish men. A height of 2 ft. 5 in. was quite sufficient for safety. He had always adopted that rule except in the case of staircases where great grandeur was demanded. Balusters should be designed of such forms as were capable of being easily turned in a lathe. Any carving or other elaborate work on them was quite a mistake in small staircases. He did not quite see the objection to the plaster soffit, but he did think that a soffit of panelled woodwork to a small staircase would have a very "boxy" appearance. The difficulty of dealing with the cornices (if they must be had) of the ceilings of landings could easily be surmounted.

Mr. Cole A. Adams, in moving a vote of thanks to Mr. Aston Webb for his paper, illustrated on the blackboard some points touched upon in the paper, as did

Mr. S. Flint Clarkson, who, in seconding the motion, observed that one reason why a plaster soffit was objectionable in a staircase was that the latter was generally one of the most carefully-prepared pieces of woodwork in the house, being necessarily made out of seasoned material. The application of the wet plaster to it, however, had a tendency to dislocate the joinery. With regard to winders, he was generally disposed to agree with what had been said of them in the paper, and he might adduce, as an additional practical reason why winders were undesirable, the difficulty of covering them with stair-carpet. He did not go quite so far as Mr. Webb in disparaging the central position for the staircase; indeed, he thought that for a large town-house the central staircase was the one to be preferred, subject to the provision of a sufficiently large and adequately lighted well. Mr. Webb had given a very practical and useful paper on staircases, which very properly followed the excellent one on windows read by him two years ago.*

The motion having been carried,

Mr. Webb, in replying, said that the question of the drugget was a matter of taste, and with regard to it he still held to his own view as opposed to that of the President. With regard to the height of the handrail, he thought Mr. Porter was mistaken in advocating a height of only 2 ft. 5 in. A case had occurred (he thought at the Travellers' Club) where a man fell over a rather low handrail and was killed, whereupon there was serious talk of arraigning the architect for manslaughter.

The next meeting will be held on Friday, Jan. 7, 1881, when an account of the Association's last excursion will be read by Mr. C. R. Pink.

GARIBALDI ON THE DECLINE OF THE ITALIAN RACE.

WRITING a few days ago from Alessio, Garibaldi, in his usual plain and unvarnished style, expresses his opinion of the physical characteristics of his countrymen. The General's letter, which is addressed to the editor of the *Secolo*, of Milan, is as follows:—

"My dear Moneta,—I beg you to publish the following lines:—The *New York Herald*, speaking of Italian immigrants into the United States, says: 'Of all the emigrants coming here from Europe the most deformed, rickety, dirty, wretched, and thievish are the Italians.' Painful and humiliating assertions these, but true. Let us see what are the causes of such degradation. I will not refer to the excessive burdens of taxation which are ruining this poor nation, and driving it to despair. I will content myself with pointing to other blots which are less obvious, but which, like that just mentioned, disfigure our country. The Royal Cuirassiers must be picked men, the Royal Carabinieri must also be picked men, so must the soldiers of all arms of the service; so must the customs officers, the excisemen, the police, the municipal guards,—all these must be picked men. The monks, too, and the Jesuits receive no misshapen persons among them. What, then, remains to propagate the Italian race? The narrow-chested, the rickety, the scrofulous, the deformed, the lame, and all that sort of people. And now let those who rule the Italian nation tell me whether it is not inevitable that the Italian race should become degenerate.—Ever yours, G. GARIBALDI."

In drawing attention to this letter from Garibaldi, to be found in the daily papers, we desire to intimate that there are other reasons for the deformed, rickety, dirty, wretched, thievish inhabitants of Italy than those enumerated, namely, a total absence of proper sanitary arrangements in Italian towns and villages, from the palace to the hovel and roomtenement. Italy,—the land of sunshine, art, and song,—is a land of filth and vermin. There are marble palaces, art galleries, and blue skies, but neither sewers, drains, nor adequate scavenging. Hence, strangers who are tempted to visit the world-renowned cities pay a fearful penalty in risks from fever and certainty of mosquito stings, as also of punishment from other domestic torments. There is not one Italian city properly sewered, drained, and scavenged. The best hotels use cesspools, out of which pass foul gases and putrid fluids, to contaminate both air and water. Proper scavenging implies daily cleansing, not only of public streets and places, but of all back streets, lanes, alleys, yards, and tenement houses, with a removal of *excreta* and refuse at short intervals, never exceeding one week. As to proper sanitary works, a full supply of pure water is necessary, not merely for display in public fountains, but laid on by appropriate services to every occupied dwelling, however humble. The regulations of a Common Lodging House Act should be enforced in every slum and wretched room-tenement, and all the places unfit for human habitation should be sternly closed, and proper accommodation provided. When the improvements herein suggested have been adopted and are continuously carried out, there may be hope for the regeneration of Italy. Ironclads with 100-ton guns, Royal Cuirassiers, Royal Carabinieri, customs officers, excisemen, police, municipal guards, and Jesuits will avail Italy nothing in removing the fearful causes of disease and human distortion. When will statesmen learn that the greatness and strength of a nation are not alone in magnificent cities, palaces, ironclads, and standing armies, but in the health, comfort, and content of the people? The further lesson also requires to be learned, namely, that where the mass of the people are allowed to grovel in filth and misery, there can be no true security for property. A whiff of grape-shot will not cure such disease.

* See vol. xxxvi. (1878), pp. 1246, 1281.

THE MIDLAND RAILWAY AND ITS WORK.

OF our British railways, the Midland is the best known. It is not the largest, but it possibly penetrates into a wider reach of country than any other; and the boldness of its policy, the magnitude of its undertakings and extensions, and the substantial benefits it has conferred upon the travelling public, have given it the first place, possibly, in the estimation of the public. Springing from a very slight and small railway, it has become one of the four great lines in the kingdom. In its thirty-seventh year it has become so vast that its paid-up capital is over 67,000,000*l.*,—an immense sum to have been spent even in less than twoscore momentous years on railways, works, lines, and stock. But if a map of that great railway he looked at, it will be seen that it has a widely-reaching length of line. Its limbs are found far in the south-west, reaching down to Bournemouth, and stretching from Worcester to close upon the Welsh coast. St. Pancras is the central southern point, and direct north-west its line penetrates into the heart of the district whence it takes its name, gridironing it with branches, and sending out arteries to the east coast of Lincoln, to Manchester and Chester, and over to Liverpool, its trunk-line passing on to Normanton, and there severing, to make that wonderful extension to "merry Carlisle," which is justly ranked as one of the chief railway feats of the age, and again crossing to the west, to tap the great mineral resources of the rich Furness district. Except in the north-east, it may be said to have its lines spread in all parts of England, and it is the one railway which enters the six greatest towns and cities in the kingdom. Over 1,100 miles of line actually owned by itself its trains travel; and with lines leased, partly owned, and worked over, there is a total length over which Midland engines travel of 1,700 miles.

In these miles most varied scenery is enclosed. In its heart there is that of the well-wooded and undulating country from Buxton to Derby; the deep ravines, limestone rocks, and dense pine nooks round Matlock, with the rugged beauties of the Peak country, and its embowered halls; southward, it traverses Worcestershire, and down to the softer clime of Dorset; the waving wolds near Cheltenham, the ravines in Gloucester and Somerset, and the bleakness that bathes in the summer beauty of the south-west. No greater alternation with this could he found than that of the great northern extension to Carlisle up the Ribble valley, over and through Blea Moor into Garsdale, and over the great viaduct at Smardale, up the fine valley of the Eden, by castle-crowned Armathwaite, and on to Carlisle. Compared with this, the scenery round Carnforth and thence to the Lakes becomes tame; whilst that of the little Lune valley, and that around the most beautiful ruin of Kirkstall, and that in the Wharf valley, is as the river to the ocean. Alike through sylvan scenes, the dinginess of the "Black Country," the fat southern valleys, the homes of the worsted and woollen trades, the pleasure-grounds of the west, and the mountain fastnesses of the north, the Midland dashes; and whether it is the coalfields of Yorkshire, the ports of the west, the cotton and cloth districts, the lead-mining fields of Derbyshire, the hematite iron regions of Furness, or the multiform trades of the metropolis,—they are all tapped and toll taken of by this great company.

The Midland is now our chief coal-carrying railway, for every month it carries a million tons, a sixth part of which it conveys to the metropolis by rail; whilst of iron, lead, and other minerals there are proportionately large quantities taken over the line. From mineral traffic alone it has a monthly income of 150,000*l.*; from its vaster goods traffic, one of 249,000*l.*; from parcels, horses, &c., one of 23,500*l.*; and from live stock other than horses, one of 6,000*l.* Its passenger traffic is growing immense; every month it carries over two million passengers, of whom eleven-twelfths travel by its popular third-class, and from these two millions it receives 122,000*l.* monthly. In the total its monthly receipts are 540,000*l.*, the income of many a kingdom. Its working expenses are necessarily vast; for fuel for locomotive power alone it pays 14,000*l.* monthly; wages and salaries cost it in the same period 165,000*l.*; and for clothing for its officials it pays 2,000*l.* a month. Every month its trains travel two million miles; it owns 1,400 engines, a total rolling-stock of over 93,000, and it has the not inconsiderable stud of 2,735 horses. Its Parliamentary and law charges are from 1,000*l.* a month upwards; on the unsatisfactory item "compensation," in the same time, it expends 3,300*l.*; for rates and taxes it pays 14,000*l.* monthly, and finally it may be said that, after meeting all its working expenditure, it divides 250,000*l.* monthly amongst its 24,000 shareholders. This is the summary of what the Midland does, and it is no inconsiderable work; and when it is remembered that nominally the Midland Railway dates back only to 1844, and its earliest constituent branch only to six years earlier, it will be seen that the little branch from Derby has grown into a goodly line. It has not been all smooth-sailing, as those know who knew it in the dark days when "King" Hudson left the board of direction, or in those when the competition with the Great Northern was so severely felt that amalgamation with a greater company was thought of. Hence there is the greater credit to the Ellis and the Allports who have made the Midland; for it was not born great,—it has emphatically achieved greatness. The projection of the trunk-line from Bedford to London and from Settle to Carlisle are amongst the chief of the trophies it has won, and the works that have enfranchised it; and it is possible that in the future the Midland,—now the fourth in rank of British railways,—may in the north-east find a field to raise its status still higher.

BELFRY, SCHWABISCH GMÜND.

THE belfry of the Church of the Holy Cross at Schwabisch Gmünd is especially interesting, because it is a remarkable example of a cheap Mediæval structure, and shows us that it was not only in the costly and magnificent architectural building that the old architects excelled, but that they knew how to impart dignity to cheap and even temporary structures; for to the latter class this building undoubtedly belongs.

The magnificent Church of the Holy Cross occupies the site of an earlier building of the twelfth century. The present church was erected during the fourteenth and earlier part of the fifteenth century. An inscription on the doorway to the north choir aisle is as follows: "Anno Dom. 1351, ponebatur primus lapis pro fundamenta hujus chori XVI. kal. Augusti," and another inscription records the completion of the choir in 1370. The nave was commenced

ahout the same time that the choir was completed, and finished in the year 1410, when the whole was consecrated. The two towers of the former church were left standing between the nave and choir, hnt the arch which formerly connected them was removed in order to obtain a hetter view of the choir vaulting. This, however, weakened the towers, and on the night of Good Friday, in the year 1497, they fell to the gronnd with a crash, hut fortunately no one was injured by the accident, although there were several people in tho church at the time watching the Good Friday sepulchre.

The present helfry was erected immediately after this accident to hold the hells until a tower could he erected; but probably the events of the Reformation period, which shortly after intervened, prevented thie heing carried out, and thus, what was intended to he a mere temporary strncture, has now existed for nearly 400 years. The walls are of considerable thickness, and the whole of the npper portion of the tower is composed of timber covered with highly-glazed tiles, disposed in patterns red, green, and yellow in colour.

There are four hells, of which the earliest dates from the middle of the thirteenth century. The other three are all dated, and were cast in the following years,—1456, 1515, and 1595.

THE NORTH LONDON HOSPITAL FOR CONSUMPTION, MOUNT VERNON, HAMPSTEAD.

This new hospital, of which we illustrate the north-eastern or entrance front and the plan, is now in course of erection. It will stand in its own large and well-wooded grounds, near the highest part of Hampstead, and will front to Frogual Rise with a nearly north-east aspect. The garden front consequently looks sonth-west, and commande splendid views of Middlesex and the Surrey hills. All the windows will catch the sun at some part of the day, and the greater part of them will be in sunshine almost all day long. The situation has heen selected in order to carry ont the views of those who advocate a dry and pure air in preference to a mild climate for the treatment of pnlmouary coraplainte.

In plan the hospital is to he a compact rectangular structure, about 160 ft. long hy 55 ft. 6 in. deep. It is intended for 110 patients. It has a very ample and light corridor, of fire-proof construction, running from end to end on each floor. The principal entrance is to he at the centre of the uorth-east front, and here an open and roomy main staircase rises through the principal floors, and adjoining it a service-staircase is carried from the hasement to the attic floor, combined with which will be a lift for patients and general purposes.

The hospital is five stories high. The hasement floor, owing to a rapid fall of the ground, is almost entirely above gronnd at the western end, and here is placed the out-patients' department, with surgery, dispensary, and ample waiting-rooms, the remainder of the hasement heing chiefly devoted to storage, cellarage, and heating apparatns.

On the main or ground floor are provided the rooms for administration. Here, for example, are the hoard-room, committee-room, and rooms for the secretary, matron, chaplain, physician, assistant medical officer, and clinical clerks; a receiving-room, visitors' room, two day-rooms for male and female patients respectively, and one or two small warde for special cases, complete the accommodation provided. There will he direct access to the garden and grounde from this floor.

The next two floors are devoted to the wards for patients, — one floor for women, the other floor for men. In the size and disposition of these wards snch a hospital as this differs of necessity from a general hospital. The patients are here to be treated in wards of moderate size, as cheerful, airy, and pleasant as they can be made; and more home-like in their appearance than the great ward of an ordinary hospital. These will be heated hy open fires, and their warmth and dryness will he contributed to hy the fact that nearly all the external walls are built hollow. No ward is intended to receive more than eight beds and in some only four, and in others only two, hede will he placed. On each of these two floors a day-room, 35 ft. long, is provided, and here the patients will take their meals and may sit. On the sunny side of the building are also provided open arcades, communicating with the day-roome and with the greater number of the wards. These will provide large and sheltered hut airy haloonies, in which patients may sit and enjoy the air, the sunshine, and the almost matchless view. There will he eight of these in all, four on each floor, and they will prove, it is hoped, a comfort and a solace to many of the inmates of the hospital. Nurses' rooms, Sisters' rooms, as well as hath-rooms, and other such appliances, will he provided on each floor.

The kitchen-offices, servants' dormitories, rooms for nurses off duty, and eome of the household stores, will he provided for in the roomy attic story, which, thanks to the large space secured hy the high-pitched roofs, is lofty as well as spacious. It ie no novelty in modern buildings for the kitchen to occupy the attic story; but in many cases this arrangement could not he suitably attempted in a hospital. In the present instance, however, the convenience of the whole establishment will he best served by it, and the provisions will descend direct to the day-rooms of the patients, while the smell and heat of cooking will he kept entirely away from them.

In the sanitary arrangements, simplicity and thoronghness have heen aimed at, and the ventilation of draine and isolation of water-supply have not been forgotten. The ventilation of each ward ie carried on eeparately, an outlet-flue heing provided alongside the smoke-flue in every case, air being introdnced through one or more inlet ventilating-channels.

The huilding, which is of hrick with etone dressings, and with tiled roofs, is heing carried on in sections. The western section, the one first taken in hand, has been for some time complete in carcase, and the finishing of it ie now far advanced. This comprises rather more than one-third of the entire huilding. The foundation-stone of the central section was laid in Octoher hy H.R.H. the Duke of Connanght; but this work will not he proceeded with till after the patients have been removed from an old house, occupying the site, and in which they are at present accommodated, into the new huilding.

The architect is Mr. T. Roger Smith, F.R.I.B.A., and the general contractore are Messrs. Higgs & Hill, of Lambeth.

DERWENT HALL, DERBYSHIRE.

The works at Derwent Hall, now the seat of his Grace the Duke of Norfolk, with the exception of a few minor details, were sufficiently completed in time for his Grace and gnests to take up their residence there during the shooting season this year.

The old hall, situated near the interesting village of Derwent, was originally in the possession of the Balguy family, of Cheshire, and after eome changes of ownership eubseqnently became the property of the Newdigate family, from whom the present Duke of Norfolk hought it for the purpose of a shooting-hox. The accommodation afforded by the huilding proving, however, inadequate to the Duke's requirements, the old hall has made way for an almost entirely new hlock of huildings, of which the following description may prove of interest.

Entering hy the old doorway (with the Balguy arms and the date 1672), on either eide of the entrance-hall, which is hung with tapestry from Worksop Manor, two quaintly-carved doors open on the left to the Duke's etndy and servants' department respectively, two on the opposite side giving access to the old staircase and corridor in the right wing leading to the duchess's room and library, these rooms, with the entrance-hall and the duke's study hefore mentioned, heing that part of the old building utilised in the present arrangement.

We may here mention that these rooms have heen re-decorated and finished in a corresponding style with the rest of the work, in which every endeavour has heen made to unite the character of an old English country-house with modern requirements. The right wing also includes the new dining-room, and, further on, the drawing-room, of which we give an interior view, showing a fine oak chimney-piece from Norton Hall. The continuation of the corridor connecting these rooms forms for the family a means of approach to the comfortable private chapel, the servants heing provided with a separate entrance from the outside.

Ample bedroom accommodation also is provided, the rooms heing panelled from floor to ceiling, and otherwise finished in a eimilar etyle to the ground floor.

Leaving this part of the house, the left wing contains butler's and housekeeper'e rooms, kitchen and other offices, servants' hall, gamekeepers' mess-room, dairy, game and meat larders, and a new block of stables, with accommodation for eight horses in the stalls, two loose hoxes, trehle coach-house, and separate harness-rooms for his Grace and gnests.

The works, including the chapel, have exteuded over a period of nearly four years. Messrs. Dennett & Co., of Whitehall, were the contractors for the Early English chapel and a part of the house, the remainder of the work having been done without a contract, nnder the sole management of the architects, Messrs. J. A. Hansom & Son, of Alfred-place West, South Kensington, Mr. J. Firth being the clerk of works.

The stone, hoth for ordinary masonry and dressings, was at first obtained from Moscar, at considerable expenditure; hnt latterly a quarry on the estate has heen opened out.

Tbe house is fitted up throughout with electric hells, hy Messrs. Edmundson & Co., of Westminster. The general work, including most of the oak panelling, has heeu done by Messrs. Dealy & Horner, of Sheffield; the carving and the remainder of the panelling, including that in our view, heing hy Messrs. Farmer & Brindley. The cost of the works up to the present time is nearly 30,000*l.*

The old huilding has heen enlarged, altered, and pulled about a good deal at different times, to suit different tastes and requirements; but every effort has heen made to retain the genuine old parte wherever character was displayed and the etahility of the buildings allowed it. Unfortunately, however, the Hall had, under previous owners, heen dismantled of many quaint accessories, in the way of wainscot panelling inside and lead-work outside, while the plasterer had had only too free a run of the house.

Tbe stained glase in the chapel, and tbe door and shutter furniture, which is of iron treated with Professor Barff's process of oxidisation, were supplied hy Messrs. Hardman & Co. We believe this is the first time of Professor Barff'e treatment heing used for a similar purpose, and it harmonises admirably with the oak doore and panelling. We propose shortly to give a view of the exterior.

THE SCHUMANN MONUMENT, BONN.

When, in the August of 1873, the most eminent German and foreign artists met witbin the walls of the pleasant university town ou the Rhine to do honour to the memory of Robert Schumann hy a musical festival, this was done also with a desire to erect a snitable monnment to the composer in his last resting-place, the cemetery of Bonn, the proceeds of the meeting to supply the means for its erection. A local committee was appointed at the time, and this hody, after careful consideration, commissioned the sculptor, Herr A. Donndorf, to execute the work. Professor Donndorf is well known hy hie Luther Monnment at Worms, the equestrian statue of Karl August at Weimar, the Freiligrath Monument, and other equally meritorious creations. The monument, of which we give an illustration, and which has been erected in the Friedhof of Bonn, is entirely of white Carrara marble, and was executed at Carrara nnder the personal superintendence of the sculptor. It was unveiled last May.

In keeping with the place for which it was intended, the sculptor has imparted to his work a solemn, elevated character. On a hroad hase rises a powerful eqnare socle, which eupports the monumental stone, tapering eomewhat towards the top, and crowned hy a moulded coping with acroteria. Its front hears a faithful medallion portrait of Sohnmann, surrounded hy branches of oak, roses, and laurele, and snpported hy a rising swan with outspread wings; below, simply his name, Robert Sohmann. At the foot of the socle the master's muee is seated, to which the sculptor has given, with true poetio and historical instinct, the youthful featuree of Klara Wieck, the noble wife and congenial life-companion of the great composer. It is a charming, thoroughly German figure, this muse, a type of sweet, ideal womanhood, of poetic temperament and devoted inspiration. Draped in modest folds, the expressive face turned upwards to the right, she rests her left hand, the fingers of which enclose a partly-opened roll of music, npon the lyre, while the right, resting in her lap, holds a laurel wreath. The ideal

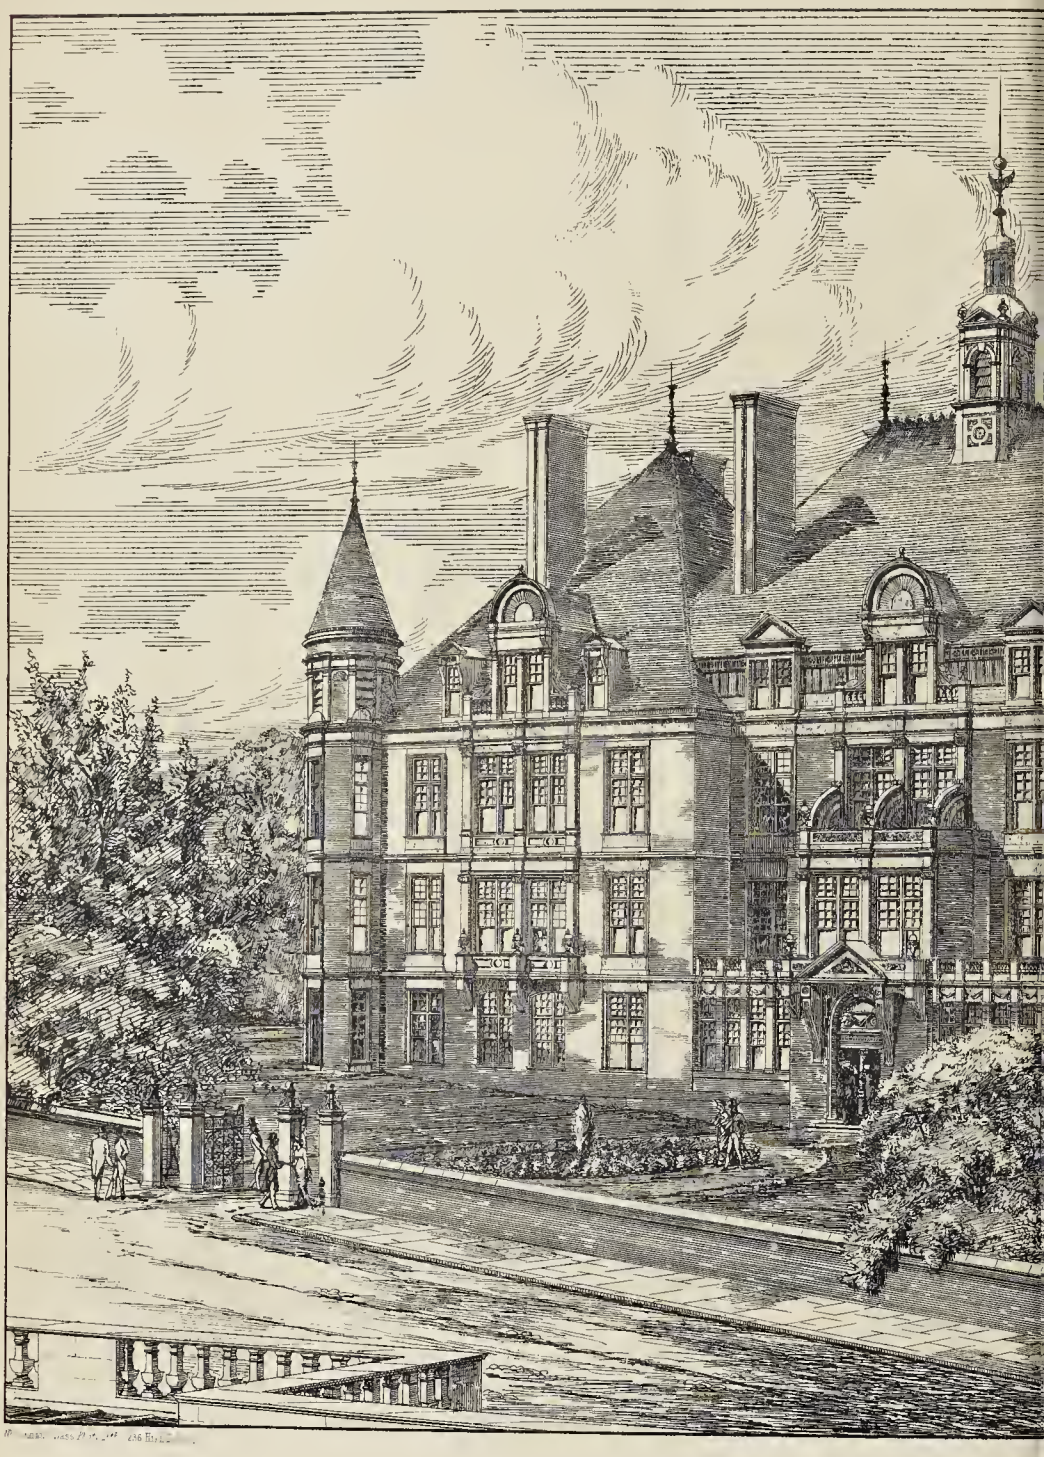
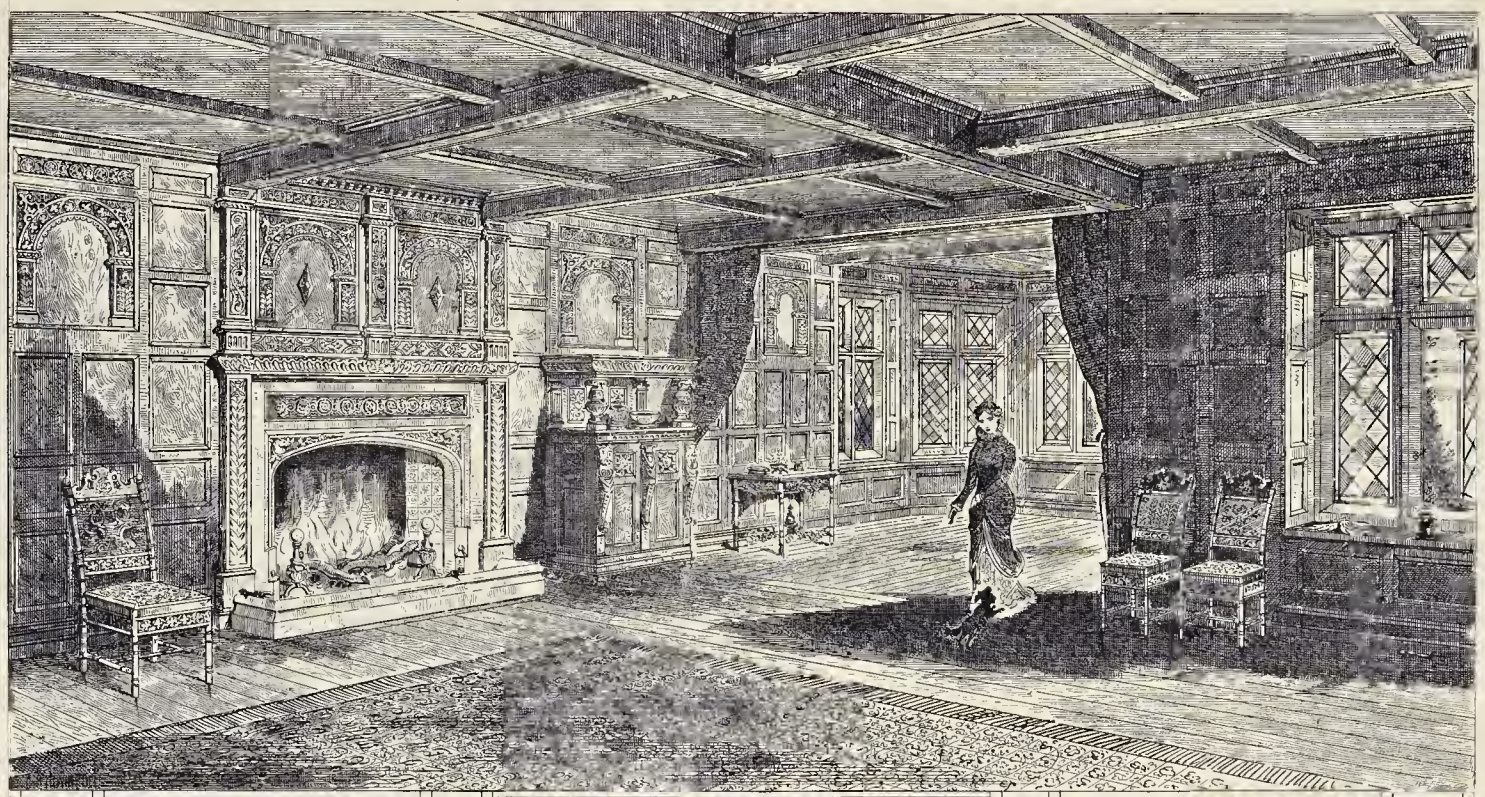
CONSUMPTION HOSPITAL, HAMPSTEAD



THE NORTH LONDON HOSPITAL FOR CONSUMPTION, MOU

ERNON, HAMPSTEAD.——Mr. T. Roger Smith, Architect.



INTERIOR OF THE DRAWING ROOM

HARDWICK HALL, DERBYSHIRE, the seat of HIS GRACE the DUKE of DEVONSHIRE K.G.

MESSRS. J. M. TAYLOR & SON, ARCHITECTS

Whitman & Brass *Photo Litho* 236 High Holborn

Wyman & Sons, Printers, 74 Queen St

THE MONUMENT TO ROBERT SCHUMANN, BONN.—Professor A. Donndorf, Sculptor.

importance of the special muse of the composer could not have been more convincingly expressed. On either side of the muse are seated, on separate pedestals, two genii,—the singing Psyche and the fiddling Amor.

The monument is about 13 ft. high, and has a breadth of 6 ft. 6 in. All the figures are in a much lighter marble than the architectonic parts, and are somewhat above life-size, so that in the open they have the effect of natural proportions. The head of Schumann not only forms the centre of attraction, but also the lightest part of the monument, marble of the most excellent quality having been selected for it. The total cost of erecting the monument is 1,250*l.*

A PLEA FOR VENTILATION.

The discussion upon Mr. E. C. Robins's paper upon "Sanitary Science in its Relation to Civil Architecture," on the 29th ult., was adjourned, to be resumed on the 17th of January next. In the meantime, public attention will be absorbed by all-engrossing politics, and unless, Sir, your influence can be exerted, the good which might have resulted from Mr. Robins's comprehensive paper will to some extent be lost.

If you will allow me space to comment upon the observations of the several speakers at the discussion in question, I will conclude with an endeavour to fix the *onus* for neglected ventilation upon the right shoulders.

My remarks shall be strictly confined to ventilation combined with warming, since these should never be severed; and, moreover, my practical experience has been chiefly confined to these branches of sanitary science.

The observations made by Professor Corfield, who commenced the discussion, had reference chiefly to sites and drainage, the ventilation of sewers, &c., but did not touch upon the ventilation of dwelling-houses.

Mr. E. R. Robson, who followed, made several sound and practical observations, and rightly insisted that what the architect has to do is to follow natural laws in the main. He advocated the provision in all houses of efficient warmth and ventilation to the corridors and staircases; forming reservoirs, in fact, of fresh warm air outside the rooms.

It would be no valid objection to this view to suggest that, by so doing, in London houses especially, the heat and odours of the kitchens and basement offices would be attracted upwards. Such a result can and ought to be rendered impossible by the efficient ventilation of those departments of essential work.

I cannot, however, agree with Mr. Robson in his preference for the American steam-heating system, which, as pointed out by Capt. Douglas Galton, C.B., does not, like the low-pressure hot-water system, admit of easy regulation to meet the ever-varying temperature of our climate.

Neither can I endorse Mr. Robson's condemnation of the principle of warming the fresh air by contact with low-pressure hot-water pipes in basement chambers, and distributing it, in large quantity, moderately heated, to the several rooms of a school or other building. It may well be that many of the earlier constructions upon this principle with which Mr. Robson is acquainted have had their basement chambers too small to admit of periodical cleansing, or even for the reception of sufficient air to be warmed and passed on to the several rooms. That such fresh-air channels should speedily become foul and dirty, and affect the salubrity of the air, cannot be surprising, while others, sufficiently large for workmen to pass from end to end to cleanse and lime-white their interiors, may be referred to without hesitation as the very best means of warming and ventilating rooms designed for the reception of large numbers of persons. Such are those of the Museum of Comparative Anatomy and the Selwyn Divinity Schools at Cambridge.

The inequality of temperature in large rooms warmed by open fires, to which Mr. Robson adverted, ought not to arise where the best kind of warm-air ventilating-grates are used.

Of these it may be safely asserted that they maintain a temperature varying not more than 2° between the most opposite points, premising, of course, that the size of the grate (fire) has been judiciously chosen, and no extraordinary amount of cooling surface nor deep recess or bay occurs to make the spot in question altogether exceptional. It is to be hoped that the members of the Institute will accept Mr. Robson's invitation to inspect and judge of the two school buildings to which he referred, the one warmed by the "Hygiastic Grates," and the other by the "American Steam-heating System." If the latter, by radiation or convection, shall efficiently warm the air of the rooms, while the Whitehurst-Tobin principle of cold-air supply shall impart the needful freshness, without cold draughts, its success will make the deeper impression from the fact that theoretically it is in opposition to the views of our first authorities.*

Captain Douglas Galton, C.B., bore testimony to the greater success of American architects in dealing with ventilation than obtains in England, attributing this result to the greater scope allowed them for improvements. He referred especially to Dr. Hall's Presbyterian Church, and to the theatre in Madison-square, New York, but beyond the statement that the ventilation was effected partly by means of propulsion and partly by extraction, no practical suggestions were afforded. Mr. Ewan Christian cordially endorsed the eulogium of Captain Douglas Galton upon the admirable ventilation of Dr. Hall's Church, but if he brought away with him any definite conception of the mode of its accomplishment he failed to convey it to the anxious minds of the junior members of the profession, whose ears were open for its reception. Indeed, these young men, who doubtless made mental notes of the scientific works they were recommended to study by one of the earlier speakers, another F.R.I.B.A., must have felt their ardour in the pursuit of good ventilation considerably damped, when their highly-respected senior wound up his remarks by stating that "he had tried many plans [of ventilation], but always found all the holes stopped up within a month or so. Nothing was better than a roaring fire and an open window."

Would it be unfair to ask Mr. Christian whether the fact stated as to the "many plans" and the "stopped holes" proves anything more than that want of knowledge which hinders the use of inlets and outlets for air, where they would inevitably act as desired? I fancy too many architects would delight in ridding themselves of all enthusiastic advocates for scientific ventilation by placing them within the range of "open window" and "roaring fire."

Mr. G. J. Symons, F.M.S., drew attention to the system of a Glasgow firm for the ventilation of large rooms by means of two large iron vessels alternately rising and falling in the roof space for the extraction of vitiated air. This system would appear to require steam or other power. There are many efficient modes of extraction where power is available, but the remarks in the present paper chiefly refer to ordinary buildings where such is not the case.

Professor Ayrton's condemnation of the highly-heated American stoves accords with the established preferences of Englishmen. The statement that carbonic acid gas passes easily through heated wrought iron will be a surprise to many persons, and it would at least be useful to know to what temperature the iron may reach before attaining this objectionable result.

Lieut.-Colonel Prendergast, who last addressed the meeting, referred especially to the "brand new" barracks at Knightsbridge, where he appears to imply that the proverbial result has followed the employment of "too many cooks"! "The admirable grates devised by Captain Galton have been rendered nugatory by ventilating engineers on the one hand, and doctors on the other"!

But the remarks of Lieut.-Colonel Prendergast are not sufficiently precise or explicit to admit of criticism, while they indnce a strong desire for further information; and this we must hope to obtain.

And now, sir, for the promise, illustration, and reference, given in the second paragraph of this paper.

When, several years ago, the plans for the Foreign Offices were in course of preparation, I determined to induce, if possible, some consideration for poor, neglected "ventilation" at the hands of the distinguished architect, Mr. (afterwards Sir) George Gilbert Scott, and I approached him armed with a letter of introduction from his brother. I was courteously,—not to say kindly,—received; the subject was admitted to be an important one; and I was requested to obtain an interview with the then First Commissioner of Works, the Right Hon. Wm. Cowper.

My opening visit with the First Commissioner appeared, to my inexperience, a very promising one; and I returned to Mr. Gilbert Scott with the message that Mr. Cowper would be very pleased that Mr. Scott should go into the question with me in order that something might be done.

It was not easy for a mere "projector of ventilation" to command ready access to two such distinguished men, and I had a weary time of it, and several unproductive calls upon Mr. Gilbert Scott, before I was informed that the architect had no money for ventilation, and that the First Commissioner should start by providing a further 10,000*l.* (!) to enable the architect to entertain the question seriously. At length, when I succeeded in obtaining another interview with the First Commissioner, I was doomed to hear that more money was out of the question, and I was asked, "Could ventilation really be so essential for such large and lofty rooms?" It was in vain that I argued that large rooms were usually built for large numbers of persons, and that even when occupied by few persons only, stuffiness of atmosphere was merely a question of time, and inevitable, sooner or later, in the absence of means for exchanging the air. I next tried the "*argumentum ad hominem*," by reminding the Right Hon. First Commissioner of his own highly-interesting paper upon this very subject of ventilation at a recent popular Reading; and I was rewarded by a smile, and some allusion to autumnal leisure, and the duty of contributing to the edification of the people.

I have known it to be maintained by many architects that there is no desire for ventilation on the part of the public, their clients, and hence that they are unwilling to pay for it. But surely it should be the province of the architect to insist upon its provision, in view of the overwhelming evidence of its necessity afforded by the researches of scientific men. The principles which underlie the construction of chimneys which shall not smoke, of ventilating-flues which shall pass their currents as desired, of drains which shall not poison their surroundings, of damp walls and basements which shall be conspicuous by their absence, are very much of one order, and may be understood by any one who brings a very little science, experience, and common sense to bear upon them. They partake perhaps too much of the practical to be popular with the æsthetic; but architects who neglect them after all the aids afforded, as was well suggested by Professor Corfield, will assuredly be left in the rear of progress; for the time must come when they, and they alone, will be held responsible for the neglect of this and all other branches of sanitary science.

D. O. Boyd.

A CHRISTMAS VISION.

One night I chanced to pass the time
With Christmas tales, in prose and rhyme,
Of ghosts and phantoms eerie,
And then to "shop" for change I turn'd
And read how limes should not be burn'd,
Till brain and eye grew weary.

I read how great the works of old,
How style did newer style unfold,
How Art from Nature grew;
How, first inspired by her grand skill,
Man needed, reason'd, built,—until
His earth was dress'd anew.

I read till past that "witching hour"
When spirits may assert their power
To visit earth again.
At length I laid the volume down,
I lit my pipe, put on my gown,
And fell in musing strain.

The wreathing smoke did upward curl
In many a circling, wavy twirl,
And from its shade there grew
A form impalpable, though near,
Whose shadowy presence grew more clear
The more the smoke I blew.

His lustrous eyes, his olive cheek,
His raven hair, his air, bespeak
Him born in foreign clime;
His massive head and lofty brow
Denote the intellect which now
Defies the power of Time.

Aghast I gazed in trembling awe,
When at his side arise I saw
A form far less imposing;
The latter's brow is more serene,
His dim eyes lack those glances keen,
The mind's own fire disclosing.

But yet they did engage, methought,
In wordy war, for oft I caught
The arms outstretch'd, and guess'd
That he who first appear'd did chide
His fellow's want of proper pride
In arts which he profess'd.

Whereat he of the modern school
With twitching mouth, demeanour cool,
Look'd as though he'd say,
With you *in toto* I agree,
At least—that is, in theory:
In practice 'twill not pay.

Ere long less stupefied I grew,
And seem'd to understand the two
Disputed as to Art;
The ancient's accents fluent roll'd,
Mellow, rapid, deep, and bold,
As pouring from his heart.

"O Friend," he cried, "art thou content
To copy merely what was lent
As precept and example?
Have minds become so barren now,
That e'en Invention's needy plough
But turns the ancient samples?"

"No," quoth the other; "but you see
The public are æsthetically
Inclined, and swear by you;
True art but lived in days of yore,
They say, and praise the copy more
The more the copy's true."

"The public—bah! And what know they?
Unletter'd, rude, and, sooth to say,
Aye clamouring for the moon!
We work'd for art, and when we caught
A Heaven-inspired notion sought
To give it life full soon,

All careless whether those around
Contemn'd or flatter'd, if we found
New beauties spring to life.
O Friend, our all was in our art,
'Twas of our very soul a part;
We knew not jealous strife."

"But, Sir," the Modern next replied,
"From then to now is period wide;
Permit me, too, to show
The public is to us what you
But found in patrons, though 'tis true
They both but little know.

You'd but to please a tyrant rude,
While we must please the multitude,
From pot-house to the Throne;
For, strange to say, 'midst all our cares,
We all of other men's affairs
Know more than of our own!

And had I follow'd when on earth
My art for art's intrinsic worth
I had been in a fix
When friendly Charon ask'd for toll
To row my disembodied soul
In comfort o'er the Styx."

"Unhappy man! and canst thou now
Scoff lightly at thy art? Didst thou
On earth so plainly mock it?"
"Nay," quoth the Modern; "then, I grant,
I used the necessary cant,
Nor wantonly did shock it;

For had I striven 'gainst the tide
Of taste my hobby-horse to ride,
Without it was the rage,
I had been call'd a dunce, a prig,
An ass, who, with conceit swell'd big,
Did strive to guide the age."

"Alas, alas!" the Ancient cried;
"Alas, alas! that thus the bride
And lover true should part!
That she should go to Mammon's bed!
That he should sacrifice for bread
His duty to his art!

While sciences and laws progress,
How is't the sister arts do less
Than keep their ancient lines?
To-day's are not the same demands
Which fired the brain and nerved the hands
That raised Athenian shrines!

Be not withheld,"——The spirit here
Stretch'd forth his arm. To plainer hear
I forward lean'd, and broke
The vapoury cloud which hung around,
When, lo! my vision had, I found,
Consisted all of smoke!

HERBERT.

The Liverpool Land and House Owners' Association held its twenty-first annual meeting on the 17th inst. The report stated that during the past year the council had sent a memorial to the Right Hon. R. A. Cross, M.P., suggesting that a Bill might be introduced into Parliament in favour of a national water supply, and against exceptional legislation for London; also a memorial to the City Council urging postponement in carrying out the Vyrnwy water scheme. The proposal of the City Council to erect 2,560 lamps in courts and passages, at an expense of 15,800*l*., to be paid by owners of property, was protested against. After referring to the opposition of the council to the second Nash-grove scheme for building artisans' dwellings, the report expressed the hope that the last had been heard of "four and five-decker houses" [dwellings in flats, we suppose], and that the land would be disposed of in the open market in the usual way. The council had suggested to the City Council that they should apply to Parliament for power to take down the whole property in the old parts of the city, that wide roads might be laid out for properties of every class to be built to the fronts of them. It was believed this would have the effect of reducing the high death-rate. The report was adopted.

ENGINEERING WORKS AT HOME AND ABROAD.

CIVIL AND MECHANICAL ENGINEERS' SOCIETY.

MR. H. ELLIS HILL, A.-M. Inst. C.E., in the course of the address delivered by him as President of this Society at the opening meeting of Session 1880-81, commenced by referring with satisfaction to the fact that the Society, which has now been in existence for twenty years, has recently acquired offices and a meeting-room of its own in Westminster Chambers. He next proceeded to review the progress made in engineering works during the past year, specially mentioning and briefly describing the Royal Albert Docks at North Woolwich, recently opened, and which, it may be noted, consist of a main floating-dock of 75 acres area, with an entrance-basin of 9 acres. The entrance lock is 800 ft. long and 80 ft. wide, with 30 ft. depth of water over the cills. The main dock is a mile and a quarter long and 490 ft. wide, the total length of dock walling being three miles and a half. As we pointed out in our description of the works three years ago,* the dock-wall is of concrete (500,000 cubic yards being used, requiring 80,000 tons of Portland cement). This work, perhaps the most gigantic of its kind, was cited by Mr. Hill as affording evidence of the great value of concrete in such constructions, on account of its strength, cheapness, and adaptability, and as having almost revolutionised the practice of the civil engineer in such works. Another fine example of the use of concrete is to be seen in the Dock Extension works at Chatham. Amongst other works completed during the past year are the landing pier and breakwater at Douglas, Isle of Man, where, again, the material used was concrete, with the result that the works have been constructed at probably a less cost than any kindred works of similar magnitude in the country. The necessity for adequate dock accommodation for ocean-going steamers is making greater demands upon the engineer, in consequence of the continually increasing size of those vessels. Steamers of 5,000 tons burden, 500 ft. long and 26 ft. draught, are now traversing the ocean, and vessels of 8,000 tons and 10,000 tons seem likely to become common. Alluding to the proposed Panama Canal, Mr. Hill paid a warm tribute to the energy and genius of M. de Lesseps, and stated that in connexion with the works there would be constructed a flood storage reservoir having a capacity of 1,000,000,000 cubic mètres. The dam for forming this reservoir would be 147 ft. high and 787 ft. wide at the crest, and would require 26,000,000 cubic yards of material. The total amount of excavation for the canal was estimated at 100,000,000 cubic yards, about one-half being in rock. Owing to the peculiarity of tidal change, a basin with three lock chambers would be necessary at the Panama end, the rise of tide being from 7½ in. to 19 in. at one end, and from 8 ft. to 21 ft. 3 in. at the other end of the canal. As a maritime nation, it could not be said that England was yet well supplied with accommodation for shipping. Our shores were proverbially dangerous, and harbours of refuge were few and far between. The railway works completed during the year include the St. Gothard Tunnel, and, amongst those nearly completed is the Manchester Central Station, having a roof of 210 ft. span and 550 ft. long, and in which the weight of ironwork used is 2,400 tons. The lamentable failure of the Tay Bridge was referred to as showing the necessity, not only for careful consideration of the design and proportionment of parts to work to be done, but also, — and of not less importance, — the obtaining of good material and workmanship. With regard to the future prospects of the engineering profession, Mr. Hill said he did not share the gloomy view held by many, that in this country engineering is worked out. Of course, with regard to railways, not many (if any) large trunk lines would be required, but there was still much work to be done in the way of providing branch lines. As to street-tramways, there was no reason why they should not be very greatly extended, and horse draught-power largely if not entirely superseded by steam or other motive power. The problem of dispensing with animals for draught-power had not yet been entirely solved, however, for the crude expedient, now being tried in some of the Northern towns, of coupling an unwieldy and cumbersome engine and boiler to an ordinary tram-car could not be considered a success. There was much room for ingenuity in devising a simple and easily-managed mechanical motor for street tramways. With regard to sewerage and drainage works, Mr. Hill observed that fame and fortune had still to be won by sanitary engineers in devising a system of dealing with sewage which should be effectual and generally applicable. Gas and water engineers, electricians, and representatives of other branches of the engineering profession had also much work before them. Discussing the question of transferring the management of gas and water-works to municipalities instead of leaving such matters to private enterprise, Mr. Hill doubted the advisability of the change, on the grounds, amongst others adduced, that there would be a less direct incentive to the obtainment of commodities of good quality (whether water or gas) for the sake of the custom, or to the attainment of cheap distribution for the sake of the profit, and the consequence would be, in Mr. Hill's opinion, that the consumers would suffer. In considering the work of the Civil and Mechanical Engineers' Society as an aid to the education of the young engineers who constituted the bulk of its members, he touched upon the connexion subsisting between *civil* and *mechanical* engineering, and then summarised the qualifications required by the followers of these two main branches of the profession of engineering, adding what may be called a *précis* of some of the chief practical points arising in professional practice. While the two branches of the profession were to some extent divergent from each other, yet he was convinced that it was next to impossible to be a sound and successful civil engineer without a considerable acquaintance with the work of the mechanical branch of the profession. It might be, and was, argued by some that it was always possible to separate the work of the two branches, leaving the purely mechanical engineer to work out the practical details of construction after the broad outlines had been arranged, it being, it was urged, too much to expect one man to possess an intimate acquaintance with many and varied details. While that was true to a limited extent, it was none the less true that an engineer could more correctly design large works if, at the same time, he knew how the details of construction should be carried out. In these days of large public works and special appliances, it was not sufficient for an engineer to be able to design correctly the various parts of a structure; he should be capable, if called upon, of designing special plant for special requirements, in order to secure economy of construction. This might seem to be more directly the business of the contractor, but many works were constructed without the intervention of a contractor, and in such cases the engineer was responsible, not only for the design, but for the construction of the work; and even where a contractor was employed, the same knowledge was required from the engineer, because an acquaintance with the best means and appliances for construction under special circumstances might so modify the details of design as to cheapen a structure without impairing its efficacy. As an example of this, Mr. Hill cited the case of the Dublin river wall, where huge blocks of concrete, weighing each nearly 400 tons, had to be lifted, transported, and deposited in place; and much ingenuity was displayed by Mr. Bindon Stoney, the engineer, in designing the monster machinery for that work. A barge was employed carrying floating shears with an overhanging jib capable of suspending a large block over the end of the barge, and in that position transporting it to the required position in the work. Manifestly this system could only be employed in smooth water. A similar problem had presented itself in the works at Jersey, but under different conditions. There the blocks were from 70 tons to 100 tons in weight, and had to be deposited in the open sea. There, as at Dublin, a barge was employed, but instead of the overhanging shears,—which with a small wave movement would cause a great oscillation of the suspended block of concrete or stone,—the block was suspended underneath the barge from a strong framing on deck, and manipulated by a powerful winch arrangement. On the blocks so deposited at Jersey a superstructure of concrete blocks, each weighing 12 tons, was raised, the blocks being set in place by a specially-designed overhanging travelling-crane, called a "Hercules," having a traverse of over 50 ft. At a work now being carried out

* See vol. xxxv. (1877), p. 727.

in South Africa a similar machine was employed, with somewhat less overhang, but capable of dealing with blocks of 25 tons each, and also capable of being used for depositing from a box large bags of concrete to form the substructure to receive the blocks. In Ceylon, in connexion with other large works of the kind, a similar machine was being used for depositing blocks of between 30 tons and 40 tons weight. These machines had all been designed by Sir John Coode to suit the special requirements of each place, and they were all so contrived that the blocks could be brought from the block-yard and then picked up by the machine and set in the work, the machine moving forward as the work proceeded, thus obviating the necessity for temporary staging, which was not only a very expensive item in first cost, but was always liable to damage during stormy weather, whereas the machine could be run back to a place of shelter. Similar machines had been designed by Mr. Parkes for his works at Kurrachee and Madras, to deal with blocks of 27 tons weight. There was no doubt that in the future, where works of magnitude had to be constructed, special appliances would come in for much attention. As an evidence of this it was only necessary to mention that the estimated cost of plant in connexion with the harbour works at Batavia was 83,000*l.*, while within the last six years more than 85,000*l.* had been expended on plant at the Antwerp harbour works. With regard to mechanical engineers, Mr. Hill, in concluding his paper, insisted that they should be trained in engineers' workshops.

On the motion of Mr. A. T. Walmisley, seconded by Mr. R. Harkness Twigg, the thanks of the meeting were given to Mr. Ellis Hill for his address, of which the foregoing is but an abstract.

FROM ABROAD.

Those, and they are many, who fear the danger of a multitude of counsellors in questions relating to the fine arts, will have reason to be somewhat astonished at the extended and complete nature of the council which the French Government has called together to assist the Secretary of State for the Fine Arts in his arduous duties. A reconstitution of this council has recently been officially announced. Its composition offers some features of interest apart from the fact that we meet with most of the names familiar to us in the artistic world of Paris. Were it only to show the practical importance attached by our neighbours to the consideration of the numerous art questions that present themselves, and the desire of the Government to meet every contingency, an enumeration of the officials who form this council is of instructive value. Presided over naturally by the Minister of Fine Arts, are nominated members "by right," the Prefect of the Seine, the secretary of the Academy of Fine Arts, the Administrator of the National Museums, the Director of the "Bâtiments civils," the Inspector-General of Drawing, the Director of the National School of the Fine Arts, the Director of the Conservatoire of Music, the Vice-president of the Commission of Historic Monuments, the Director of the School of Decorative Art, the Curator of the Museum of the Luxembourg, the Commissary-General of the Fine Art Exhibition.* The council thus far constituted, a further addition is made by the annual election of twelve artists, members of the French Institute, who take the place of our own Academicians, and what may be termed "outsiders"; six painters, two sculptors, two architects, an engraver, a musician, a member of the French Academy, a member of the Academy of Inscriptions, two member of the Superior Council of Public Instruction, two senators, two deputies, a councillor of State, a member of the directing body of the Sèvres manufactory, as also of the Gobelins tapestry works, two representants of the arts applied to industry, an inspector of fine arts, and six persons distinguished for their literary acquaintance with art. The council thus constituted is to meet every three months, but it can at all times be convoked by the Minister of Fine Arts. Sub-committees will be formed for the preparation of special reports. The subjects for consideration of the council are numerous, the annual exhibitions, the various competitions, the national manufactures, the archæological or artistic missions to foreign countries, and a number of other questions relating to art, the Minister of Fine Arts will submit to the attention of the council. Thus formed, the council for this year gathers together a characteristic choice of names, many, if not most, familiar to the public. Among the painters, Henri Lehmann, Cabanel, Gerôme, Bonnat, Breton; sculptors, Barriae and Chapu; Boeswillwald, Inspector-General of the Historic Monuments, and an eminent architect, together with M. Garnier; Flameng the engraver; M. Renan, of the French Academy; M. Perrot, the archæologist; M. Galland, of the École des Beaux-Arts; M. H. Bouilhet, of the Union Centrale, a manufacturer who worthily represents the application of the arts to industry. Among the art critics, MM. Alexandre Dumas, Edmond About, Charles Clement of the *Débats*, Eugene Véron, director of the journal *L'Art*, and Charles Blanc. This assemblage of names, including so generously the most widely-differing opinions in a council intended to watch the artistic interests of the country, is characteristic of the method in which our neighbours treat the consideration of the fine arts in their bearing on the community. Mr. Mundella was right, the other day, in expressing his belief that without the efforts for the encouragement of art made of late years our trade would have suffered by millions.

That importance which is attached in all thinking minds in England to the proper education of the workmen, the manufacturers, the employers of labour in future, is no less felt abroad. Only a few days since M. Jules Simon, in reading before the Academy of Inscriptions and Belles Lettres a portion of his collection of Reports on the Exhibition of 1878, successfully showed how completely we may attribute the advance of industry in the present day to the progress made in science and intelligence, the work of our superior schools; to their still greater development he looks for the future of industry. "Let us give professional schools," the eminent statesman and Academician said, in concluding his address; "let us give professional schools to our miners, our blacksmiths, our decorators, to our weavers, our watchmakers, to our carvers, our cabinet-makers, to our cultivators. But let us remember to make of them men, because it is with men that workmen are made manufacturers and *savants*; primary and secondary schools to make men, schools of apprentices to make workmen, schools of application to make engineers and chemists, superior schools to make *savants* and professors. Let us make a crusade for education and science. In the situation in which the course of events has placed us, it is no longer possible to be ignorant,—to stop. We must advance, or fall."

The interesting Château de Blois, it may not be uninteresting to many to learn, is at present undergoing important repairs, in accordance with the determination of the Historic Monuments Commission. The works consist in the restoration of the roof and the upper portions of the château built in the time of Francis I., in which the chimney-stacks and the skylights are in a far from proper condition, although they by no means belong to the original building.

From Amiens we learn that at the cathedral have been terminated the series of casts which are to form part of the Museum of Comparative Sculpture to be installed at the Palace of the Trocadéro in conformance with the proposal of the late Viollet-le-Duc, as was announced in these columns at the time of the eminent architect's death. Successful casts have been taken of a number of the characteristic figures, the "Vierge Dorée" and two apostles from the great portal, that of St. Sauveur, with its pedestal and the various ornaments which form the general surrounding decorations; in the interior, a cast from the figure of the bronze tomb of Erarde de Foulloy and of Godefroid d'Eu. It is to be hoped that our Government may obtain duplicates of these delicate works. Is it not time, when we consider what is being done abroad, for our Government to bethink itself of again taking up a proposal which has been more than once put forward, the establishment of a special museum of casts?

The three so far promised exhibitions of next year are each, from all accounts, in admirable train. From the *Frankfort Gazette* we learn that owing to the activity displayed by the committee of the exhibition of "Patents and Trade Marks," which was announced in these pages, the number of exhibitors has already reached 1,200, while the site of the exhibition has had to be enlarged from 8,000 to 14,000 square yards. We may look forward, therefore, to an interesting show.

The Paris Exhibition of Electricity is also now completely decided on, and a recent official announcement states that the bureau of the exhibition and the commission of the International Congress of Electricians are now installed at the Palais de l'Industrie in the Champs Elysées, where all information can be obtained. The arrangements of the exhibition were definitely agreed upon only a few days since. The exhibition opens on the 1st of August next, to close on the 15th of November. Foreign exhibitors will be represented by a special commissioner for each nation; by a wise arrangement the exhibitors will not be called upon to pay for the space they occupy. The principal classes to be represented are telegraphy, telephony, the production and distribution of light, light-houses and signals, electric motors applied to industry, wires and cables, galvano-plastic, and the various applications of electricity to the fine arts. A lithographic collection and an historical museum will complete the show. It has wisely been determined to distribute among the workshops a large number of free tickets.

As for the Milan Exhibition, the Milan papers duly record the progress being made. The Italian Government has recently determined that an important feature of the show is to consist of an industrial museum formed of a complete collection of specimens, each to be price-marked, of all Italian manufactures or products which are capable of being made staples of an export trade. Should this collection be really completed we may look for some curious and interesting results.

The mention of Milan may, perhaps, be considered sufficient excuse for the introduction here of a charming artistic anecdote related of Garibaldi by a correspondent of one of the French papers during the recent visit of the popular Italian hero to Milan. Among the numerous persons presented to him, Garibaldi received the representant of one of the Paris illustrated papers. "Be welcome, dear sir," said the old soldier to the artist, "you are one of my friends; for I am like the children,—I like picture-books, and I love those who make them."

THE FOG QUESTION.

In the paper read at the Society of Arts the other evening, Dr. Alfred Carpenter, after demonstrating the nature of the black fogs of modern times, proceeded thus:—It is much easier to point to a nuisance than to get it removed; I always object to criticism, unless it shows a better way of doing things. I object to overthrow an institution without being provided with something better to put into its place, even if that institution is a nuisance. The overthrow of the domain of fuel-smoke might be purchased too dearly. There is something so endearing and so national about our domestic hearth, so captivating about the ability to poke a fire, that I should never expect to remove these comforts from our midst; neither is entire removal necessary. The ability to poke a fire is the one thing which preserves many a mind from downright insanity, and to take away the power would consign many an unstable mind to a madhouse. The thing is not to be done, therefore, without due consideration. Thousands of fires, nay tens of thousands, would not produce a London fog, spread about, as they might be, over the 300 square miles which constitute the metropolitan district. A few such fires would do harm, and if such fires, being a luxury, were made to assist in performing a duty towards those who could not afford the luxury, good might come out of evil; though I would not support the notion that it is right to do evil that good may come. The question is, How are smoking chimneys to be got rid of? It is a process which the Society of Arts, with all its array of powerful names, will not be able to effect. An appeal must be made to the Legislature upon the point, and I suggest that the Society be foremost in making that appeal. Let us ask them to pass such laws as will help forward the object which we have in view, for public opinion, public spirit, and philanthropy will not alone be able to effect it. I believe that a short Act would be sufficient. That if local authorities had the power to levy a tax upon every fireplace so constructed as not to consume its own smoke, the smoke nuisance would then disappear in a very few years. They should have the power to use the proceeds of

* By a decree, published only within the last few days, the professor of Archæology of the Ecole des Beaux Arts is added to the Council.

roof, in addition to which each shop has its own independent lights. The necessary sanitary accommodation is provided at the south-west corner.

The architects of the new building are Messrs. J. & T. Tillman, and the contractor for the mason's work is Mr. Mark Howarth, and for the joiner's work, Mr. Davidson Taylor, all of Sunderland.

THE CITY CLUB, LUDGATE CIRCUS.

"Cook's Tourists" have been and still are sneered at occasionally by writers and talkers who forget that travel does a great deal to broaden people's views of men and things, and who fail to recognise that the man who makes travelling easy and cheap is a real benefactor to his race. The firm of Thomas Cook & Sons led the way in providing well-organised facilities of travel, and still maintain the lead; and it is to the managing partner of the firm, Mr. John M. Cook, that credit must be given for having met, with characteristic enterprise and foresight, a want that has long been felt in the City, particularly in that part of it where journalists of all grades most abound, viz., Fleet-street and its vicinity. That want is supplied in the establishment of the City Club, which is located in the four upper floors of the handsome and extensive stone building which was erected some five or six years ago at a cost of some 60,000*l.*, for Messrs. Cook, at the corner of Fleet-street and Ludgate Circus, and which has return frontages to Farringdon-street and St. Bride-street. The position is excellent. Messrs. Cook's tourist offices and the Ludgate Circus Branch Post Office occupy the ground floor, the proprietors also retaining the *mezzanine* for their own use. The upper floors have until lately been sub-divided and let out as numerous offices, mostly those of press agencies and provincial journals which need (and all daily provincial journals do need) offices in London. Recently, representations were made to Mr. Cook that he would be well supported if he were to devote the four upper floors of the building to the purposes of a club for clerks and others engaged in the City in mercantile or other pursuits, with special provision for the accommodation of members of the Press. Mr. Cook happily seized the idea, and has put it into execution in a manner that has elicited the warmest encomiums from all who have seen the premises. Mr. Horace Gandry, the architect from whose designs the building was erected, has (as we stated a few weeks ago*) been employed to superintend what slight structural alterations were needed, which have consisted for the most part in here and there removing partition-walls so as to make two or three rooms into one, and in making doors of communication in the partition-walls that remain, so as to throw all the rooms on a floor into direct communication with each other, besides having separate means of access from the staircase landings. The rooms are tastefully decorated and furnished. The decorative work has been done by Mr. Laing, of Duke-street, Adelphi, and the furniture, which is good throughout, has been supplied by Messrs. Maple & Co., of Tottenham Court-road. The entrance to the club is in Fleet-street by a lobby, from which stairs run up above the *mezzanine* to the spacious entrance-hall, where members can leave their hats, coats, umbrellas, &c., in the care of the hall-porter. On the left of the hall is the "Press Writing Room," a handsome apartment, provided on either side with a row of specially-designed desks, partitioned off into spacious compartments, and provided with seats. These desks have good window-light by day, and are provided with Sugg's London argand burners with opal glass reflectors for use by night. In the centre of the room is a large writing-table for those who do not seek the privacy of the side desks. Altogether, comfortable accommodation is provided for twenty Press men to work at one time. This room is exclusively devoted to the use of members of the Press, and is open all night up to six o'clock in the morning, for the convenience of the reporters connected with the daily newspapers, although three o'clock a.m. would probably be late enough to keep it open. This feature of the club is much appreciated by Press men, who have already joined the club to the number of about 150, almost every one of whom is showing his appreciation of Mr. Cook's enterprise by bringing in new members. Well may they be grateful to Mr. Cook, for many of them (particularly reporters) are often compelled by the exigencies of their calling to write out matter for the Press under most disadvantageous conditions, cooped up in dirty corners of printing and publishing offices, in the midst of distracting noises, and not seldom in an atmosphere as warm at night, though very far from being as pure, as that of a Turkish bath. Again, reporters, attached as well as unattached to the staffs of the different journals, have frequently in one day to attend meetings held at intervals of several hours apart, and hitherto many of them have had no more improving waiting-place to resort to than the public-house. Here, again, the City Club meets a great want. On the right of the entrance-hall access is gained to the large reading-room, where no conversation is allowed, and opening out of this is a smaller, but still large, reading-room, in which conversation is permitted. These rooms are fully provided with all the London newspapers, periodicals, and magazines, and with a large and good representative collection of provincial, American, and colonial journals. Ingress or egress to or from all these three rooms is also obtainable by doors opening direct on to the landing of the capacious and well-lighted staircase, as is the case with the rooms above. On the floor next above the reading-rooms are the restaurant and dining-rooms, where members can dine or get a chop or steak and light refreshments as cheaply and as well served as at the more ambitious restaurants which have been established in London of late years. To some people one thing only will be lacking, and that is alcoholic beverages, for Mr. Cook is an earnest and consistent teetotaller, and has managed to exist for nearly half a century without using those beverages. He says boldly in his prospectus that "if the City Club cannot be conducted without the sale or use of intoxicating drinks on the premises, it will have to be given up." We imagine that few people to whom such a club is valuable will let their desire for a glass of beer prevent them from availing themselves of the other advantages which are offered to them by a public-spirited teetotaller. Mr. Cook, however, is no Puritan, for on the same floor as that containing the dining-rooms are two well-appointed billiard-rooms, while on the floor above are rooms appropriated to chess, draughts, cards, &c., besides smoking and conversation rooms. It is stated in the prospectus that many well-intentioned people had remonstrated with Mr. Cook as to the provision of opportunities for these games, but regarding such amusements as innocent and harmless in themselves, he expresses his firm determination to be watchful and to check and repress any abuses, should they arise,—and he is a man of his word. The fourth floor is devoted to the kitchen and service of the club. The whole of the club is open from ten in the morning until midnight, and on Sundays the reading-rooms, Press writing-room, and dining-rooms are open from two p.m. to ten p.m. Mr. Cook has spent more than 2,000*l.* in furniture and fittings, and states that his annual liability in respect of the establishment will be about 1,500*l.* On the present low basis of subscription (1*l.* per annum), to which the proprietor desires to adhere if possible, he will need about 1,500 members, and seeing that the club opened on the 13th inst. with 450, a number which has since increased to very nearly 600, there appears to be no reason to doubt that the venture will be a great success, and afford another illustration of the power of co-operation in such matters. The rich and titled classes of the community have long since availed themselves of this means, as the palatial buildings of Pall Mall testify; and Mr. Cook, in taking the initiative in the matter of providing somewhat humbler though still good club accommodation for business men and journalists, is making an important social experiment, in which he eminently deserves to succeed and to be imitated, even as he has been imitated in other matters.

* See p. 556, *ante*.

Smoke Prevention.—The Commissioners of 1851 having placed their testing-houses at South Kensington at the disposal of the Committee of the National Health and Kyrle Societies, it is proposed to hold an exhibition of smoke-consuming and preventing appliances, and to undertake the testing of various kinds of fuel.

PRIZES FOR ART WORKMANSHIP.

The Council of the Society of Arts have issued the following important notice:—

1. The Society's Medals in Gold, Silver, and Bronze, and Certificates of Merit, will be awarded for specimens of Fine Art applied to Industry, exhibited in 1881, by manufacturers, designers, art-workmen, or possessors of such works.

2. The works may consist of illustrations of any or all of the following processes, in combination or singly:—

1. Carving in marble, stone, or wood.
2. *Repoussé* work in any metal.
3. Hammered work in iron, brass, or copper.
4. Carving in ivory.
5. Chasing in bronze.
6. Etching and engraving on metal,—Niello work.
7. Enamel-painting on copper or gold.
8. Painting and modelling in pottery.
9. Decorative painting.
10. Inlays in wood (marquetry or buhl), ivory, or metal.
11. Cameo-cutting.
12. Engraving on glass.
13. Wall mosaics.
14. Gem-engraving.
15. Die-sinking.
16. Glass-blowing.
17. Bookbinding and leather work.
18. Embroidery.

3. To all works the name of the designer and art-workman must be affixed. Further detailed rules will be issued later.

4. It is arranged with the Council of the Royal Albert Hall that the place of exhibition for the above-mentioned works will be at the Royal Albert Hall. The time for sending in the works will be published hereafter.

5. The above regulations are issued subject to modification.

SALE OF CEMENT WORKS AT NORTHFLEET.

Extensive cement works at Northfleet, in Kent, which have for several years past been carried on by Messrs. Goreham & Son, were sold at the Auction Mart last week, by Messrs. Fuller, Horsey, & Co. The premises, which cover an area of about six acres, having a frontage to the river Thames of 350 ft. in length, were offered, with the whole of the buildings and the fixed plant and machinery on the ground. The property is held under lease for a term of sixty years from September, 1872, determinable by the lessees at six months' notice, in case of chalk not being supplied by the lessors according to the provisions of the lease, at a rent of 200*l.* per annum. The original lease contained a covenant under which the lessors bound themselves to supply the lessees with chalk at the rate of one shilling per loose cubic yard, until the 29th of September, 1894, the minimum quantity to be 20,000 cubic yards per year, but this contract has since been modified by waiving the stipulation as to quantity, and increasing the rate to 1s. 1d. per yard. There were several competitors for the property, which was sold for 3,850*l.*

Club House, Darwen.—The new Conservative Club at Darwen was opened on the 9th inst. by Colonel F. A. Stanley, M.P. The building is in the Gothic style, and has been erected from the designs of Mr. W. Perry, architect, Darwen. The principal façade in Church-street is faced with parpoints, which, together with the dressings and other stone work, have been obtained from local quarries. The elevation to Church Bank-street is built of brick, with stone heads and sills similar to those of the chief front. The building is oblong on plan. There are two main entrances in Church-street. To the right of the hall on entering is a private billiard-room (32 ft. by 24 ft. for two tables), with lavatory attached. From the hall access is also gained to the ordinary billiard-room (50 ft. by 24 ft. for three tables); and on the left to the reading, conversation, manager and secretary's, and committee rooms. A private staircase leads from the secretary's room to the lecture-hall and anterooms on the first floor. The public entrance to the lecture-hall is in Church-street. Another means of access to the ordinary billiard-room is afforded to the right of this entrance. The hall is 75 ft. long, 48 ft. 9 in. wide, 22 ft. from floor to ceiling, and 34 ft. from floor-line to top of ridge. A gallery is provided at the west end, having a storeroom and refreshment-bar underneath; the platform and anterooms are at the east end. The general contractor was Mr. J. Pilkington, Darwen.

DIGGINGS IN BŒOTIA.

Dr. Schliemann and his wife have been staying for some time past in Bœotia, at the village of Skripa, near which they have been energetically pushing on excavations with a view to discover any remains of the pre-historical city of Orchomenos, the wealthy capital of the once famous kingdom of the Minyæ. Several shafts which Dr. Schliemann has sunk have afforded little result beyond a few relics of tombs, some vessels similar to those found in Mycenæ, and several inscriptions in the Æolic-Bœotian dialect. These Dr. Schliemann regards as of great value for Greek philologists.

While Dr. Schliemann has been comparatively unsuccessful in the excavations under his own special superintendence, his wife, who has been conducting researches in another portion of the ground, has been fortunate enough to find what are believed to be the remains of the "Treasury of Minyas." In a letter to the *Ephemeris*, dated November 23, Frau Schliemann says, "About noon to-day we came on a door and passage lying to the right of the Treasury. At the end of the passage was a second door, leading apparently to a tomb or chamber, and barred by a stone tablet covered with beautiful reliefs." The Government Commissioner who is attached to the excavating party, writing of Frau Schliemann's discovery, says "The door opens into a fine passage running in another direction from the Treasury. At a distance of 3 mètres, however, lies a large stone which had fallen down from the roof and completely blocked up the passage. This stone is adorned with sculptured flowers, which may be taken as indicating that the decorated portion of the interior commenced here. The stone is rather more than 4 mètres in length, and 2 mètres in breadth. The height of the door is not yet known: it is 1·3 mètres in breadth." The remains of the Treasury of Minyas lie at the foot of Mount Acontion, on the north bank of the Cephissus. The real nature and purpose of the monument are not known. Frau Schliemann thinks that the door now discovered leads to a second chamber, which was not known to ancient excavators, and which, she thinks, may still contain treasures of very ancient date. The excavations which Dr. Schliemann and his wife are prosecuting with great eagerness will soon set this question at rest.

THE ORIGIN OF THE ARCHITECTURAL ASSOCIATION.

Sir,—It may possibly he a distinction without a difference, but I cannot see myself how Mr. Kerr, in speaking of the "Association of Architectural Draughtsmen," can say "*they joined us; we did not join them.*" If the object is simply the origin of the present Association, this would give any one reading it a wrong impression. The fact is that a certain number of young men, wishing to found an architectural society for their mutual instruction and improvement, finding the A.A.D., having very similar objects, already in existence, came to us in 1847, and we willingly at once amalgamated. We were a very limited number, it is true, but there was no question as to which body joined the other. We received them with open arms; they met for a time in our rooms; we at once altered such of our rules as they objected to, and we omitted the word "draughtsmen" from our title, which they did not like. But with these exceptions it has been one and the same Association from the beginning, and the honour of its formation is still due to James Wylson. I think I am not wrong in saying that this has always been the general feeling,—and the Architectural Association still put after their title, "Instituted A.D. 1842."

I do not for a moment wish to detract from the important part Mr. Kerr took in revivifying the body, but it is wrong to say that the A. A. D. was a mere "benefit club." We met week after week, although only a few of us, for our mutual instruction, and read papers on professional matters, and contributed drawings and sketches. These we discussed and criticised in a friendly spirit, and we instituted the very first of the Architectural Exhibitions, the permanent formation of which was for years afterwards an important object of the present Association. This original Exhibition was held at our rooms in Southampton-street, and was opened *free* to the public, and a very good show it was for so small a body. This, at least, shows that we were willing to benefit others besides ourselves. James K. Colling.

P.S.—I was not a "middle-aged married man" when the A. A. D. was formed. I was twenty-six, and most of the other members were younger. Not one of us could be called middle-aged, even in 1847.

WORKS BY THE BROTHERS ADAM.

Sir,—In reference to the notice which appeared in your last number of Mr. Batsford's valuable publication "The Architecture, Decoration, and Furniture of Robert and James Adam, Architects," it may be interesting to many of your readers to know that in the library of Sir John Soane's Museum are upwards of fifty folio volumes of original drawings made by the Brothers Adam.*

Many of these folios are filled with highly-finished designs for ceilings and wall decoration, drawn to a large scale and coloured with details given to a still larger scale. There are also some volumes of designs for chimney-pieces, mirrors and furniture, besides the more strictly architectural plans, elevations, and sections, etc.

Permit me to add that every facility is given at this Museum to students who may wish to refer to or copy from these works. Curator.

RADIATION AND CONDUCTION.

Sir,—I cannot understand the reason for the broad distinction which it is attempted to draw between radiated and conducted heat. A fire radiates heat into the room. The metal portions of a grate or close stove become heated by radiation and conduction, and they radiate that heat in the room, on the ceiling, floor, walls, furniture, and on our own bodies, and these in their turn radiate heat. The air is, undoubtedly, not heated immediately to a great extent by radiation, but that it is heated to some extent is proved by the fact that there is an ascending current of warm air in front of every fireplace. We shall never understand how air really becomes warm till we are conscious of the incessant motion which takes place in every apartment that is not almost hermetically sealed, and which causes that air to come into contact with the solid bodies that are really heated by radiation. We are conscious of the constant movement of air which we call a draught or wind, because we feel it, but we are utterly unconscious of the movement of air which is occasioned by our walking across a room; and even such delicate organs as our eyes give us no information whatever. Hence it is that no instrument which man has yet devised can indicate to us more than can be observed by the movements of the lightest of substances. Hence also it is that poisonous germs are so dangerous; not that they pervade the whole atmosphere, but because of the incessant motion of air which we only are thoroughly assured of inferentially, and by which the germs may at any moment be brought in contact with our lungs and other organs. The whole subject requires investigation by our ablest philosophers; but, in the absence of the most delicate experiments, it is easy to understand a great deal about the matter. The distinction drawn between radiated and conducted heat appears to me to be hardly worth consideration. An open fire is valuable from its cheerfulness and the change of air it occasions. This is the only distinction I can draw between that system of warming and the system of warming by stoves or hot-water pipes. We depend both on radiation and conduction in all the appliances in use.

Fredk. Edwards, Jun.

CAUTION.

Sir,—I desire to warn architects against a person who is going about seeking help under the plea of obtaining employment. He told me a most pitiful tale, and, believing him, I gave him money. Feeling desirous of helping him still further, I made inquiries respecting him from eminent London architects (whose names he freely used) only to learn that he was an impostor.

Provincial Architect.

Appointments.—At a monthly meeting of the Town Council, held on the 8th inst., Mr. F. A. Kemp was appointed assistant borough surveyor of Sheffield, and Mr. T. Tinker was appointed junior assistant.

* We mentioned and commented on these not very long ago.—Ed.

HOW THEY MANAGE THINGS AT BILSTON.

At the last meeting of the Bilston Township Commissioners and Local Board of Health, held on the 15th inst., a letter was read from the Local Government Board asking for information as to the prevalence of zymotic diseases in the town, and it is to be regretted that the Board, instead of replying to the central authority in a straightforward and dignified manner, instructed the clerk to write and refer them to the late medical officer. The population of Bilston is 25,000, and they pay their medical officer 20*l.* a year!—a salary which the London Board has refused to sanction. As a resident in Bilston, I cannot but feel humiliated at the conduct of our local Parliament in proceeding in such a manner.

They have reports both from the late medical officer of health and the surveyor setting forth the unsanitary condition of several parts of the district, and there are several houses in the following streets whose cellars are contaminated with sewage, viz., Queen-street and Bilston-street, Bradley; John-street, Tame-street, and Caledonia-street, Bilston; and John-street and Pump-street, New Village; all of which districts are under the sanitary, or, rather, unsanitary, control of the commissioners, who, I believe, desire to do their duty, but are not sufficiently educated to understand the increasing importance of sanitary administration.

Now, the sewers in the streets referred to above are literally full with black, stinking, sewage matter. There are plans in the surveyor's office, prepared by that official, showing how this state of things can be remedied. The medical officer and surveyor have called the attention of the Board to it, yet there is nothing being done! How do they excuse themselves from executing the necessary structural works? "We have not much money, and the people living in those streets do not complain." Unfortunately, the people who are in a good social position at Bilston take very little interest in its government, and they regard membership of the Board derogatory; and, however much this is to be regretted, the natural consequence is that the class of people who compose the Board is not, as a rule, what is to be desired.

Probably such a high standing paper as the *Builder* will not be read by any member of the Bilston Board, but let us hope, for decency's sake, it will be read by some of its more influential residents, and so move them to action on behalf of their benighted town. If the *Builder* were to send one of its staff to test the accuracy of this communication, I should expect to see such a description as I shall,—in the absence of such a report,—hope for in vain. A. F. G.

THE MYSTERIES OF FIGURES.

Sir,—Your correspondent "J. H.," in a letter published on the 11th inst., asked the "whys and wherefores" of a clever arithmetical puzzle, and wished to know if there were any "deep signification" in the occurrence of the numeral 9.

"H. L.," in the *Builder* of the 18th inst., gives an algebraical explanation in the case where the number is one of eight digits, and Mr. J. G. Vine, in the first part of his letter, gives a general demonstration. This seems very satisfactory, but for his slip in writing n instead of $n-1$ as the exponent of r in the last term of his equations.

With regard to the occurrence of the numeral 9, both in this puzzle and in the case demonstrated in the second part of Mr. Vine's letter, it will be found that this occurs because 9 is one less than 10, the radix of our common notation. If we try 9 as a radix, we find the numeral 8 possessed of the qualities the 9 now enjoys; and a similar case occurs with any other number as radix. Delta.

Multiply 9 by itself, or by any other of the digits, and the figures of the product added together amount to 9. The component figures of the amount of the multiplier (viz., 45) when added together make 9.

The amount of the several products or multiples of 9 (viz., 405) when divided by 9 gives a quotient of 45, and the component figures of either the dividend or quotient added together make 9.

Multiply any row of figures either by 9 or by any one of the products of 9 multiplied by

one of the digits, as by 18, 27, 36, 45, 54, 63, 72, or 81, and the sum of the figures of the product added together will be divisible by 9.

Multiply the nine digits in the following order:—1, 2, 3, 4, 5, 6, 7, 8, 9, by 9, or by any one of the products of 9 mentioned in the last paragraph, and the product will come out all in one figure, except the place of tens, which will be a 0, and that figure will be the one which multiplied into 9 supplies the multiplier; that is, if you select 9 as the multiplier, the product will be (except the place of tens) all ones; if you select 18, all twos; if 27, all threes; and so on. Omit the 8 in the multiplicand and the 0 will also vanish from the product, leaving it all ones, twos, threes, &c., as the case may be.

A. B.

COMPETITIONS.

CROYDON BOARD SCHOOLS.

The School Board for Croydon recently invited plans, in limited competition, for a new school in the Sydenham-road, and from the ten designs submitted, that hy Mr. Charles Bell, of Dashwood House, New Broad-street, has been selected for execution. The new schools will accommodate 750 children, at a cost of about 5,400*l.*

LIVERPOOL SCHOOL OF ART.

Sir,—In reply to what has appeared in the *Builder* respecting the Liverpool School of Art Competition, I shall be glad to state the following facts:—

1. The Committee of Selection consisted of ten members, several of whom have considerable knowledge of plans and elevations, and all of whom had previous experience of building competitions.

2. No competitor was informed by me that the directors would appoint a professional referee. To such as asked the question, I handed the enclosed copy of the resolution adopted by the Board.* To those asking personally for information, I gave what I could, without hint; but always with an understanding that my opinion was but an opinion, and not an "instruction."

3. The competitor who was once a member of the Board took every care to keep his identity unknown. His design was not included in the final selection.

4. I know of only one effort at "touting," and that was nipped in the bud, the design sent in being rejected at an early stage.

5. Until the moment after the awards had been made, not a member of the Selecting Committee was aware of the identity of any of the authors of the designs.

The appointment of a professional referee, and the exhibition of the designs are matters upon which the Board had a perfect right to form their own conclusion; and the competitors an equal right to differ from them thereon. That difference they are freely expressing.

To such as care to place faith in the assurance of one who has equal interest in the Committee and the Competitors, I can only say what I have before stated, that the award of premiums has, in every sense, been justly and fairly conducted; and that every step of the careful inspection which led up to the final selection has been taken without prejudice to a single person concerned.

Charles Sharp, Secretary.

"SANITARY SCIENCE IN ITS RELATION TO CIVIL ARCHITECTURE."

Sir,—As you were good enough to print some remarks of mine on small-bore drains in the *Builder*, p. 311, *ante* (Oct. 23), and which remarks were supported by Mr. Buchan in the same journal (Nov. 13), I make bold to trouble you again on a very important question raised by "A.R.I.B.A.," in your issue of the 11th inst.

Before I proceed to give an opinion as to many of the scientific dogmas with which some of our *dilettanti* seem exceedingly fond of surrounding sanitary matters, I would like to tell "A.R.I.B.A." that his ℧-trap, which has bothered him, is not a trap at all. The 10 ft. vertical lead pipe is on many occasions the long leg of a syphon, and draws the water from the trap, leaving no water seal there at all. I say on many occasions; for if only small quantities of water are thrown into the sink, the syphon is not forced into activity, there being air-space in the waste-pipe; or, in other words, the water does not descend at full bore. The very fact of it being a well-made trap and a sound piece of work is an argument in favour of its being a good syphon. Not only ℧-traps, but S-traps, performing these same antics, have come under my notice, and I have no hesitation in declaring that hundreds of traps are lied, and nobody ever gives the slightest thought as to their functional performances, or whether they have a water seal or not.

Let any one who wishes to see what can be done in that way simply dash a pail of water into a common pan-closet, which has a vertical soil-pipe, and then note carefully how much water-seal there is. He will find, as I have found, that the descending water has actually sucked away the very efficiency of the trap. Further, he will find that if this experiment is made on the ground-floor or first-floor, traps on every floor above which are connected to the same soil-pipe,—unless the soil-pipe is carried up into the open air,—will be more or less affected in proportion as the work has been well done or the contrary. I have gone into houses where the inmates have over and over again complained of the presence of the drains, torn down good work, but with no effect, until I accidentally discovered the offending cause: so I can quite sympathise with "A. R. I. B. A." in this case. Another cause of unwholesomeness about sinks is the damp, and that also may have something to do with making that particular room "*noisome*." With regard to trapping sink-wastes, I would trap the end of every waste-pipe, and the branch of every soil-pipe which should or may pass within the walls of any domicile, and also see that they were efficient ones too. The difference between the old-fashioned open drain and the modern ventilated one seems to me to depend on the swifter removal of the latter in contradistinction to the sluggishness of the former, and in this difference must lie the success of the new idea; for, if it merely depended on the abundant supply of air into close drains, the sooner we get back to open drains with plenty of fall the better.

Ventilation of drains is a very dangerous business, and instead of being a safety-valve, may indeed be a conductor of sewer gas (or sewer "air," if it be more fashionable) into our very sleeping-rooms.

For example, a fire is lighted in a bed-room. A person may possibly be lying there sick; a door is opened into an adjoining room, where there is an open fireplace, but no fire. Most assuredly the air which may happen at the moment to be around that chimney-top, where there is no fire, will descend that flue and enter the room where the fire is; and just as likely as not, a ventilator from some drain would be close to it, and the rest is easily divined. Let us imagine what kind of an atmosphere is going to be created over our heads when thousands of so-called ventilators or extractors are night and day belching forth their destroying effluvium, and saturating it with pestilential vapours. No, the last word is not said upon these things, and the *Builder*, opening its columns to a discussion of such matters, is undoubtedly conferring a real good not only on sanitarians, but on the world at large. I believe there may be sewer air, but I also believe there is sewer gas, or, at any rate, a compound which is generated in no other laboratory on earth excepting in a sewer. Anybody knows, who has to do with gas mains, that, in almost every one there is a per centage of leakage. In various ways part of this gets into sewers, and then, sweltering there in contact with sewage, becomes mixed with other vapours producing what is, no doubt, as good a name as we can give it,—sewer gas.

I do not wish to be understood as objecting to ventilation of drains, but I do contend it ought not to be carried out in the haphazard manner which is at this time being practised in many parts of London. We have something more to learn yet, and some results of this reckless jumping at pet theories may give us a startling surprise some of these days.

Practical Sanitarian.

STATUES.

The late Prince Consort.—The statue of the late Prince Consort which has been presented by Mrs. Richardson-Gardner to the Windsor Albert Institute, and placed in a niche in the façade of the building facing Sheet-street, has been unveiled by H.R.H. Princess Christian. The Prince is represented in a standing position, and attired in the robes of a Knight of the Garter.

Lord Lawrence.—The executive committee of the Lawrence Memorial, at a meeting held last week, adopted the principle of the design submitted by Mr. Boehm, who, to indicate Lord Lawrence's character, has seized on an incident related of his earlier career in the Punjab. He exhibits a sword and a pen to the Sikh chieftains, and demands to know by which they choose to be governed. Mr. Boehm will now proceed with the work. The statue is to be placed in the south-east corner of Waterloo-place, opposite that of Sir John Burgoyne.

Books.

The Sculptor Caught Napping; a Book for the Children's Hour. Designs by Jane E. Cook. The Autotype Fine Art Company, 531, Oxford-street.

This is a second edition, much elaborated, of a set of designs originally published to aid the fund for enlarging the buildings of King Alfred's School, Wantage, Mrs. Cook, the very clever author of them, being the wife of the principal of that school. The nursery rhymes, before in cameo, are given again, but are supplemented by a series of one dozen extra designs treated in the genuine silhouette style, but with the artistic touch and exquisitely graceful design peculiar to her original fancy and fertility of quaintly humorous design. The silhouettes carry on the story told in cameo, and the combination of the two is a happy way of showing the differences of the two processes, the former being, so far as we know, a novelty. Of the artistic ability of Mrs. Cook, who is the sister of a well-known architect, we have before had occasion to speak warmly. We cordially recommend her new book.

VARIORUM.

"The Architect's Legal Handbook," by Edward Jenkins and John Raymond, barristers-at-Law (C. Kegan Paul & Co.), has reached a third edition, and has been enlarged and improved. Full reports of several important cases are given in an appendix, and the Metropolitan Building Act Amendment Act, 1878, and the Bye-laws made under it, are added. A large number of our readers will find the book indispensable.——"Engine-driving Life," by Michael Reynolds (Croshy Lockwood & Co., 1881), gives stirring adventures and incidents in the lives of locomotive-engine drivers. It is pleasant reading and, moreover, calculated to give the public an insight into struggles and labours of which they know little or nothing, and induce sympathy for a deserving set of men.——Amongst the many "Christmas numbers" announced must be included, as of a somewhat interesting nature, that of the *Gardener's Magazine*. A profusion of pictures is, of course, to be expected, but the peculiar features of these special issues are the papers on plant history.——The "Railway Almanack" for 1881 contains, besides the calendar, an official list of the chairmen and executive officers of the independent lines of railway in the United Kingdom, and the dividends paid for the four previous half-years.

Miscellanea.

The Birmingham Art Gallery and Museum.—It is announced that the fund for providing works of art for exhibition in these proposed buildings has already reached the sum of 6,542*l.* 9*s.* In an appeal which the Mayor, who is treasurer, and Mr. Allen Edwards, the secretary to the fund, publish in the Birmingham papers, they state incidentally that the building of the gallery will probably occupy three years. They point out to local manufacturers how closely the prosperity of the town is associated with the knowledge and practice of art by those who are engaged in many of its staple trades. Already the ground for the proposed building is being cleared for the commencement of the works, and the plans are rapidly approaching completion in the office of Mr. Yeoville Thomason, architect. It is designed that the Art Gallery shall be built fronting upon Congreve-street and Edmund-street, and that the basement-floor shall be occupied by the offices of the Gas Department of the Corporation. The plans, so far as they are at present elaborated, include a handsome entrance vestibule, capable of being used for sculpture, of the dimensions of 57 ft. by 18 ft.; two picture-galleries, each about 60 ft. by 28 ft.; a magnificent hall for the display of objects of industrial art, 129 ft. by 53 ft., with light galleries on both sides; another room for pictures measuring 53 ft. by 26 ft.; and a principal picture-gallery, 80 ft. by 53 ft.,—all arranged in a way to facilitate the inspection of the contents of the rooms by visitors.

Æsthetics in Scotch Schools.—The *Inverness Advertiser* reports that, on the 11th inst., a meeting of the "Æsthetic Committee" of the Inverness and Ross Educational Institute was held in Farraline Institution. Mr. Jolly, H.M. Inspector of Schools, presided, and gave a short address, indicating the nature of the work proposed to be carried out by the committee, and asking that any of the teachers who had anything to report, by way of showing what had already been done, might kindly furnish him with some facts thereanent. He intended, he said, shortly to lecture at Arbroath as to the æsthetic adornment of schools, and a few tangible illustrations supplied from the Inverness and Ross districts would be very useful. Some conversation followed the address, and Mr. Jolly mentioned that perhaps the most outstanding proof in the Inverness and Ross districts of the good effects of the committee's work was to be seen in the Drumnadrochit School, which had been most tastefully decorated, owing, in great measure, to the heartiness with which the local School Board had entered into the proposals of the committee. Miss Millais, daughter of the celebrated painter, had paid a visit lately to Drumnadrochit, had gone to see the school, and had said that she had never believed a school could be made so tasteful, sweet, and attractive as it was.

Coming Exhibitions at York.—At a recent meeting of the Council of the Fine Art Institution, York, it was agreed that the summer exhibition of 1881 of works of art should be opened at the same time as the Prince of Wales's Indian presents are ready for public inspection. Simultaneously with this exhibition one will also be held of scientific appliances intended to illustrate the progress of science during the last fifty years, and in addition there will be an exhibition of art manufactures and of such mechanical operations as may be found consistent with the space at the disposal of the committee.

* "I am requested by the directors to inform you that while they do not bind themselves to appoint a professional referee, they think it probable that they will avail themselves of his advice in coming to a decision upon the designs sent in."

A "Society of Chemical Engineers."—A meeting was held on the 14th inst. at Owens College, Manchester, to consider proposals for forming a society of chemical engineers. Mr. G. E. Davies (hon. secretary) read a report which stated that at the last general meeting, in April, it was suggested that a society of chemical engineers should be formed, and that a committee was then appointed to consider that proposal. That committee had held four meetings, one in Liverpool and three in Manchester; and a circular letter had been sent out by its chairman (Professor Roscoe) to persons well known for their attainments in chemical science and chemical industry. The circular contained the following passages:—

"A committee of gentlemen interested in the progress of chemical industry, and resident in this district, has met several times during this year for the purpose of considering the advisability of establishing a society to be called 'The Institute of Chemical Engineers,' or 'The Institute of Chemical Industry.' The proposed society would be a national one, and would seek to bring into contact a large class of persons interested in the very various branches of trade and manufacture which are specially connected with chemical science. Periodical meetings like those of the Mechanical Engineers or of the Iron and steel Institute would be held for promoting scientific, industrial, and social intercourse amongst the members of the society. Possibly the publication of a journal specially devoted to the subject might form part of the scheme."

From the number and nature of the responses made to the circular, the committee advised the formation of a society without delay; and recommended that a small sub-committee should be appointed to make the necessary arrangements for an inaugural meeting in London, to draw up regulations and to take other steps which might conduce to the welfare of the proposed society. The recommendations were agreed to, and Professor Roscoe, Mr. Ludwig Mond, Dr. Campbell Brown, Dr. Hewett, Mr. E. K. Muspratt, Mr. E. Carey, Mr. E. Gossage, and Mr. G. E. Davies, were nominated members of the sub-committee, with power to add to their number. It was resolved that the new body should be called the Society of Chemical Engineers.

Proposed New Park for Hull.—At a meeting of the Town Improvement Committee of the Hull Corporation, held at the Town-hall on the 10th inst., Alderman Waller presiding, Mr. Fryer brought under the notice of the committee the desirability of securing Jalland's Hall and estate, situate in Holderness-road, for the purposes of a public park. The property was, he said, in every way suitable for the purpose, and, seeing that Hull possessed no public park of dimensions such as those at Leeds, Bradford, and other places, he thought this a good opportunity for the Corporation to open negotiations for the purchase of the estate. The new railway and dock would be in close contiguity, and there would consequently be a large increase of house property in that neighbourhood.

Sanitary Condition of Willenhall.—The sanitary authorities of Willenhall have received a communication from the Local Government Board on the exceptional mortality in that township from diarrhœa and scarlatina. As to what the causes of the exceptional prevalence of these diseases are, the *Staffordshire Advertiser* does not hazard any conjecture, but remembers that the brook which flows through Willenhall was a few years since described by the medical officer as an "elongated sewer." It is, moreover, an "open secret" that the greater part of Willenhall is still unsewered. Under such conditions, a clean bill of health is well-nigh an impossibility. The whole subject of underground drainage is, it is satisfactory to learn, under the consideration of the local authorities.

Horse and Cattle Troughs.—It has been asserted that glanders and other diseases amongst horses have of late been on the increase in London, and it is alleged that this disease has been communicated to healthy horses through drinking of the water in troughs at which unhealthy animals had previously drunk. At the last meeting of the Metropolitan Board of Works, it was resolved, on the recommendation of the Special Purposes and Sanitary Committee, "That it be suggested to the Metropolitan Drinking Fountain and Cattle Trough Association, and other bodies and persons who provide public drinking-troughs in the metropolis, that such drinking-troughs should be so constructed and used as to have a constant flow of water passing through them and running off, by means of a tumbling bay, direct to a gully; and that measures should be taken to ensure the troughs being thoroughly cleansed every morning."

The Electric Light of Dr. Siemens.—Hydraulic lifts for large hotels and depôts are very costly, and Dr. Werner Siemens is trying to lessen this by the application of electricity to the movement of the cage, according to the *Electrician*. It is as safe as the hydraulic lift, and far less costly and inconvenient. It operates through the transmission of power by the dynamo-electric machine, and the first one was put in operation recently at the Industrial Exhibition of Mannheim, where, during the few weeks it was exhibited, it lifted over 8,000 persons, the speed of the cage or chariot being half a mètre per second. The apparatus consists of a stationary dynamo-electric machine, which is intended to generate the current, and a second or receiving dynamo-electric machine, which is carried in a box below the platform of the lift. The lift is suspended by two wire ropes passing over a drum, and it is counterpoised by a weight, so that the work to be done by the current in raising it is very little compared with the whole weight of the lift. These wires act also as conductors of the current connecting the two machines. They form, in fact, the return wires. The lifting of the carriage is effected by means of a central ladder or rack, with its rungs or teeth very close together, and two toothed wheels connected to the bottom of the carriage gear with this rack. These wheels are driven by the receiving dynamo machine through the intermediary of an endless screw on the axle of the armature. The sides of the ladder act also as a conductor conveying the current from the generator, and two revolving wheels carried by the frame of the carriage make contact with the sides of the ladder, and tap the current in order to lead it to the coils of the dynamo machine. The lift is started or stopped, raised or lowered, by means of a communicator handle. This is not the first time Dr. Siemens has given a lift to electricity.

Mr. Mechi.—It is generally felt that a case for universal sympathy arises out of the complete collapse of the worldly fortune of Mr. Mechi. The *City Press* gives some particulars of Mr. Mechi's career. In early days renowned for his "magic" razor-strop, and in latter days much more renowned for his scientific farming, the unfortunate gentleman may even yet gain renown of a painful kind as a martyr to high principles and punctilious honour. In the high tide of his civic prosperity as a member of the Court of Aldermen, Mr. Mechi became connected with a bank which, at a critical moment, was found to be unequal to its engagements, and he sacrificed much of his possessions to meet its demands. Speaking generally, his career has been chequered by successes due to spirited enterprise, and disasters resulting from enthusiasm and generosity. It will probably shock public feeling to hear that the ex-sheriff and alderman, when nearing his eightieth year, is actually in want.

The Nelson Coffee-house at Salisbury.—This coffee-house, which has been in course of erection for some time in Fisherton-street, was opened on the 16th inst. by Earl Nelson. The building is well planned, and contains about thirty rooms, including a very large club-room. A lift and a tramway have been made to minimise labour, and ventilating apparatus of a very perfect character has been provided. The exterior is of a deep red tone, almost Pompeiian in its style; full-coloured bricks with dark chocolate pointing have been employed, and the dressings (window-arches, medallions, finials, &c.) are of terra-cotta, supplied by Messrs. Doulton, of Lambeth. The contractor for the whole of the works was Mr. Arthur Foley, of Fisherton, who also provided all the fittings and furniture. Mr. F. Bath, of Crown Chambers, Bridge-street, designed the building, and both architect and builder have received great credit for their work.

Royal Albert Hall.—The Albert Hall Choral Society will give the "Messiah," Monday evening, the 27th inst., with Miss Anna Williams, Madame Patey, Mr. Sims Reeves, Mr. W. H. Cummings, and Mr. Ludwig, under the *bâton* of Mr. Barnby.

Messrs. Jones & Willis have just completed a polished brass lectern for the Rev. Mr. Biggs, Malacca chaplaincy, Straits Settlement; and an oak reredos for St. John the Baptist Chapel, Hulme, Manchester.

The Heat, Light, and Ventilation Exhibition has been postponed for a few weeks, at the request of a number of manufacturers, and will be held from January 26 to February 12, at the Alexandra Palace.

Crystal Palace Company's School of Practical Engineering.—On Saturday last the certificates awarded to the successful students of this school for the winter term were distributed. Mr. Shenton, the secretary of the Crystal Palace School of Art, Science, and Literature, read the report of the examiners (Messrs. W. J. Kingshury and J. E. Lowe), who stated that they regarded the work done by the students as very creditable, and testified to the success of the system of teaching of the principal, Mr. J. W. Wilson, and of the vice-principal, Mr. J. W. Wilson, jun. Mr. E. A. Cowper, C.E., president of the Institution of Mechanical Engineers, prior to distributing the certificates, spoke of the advantage of the studies at the school. He regretted the objection of some of our manufacturers to entertain any improvements merely on account of temporary inconvenience, and stated that in America it was quite the reverse, new things being there regarded favourably, and in many cases tried and brought to perfection. After speaking of the present attempts of the City Guilds and others to advance technical education, he observed, as to new fields into which their energies might in future be directed, that the manufacture of rolled steel sleepers for railways would probably be a question of the future.

The Builders' and Manufacturers' Exchange and Subscription Rooms.—To provide these premises, Nos. 205-6, High Holborn, have been taken, and will be opened to members on the 1st of January. Particulars of the project will be found in our advertising columns. The object is to provide a convenient and central place of meeting for the conduct of business. It is intended by the proprietors to afford all the facilities offered by such establishments as the Baltic, Lloyds', Commercial Sale Rooms, Corn Exchange, Jerusalem Coffee House, &c., with the additional advantages of separate reading and writing rooms, consultation and smoking rooms, distinct from the "Exchange." An exhibition, moreover, will be opened on the ground-floor, for the display of all manufactures connected with the building trade, the admission to which will be free on presentation of an address or business card.

The Sunday Society announce the opening of the Winter Exhibition of Oil Paintings at the Hanover Gallery, New Bond-street, by permission of the proprietor, Mr. Weil, on Sunday, December 26, and on the two following Sundays.

New Cemetery for Carlisle.—Plans prepared by Messrs. Hetherington & Oliver, of Carlisle, have been adopted by the Burial Board of that city for laying out the new cemetery at Upperby.

TENDERS

For the restoration of the Parish Church, at Grendon near Northampton, for the Building Committee, including new stained-glass window to chancel. Mr. H. M. Townsend, architect. Quantities supplied:—

Ireson, Northampton	£215	0	0
Rands & Son, Wisbech	231	0	0

For the erection of a pair of semi-detached villas, at Bexley, Kent, for Mr. Jas. Carter. Mr. Richard Peters, architect. No quantities:—

Watson & Bennett, Dulwich*	£1,285	0	0

* Accepted.

For additions and alterations to the Vicarage, Lewisham, for the Hon. and Rev. Canon Legge. Messrs. E. & W. H. Nash, architects. Quantities supplied by Messrs. Franklin & Andrews:—

J. & C. Bowyer	£1,829	0	0
Banks	1,683	0	0
Jarrett	1,810	0	0
J. & J. Greenwood	1,831	0	0
Jerrard (accepted)	1,483	0	0

For alterations and additions to the Anglo-Bavarian Brewery, Shepton Mallett, for Messrs. Hill & Garton. Mr. W. H. Clark, architect. Quantities supplied by Mr. A. Deane:—

All statements of facts, lists of tenders, &c. must be accompanied by the name and address of the sender, not necessarily for publication.

We are compelled to decline pointing out books and giving addresses.

Note.—The responsibility of signed articles, and papers read at public meetings, rests, of course with the authors.

CHARGES FOR ADVERTISEMENTS

SITUATIONS VACANT, PARTNERSHIPS, APPRENTICESHIPS TRADE, AND GENERAL ADVERTISEMENTS

Six lines (about fifty words) or under ..... 4s. 6d.
Each additional line (about ten words) ..... 0s. 6d.

Terms for series of Trade Advertisements, also for Special Advertisements on front page, Competitions, Contracts, Sales by Auction, &c. may be obtained on application to the Publisher.

SITUATIONS WANTED.

FOUR Lines (about THIRTY words) or under ..... 2s. 6d.
Each additional line (about ten words) ..... 0s. 6d.

REPLIES TO ADVERTISEMENTS,
Addressed Box —, Office of "The Builder,"
Cannot be forwarded, but *must* in all cases be *called for*, and the Office Receipt produced.

THE CHARGE FOR A BOX IS AS UNDER:—
For "Situations Wanted" Advertisements ..... 3d. per Week.
For all other Advertisements ..... 6d. per Week.

PREPAYMENT IS ABSOLUTELY NECESSARY.

*.** Stamps must not be sent, but all small sums should be remitted by Cash in Registered Letter or by Money Order, payable at the Post-office, King-street, Covent-garden, W.C. to

DOUGLAS FOURDRINIER, Publisher,
Addressed to No. 46, Catherine-street, W.C.

Advertisements for the current week's issue must reach the office before THREE o'clock p.m. on THURSDAY.

The Publisher cannot be responsible for DRAWINGS, TESTIMONIALS, &c. left at the Office in reply to Advertisements, and strongly recommends that of the latter COPIES ONLY should be sent.

TERMS OF SUBSCRIPTION.

"THE BUILDER" is supplied *direct* from the Office to residents in any part of the United Kingdom at the rate of 13s. per annum, *prepaid*. Remittances payable as above.
