The consideration of the difference which would have to be made in ornamental detail, especially of the Classic type, in transferring it from marble or stone to terra cotta or painted and glazed stoneware, suggests another influence in the nature of the material which must also affect the ornament executed in it. This is, the impossibility of trusting to terra cotta for absolute symmetry in the result, where ornament of very fine and precise outline is concerned. However well mixed and burned, the necessary shrinking and the almost inevitable slight degree of twisting in the kiln (though care and experience may reduce the latter to a minimum), render it impossible to trust to terra cotta to give the precise, clear, and sharp symmetry of Greek detail, for example. And here is the meaning of that tendency to "twisty" detail which, as above remarked, shows itself in the North Italian terra-cotta work, in the twisted rope-like ornaments of the cornices, in the columns with twisted or spiral flutings, as if they had undergone a test for torsion. The prevalence of this "twistiness" was the result of an intuitive perception on the part of the terra-cotta architects of Italy, that as the material would warp and twist more or less (and their terra cotta probably twisted much more than our more scientifically mixed and burned stuff), it was better to import a certain degree of twisted character into the details, to avoid hard straight lines and attempts at symmetrical detail, and to impart to the design such a degree of irregularity of line that accidental irregularities arising in the manufacture would be the less observable. Following out this idea, we have attempted one or two sketches of the manner in which well-known Greek details might be modified so as to bring them within the proper scope of terra cotta. Take the Dorio capital to begin with; the characteristics of that, as executed by the Greeks in marble, are the heavy and massive abacus, the peculiarly delicate curve of the profile of the echinus, and the succession of thin hard parallel lines produced by the grooving below the echinus, and which give so much of the character of united refinement and strength to the complete Doric capital of the best period. Now the first quality, the heavy abacus, we deliberately set aside; we substitute a thinner abacus (see fig. 5), because that is more in keeping with the idea of a *tile*,—a thin but very hard and coherent plate of burned clay. The delicate curve of the echinus we cannot depend upon getting in terra cotta; if we could model it precisely in the clay, the kiln would almost certainly disturb it, and therefore we will not depend upon the mere completeness of the outline; we follow the usual outline in the main, but we break up the face of the echinus by fluting, which attracts the eye from the mere consideration of the curve, so that any failure in its exactitude is not so much noticed. We cannot work the thin clean lines of the annulets satisfactorily in terra cotta, so we take a hint from one of the older forms of Doric at Pæstum, in which the annulet is less conspicuous and there is a deep gorge or throating, ornamented with a leaf repeated all round, and which suits our purpose very well. The fluting of the column we will work spirally instead of vertically, to avoid being caught in any distortion of lines which ought to be rigidly straight (or to be worked with an entasis curve much too fine and delicate to be executed in terra cotta), and also to assist in giving to the design that partially picturesque character which is suitable to terra cotta, and which it is our object to attain. We may call this a translation of marble Dorio into terra-cotta Doric; it being borne in mind, however, that the Dorio column could not with any advantage,—perhaps could hardly at all,—be carried out in terra cotta on a really large scale, such as the Parthenon order: this must be a small and domestic Doric, perhaps for internal use, but recalling its great original, while showing that it has been deliberately modified to suit the condition of a new material. If it be worked in stoneware, then the fluted echinus and the gorgette would present opportunities for the effective picking-out of the capital in colour.

Taking the Ionic capital in hand, we discard the usual form of the volute with its numerous and precisely-defined spiral lines, one within another; to obtain these in terra cotta with the requisite purity and precision of line would be nearly impossible. So we reduce the spiral to a simpler form (figure 6), and substitute a free bit of foliage ornament for some of the inner spirals; we give the crowning ovolo a freer and more Gothicised surface ornament than the orthodox Greek egg-and-tongue decoration; we treat the ornament below, on the neck of the capital, with more free and naturalistic foliage than the Greek carver in marble would have introduced: in this example this ornament is founded on the nasturtium flower and leaf. We will suppose this to be a coloured stoneware capital, and the centre of the flute is occupied by a coloured boss, a treatment which is, after all, in harmony with Greek practice, for there is no doubt that bosses of coloured material were introduced in this kind of manner in Classic Ionic capitals. The volutes are spiralised as before, but an additional richness is imparted to the shaft by rows of little beadings on the fillets between the flutes. Figure 7 is an adaptation of the Corinthian capital. Here again some of the repeated spiral lines usual in the volute are omitted, and the whole volute is made simpler and more massive than in the Classic marble volute, and its centre filled with a bold projecting coloured boss. The lines of the abacus are made bolder and more massive, and the upper member decorated with a waving or zigzag ornament to distract the eye from dwelling too much on straight lines and pure curves, which we cannot be certain will come out quite straight and pure. The symmetrical and highly conventionalised acanthus leaves of the Greek capital give place to a much freer and more sketchy treatment, which may be varied in every capital in the colonnade, and which in this case is founded on the leaf of a French variety of fern, the serrations of which bear a curiously close resemblance to the conventional serrations of the Classic acanthus-leaf, but the general form of which is different,—longer and more pointed than the acanthus. In figure 8 is shown a varied treatment of the Temple of the Winds capital; a form of capital which, as sometimes executed in stone in some of our buildings, is singularly ineffective in a northern town atmosphere, but which, executed in coloured stoneware, would be susceptible of admirable effect. The upper large leaves in this example, with their curious divided or duplicate form, are taken from a foreign shrub, of which a good many varying examples are to be found in the hot-houses at Kew. The name has escaped us. Figure 9, as will be seen, is a treatment of one form of the Classic base, on the same principle of introducing curvature and twist in the modelling, as we saw exemplified in the spiral mouldings of the Pavia cornice.

Another point in regard to the general treatment of the walling of terra-cotta buildings may be noticed: in many of the Cinquecento terra-cotta buildings there is an entire absence of any attempt to obtain a completely homogeneous wall surface, in regard to tone and colour; the surface is as varied and broken up in this respect as that of a brick building. This, again, carries out our idea as to terra cotta as the material for varied and picturesque effect rather than for symmetrical finish and neatness. In this respect it seems to us peculiarly valuable as affording an opportunity for giving to buildings of Classic type of design the variety of detail and of surface which is desirable in a northern climate and in the smoke of large cities. For our decided conviction is that terra cotta architecture is essentially suitable rather for Classic than for Gothic types of building. It has an appearance of surface treatment about it which is much more in harmony with the feeling of Classic, or at least of Renaissance architecture, than of Gothic, in which latter we look rather for the appearance of great mass and solidity than

of elegant surface ornament; and if the revived taste for Classic design which seems to be impending is really developed, it may perhaps be found that terra cotta will offer to architects a material in which they may carry out the Classic types of design with a great deal of really new modification, and in a material admirably suited to the conditions of modern city architecture.

"ECCLESIASTICAL ART EXHIBITION."

The Ecclesiastical Art Exhibition building, intended to be erected upon the well-known Savoy site upon the Victoria Embankment, has been unavoidably postponed, owing to the nature of the requirements of the Metropolitan Board of Works, which entailed too large an expenditure for a mere temporary exhibition, as at first proposed.

The design, shown by the elevation we publish this week, was prepared by the architect to the undertaking, Mr. John P. Seddon, in order to fulfil the above-named requirements.

As often happens in such enterprises, more than one change has to be adopted before the final one that is carried into effect. So it is in this case. A proposal having recently been made to those connected with the undertaking to incorporate with their building for the Ecclesiastical Art Exhibition one for a panorama, upon the scale of the largest of those which have been erected on the Continent, upon terms considered favourable, it will become essential to modify the design afresh. Mr. Seddon is now engaged upon this work, which will doubtless come before the public presently in its entirety. Under existing circumstances it is unnecessary to explain further than is represented by the accompanying elevation, which, as it had been prepared, we offer simply to show that the building is intended to be of a more permanent and architectural character than at first proposed, and more worthy of the fine site and its surroundings which it is intended to occupy. The cost, it is stated by those concerned, is not likely in any case to be less than 50,000*l.*

CHRIST'S HOSPITAL.

PROPOSED NEW BUILDINGS.

The Charity Commissioners have issued the draft of their new scheme for dealing with this important institution. Among the principal clauses are the following:—

"The schools of the foundation shall be hospital and boarding-schools for boys and girls respectively, and such schools respectively shall be maintained in the present school buildings of the foundation in London and at Hertford, until other suitable buildings shall be provided, as hereinafter directed. . . . Within three years from the date of this scheme, or such further time as may be allowed for the purpose by the Charity Commissioners, the council of almoners, by acquiring, by purchase, lease in perpetuity, or otherwise, a suitable site, within a convenient distance from the city of London, and acquiring or erecting buildings thereon, shall provide proper hospital and boarding-school buildings, with hall, chapel, infirmary, and residences for masters and for the treasurer, and for the other officers, if any, who may be required to reside in such buildings, suitable for 1,000 boys as boarders,—that is to say, 200 boys in the upper or Grecian school, 400 boys in the middle school, and 400 boys in the lower school,—all such buildings to be planned with a view to convenient extension, and the buildings of the lower school to be so planned as to facilitate the separation of the younger from the elder boys. For these purposes the council of almoners may apply for the purpose a sufficient sum, to be provided or raised out of the building and repairs fund, and, so far as may be necessary, out of the general fund of the foundation, by sale or otherwise, but for all the purposes of this clause they shall act subject to the consent and approval of the Charity Commissioners. The said site and buildings shall be vested in the official trustee of charity lands in trust for the foundation, but shall be managed by the council of almoners. When the said buildings are complete and ready for occupation the council of almoners shall remove the whole of the boys' schools of the foundation from London and Hertford to such new buildings. Within three years from the date of this scheme, or such further time as may be allowed for the purpose by the Charity Commissioners, the council of almoners, either by altering or adding to the present school buildings at Hertford, or otherwise by acquiring or erecting buildings upon some convenient site, shall provide proper hospital and boarding-school buildings, with infirmary and residences for mistresses, and for other officers, if any, who may be required to reside in such buildings, suitable for not less than 400 girls as boarders,—that is to say, 200 girls in the upper school and 200 girls in the lower school,—all such buildings to be planned with a view to convenient extension, and may apply for the purpose a sufficient sum to be provided or raised out of the general fund of the foundation, by sale or otherwise, but for all the purposes of this clause they shall act subject to the consent and approval of the Charity Commissioners."

Mr. E. J. Reed, C.B., formerly Chief Constructor of the Navy, has received the honour of knighthood.

DEFECTIVE BILLS OF QUANTITIES.

In a paper on "Bills of Quantities and Measuring Builders' Work," by Mr. E. Hughes, read, as we have already mentioned, at the meeting of the National Association of Master Builders, held at Bristol, July 27, the writer makes some very strong statements in respect of the improper way in which bills of quantities are sometimes prepared. It seems desirable that these assertions should be made public, with a view to proper consideration of them:—

We frequently find surveyors measuring so many cube yards excavating and wheeling, omitting altogether the depth and distance to wheel, &c. The same applies regarding drains. I have known ornamental brickwork described as so many yards or rods of common brickwork, "the price to include all cutting, double course of blue brick plinth, moulded string-course, ornamental projecting stock-brick cornices, gauged arches," &c., &c., "as shown upon the drawings." I should like to know a builder who could properly price such work from such quantities.

I met with a recent case where an architect had succeeded in obtaining by competition the commission for an important public building, with an elaborate tower as part of the structure, built with dressed stone, the work being what may be described as of a "monumental" character. The quantities gave this work as so many cube feet of stone, including all labour of every description, this phrase being on the heading, and not with the quantity. The result of separate tenders for the upper part of this tower was that they varied from 500*l.* to 1,700*l.* The lowest tenders were undoubtedly priced as stone and setting only, omitting all labour.

I have before me quantities for a public building, for which the architect's charges are two per cent., wherein he describes so many "superficial feet of moulded both sides swing-doors, hung folding, including quarter-inch polished plate-glass upper panels, protected by six wrought-iron bars, and patent swing-hinges to stand open." No size of glass, no size or quality of bars, and no size or quality of hinges mentioned!

In many other items he gives superficial feet of doors, including best mortise locks, and rebated and moulded frames, and neither number of doors, quantity or size of frames, nor number, size, or quality of locks. You all know in the matter of locks "best" is a wide term. It means anything from 7*s.* 6*d.* to 75*s.* In one door he gives superficial feet of door, including 4-inch best butts, 5 by 4 rebated and beaded frame, two barrel bolts, strong chain, drop-latch lock (value 13*s.* P.C.), *and approved bell-pull*. Another item is, "Provide and fix cistern on strong bearers, and form trap-door," without dimensions or particulars of any kind.

In many items of this architect's quantities, in addition to jumbling up doors, locks, hinges, bolts, &c., by the foot he hangs on the words—"including painting." This is notwithstanding the fact that there is a separate bill for painting. Great numbers of items of importance are given by this architect as lineal measure with no sizes. Some items are described as "fixed," while others have added to them the words "including fixing." In the former case the builder cannot tell whether the item is to include materials or not. Another specimen is—"Superficial feet of *plain* 1-in. boards (see plan)." The last two bracketed words convince the builder that quite the opposite of *plain* is meant; but he is to be paid plain price.

I cannot for one moment believe that the architect who has issued these quantities has personally any hand in them, but they are in his name, and he is to receive the fees, although they have most probably been taken by some impostor who has succeeded in obtaining a place in his office. I say such measuring is nothing less than a fraud upon the proprietor. This architect holds an important public appointment, and the work in question is public work.

I have recently seen a surveyor's final measured account for a building which had been prepared in draft, then altered, checked, re-checked, and lithographed for the purposes of an arbitration by order of the High Court of Justice. On this surveyor being examined before the arbitrator he was forced to admit scores of errors in computation,—merely errors that would disgrace a charity school-boy. In one page of his account he admitted no less than six most stupid errors, several of them consisting of the pounds and shillings being placed in the wrong columns. For instance: eight and a-half feet at 4*d.* per foot was deducted as 2*l.* 10*s.* instead of 2*s.* 10*d.* This architect and surveyor made such an exhibition of himself that his client called the builder (who was plaintiff) aside, "threw up the sponge," and offered to pay debt, costs, and interest.

I have known in one church contract the surveyor omitting to add up an item of 10,000 ft., being the left-hand figure of a five-figured item in his abstract for stone facings. He also omitted the whole of the dressed stone, sills, jambs, and arches to the inside of all doors and windows; the whole of the brick lining to the church, and the gutters and down-pipes of one side of the church; besides other items, amounting in all to the value of 3,000*l.* to 4,000*l.* This work was done by the builder without obtaining one shilling in payment.

In another case I find a surveyor describing in a bill of quantities most elaborate carved mahogany newel-posts by the lineal foot. Thus, " feet run of eight by eight Spanish mahogany newel-posts, cut, turned, moulded, and carved to details to be supplied, including drops and finials where required." From this description and by the additional precaution of an examination of the contract drawings it is impossible for any builder to say what the real value of the work may be. It might be any sum from 10*s.* to 50*s.* per foot according to the caprice or conscience of the architect when he subsequently designed the work in detail.

The same surveyor described doors of an ordinary size, but containing about sixteen panels each, some of them with raised panels and bolection moulds, and the remainder with cusped tracery planted on the panels. These doors were described as ordinary doors, but with the words "see drawings." On reference to the drawings they were found to be ¼-in. scale only, on which it was impossible to show what work the architect might contemplate, when at a subsequent period (after the contract was made) he furnished details. Such details might show work worth any sum from 2*s.* to 6*s.* or 8*s.* per foot, and yet be in accordance with the ½-in. scale general drawings.

I have seen in another schedule for competition a number of ornamental wrought-iron grilles, or panels for doors, described simply by number, "to details to be subsequently supplied." It is impossible to approach the value of such work from such description; each grille might be worth any sum from 10*s.* to 10*l.*

In another case, an architect who was his own surveyor required a wrought-iron cresting on the top capping of some gates to the back-yard of a house, and described it by the running foot, without the height being mentioned, or a drawing of any kind to show the character of the work. The builder priced the work at 1*s.* 6*d.* per foot, or 15*s.* for a 10-feet gate. After the contract was settled, the architect furnished a detail that would cost 30*s.* per foot, or about three times the value of the gate itself. More than this: he claimed the right to order two additional gates and crestings to be supplied at the same contract prices.

This architect inserted in the same schedule a large sum as "provisions" for stained glass, grates, chimney-pieces, heating apparatus, stable fittings, &c., all of which goods he ordered himself from his own tradesmen, altogether unconnected with the contractor in any way, and he sent each of those tradesmen certificates for their account to be paid by the contractor. This work, being in a difficult country district, the contractor in his competition tender priced the work at home prices, and added ten per cent. at the foot of his estimate as the most convenient way to increase his prices. In the final account prepared by this architect he deducted all the provisional sums and the ten per cent. the contractor had himself added in his tender, and added the net amount of his certificates to his tradesmen, and further deducted a fee from the tradesmen, and further deducted a fee from the contractor for measuring the additions and deductions in connexion with these provisions.

The result of this system of dealing with the account was this:—The contractor's accepted tender provided for his being liable to a reduction of (say, for example) 500*l.* if the proprietor provided certain goods himself. These goods were so supplied, but instead of 500*l.* being expended the architect expends 600*l.* He orders the builder to pay his tradesmen 600*l.*, giving him credit for that sum net in the final account,

but debiting him with 550*l.* plus measuring fees. The contractor thus had to advance the money, or, in other words, he acted as banker to the proprietor, forfeiting his own legitimate profit as contracted for, and paid the architect a fee for the privilege of having been permitted or forced to do the work for nothing. This architect did not dispute the facts as stated, and he did not attempt to explain his account, but claimed absolute authority to debit or credit any sum he chose, and that his decision was final and binding.

I believe this architect charged altogether over five per cent. fees on the work done in respect of the first quantities and subsequent measuring of additions and omissions, and, as is often the case, the larger the fees the worse the work. The whole of the work so done was not worth so much as the paper on which the quantities were written, while the grossest possible ignorance of such work was exhibited.

In conclusion, the question will probably be put,—What remedy do you propose? This is a large and difficult question, which I will not at this time venture to fully discuss, but I will just give one or two sentences, and I have done.

1. I earnestly urge builders, individually and collectively, to do their best to put an end to such a state of things, by rejecting all quantities that show on their face they are not genuine, and are the work of unqualified persons. If an end be put to the demand for such quantities the supply will cease.

2. Insist upon the quantities being the basis of all contracts.

3. This Association should at an early date calmly consider the question as to whether it is practicable, in conjunction with architects' associations, to agree to some line of action, whereby impostors, calling themselves "surveyors," can be weeded out and prevented from following the profession of quantity and measuring surveyors; and that all men undertaking such work should, by some effectual means, qualify themselves, by licence or diploma of some kind, to prove their fitness for the duty. I understand some such plan is prevalent in Scotland, and it would be well if we could ascertain what the practice is in France, Germany, and Belgium.

THE DEATH-RATE IN SALFORD.

The Registrar-General's report for the 9th inst. says:—"The annual rates of mortality per 1,000 last week in twenty large English towns, ranged in order from the lowest, were as follow:—Bradford, 17; Newcastle-upon-Tyne, 18; Bristol, 19; Sunderland, 19; Wolverhampton, 21; Oldham, 21; Nottingham, 22; Hull, 23; Sheffield, 23; Leicester, 23; Portsmouth, 23; Leeds, 23; Plymouth, 24; London, 24; Norwich, 24; Birmingham, 24; Brighton, 25; Liverpool, 26; Manchester, 28; and *the highest rate was* 31 *in Salford*. The annual death-rate from the seven principal zymotic diseases averaged 6·9 per 1,000 in the twenty towns, and ranged from 3·5 and 3·7 in Newcastle-upon-Tyne and Bristol to 10·0 and 12·1 in Leicester *and Salford*." Week after week and month after month Salford is shown to enjoy this pre-eminent position. Thousands of people are dying before their time simply because they live, to use an Irishism, in Salford. Can nothing be done to stop this wholesale unnecessary slaughter? A complete investigation should be made immediately by thoroughly competent persons unconnected with the town, and their advice as to the best means of bringing about a better state of things should be followed at any cost.

Islington District Surveyorships.—At the Metropolitan Board of Works on the 13th inst., a report was presented by the Building Act Committee with reference to the district of West Islington, vacant by the decease of Mr. William Moseley, late district surveyor, recommending that the portion of such district bounded on the north by the centre line of Copenhagen-street and Elizabeth-terrace, and by the southern enclosure of the Agricultural Hall, be added to the adjoining district of St. James and St. John, Clerkenwell, and that the remainder of the district be divided into two portions by a line drawn down the centre of Camden-road, the part north of such line to be designated North-west Islington, and that south of the same South-west Islington; and further recommending that the usual course be taken for filling up the vacancies in the office of district surveyor for these two districts, that advertisements be issued inviting candidates for the appointments, and that the Board do proceed to the elections on Friday, the 8th of October next, at twelve o'clock at noon. It was stated that the income of the late surveyor was something over 1,000*l.* a year. The report was adopted.

MODERN MANSION.

Home hollow of swallow,
Mud hut 'neath the eaves,
To creep in and sleep in
Warmer than the leaves,
Made duly and truly:
Never bird deceives.

Not so you of the new
Mile-long-line estate;
Where lie thick run-up brick
Houses for the great,
False and smart with bad art,
Cheap beyond debate.

Glazton wall never fall,
Tell your tale to me;
Holy men there were then,
Worked, my God, for Thee:
Now selfish, gone selfish,
Stained with vanity.

Holy men, modern men,
Own the truth to me;
Can you get, will you get,
Churches fair and free,
With many—so many
Steeped in vanity?

Well, away! had brick lay,
Build the lofty pile;
Servants' laire up long stairs
Cellular and vile;
Dining-room—ruddy gloom
(Renaissance your style).

Rooms for night, inside bright
(In which Rossini,
With love-strain, long 'll reign
With poor Bellini);
Then to suit, outside fruit
And amorini.

"Let or Sold," long leasehold;
Tall the stories rise.
Bolt the bait, home ornate,
White against the skies:—
It is but a mud hut,
Though of larger size.

E. C. Ireland.

NEW BUILDINGS ON THE SITE OF THE QUEEN'S BENCH PRISON.

The site of the old Queen's Prison, which was some time ago purchased by Mr. Hobbs, builder, of Croydon, is now being rapidly covered with new residential buildings, and will shortly be occupied with a different class of tenants from those which, in past years, rendered it historically famous. The structures to be erected on the site are intended to be of a varied character, consisting of shops, residential chambers, and houses in flats, but mainly of the last-named class. The first block of these is already in a forward state, and will be covered in in the course of a few days. The block is situated on the south-west side of the site, having its principal frontage to Southwark Bridge-road, and extending to the Borough-road, where it will have its outlet, and thence into High-street, Borough. The title given to the new property is the "Queen's Buildings." The Southwark Bridge-road frontage of this block, which is 47 ft. in length, and 70 ft. in height, is in stock and red brick, with stone dressings, and of a rather ornamental character. It contains five stories above the ground-floor. The long return frontage extending from Southwark Bridge-road to the Borough-road, is of the same height, and contains the same number of floors, the ground-floor portion consisting entirely of shops. The lower portions of the Southwark Bridge-road frontage, including the ground-floor, and the first and second-floors, are, it is stated, to be appropriated as a coffee palace or tavern, on a comprehensive scale, combined with news-rooms, billiard-rooms, and other attractions. A new thoroughfare, to be called Scovel-road, 50 ft. in width, will run parallel with this block, between Southwark Bridge-road and the Borough-road, and on the opposite side of the street a similar block to that just described will next be erected, the remaining portion of the ground, on the north-east side, being ultimately intended to be covered with further blocks of buildings of a like character. It will be remembered that about the time negotiations were in progress for purchasing the site from the Government, a strong effort was made on the part of the vestry of St. George-the-Martyr to secure a part of it for the erection of public baths and washhouses, and it is stated that the local authorities will have the opportunity of securing, for this purpose, a portion of land on the south-east side of the ground, bounded by Collison-street and Montague-street. When the whole of the several blocks to be erected upon the site are completed, it is estimated that there will be upwards of 600 family tenements, having accommodation for an aggregate population of about 3,000 persons.

The buildings we are informed, have all been designed in Mr. Hobbs's Office, Mr. W. F. King having the charge of the architectural department.

VESTRYMEN AND SPECULATING BUILDERS.

MATERIAL FOR BAD MORTAR.

The Rotherhithe Vestry, at its meeting on the 2nd inst., devoted considerable time to the discussion of some very questionable proceedings on the part of a few of its members. It was stated by a member (we quote from the report in the *South London Press*) that certain material belonging to the parish had been found on the premises of certain members of the vestry.

Mr. Deavin said he would admit that he had some of the road sweepings on his premises. It was the custom for contractors to get rid of the stuff in the best manner they could, and he had on more than one occasion received money for taking it off their hands and utilising it. With respect to the sweepings taken off the vestry roads, he was asked,—as other vestrymen had been,—if he could take seven or eight loads, and he consented, as he knew it would save the parish expense to get rid of the material in such a way. The parish had to hire a shoot in order to dispose of these sweepings, and surely if other people could utilise them the parish would thus be saved much expense.

Mr. Bulmer said that before he made any observations he should like the inspector (Mr. Thomas) to say by whose orders the sweepings had been taken to the different premises where they were found.

Mr. Thomas said the sweepings had been disposed of by his orders. It was his (Mr. Thomas's) duty on all occasions to improvise a shoot for the disposal of this refuse, which must be removed as speedily as possible for sanitary purposes. They had always been to the expense and trouble of removing it in vestry carts to the shoots which they hired, but if anybody would have it they offered it to him in place of charging the shoot with it. The vestrymen who received the refuse did not apply to him; he (Mr. Thomas) asked them if they would take it, and receiving an answer in the affirmative, it was accordingly sent.

Mr. Bulmer.—Mr. Thomas asked us whether we would have some.

Mr. Thomas.—I give it not only to vestrymen, but to builders in general who want it.

Mr. Walker said he could not reconcile the admissions of Mr. Thomas with the statement he previously made with reference to this subject. His (Mr. Walker's) opinion was emphatically that no vestryman of the parish, no matter who he was or what he was, had a right to any material belonging to the vestry. In the present instance, it was found by the General Purposes Committee that Messrs. Bailey, Chafen, Bulmer, and Deavin were all concerned in this matter. It was stated by one of the gentlemen that one of his brother vestrymen had had no less than 150 loads of this kind of stuff, which was a sandy material quite fit for building purposes. Mr. Thomas, the inspector of pavements, said it was offered to all builders in the parish; but he (Mr. Walker) had asked several if they would like to have some, and the reply he received was that they would like very much to have the material as cheap as vestrymen got it.

Mr. Bulmer acknowledged that he had some of the scrapings of the roads, and, like Mr. Deavin, he was asked if he could take the stuff. (A voice: "You all do it," and laughter.) The material he received had been ground to a powder on the road, splashing everybody that passed in wet weather, and spoiling the railings he had newly painted.

Mr. Wilson said that if vestrymen would retain their self-respect, they must refrain from such acts as this.

Mr. Bulmer.—Is it worse than sending in a price for ironwork for tramways when you are sitting on a committee that is considering the same subject?

Mr. Williams said he had been round with the committee and inspected the sand in the yards belonging to vestrymen. He did not think the sand off the road was of any particular value, though doubtless of some value; but he did think it was time to object when he found, as he did in Mr. Bulmer's yard, forty loads of materials that would be valuable to the vestry. Mr. Bulmer stated that the contractor gave him that material as a matter of right, but Mr. Bulmer might also have added that there was a clause in the agreement between the contractor and the vestry whereby any material of value taken off the roads was the property of the parish. He (Mr. Williams) considered that the material in Mr. Bulmer's yard was worth from 3s. to 4s. per load, and he thought that the dabbling of vestrymen in such matters ought to be put a stop to. It was a matter of common notoriety that speculating builders in Rotherhithe rapidly made money when they became vestrymen.

The Chairman said it appeared to him, from what he had heard, that this material was of very little value to the parish. Moreover, the surveyor admitted that this kind of thing had been going on for years (cries of "Shame"), and it might be advisable that the matter should be referred to the General Purposes Committee to say what ought to be done in the future,—to see, for example, if some small acknowledgment could not be paid for this material.

At a subsequent meeting of the Vestry, the discussion of the subject was resumed, and on motion being made that the Vestry proceed to the next business, it was moved, as an amendment, that a vote of censure be passed on the surveyor (Mr. Thomas) for allowing the material to be delivered to vestrymen and others without the order of the Vestry. After many personalities and recriminations had been indulged in, the amendment was withdrawn, and the discussion terminated.

[It would appear, from this interesting discussion, that in Rotherhithe and its neighbourhood it is a common thing to use road *detritus* in lieu of sand as a constituent of mortar. Mixed, as such refuse necessarily is, with decaying animal and vegetable matter, it is totally unfitted for use as an ingredient in mortar,—on structural grounds because the animal and vegetable matters interfere with the chemical combination of the lime and sand, and so rob the mortar of its adhesive and cementitious qualities; and on sanitary grounds because the building-up into the walls of dwelling-houses of a mass of filth must inevitably promote the spread of disease, especially in situations where the walls so built are subject to damp.]

SALE OF FREEHOLD PROPERTY NEAR ALDERSGATE STREET.

Last week Messrs. Norton, Trist, & Watney sold, at the Auction Mart, several lots of valuable freehold property, in the City, situated in Bartholomew-close and Albion-buildings, near Aldersgate-street, and immediately adjoining the Albion Tavern. The property comprised nine lots, let on leases producing altogether an annual rental of 722*l.*, but said to be worth at the present time a much larger yearly sum. No. 20, Bartholomew-close, let on lease for a term of twenty-one years, from Midsummer, 1878, at a rent of 40*l.* per annum, was sold for 1,000*l.*; No. 14½, Albion-buildings, Bartholomew-close, let on lease at a rent of 150*l.* per annum, sold for 2,840*l.*; No. 15, Albion-buildings, rental 40*l.* per annum, realised 1,020*l.*; Nos. 16 and 17, Albion-buildings, rentals 50*l.* and 52*l.* 10*s.* per annum, were each sold for 1,300*l.*; Nos. 18 and 19, Albion-buildings, producing together an annual rental of 60*l.*, fetched 1,720*l.* The next lot, consisting of No. 14, Bartholomew-close, and occupying an area of 4,420 superficial feet, let on lease for an unexpired term of sixteen years, at a rental of 190*l.* per annum, was sold for 4,450*l.* A public-house, facing Aldersgate-street, at the corner of Bartholomew-close and Albion-buildings, known as the Goldsmiths' Arms, together with the adjoining dwelling-house, No. 14, Albion-buildings, let on lease for an unexpired term of sixteen years, at 140*l.* per annum, was sold for 2,880*l.*, the aggregate proceeds of the sale amounting to 16,510*l.*

Barrow.—The joiners in the employ of the Barrow Shipbuilding Company have struck work.

ON THE NUDE IN ART.

A THEORY.

Eve in her innocence shocks no society,—
She stands full of dignity, does not look shy,—
Adam looks on and sees no impropriety,—
Her husband admires her costume,—May not I?

But then, after eating the apple so recently,
Why paint her in fig-leaf all fitted awry?
Poor soul! Now she knows she's apparell'd indecently,—
Her husband won't look at her,—Why, then, should I?

When Perseus is shown saving beauteous Andromeda,
He does not feel shame when her charms meet his eye,
Nor does she, for the matter of that,—Not a bit of it,—
She wants no petticoats,—Why, then, should I?

When a tree is display'd with a lady fix'd tight to it,
The knight gets behind it the knot to untie.
We all praise his modesty,—Why, then, not copy it?
He won't stand in front of that tree,—Why should I?

And Phryne, who would not behave in a steady way,—
Why paint the old court where that beauty they try?
It's a matter of taste,—but, when she turns her head away,
When even Phryne turns away,—Why should not I?

J. Mackenzie.

PAVING NEW STREETS.

At the Marylebone Police Court Mr. John Nash, owner of a number of houses in Montpelier-road, Countess-road, and Dunollie-road, in the parish of St. Pancras, was summoned by the vestry for paving demands.

There were sixty summonses against the defendant, and the total amount demanded was 1,003*l.* 6*s.* 5*d.*

The defendant did not dispute the apportionments, but said he wanted time for payment, and asked for two years.

Mr. Shiel said he must ask the vestry for time. An order would be made for the payment of the money, with 12*l.*, the cost of the summonses and orders.

Surely the Act provides for the distribution of the payment over a number of years?

HEIGHT OF CHIMNEYS.

METROPOLITAN BUILDING ACT.

Last week, at the Marlborough-street Police Court, before Mr. R. Newton, the case of Korr *v.* Webster was heard, in which the complainant, as district surveyor of St. James's, Westminster, summoned Mr. William Webster, builder and contractor, for having disobeyed an order of the Metropolitan Board of Works to alter the construction of a chimney at the Criterion Restaurant, by providing and fixing an additional stay of H-iron, 9 in. deep, secured at the foot by a wrought-iron strip passing round the said chimney-stack "in the manner shown upon the half-inch scale drawing supplied by Mr. Verity, architect of the building, who appeared before the Board on the builder's behalf in respect of his disagreement with the said district surveyor." Mr. Taylor, solicitor, appeared for the defendant:—

Mr. Kerr, having been sworn, stated that in the month of May, 1879, the chimney in question was discovered by him to have been erected on the old building of the Criterion Restaurant without notice having been given. The chimney reached to a very great height, something like 40 ft., which was considerably more than six times the least width, the latter being the limit prescribed by statute. On discovering that the chimney had been so erected, he (witness) communicated with Mr. Thomas Verity, the architect of the building. They corresponded for several months and he was under the impression that Mr. Verity intended applying for the sanction of the Board of Works. He did not do so, however, and witness's patience being exhausted, he, in September, 1879, gave Mr. Webster, the contractor, notice to amend the work, and summoned him, in November, 1879, for neglecting to obey the notice. The case came before Mr. Mansfield, when the preliminary objection was taken that the Criterion was a public building, and although witness contended that the clause in regard to public buildings could not safely be held to apply to a chimney, Mr. Mansfield eventually decided that it was a public building. After that the dispute between witness and defendant was, by agreement, referred to the Board of Works, and the result was that they ordered the work to be amended in the manner set forth in the present summons.

Mr. Newton.—Did you say that Mr. Mansfield decided that the Criterion was a public building?

Mr. Taylor.—Yes. It is a public building, being licensed for dancing and all the rest of it.

Mr. Newton.—That does not make it a public building.

Mr. Kerr.—When we got the decision of the Board, Mr. Verity signified that their order would not be obeyed, and therefore I had to bring this summons before you.

Mr. Taylor then proceeded to take a number of technical objections, which were ultimately overruled by the magistrate.

Mr. Taylor.—If you are against me on the question, you can make an order, so that we can appeal against it.

Mr. Newton.—Very well. I will make the order; and when the Queen's Bench next sits you can ask for the order to come before them, and move to quash it.

Mr. Taylor.—Yes; we will either do it that way, or leave it to be enforced.

Mr. Newton then made the order, observing that Messrs. Spiers & Pond would find it much cheaper in the end to do what Mr. Kerr asked than to waste time and money in litigation.

It seems to us that the public are indebted to the district surveyor for his persistence in this case. An important regulation of the Building Act, having in view the safety of the public, has been notoriously disregarded, and money and ingenuity have been expended without stint to prevent its enforcement. We have a strong opinion as to the course which has been taken in this case by the parties acting for Messrs. Spiers & Pond.

BREACH OF BUILDING BYE-LAWS.

DAMP-PROOF COURSES.

At the Highgate Police Court last week, Messrs. George Cooper & Henry Perkins, builders, of Hamilton-road, Manor Park, Finchley, were summoned before Mr. J. H. Lermitte, at the instance of the Finchley Local Board, for erecting two dwelling-houses with improper materials, and not causing the whole ground surface to be properly asphalted or cemented. There was a second summons against the defendants for neglecting to cause every wall of such buildings to have a proper damp course of sheet lead, asphalte, or slates, or other materials impervious to moisture, beneath the level or lowest timbers. And there was a third summons for neglecting, within a reasonable time of erection, to give notice to the surveyors or Board of their completion.

Mr. Stevens, solicitor to the Board, prosecuted.

The evidence of Mr. Brooking showed that the damp course put in was of roofing felt, which would in a short time become useless for the purpose of preventing the damp rising, and the houses would, in consequence, be unfit for habitation.

In reply to the magistrate, the witness said the houses would have to be pulled down to put another damp course in.

The defendants admitted the facts to be substantially correct, but contended with regard to the damp course that in other parishes builders were allowed to put in roofing felt, and they thought they could do so in Finchley.

Mr. Lermitte said it was allowed in Finchley until lately, when the new bye-laws were made, of which defendants had had a copy. The defendants, for not complying with them, would have to pay, on the first summons, a fine of 40*s.*, a like amount on the second summons, and 5*l.* on the third, together with 4*l.* 7*s.* cost.

The defendants, after paying the fines, asked whether they would have to make good the damp course, because, if so, they would have to pull down the houses.

Mr. Lermitte replied that defendants would have to satisfy the Local Board, whose surveyor would, no doubt, give them notice of what they would require them to do.

SEWERAGE AND WATERWORKS.

The Sowerby Bridge Sewage Scheme, designed by Messrs. Ulsby & Gray, civil engineers, of Halifax and Sowerby Bridge, has now received the approval of the Local Government Board. Mr. Godfrey Rhodes, solicitor, clerk to the Local Board, received on the 9th of August inst. the official intimation that the plans and estimates were passed, and sanction granted to borrow the amount (15,143*l.*) required to carry out the works, repayable as to the sum of 10,643*l.* in thirty years, and the remaining 4,500*l.* in fifty years. The works comprise four miles of main sewers, with all necessary manholes, ventilating-shafts, and flushing arrangements. Also two wrought-iron syphons under the river Calder, one cast-iron crossing under the Rochdale Canal, and one under the Ryburn, together with the tanks, buildings, &c., which are designed upon the best modern principles for economically and effectually treating sewage. The outfall works will be constructed in the Holmes, between the Lancashire and Yorkshire Railway and the river Calder, immediately opposite Messrs. Norris's Chemical Works. Mr. Hanson's process of treating the sewage was explained by the patentee at the public inquiry, held by Mr. Robert Morgan, C.E., on the 11th of June last, and has been approved by the Local Government Board in conjunction with this scheme.

Frith-hill, Godalming.—The waterworks at Frith-hill, Godalming, which have been some time in hand, consist of a well about 62 ft. deep, sunk in close and fine sand, very hard to work, and very difficult to exclude from the inflow of water, but which has happily been accomplished. The engineer is Mr. Jabez Church, of Great George-street, Westminster. A reservoir 80 ft. by 60 ft., holding 360,000 gals. for the supply of the town, is fed by the pumping-engine at the rate of about 7,000 gallons an hour. A circular

iron tank, about 20 ft. deep, with capacity of about 28,000 gallons, and standing 45 ft. above the upper level of the reservoir, is to be used for houses situated at a higher level, chiefly those connected with Charterhouse School. This iron tank is enclosed in a water-tower, constructed of Bargate-stone and red brick, having curved projections on the four faces corresponding with the curve of the iron tank inside, standing on four massive piers connected by pointed arches. The whole structure is crowned with a battlemented cornice, an angle turret corbelled out in brick and stone-work rising to the highest point of all. The care with which this has been studied by the architect, Mr. C. F. Hayward, F.S.A., is evident from the detail, and the successful result is seen for many miles round. The total cost appears to have been about 10,000*l.*

Slough.—A new system of sewers, about seven miles in length, has been laid throughout the town. Storage-tanks, an engine-house, and engine driver's cottage have been built; two pumping-engines of ten-horse power each have been erected by Messrs. J. Watt & Co., of Birmingham; a rising main, 2,830 yards in length, has been laid, and a portion of a farm of twenty-five acres has been laid out for irrigation. The principal feature in the works is the separation of the rainfall and subsoil water from the sewage. The house connexions are not yet made, but after careful testing it is asserted that the leakage into the sewers at present amounts only to six gallons per minute, or less than one cubic foot, and this notwithstanding that some of the sewers are laid in a soil containing water nearly on a level with the water of the Thames. The surface water-drains to carry off rainfall are connected with the town sewers which were laid some years ago. The works are designed and have been carried out under the superintendence of Messrs. R. B. Grantham & Son, Mr. F. Smith being the clerk of works.

Stapleton and St. George's, Bristol.—At a recent meeting of this Board, the Chairman made an extraordinary statement to the effect that certain new sewers had been so constructed as not to admit the Stapleton sewers as arranged between the two Boards. This was owing to an error of about 2 ft. in the level, the mistake having been made in the designs of Messrs. Ashmead, who prepared the plans for the sewers. He added that several plans had been suggested for remedying the matter, the most feasible of which appeared to be the proposal for constructing a new sewer from the junction of Fishponds and Stapleton roads, across the pathway near the Barton Regis Workhouse, and connecting the St. George's intercepting sewer 200 yards north of St. Mark's Church. At a subsequent meeting, Messrs. Ashmead said they had failed to discover satisfactorily what had led to the error, and left themselves in the hands of the Board. The cost of the plan determined on for rectifying the error was shown to be 750*l.*, and, the Board taking the matter in good part, it was arranged that Messrs. Ashmead should pay 200*l.* towards it, and make no charge for their services in connexion with the required work. It is hard to understand how such a mistake occurred.

Bentham.—On the 10th inst., Capt. R. C. F. Hildyard, one of the engineering inspectors of the Local Government Board, held an inquiry at Bentham, near Settle, Lancashire, into a proposal by the Settle Union Sanitary Authority to borrow the sum of 3,000*l.*, for thirty years, from the Public Works Loan Commissioners, for the carrying out of a scheme of improved water-supply, according to plans prepared by Mr. E. Firth, C.E. The scheme is a gravitation scheme, and it is proposed to take the water from the source of a small stream called the Bright Syke, on Burnmoor. That stream, after flowing for a very short distance, joins another small stream, Gill Beck, and, after receiving numerous feeders in its course, flows into the river Wenning. The present water-supply of Bentham is principally from wells, and, according to the medical officer of health, Dr. Barry, is so largely polluted as to increase the rate of mortality.

New Board Room, Fulham.—At the last meeting of the Fulham District Board of Works, it was unanimously resolved that Mr. A. C. Bean, the Board's surveyor, be paid 175 guineas for his extra services and out-of-pocket expenses in connexion with the new Board-room and alterations at Broadway House.

JULIUS SAX'S MECHANICAL AND ELECTRIC WATER GAUGE.

To enable the engineer in the basement of the Prudential Assurance Company's Offices in Holborn to know how the water stands in the cistern at the top of the building, 100 yards off, Mr. Sax, whose electric bells are well known, has fitted up one of his mechanical and electric water gauges. This apparatus consists of two parts:—First, the mechanical indicating water-gauge fixed at the top of the cistern; and, second, an electrical counterpart which may be fixed at any distance from the cistern.

The mechanical water-gauge carries a metal float, which is so arranged that its rising and falling will cause the hand on the dial to move forward or backward, as the case may be, and if once set so as to point on the dial the height of the water in the cistern, the hand would always follow the same, and so indicate it.

The hand on the electrical dial is made to follow the movement of the hand of the mechanical dial by reversed currents. If the pointer of the electrical dial is set to correspond with the pointer of the mechanical dial, the former would always follow the latter whether it went forward or backward, and so show the state of the cistern at any distance from it.

The mechanical dial is also arranged to set an alarm-bell ringing when the water in the cistern has reached either the highest or lowest point.

The arrangement appears to be perfectly efficient.

ARCHÆOLOGICAL SOCIETIES.

London and Middlesex.—The annual summer excursion of this society took place on the 10th instant to Enfield, when about eighty of the members and friends assembled at the Grammar School, to hear papers read on "The History of Enfield," by Mr. J. O. Ford, and on "The Church and its Monuments," by the vicar, the Rev. G. H. Hodson. The company then inspected the house forming part of the old palace, which contains a beautifully-panelled room of the Elizabethan period, and a chimneypiece of most elaborate design. Progress was then made to Oldbury Camp, and to "Durrant's," a brick-built moated house, once the residence of the famous Judge Jeffreys. "Forty Hall" was next visited, where, by the kindness of the owner, the fine pictures and house (erected by Inigo Jones) were inspected. The next session will commence in November, when the evening meetings will be resumed at 4, St. Martin's-place, Charing-cross.

Sussex.—The annual general meeting and excursion of the Sussex Archæological Society was held on the 12th inst., at Boxgrove. New rules for the government of the society were adopted, and thanks were, on the motion of Mr. Gordon M. Hills, passed to Mr. Tower for past services in editing the "Sussex Archæological Collections." Mr. Lacy W. Ridge, architect, read a paper on Boxgrove Church and Priory. After alluding to the early history of the Church and Priory with which it was connected (as exhaustively described in the papers published in the Society's volumes), Mr. Ridge said that of the first transitional period (from Norman to Early English) they had the ruined nave, Norman in general tone, but pointed in its arches, and first presenting that system of coupled bays which gave so marked a character to the choir; the arches of the crossing with the pointed arches and great circular caps and bases which swept round and gathered up the old sharp-pointed mouldings of the piers and arches, so characteristic of a state of transition wherein the pointed form was applied experimentally, and the due subordination of arch and pier was not yet reached; the arcaded bell-story, heavy in its proportions and its details, with square abacus and coarsely-moulded but pointed arches; and last, probably quite late in the transition, the bell-story, with circular-arched openings, but having on their inner arches a moulding under-cut and refined to an extent far in advance of any of the preceding work, which might well be a standing warning not to trust too implicitly in assigning dates to buildings by the form of the arch. Coming to the Mediæval period, when the apsidal east end no longer satisfied the architectural taste of the day, and pointing out that in no cases were the changes more apparent than in West Sussex churches, Mr. Ridge showed the close relationship of design between the choir of Boxgrove Church and the presbytery of the cathedral at Chichester. He concluded by alluding to the somewhat burning question of the day amongst archæologists as to the dual use of Boxgrove Church for monastic and parochial purposes. A vote of thanks was accorded to Mr. Lacy Ridge for his interesting paper; and at the request of the Rev. W. Burnett, the vicar of Boxgrove, the exterior of the church and conventual buildings were described by Mr. Gordon Hills, who said that, although the fragments of the Priory were scattered, enough was left to enable the general arrangements of the monastery to be traced. Directing attention to the arches running at right angles from the north side of the church, he said they might be, and had been, taken as belonging to an early church; but any one acquainted with monastic buildings would see that it was the entrance to the chapter-house. Halnaker House (the ruins of the entrance of which are good specimens of cut-flint work,—even the quoins and arches being of cut flint) having been visited, the excursionists drove to Goodwood Park, where, in the Society's large marquee, they sat down to luncheon. The company, which numbered 220, was presided over by the Bishop of Chichester. Goodwood House was afterwards visited, by permission of the Duke of Richmond and Gordon.

THE FORCE OF HABIT IN MATTERS OF TASTE.

Sir,—Reading the remarks made in your excellent leader of Saturday week on fashion in decoration, recalled to my mind the subject which forms the heading to this letter, a subject to which I have long desired to direct public attention. It is an old adage that "use is second nature"; nevertheless, this great fact is lost sight of, important factor though it be, in giving tenacity of existence to wrong in everything.

The force of habit is taken very little note of in discussing matters of taste, though it is upon this modifying factor in our nature that the eccentricities of fashion in life, literature, and art are enabled temporarily to usurp the thrones of the right and the beautiful. It is upon the modifiability of the human nature by habit that Chinese, Japanese, Gothic, and other eccentric styles become tolerable and persistent, and we even meet with men who ought to have been superior to such corrupting influences in taste, who have become fascinated by dwelling upon some peculiar and eccentric style, till they fell entirely under its dominion, became adapted to, and believed in it; and by precisely the same process that bag-wigs, powder, patches, ruffs, hoops, &c., came to be thought the thing, and to have their day.

The Mediæval artist and people were in all probability totally insensible to all those quaintnesses of style which to us moderns appear as pronounced and as eccentric as the costumes of the time. Men become by habit insensible to a dominant bias in their surroundings, just as they do to the tone of objects illuminated with a prevailing hue. The value of this factor of "habit" must not be underrated. The force of habit ought to caution us against forming a too hasty conclusion respecting the characteristics of the taste of our own time, for if those styles which now strike us as being so peculiar, so eccentric, appeared to be destitute of bias, or peculiarity, to those who practised and contemplated them, may not ours exhibit to the eyes of posterity an equally strange and eccentric spectacle?

There can be but little doubt that there is a style which is free from all peculiarities, an "everlasting" style, free from all bias,—using the word everlasting in the same sense as Addison, when he spoke of sculptors clothing their statues in an everlasting drapery, to escape the fashions of the time. There is an everlasting right in art, as there is in ethics, and it is this central taste and style, the taste and style "for all time," which should be striven after, which we should endeavour to realise by eliminating every form of peculiarity or eccentricity from each and every of its manifestations.

W. Cave Thomas.

The New Free Library, Newcastle-on-Tyne, which will contain 20,000 volumes, is to be opened on Monday, Sept. 13.

NEW PUBLIC BUILDINGS AT ASTON, BIRMINGHAM.

On the 12th inst. the memorial stone of the new public buildings for the Manor of Aston, now in course of erection in the Witton-road, was laid by Dr. Keyworth, Chairman of the Local Board of Health. Building operations have been in progress for about two months, and the foundations have been constructed. Two years since the Board advertised for competitive designs for public offices, free library, baths, and other buildings, and in response a number of architects submitted their designs. The Board very wisely referred the selection of the most suitable designs to Mr. Alfred Waterhouse, A.R.A., who in due course reported in favour of those by the then firm of Alexander & Henman, architects, of Stockton-on-Tees and Middlesbrough. The Board adopted the recommendation, and eventually, when Mr. Henman, having disconnected himself from his former partner, had settled in Birmingham, entrusted him with the superintendence of the work and the remodelling of the plans, necessitated by the plea for economy in consequence of the depressed state of trade in the district. The new buildings consist only of the public offices of the Board and rooms for the Free Library, under one roof, the erection of the baths and stabling being for the present deferred. There are, however, many in the manor who consider these to be necessary requirements, and consequently trust that the Board will take them in hand at the earliest possible date.

At the angle of the Albert and Witton roads, with a separate entrance in Witton-road, is the Free Library, with a large and well-lighted reading-room, lending library, and reference library, the whole having a floor area of over 2,000 superficial feet. The entrance to the Public Offices, being in Albert-road, gives access through an open porch and vestibule to the ground-floor, where are situate the rate collector's public and private offices, the medical officer's room, and public and private offices for the sanitary inspector; also a public waiting-room, lavatories, &c. A stone staircase ascends to the first floor, where are situate the Board-room and two committee-rooms over the library department, offices for the clerk, sub-clerk, surveyor, building surveyor, and the drawing-office, as well as another waiting-room for the public, lavatories, &c. In the basement is the fire department, with standing-room for two fire-engines, firemen's rooms, and hose-room; and there is ample store room. The frontages will be of brick and stone. The present contract, taken by Mr. W. Robinson, of Spring Hill, amounts to 8,270*l.*

FOOTINGS ON ANOTHER MAN'S LAND.

Sir,—I have contracted to build a house for a freeholder who wishes his footings placed on the adjoining freeholder's property, so that the frontage of his building may be to the full extent of his property, otherwise he will have to set back 1-1 in., which will be lost. Will any of your subscribers kindly give me their experience on such a matter, as the adjoining freeholder objects to the projection of the footings being on his property? A Small Builder.

*** The statement is not very clear. On the broad question, a man has no legal right within the metropolitan districts to place his footings on an adjoining owner's land, though it is constantly done, and may be almost said to be justified by custom. The district surveyor would doubtless assist our correspondent. Building Bills which have been brought before Parliament have contained a clause giving right to a building owner to place footings on adjoining owner's ground.

PROPOSED THEATRE IN BEAUFORT-BUILDINGS.

Sir,—The article in your issue of the 7th instant, on "The Proposed Theatre in Beaufort Buildings," being calculated to prejudice my client, the plaintiff in the pending action of Emden *v.* Carte, I ask you to give insertion to the following:—

My client claims as an essential part of his plans the placing of the carriage and principal entrances in the street described by you as from the Thames Embankment to Savoy-place; and further, that this street was actually re-made and opened in consequence of his negotiations (commenced so far back as the middle of 1878) with the Metropolitan Board of Works.

On a recent motion to the Court Mr. Carte gave an undertaking not to use my client's plans.

Frede. Tudor, Solicitor for Mr. Emden.

August 13th.

PITCH-PINE.

Sir,—Referring to the letter in last week's *Builder*, allow me to remind "Pinus" that pitch-pine is not a "hard wood," and consequently inserts moisture; and when we change the wording in our specifications that we are so accustomed to,—viz., "deal-cased frames, *oak* sunk and weathered cills, brass axle pulleys, and best patent flax lines," let the substitute be, not a *softer material* for the cill, but, as armour-plated vessels have taken the place of the wooden walls of Old England, let the substitute be a "hard wood,"—say teak, for instance,—which is cheaper than oak, and makes a capital cill except as to colour; and being a "hard wood," it throws off the moisture, so essential in a cill to a window-frame, and, indeed, most other cills. The above preamble does not, of course, apply to first-class work, when we should have our wainscot frames, &c., at all events, wainscot pulley stiles; neither does it apply to work that has not to stand any longer (on account of the wear and tear) than wood paving, referred to in the ably-written letter from "A Civil Engineer" that appeared in the *Builder* for the week ending the 7th of August last. William H. Pipe.

I have been looking with some little anxiety for a categorical reply to the inquiry of "An Architect" contained in your issue of the 31st ultimo as to the fitness of pitch-pine for window-cills.

Interesting and instructive as is "A Civil Engineer's" general dissertation on woods, in your number of the 7th, I am at a loss to find in it any direct answer to the inquiry. I know it is one in which more than your first inquirer are interested. Woods that will stand well betwixt wind and water have nothing to do with the matter. The pitch-pine is not intended to be used either for piles or for camp-sheds, but for window-cills; and until I have much better information that pitch-pine, with its natural indication of resin and turps, is not as good a material as can be used for sash-cills (saving, of course, English oak), I must venture to enter a *caveat* against the inference that is to be drawn from "A Civil Engineer's" otherwise instructive letter. Another Architect.

SELF-PROTECTION FOR ARCHITECTS.

Sir,—For the chaotic state now existing with regard to English architecture we are mainly indebted to an ignorant class of so-called architects, not only ignorant of the first principles of syntactic art, but even deficient in the elements of ordinary education; not only ignorant of the *five orders*, but of classics, mathematics, and the higher branches of arithmetic. Why do not architects use the same means of keeping pretenders at a distance that members of the legal and medical professions, and even market gardeners and florists, adopt? I mean the use of the Latin language. There might then be some hope of putting an end to that source of disfigurement of our towns, "the pleasing school."

Walter Scargill.

PROVINCIAL NEWS.

Halifax.—A large mill for the Halifax Flour Society was opened recently. The society affords a striking instance of the power of co-operation. At the meeting, Mr. Councillor Pearson, president, said the first mill built by the society was opened in 1848. This mill was fitted with eight pairs of stones, and corn-grinding machinery, and was worked until 1863, when a larger mill, with a grinding capacity of twenty pairs of stones, was erected, partly on the same site. In May, 1872, the Bailey Hall estate was purchased for the sum of 21,654*l.* 13s. 8d., and one of the buildings standing upon it was altered and adapted for corn-milling purposes, at considerable cost, but was only used for about six months. In 1877 the ground was partially cleared for the erection of the new mill, warehouses, and other premises, and building operations were shortly afterwards commenced, from plans supplied by Mr. Richard Horsfall, architect. The new buildings are large, and fitted with machinery of the most modern construction. Thirty pairs of stones were already fixed, fourteen of which were now running, and it was expected that the other sixteen pairs would be in full operation in a few weeks. The total working capacity of the new mill was fifty pairs of stones. The total cost of the new mill has been 10,200*l.* It was stated at the meeting that since the formation of the Flour Society the sum of 160,000*l.* had been distributed amongst its members.

Devonport.—The memorial stone of the new Public Hall now in course of erection in Fore-street, Devonport, was laid on the 28th ult. We recently (vol. xxxviii., pp. 481, 483) published view and plans of the building, of which Mr. Samuel Knight, of London, is the architect. Mr. Matcham, of Plymouth, is the contractor for the erection of the building, which is estimated to cost about 10,000*l.*

Non-Arsenical Papers.—The Council of the Sanitary Institute of Great Britain have awarded to Messrs. W. Woollams & Co. a medal "as a special mark of merit" for their paperhangings "free from arsenic," exhibited at the late Croydon Exhibition. In our notice of this exhibition we mentioned that Messrs. Woollams' exhibits had been reserved for examination by experts.

CHURCH-BUILDING NEWS.

Paddington.—St. Martha's Mission Chapel has been erected both as a mission chapel and chapel-of-ease to the neighbouring church of St. Mary Magdalene. It stands on the site of "Desborough House," said to have been the residence of General Desborough, in Cromwell's time. Portions of the house were found to be of timber-framing, with brickwork filling-in. The building had been modernised into "Strawberry Hill Gothic." At the back had been built a boys' school, using some of the old rooms of the house as class-rooms, &c. It was therefore determined by the vicar, the Rev. R. Temple West, to retain these school buildings, and enlarge them by extending them over the whole area, and to build the chapel above them. These works have now been carried out under the architects, Messrs. Carpenter & Ingelow. The chapel consists of a chancel and vestry, organ-chamber over, nave, and side aisles, with a staircase at the north-west angle occupying the space of one bay of the aisle. The arcades have moulded brick arches, with Portland stone columns standing on cast-iron columns and stanchions in the schoolroom under, all these being tied together and also tied to the walls by rolled iron and riveted girders, which also carry the chapel floor. The internal facing is of red brick, the walls being lined with tiles up to the string-course under the windows. The reredos and the lining of the chancel walls are not yet executed. The fittings and the screens are in pitch-pine, and the body of the chapel is seated with chairs. The exterior is faced with white Suffolk bricks for the purpose of throwing as much light as possible into the girls' school on the opposite side of the narrow court. Wood blocks are used for the floor of the schoolroom and chancel; the altar is of cedar, and executed by Mr. J. Forsyth; the organ is by Messrs. Hedgland. The contractor is Mr. Scott, of South Molton-street, the ironwork being executed under him by Messrs. Shaw & Co. Mr. Nash has been the clerk of works.

Blankney (Lincolnshire).—St. Oswald's Church here has just been restored at the cost of Mr. H. Chaplin, M.P. It is an interesting Early Pointed rebuilding of a still earlier church of the same period; the nave has arcades, each of three wide and lofty arches, the columns of which have delicately-moulded capitals and bases, the latter resting on a projecting stone surbase, which forms a seat round the column. The aisles had been altered in the fourteenth century, and traces of their two-light windows remained, with the water-tables of the steep early roofs. The chancel has long, narrow lancets, with a very early three-light window, with intersecting tracery, in which there had not been any of the soffit cusping usually found in such windows. The tower is a rebuilding (some fifty years ago) of a fine Perpendicular one, with great coupled windows, rich parapet, and pinnacles of a local type. The north aisle of the chancel is of Perpendicular date, and takes the place of an Early English aisle or lady-chapel. The whole church had been modernised, and presented, with its whitewashed walls and ceilings and high pews, a trim and "respectable" appearance, but its fine roofs had been removed and re-used as joists (which were found utterly rotten). All tracery had been cut out, the floor raised 2 ft. above the old one, the chancel shortened, and high pews and galleries had been erected; while a great vault, 5 ft. above the pavement, occupied the whole of the "Chaplin Aisle" (the north aisle of the chancel). Under the direction of Messrs. Carpenter & Ingelow the church has been brought back to the appearance it presented in the fourteenth century. The chancel has been restored to its original length, and the Chaplin Aisle also lengthened, the vault in it being reconstructed below the pavement. New high-pitch roofs have been erected, excepting to the Chaplin Aisle, where the original low-pitch one has been restored, re-using some fragments of the ancient one. The floor has been restored to its original level, and the porch rebuilt, introducing its ancient archway,—brought from an adjoining stable-yard. A new arch has been made in the tower, as this feature had not been reproduced when the tower was rebuilt. The whole has been re-seated with movable open benches, and the Chaplin Aisle is separated off by rich screens of oak, in the positions where ancient ones had existed. The great chancel screen has not yet been executed, nor has the reredos. The east window is filled with stained

glass by Messrs. Clayton & Bell. The west window is by Mr. J. Pace. All the works have been executed by Mr. Halkes, of Dunston.

Newcastle-on-Tyne. — Trinity Church, New Bridge-street, Newcastle-on-Tyne, has just been re-opened, after undergoing important alterations and improvements. Messrs. Copland & Rollo, and Mr. James Smart, Newcastle, were the contractors for the several departments of the work. Mr. J. J. Lish, Newcastle, was the architect.

Hackney.—The foundation-stone of a new church, to be erected on the site of the old South Hackney Church, Well-street, at a cost of about 1,250*l.*, was laid by Mr. W. A. Tyssen-Amherst, M.P., on the 11th inst. The architect is Mr. Gilbee Scott, and the builder Mr. Thomas Boyce, Hackney.

STAINED GLASS.

Houghton.—A three-light window has just been placed in Houghton Church, Walsingham, Norfolk. The subject is, in the centre, "The Crucifixion," and, in the side-lights, the figures of the Blessed Virgin and St. John. The window has a ruby background, with leaded conventional foliage. It has been executed by Messrs. Gibb & Howard.

Bradford (Yorks.).—Four additional stained-glass windows have been placed in the Church of St. John, Horton-lane, Bradford. They stand side by side within the great west arch of the church, and immediately beneath, and, as it were, crowned by the large rose-window of that arch. Each is a single light, and is occupied by a figure of one of the four Evangelists. These windows are from the studio of Messrs. Powell Bros., Leeds.

Derby.—There has just been placed in the east end of the church of St. Andrew, Derby, a memorial window, in memory of Charles and Martha Humphreys. It is in the style of the fifteenth century, from the atelier of Messrs. Lavers, Barraud, & Westlake, of London. The two chief lights are occupied with two New Testament and two Old Testament pictures, viz.: The Annunciation, The Nativity, Moses and the Burning Bush, and the Fall of Man. The late Councillor Humphreys was for some years churchwarden of St. Andrew's, and this window is a very beautiful token and memorial of his connexion with the edifice.

Miscellanea.

Cavendish College, Cambridge.—A new wing has been opened. It contains, besides a lecture-room, accommodation for thirty-four students and three tutors. The chairman, Prebendary Bunton, in his address, said that a new college in an old university, if it were not a mere intrusion and impertinence, must show that it satisfied the requirements of an enlightened public opinion in the university and the outside world. Cavendish College fulfilled the first of these conditions by furnishing an education which was at once inexpensive and complete, and combined necessary discipline with the advantage of university life. The financial success of the scheme is now assured, the strictly inclusive charge of 84*l.* per annum having been proved sufficient to cover all expenses of board and tuition.

Competitive Designs for Christmas and New Year Cards.—Mr. Raphael Tuck, fine-art publisher, has offered fourteen prizes, amounting to 500*l.*, for the best original sets of designs for Christmas and New Year cards. Mr. H. S. Marks, R.A., Sir Coutts Lindsay, bart., and Mr. G. H. Boughton, A.R.A., have agreed to act as judges. All designs submitted will be exhibited in the Dudley Gallery.

Revolving Shutters. — Messrs. Salmon, Barnes, & Co., of Ulverston, have just completed the fitting-up of Child's Bank, Temple Bar, with their iron revolving bank shutters, worked by their patent balance-weight motion, with special arrangements for raising or lowering them from the inside.

Iron Sashes.—We are asked to mention, with reference to the illustrations of No. 16, Token-house-yard in our last, that the whole of the iron sashes used in that building were made by Messrs. Burt & Potts.

Imperial Yacht "Livadia." — Messrs. C. H. Sharp & Co., of 104, Newgate-street, have received orders for their "Crown Ejector" for the ventilation of this yacht.

Bournemouth Pier.—The length of the new pier is 833 ft.; for a distance of 650 ft. it is 35 ft. wide, but for the remaining distance it is 110 ft., whilst the decking in the centre part of the sea has been slightly raised. At the entrance there is an ornamental structure, with covered resting-place, &c., arranged so as to give prominence to the approach. Here there are also lavatories and waiting-rooms, and over the centre portion of the structure is a small clock-tower, in which it is proposed to place an illuminated clock. The building itself is of pitch pine and plate-glass, with majolica panels. It has been painted and decorated. Immediately inside the pier there is a wide open space which has been laid with Minton's tiles. The pier itself is constructed of iron, with pitch-pine decking; the narrow part is supported by seven clusters of iron screw piles, and beneath the broad end there are fifty-six piles, braced together. Running round the exterior of the broad end, and passing under one part of the pier, is an inclined landing-stage for steamers and boats, having a length of about 1,060 ft. The lowest part is only covered by a few inches of water at high tide, and the other parts are at all times accessible. It is constructed of open plates, with timber piles, and being quite independent of the pier itself, enables vessels to approach the larger structure without striking it. Light shelter-boxes, fourteen in number, are placed at regular intervals on either side of the narrow part, and are formed of glass, so that whilst resting the visitor is able to view the entire bay. The Commissioners have obtained sanction from the Local Government Board for the erection of a handsome pavilion at the platform end of the pier, the cost of which would be about 6,000*l.*, which sum was included in the 30,000*l.* which formed the original estimate. There is no probability, however, of this being proceeded with at present. The engineer of the structure is Mr. Eugenius Birch, C.E., and the contractors were Messrs. Bergheim & Co.

The Results of Strikes.—The ironmasters of Lanarkshire last week resolved to blow out their furnaces and stop making iron rather than pay more wages. This illustrates the laws which regulate wages more pointedly than any amount of argument. Wages are regulated by the demand for labour; and, as the ironmasters can do without any labour at all, it is not likely they are disposed to pay an artificial price for the little they want. Supposing there are 10,000 men getting 1*l.* a week, and they strike for an extra shilling. The employers prefer to stop work. These workers will lose 10,000*l.* in a single week, a sum that it would take them twenty weeks to regain, even if they got the advance; and three weeks would cost them more than a twelvemonth's advance to get back. It is strange that workmen are so slow to learn that it is only secretaries or union delegates that prosper by strikes. If they had a rule in their unions that no man should be eligible for office except he was open for a job, and that all union work should be done gratuitously, they would have better advice and less misery from strikes.—*Glasgow News.*

The Southwark Music Hall and Theatre of Varieties, known as the "South London Palace," has been re-opened after re-decoration and alterations. The designs of Mr. Thomas Rogers have been executed, so far as the gilding, &c., was concerned, by Mr. J. T. Warren, of Earl's-buildings, City-road. The lighting, by means of twenty-two pendant chandeliers, is by Defries & Sons. The reserved stalls have been enlarged and furnished by Lyons, of Holborn, and the bar-fittings have been decorated and painted by Mr. C. King, of Blackfriars-road. The new act drop, painted by Grieve & Son, represents a distant view of Westminster Bridge and the Houses of Parliament. The orchestra has been lowered, and the addition of a new cigar stall and a tea and coffee buffet, at which latter non-intoxicating drinks are sold, are features in the alterations, which have been wholly carried out under the direction and supervision of the surveyor, Mr. Edwin Clarke.

The New R.C. Church of St. Joseph, Ramsbottom, the foundation-stone of which was laid on September 27th, last, is nearing completion. The church is built in the Early English style, from the designs of Messrs. Bird & Whittenbury, of Manchester. As opened, it will consist only of nave and aisles, constructed at a cost of about 2,400*l.* At some future period a spire and other portions will be added, the cost of the complete design being estimated at upwards of 3,000*l.*

Liverpool Deputy-Surveyorship.—At the last meeting of the Liverpool City Council it was resolved,—"That, having regard to the long and faithful service for upwards of thirty-five years of the Deputy Corporation Surveyor, Mr. George Handson Rollet, he be relieved from the more active and responsible duties of his office, and that he be retained upon the staff at 300*l.* per annum, being two-thirds of his present salary, with the understanding that he affords to the Finance and Estate Committee from time to time, when called upon, any information or assistance they may require from him; this resolution to take effect from and after the 31st of December, 1880."

Royal Indian Engineering College.—The following, in order of merit, are declared by the Civil Service Commissioners to have been the successful candidates at the recent open competition for admission to the Royal Indian Engineering College, Cooper's-hill, Surrey:—Samuel P. H. Dyson, Henry R. Hackman, Adolphe E. Orr, H. E. Pellereau, Cyril E. A. Jones, Thomas H. Clowes, Edward H. S. Napier, Henry M. J. Bacon, John N. A. Eaton, Henry H. Green, Frederic J. Robinson, James M. Jamieson, Thomas T. Bonhote, Alfred Rowland, George W. Appleby, Cyril V. Joakim, Benjamin Douglas, Thomas R. J. Ward, Henry S. Jones.

The Obelisk.—The first of the two sphinxes intended for the pedestals at the foot of Cleopatra's Needle on the Embankment is now about to be reproduced in metal at the Eccleston Works, Pimlico. The casting will be about 5-8ths of an inch thick, and the colour of the metal as it runs in is, we are told, to be graduated, so that the face will be lighter in tint than the body. The second sphinx will afterwards be proceeded with. It is to be hoped no more time will be lost, so that the monument may be completed. Some elaborate lamp-standards for Northumberland-avenue are in course of production at the same foundry.

Trade Unions Congress.—The Thirteenth Trade Unions Congress will be held at Dublin during the week commencing the 13th of September. The Parliamentary Committee, of which Mr. Broadhurst, M.P. for Stoke, is secretary, state that they are meeting with the hearty co-operation of the various Irish trades, and that at least thirty Irish delegates will attend the Congress. Dr. W. Neilson Hancock, Q.C., Professor Ingram, LL.D., Fellow of Trinity College, and Mr. Thomas Brassey, M.P., have undertaken to deliver special addresses.

Clacton-on-Sea Improvements, — The slipping and disintegration of the cliffs, and consequent wasting-away of the land on the Essex coast, have led to the formation of a Board of Commissioners, under an Act obtained this session, for the purpose of raising money to carry out certain sea-defences at Clacton-on-Sea. Designs for a new sea-wall, with promenade, concrete groynes, and other works, have been prepared by Mr. Charles W. Whitaker, of Westminster, and these works are to be commenced immediately. The sea-wall and promenade are to be about a mile and a quarter in length, and the face of the cliff is to be laid out in slopes and paths of an ornamental character.

Repairs to Thames Bridges.—At the last meeting of the Metropolitan Board of Works, the Board accepted the tender of Mr. Manley, amounting to 427*l.*, for painting the ironwork of Albert Bridge; the tender of Messrs. Nowell & Robson, amounting to 4,198*l.*, for works of repair to the carriage-way of Albert Bridge; the tender of Mr. Cook, amounting to 3,700*l.*, for altering and repairing the carriage-way and footways, and repainting the ironwork of Wandsworth Bridge; and the tender of Mr. J. Knight, amounting to 4,697*l.*, for paving the carriage-way of Waterloo Bridge with granite.

The Employers' Liability Bill.—In the House of Commons on Wednesday, Mr. Gorst moved an amendment that the provisions of the Employers' Liability Bill be extended to Government workmen. This was negatived, and the Bill was read a third time and passed without a division.

Tylers' and Bricklayers' Company.—The following gentlemen were elected, on the 10th inst., master and wardens of this company for the year ensuing:—Master, Mr. Augustus Bird; upper warden, Mr. Stanley George Bird; renter warden, Mr. Frederick Mansfield.

A Presbytery and Sacristy are to be built at South Bank, near Middlesbrough, for the Rev. Thomas Holland. New schools to accommodate 250 children will subsequently follow. Mr. Martin Carr, of Sheffield, is the architect.

The Old Monastic Houses of Oxford.—On the 5th inst., the Rev. Father Goldie, S.J., gave a lecture in the public room attached to the Church of St. Aloysius, St. Giles's, on "The Old Monastic Houses of the City." The lecturer said that in 1111 Canons Regular of St. Augustine were installed in the Church of St. Frideswide, and continued here till 1542, when they were transferred to other houses to make room for the grand college contemplated by Cardinal Wolsey. The monastery of Osney was also in the hands of the Canons Regular of St. Augustine, and stood close to the cemetery outside the Great Western Station. It was one of the largest monasteries in England; the church measured 352 ft. long by 100 ft. in width. The Dominicans came to Oxford in 1221; here it was that Robert Bacon, elder brother or uncle of the celebrated Franciscans, became a Dominican monk, and having taught theology previously, continued to do so after his profession. He was an intimate friend of St. Edmund of Canterbury. The Franciscans, or Grey Friars, came in 1224, and found a home between Littlegate and St. Ebbe's Church. The Carmelites, known as White Friars, came in 1238, and lived in Worcester-street; it was here that St. Simon Stock graduated in 1244. Later on they received from Edward II. the royal palace of Beaumont, facing their convent. The Austin Friars came in 1252, and took up their residence in Holywell parish, outside the City wall; it was in their hall that the public defensions in theology were carried on till the middle of the fifteenth century, and the disputations in logic and philosophy till the dissolution. The Benedictines possessed Cloucester Hall from the year 1283, on the site now occupied by Worcester College; it was here that Thomas of Walsingham, and Winchcombe, the chronicler of Evesham, were educated. Durham College was founded in 1290, in Broad-street, by the Prior of Durham Abbey, for the young men from his monastery, and St. Mary's Hall was erected by the Canons Regular, for the same purpose, in 1435; Erasmus was here a guest in 1498. Archbishop Chichele built a house of studies for the Cistercian monks in 1436, and the church attached to the same was not consecrated till as late as 1530. The building is now known as St. John's College.

Oxford Main Drainage Works.—Acting on counsel's opinion, the Oxford Local Board have been unable to act upon a proposal to award their engineer, Mr. W. H. White, a gratuity of 1,000*l.* in consideration of extra services in connexion with the new main drainage works of the city. The total cost of the works, excluding the purchase of land, has been upwards of 120,000*l.*, and they were carried out and successfully completed by Mr. White, who prepared all the plans, specifications for contracts, took out quantities, and generally superintended the whole works without the assistance of any consulting engineer. It is calculated that if a consulting engineer had been employed his charges and commission would have amounted to 6,000*l.* at least. Mr. White's salary since 1873 has been 360*l.* per annum.

Arbitration: Lambeth Infirmary.—At the meeting of the Lambeth Board of Guardians on the 14th inst., a letter was read from Mr. Taylor, the builder of the new infirmary, asking the Guardians to devise some means of coming to a settlement with him, the arbitrator, Mr. Stephenson, being still very ill, and it is uncertain when he will be well enough to resume the arbitration. Mr. Smallman observed that, in the event of the arbitrator not being able to resume the arbitration, there was a possibility that the whole case would have to be gone through again. Up to the present the Guardians had incurred expenses amounting to over 550*l.* It was stated that Mr. Taylor's claim was 6,000*l.*, but that, while he had offered to take 3,000*l.*, the Guardians only offered 1,000*l.* It was resolved to lay the matter before the Board's solicitor and the architect, to try and effect a settlement.

The Stratford Vegetable Market.—The Great Eastern Railway Company's fruit and vegetable market at Stratford has proved so successful that it has been enlarged. Messrs. Bangs & Co. were the contractors for the work, their foreman being Mr. Hollow. The central vaenue of the enlarged premises is nearly 700 ft. in length and 50 ft. wide, and the twenty-one compartments, or warehouses, are well adapted for the transaction of any trade. There are several lines of railway which afford every facility for the conveyance of goods.

Health Precautions for Factory Operatives.—A recently-published German work gives details of the precautions taken to preserve the health of the workmen in a large manufactory of coal-tar colouring materials, on the river Main, where more than a thousand workmen are employed. The men are not only requested, but practically required, to spend twenty-five minutes a day in the bath, and this time is reckoned as a portion of the working-hours. Bath tubs of special construction are provided for the use of those engaged in the violet and green rooms, while all the workmen actually occupied with colours receive clean suits of clothes every week from the proprietors.

Viollet-le-Duc.—It may not be uninteresting to those familiar with the deceased artist's works, to learn that the proposal to erect a monument to his memory has resolved itself into the resolution to publish, with the subscriptions gathered and yet to come in, a volume of a hundred plates, producing the more remarkable compositions of the deceased artist, —not alone his purely architectural designs, but those be prepared for the decorative painters, the sculptors, the metal-workers, and the carpenters. It would be difficult, we imagine, to find a means of keeping alive his memory which would be more in accordance with the undeviating modesty of the late eminent architect.

International Exhibition at New York in 1883.—The Act of Congress incorporating an International Commission for holding a World's Fair at New York in 1883, calls for the appointment of two commissioners from each State and one from each Territory, these to be joined to the commissioners named in the Act, the entire number to constitute a commission for initiating and conducting the enterprise. Pursuant to this Act the necessary appointments have already been made, and the Commission will soon commence active work.

The Value of Health.—The Ashford Local Board (according to the *Daily Chronicle*) recently appointed Dr. Wiglesworth, of Hamstreet, a village near that town, medical officer of health for their district, which comprises a population of 10,000, at a salary of 25*l.* per annum. The Local Government Board refused to sanction the appointment at such a salary, but the Ashford authority have now appointed Mr. Philip Phelps, another local surgeon, at the same stipend, after a proposition that the salary should be 15*l.* It remains to be seen what further steps the Local Government Board will take.

Completion of Cologne Cathedral.—At ten o'clock on Saturday morning, the 14th inst., the last stone of the cross ornamenting the top of the pinnacle of the second of the two great spires of the cathedral of this city was finally fixed in its place. On all the public buildings and many private houses flags waved in honour of the event.

Death of a French Sculptor.—M. Lemair, the French sculptor, died on the 4th inst. at the age of 82. Among his best-known works are statues of Kleber and Hoche, and Louis XIV. at Versailles, and the Madeleine front in Paris, representing Mary Magdalen at the feet of Christ.

TENDERS

For Holy Trinity Church, Burton-on-Trent. Mr. J. Oldrid Scott, architect:—

J. & R. Roberts, London	£21,872	0	0

* Accepted.

For additions to the Wilts and Dorset Bank at Christchurch. Mr. Fred. Bath, architect:—

Davis & Son	£964	6	0
Hyde	924	14	0
Cooper	836	8	0
Jenkins & Son	819	0	0
George	730	0	0
Walden (accepted)	702	15	0

For additions to a residence at Milford, Salisbury. Mr. Fred. Bath, architect. Quantities supplied:—

Wort	£671	2	4
Matthews & Tomkins	636	11	1
West	595	8	0
Harris	547	14	0
Walker	543	6	0
Dolman	542	0	0
Cooper	536	10	0
Young & Sons (accepted)	520	0	0

For roads and sewers on the Old Park Estate, Enfield, the property of Mr. S. Sugden. Mr. S. Hickson, surveyor:—

Bell (accepted)	£2,095	0	0

For the erection of ironing-room, offices, and shops, Marsh-lane, Southampton, for the South Hants Steam Laundry Co., Limited. Mr. W. H. Mitchell, architect:—

Brinton & Bone	£1,739	0	0
Rowland	1,698	0	0
Chapman	1,666	0	0
Dyer	1,580	0	0
Crook (accepted)	1,547	10	0

For the erection of a villa residence in the Overhill-road, Lordship-lane, for Mr. James Henderson. Mr. R. Peters, architect. No quantities:—

Watson & Dennett, Dulwich (accepted)	£1,450	0	0

For gardener's cottage, including fence-walls, Finchley, for Mr. A. Saunders. Mr. Walter Graves, architect:—

Cooper (accepted)	£332	0	0

For alterations and additions to two houses, Wimbledon-hill-road. Mr. Alfred G. Olley, architect. Quantities supplied:—

Brazier, Wimbledon	£1,972	0	0
Ackermann, Wimbledon	1,854	0	0
Rodwell & Smith, Brixton	1,695	0	0
Harmer, Wimbledon	1,649	0	0

For offices in Fisherton-street, Salisbury, for Messrs. Toomer Brothers. Mr. Fred. Bath, architect:—

Cooper	£284	0	0
Young & Sons	280	0	0
Harris (accepted subject to revision)	235	0	0

For repairs to the lodge at Lewisham Cemetery. Mr. Horace T. Bonner, architect:—

Godart & Co., Mile End	£344	0	0!
Carter, Deptford	325	0	0
Davis, Peckham	289	0	0
Jeal, Lewisham	268	0	0
Taylor & Sons, Upper Thames-street	249	0	0
Higgs, Dorset-square	248	0	0
Benson, 19, Red Cross-street	219	0	0
Ayres, Woodford	210	0	0
Buchan, Camberwell	195	0	0!

For building two houses, Sidcup. Mr. Horace T. Bonner, architect:—

Smith & Scarborough, Peckham *	£1,150	0	0

* Accepted.

For alterations to the Green Dragon, Bermondsey-street, Bermondsey. Mr. Horace T. Bonner, architect:—

Godart, Mile End (accepted)	£173	0	0
Higgs, Dorset-square	163	10	0
Pitcher, Mile End	155	0	0

For the erection of a dairy, The Broadway, Wimbledon, for Mr. A. Gorton. Mr. William Crisp, architect:—

Dunford & Langham	£703	0	0
Johnson	558	0	0
Row (accepted)	518	0	0

For lodge, mortuary-house, boundary-fences, ground-work, and drainage, at St. James's Church, Enfield Highway, for the Enfield Burial Board. Mr. F. W. Searle, surveyor:—

	Lodge, mortuary, boundary-fences, &c.			Ground-work and drainage.

For repairs, decorations, &c., at 5, Park-crescent, for the Lord Mayor. Mr. William Wimble, architect. Quantities not supplied:—

Macintosh	£432	0	0
Colls & Sons	326	0	0
Jackson & Graham	317	0	0
McLachlan & Sons	312	0	0
Vernell & Griffiths	299	0	0

For cottages and shop, for Mr. Thos. Phipps, Swindon. Mr. William Drew, architect:—

Henly	£1,125	0	0
Pettifer	1,044	0	0
Conway	978	0	0
Franklin	931	0	0
Webb	912	0	0
Cavill (accepted)	900	0	0

For alterations at the Foresters' Arms, New Swindon, for Messrs. Arkell & Sons. Mr. William Drew, architect:—

Kent	£238	0	0
Phillips	220	15	0
Henly (accepted)	205	13	0

For new hilliard-room, &c., at the Great Western Hotel, New Swindon, for Messrs. Arkell & Sons, of Kingsdown Brewery, Swindon. Mr. William Drew, architect:—

Webb	£768	0	0
Phillips	759	0	0
Looker	742	10	0
Wiltshire (accepted)	734	12	0

For additions to dwelling-house in Castle-street, Salisbury, for Mr. George Fulford. Mr. Fred. Bath, architect. Quantities supplied:—

Hale & Sons (accepted)	£600	0	0

For two detached villa residences, Middle-lane, Hornsey, for Mr. L. Koller. Mr. J. Farrar, architect:—

Grover	£4,573	0	0
McFarlane	4,405	0	0
Smith	4,396	0	0
Lawrance	4,379	0	0

NOTE.—The responsibility of signed articles, and papers read at public meetings, rests, of course with the authors.

NOTICE TO SUBSCRIBERS.

THE INDEX and TITLE-PAGE for Volume XXXVIII. (January to June, 1880) was given as a Supplement with our Number for July 10.

A COLOURED TITLE-PAGE may be had, gratis, on personal application at the Office.

CLOTH-CASES for binding the Numbers are now ready, price 2s. 6d. each; also

READING-CASES (Cloth), with Strings, to hold a Month's Numbers, price 2s. each.

THE THIRTY-EIGHTH VOLUME of "The Builder" (bound) is now ready, price Twelve Shillings and Sixpence.

SUBSCRIBERS' VOLUMES, on being sent to the Office, will be bound at a cost of 3s. 6d. each.

TERMS OF SUBSCRIPTION.

"THE BUILDER" is supplied *direct* from the Office to residents in any part of the United Kingdom at the rate of 19s. per annum, *prepaid*. Remittances payable as above.

The Builder.

Vol. XXXIX. No. 1960. Saturday, August 28, 1880.

CONTENTS.

Bricks, and their Historical Interest.

IN the antiquity of the brick as a building material it is needless, nor is it indeed our intention, to insist. The great national collections of Europe, the British Museum foremost in the number, show us bricks, sun-dried and baked, from the ruins of Nineveh, and from the days of that city to the present moment bricks have never ceased to be an important instrument in the hands of the builder. That throughout Asia Minor they were largely employed we have seen only very recently proved in these columns, M. Rayet, in his work on Miletus,* having shown that the far-famed palace of Crœsus was built of no more costly materials than honest brick; what those bricks were, and their quality, are even to this day appreciated by the natives, who, for many centuries, have plundered the ruins to build or to patch up their own even more ruinous houses. The use of bricks among the Romans, who largely employed them as building materials, as we see in the familiar instance of the Temple of Concord, has been more than once the subject of the inquiry of industrious antiquaries, for the Romans were not content with producing the flat, tile-like brick which is so often to be met with in the lower portions of antique structures scattered over the Empire, and that are known in England, but their bricks were indelibly stamped with the mark of their maker, the names of the reigning consuls, and sometimes the year. From this source, then, more than one patient archæologist has gathered a rich store of information. But few inquirers have ventured far on the apparently arid and difficult road, which has hence remained little explored. Some curious information has, however, been lately thrown on the question by the researches of a French antiquary, M. Descemet, who has published in a recent number of the *Bibliothèque des écoles d'Athènes et de Rome*,—an excellent publication, founded in 1877 and now at its seventeenth number,—an article on the "Inscriptions doliaires latines" or Roman brick-marks, more especially relative to the *gens Domitia*, in antique Rome the most renowned brick-makers.

From an epigraphical point of view the brick-marks of the Romans have aroused the attention of more than one archæologist, but the difficulties which have stood in the way of procuring the stamps, added to the enigmatical nature of the inscriptions themselves, have led the inquirers to fields where the results were more showy and more easily obtained. M. Descemet has long been known to the antiquarian world; as far back as 1857 his "Fouilles de St. Sabina" attracted no little attention, as also, in 1876, his study, "Sur quelques Règles de Briques antiques," published in the *Bulletin de Correspondence Archæologique*. In possession of a valuable collection of stamps of his own, together with copies from the brick-stamps of the Vatican Museum, M. Descemet had at his disposition more than ordinary sources of reference, and the result of his study has been the work the title of which is above given.

The Italian antiquaries of the seventeenth and eighteenth centuries, Nardini, Ciampini, and their contemporaries, had not largely drawn on the store of historical information afforded by the Latin brick inscriptions; Fabretti was, indeed, the first to set into any order the more remarkable of these, but his efforts were merely tentative; his collection of inscriptions was unclassified and incomplete. It was reserved to the worthy Abate Gaetano Marini, the curator of the Vatican Museum at the close of the last century, to put together in a methodical manner the stamped bricks of the choice collection under his control; this task he admirably performed, preparing a learned catalogue which however remained at his death in an incomplete and manuscript form; but, such as it is, this manuscript, preserved in the Vatican Library, has proved a mine of information to all subsequent writers. Marini's catalogue was arranged with admirable order and carefully classified, each brick of the collection being the subject of numerous commentaries.

In spite of Marini's method, M. Descemet has adopted another system more suited to the requirements of the day, as rendered necessary by the considerable additions made to the list of brick inscriptions since the recent excavations. In his introduction, M. Descemet has carefully shown the importance of the study of these brick inscriptions by which the date of the erection of a building may be approximately ascertained. But as the author hastens to add, the fact of bricks bearing dates, or stamps being found in certain spots, is not, of course, conclusive evidence to the archæologist. Thus, in 1844, at Aix, in Provence, a brick of the year 123 was found, stamped with the mark of a Roman workshop, but the presence of this brick can alone be accounted for by the effect of accident, as it was scarcely possible that a town near Marseilles, so long famous for its pottery, should receive its bricks from Rome. On the shores of the Adriatic, at Pola and Zara, and in other towns of Istria and Dalmatia, the existence of a large number of bricks bearing the stamp of Rimini would tend to show that the brick trade, which still exists on both sides of the Adriatic, can be traced back at least eighteen centuries.

But apart from the geographical information these stamped bricks afford, the inscriptions they bear throw not a little light on an ill-known state of Roman society,—the education of the slaves, who though we have classic evidence proving that they were placed under schoolmasters, would seem to have little profited by this education, as the inscriptions it was their duty to stamp could only have had their letters placed upside down or transposed (as they are often found) by persons unable to read, who copied as well as they could a model under their eyes.

How these stamps and brick inscriptions were made is a point of some uncertainty. Had the ancients moulds, or did they use movable types? This latter method would suppose a great invention of the fifteenth century to have been forestalled. M. Descemet, who devotes some pages to the discussion of the question, concludes in favour of the mould, such as we see examples of in more than one national collection. The stamp was cut in relief, or incised, and then,—like the hatter-print of the present day,—made use of. As for the character of the spelling to be met with, this would naturally arise from the want of education of the workman.

Among the various other points considered by M. Descemet, the reason why the Roman bricks bear the date of their production is not the least curious; but when Pliny's advice to the architect is remembered, only to make use of bricks when two years old,—"*ædificiis nonnisi bimos probant*,"—an explanation may, perhaps, be found. A point has been omitted by M. Descemet,—one to which attention is drawn in a recent able article in the *Revue des Questions Historiques*,—in his neglecting to refer to the palms, pine-cones, and animals so often found stamped on the Roman bricks. It is now known that with the potters whose name represented or recalled any object or animal, this object he stamped on the pottery or brick of his make. Thus, where we meet with the stamped image of a wolf, we may be sure that the workman's name was Lupus.

As the title of the work shows, it is alone to the brick inscriptions relative to the *gens Domitia* that attention has been paid. Why this *gens* has been chosen the author explains. It would appear that the *gens Domitia* possessed the largest and most important of the brick manufactories of ancient Rome. Apart from this, the *gens* takes no mean place in the history of Rome; in the person of the virtuous Marcus Aurelius, it ascended the imperial throne. From the brick inscriptions gathered, the wealth of this emperor would appear to have been enormous, as we learn by the large number of workshops his *gens* employed, in company with those

* See *Builder*, *ante* vol. xxxix., p. 39.

of the *gens Aria* which he inherited through his marriage with Faustine.

The interest of this quiet and apparently little-inviting study would be thus seen to be great. Its historical value is no less appreciable. We are comparatively far from the days when the history of ancient times was merely gathered from former texts; the aid afforded by numismatics and epigraphy is largely called into requisition by the more serious modern historians. This little work of M. Descemet shows us how, even from the humble sources of the brick inscriptions, important facts may be gathered. The careful and beautifully-cut Roman stone inscriptions, so easy to read, are not sufficient; the research can be carried farther, as we see, for instance, in the study by M. Dumont on the ceramic inscriptions of Greece,* and even more strikingly in the delightful study which M. Dressel published some time since on the shattered *débris* of Monte Testaccio.† M. Descemet's inquiry into the brick-marks of ancient Rome has already yielded some curious information; it is to be hoped that his success will encourage him to further study in this yet far from exhausted field of archæological research.

BUILDING AND SCULPTURE IN LIVERPOOL.

The most important building in progress in Liverpool at present is the new Law Courts, which form a large rectangular block in the rear of the municipal buildings. The building is solid and sensible, rather than picturesque, in this respect forming a curious contrast to the Police Courts' building, at Manchester, in which picturesqueness of arrangement and effect was perhaps even too obviously aimed at. The Liverpool building is Italian in style, of very orthodox type in the main; the principal entrance-door is treated with some originality in detail, and seems to be an excellent bit of mason's workmanship. The building is now approaching completion as far as the shell is concerned. Not far from it the two principal Liverpool papers—the Liberal *Daily Post* and the Conservative *Courier*—are established in large and handsome premises opposite to each other; the latter has been there for some little time,—the building for the former is nearly new, and is noticeable as being one of the few specimens in Liverpool of the recent brick-style which has become so popular in London. The building has been carried out by someone who understands the style in question as at present accepted. The workmanship is excellent, and some of the detail in the lower part of the building is good, absolutely; the upper portion is good, relatively, that is to say, it is good in the eyes of those who care for festoons in cut brick, and that kind of *rococo* ornament. These buildings form part of the new lining of the wide street which was made some years ago as a central line of route from the Pier-head and Town Hall neighbourhood up to St. George's Hall and its *place*, cutting through a number of small alleys and back streets,—doing for Liverpool, in fact, pretty much what in London we are waiting to see done between St. Martin's-lane and Tottenham-court-road. The new street, however, has been slow to fill up with new buildings, and has still a good deal of blank margin. The Law Courts before mentioned abut upon it, and have their principal entrance from it. From this street a good view is obtained of the buildings on the rising ground where St. George's Hall stands; the group of buildings on the left, the Free Library, Picton Reading-room, and the Art Gallery, showing in a very agreeably varied perspective,—the Reading-room looking better here than from a nearer view, since its domed roof can be seen. When mentioning the opening of the Reading-room some time ago, we noticed the very large amount of echo in it, yet hoping that this would not be a serious drawback in a room intended for reading, and not for speaking in. We have since heard, however (and the fact is worth record for the attention of those who have to build reading-rooms), that the echo has proved a very serious annoyance, the merest whisper in some parts of the room sufficing to disturb readers very much. The room is evidently more or less modelled on the British Museum Reading-room, and the reason why an annoyance from echo is felt in it which is not felt in its prototype we take to be merely the difference of size. The British Museum room is undoubtedly a success (except in regard to its abominably bad ventilation), but then it is so large that speech in a low voice does not disturb the air sufficiently to awake the echo always latent in a circular building. The Liverpool room being so much smaller, the disturbance of the air caused by speech has not distance enough to allow it to break up and be lost before reaching the walls, and it all comes back again with its original force little diminished, and focussed probably on to some unfortunate person who happens to be in the right position to receive the full benefit of it. There is no doubt that for the arrangement of the traffic and service of a reading-room the circular form is the best, as a matter of planning: and we should opine that the matter of echo might have been very easily dealt with, while leaving the circle, for all practical purposes of administration, intact. Instead of building the walls in a regular curve, in such a case, let the general plan of the circle be followed, but let the walls be built in sections canted slightly in alternate directions from the tangent of the circle, — in other words, forming a continuous zigzag with very obtuse angles. The varying direction of the wall-planes would thus break up and disperse echo, while preserving the circular form in the main. It wants nothing but a little exercise of common-sense, the quality in which modern architecture is so sadly deficient.

The middle portion of the view we are now taking from Victoria-street is filled by the western flank of St. George's Hall, with Elmes's admirable adaptation of Egyptian architecture in Greek form, the centre of which is cut across by the unsightly old church of St. John the Evangelist, the churchyard of which forms a large waste triangular space abutting against the flank of the Hall. One can hardly venture to expect the ultimate removal of the church, though it has not a single architectural feature to redeem it, and is a great eyesore in regard to the view of the Hall in its rear, but some attempt might be made to render the churchyard less waste-looking, by laying it out afresh and making it a little ornamental. A straight path has just been made across it (at least it seems quite a recent operation), a flagged footway, raised above the level of the churchyard, as a short cut from the lower to the upper angle of the churchyard, continuing the line of street, which the churchyard intercepts: this should have a good-looking railing, and, if possible, a row of small trees on either hand. Both this churchyard and another, that of the Corporation Church of St. Nicholas, near the pier-head, seem to want reform very much: that of St. Nicholas, which is finely situated, so as to overlook the river, is becoming gradually surrounded with a better class of buildings (offices, &c.) than before, but the churchyard itself is a desolation, —old battered gravestones, with grass showing fitfully between them. The churchyard is a public thoroughfare, the shortest footway between the pier and the Lancashire and Yorkshire Railway Station, and its present condition is not reputable. There are, of course, difficulties in dealing with churchyards so full of old graves as these; but something must be done with them sooner or later, and it might as well be "sooner." The example has been set in different parts of London (East London especially) as to what may be done in the way of making disused burial-grounds into places agreeable to those who are not yet buried; and the larger provincial towns should follow the example.

The new half of the London and North-Western Railway Station (that known in "Bradshaw" as "Lime-street") is now open for traffic. The station is now probably the largest in area, though not the longest, of all provincial terminal stations, and great expense and trouble must have been incurred in widening the railway approaches, and throwing open part of the tunnel with this object. The whole station is now comprised under two great iron roofs of very large span, the new roof starting from iron columns contiguous to and coupled with those which carry the eastern side of the old roof. The old part of the station is fronted towards the street by Mr. Waterhouse's North-Western Hotel; the new portion, if the present termination represents, as it apparently does, what is ultimately to be the visible elevation, has been fearfully bungled from an architectural point of view. There is a slight angle in the line of ground at the end of the station, that is, there must have been some such angle in the boundary-line of the property to give any excuse for the treatment of the front, which is bent at an obtuse angle outward, just in the centre, without any attempt to mask the deformity by treating the design of the front in accordance with this circumstance. The "design" consists, in fact, of nothing but a row of pilasters under the end of the iron roof, and this pilaster front is broken-backed, and the end roof-principal the same. Anything more gratuitously clumsy in appearance could hardly have been done. When one considers how much effect might be got out of railway stations if they were treated with average architectural taste, it is really vexatious to see this kind of thing done.

Since we last said anything about Liverpool the town has become the seat of an episcopal see, a fact which we allude to merely to mention the pro-cathedral church, the old parish church of St. Peter, which stands on one side of the street named after it, Church-street. Here is another large and disused churchyard with which something ornamental should be done: part of it, a strip lining the street, was disturbed a good many years ago in the necessary operation of widening the street. As to the church itself, it certainly is a very staid, respectable, rather dingy edifice, and yet there is a certain character about it, and it is one of the relics of old Liverpool, for both of which reasons we hope the town will not by any means be led into removing it to make way for a new church; the site for the latter, when the money is forthcoming, had much better be found elsewhere, and the old building left as a church of historical interest, and possessing, moreover, an interior very well adapted for congregational worship and capable of some "treatment" in a decorative sense.

The rebuilding in a better style of Lord-street, Church-street, and Bold-street, which, nearly in a line with each other, form the principal shopping streets of Liverpool, seems to proceed much more slowly than elsewhere: we have before noticed the same thing in Manchester, where every street seems in course of improvement and beautifying except the main street, Market-street. Probably the reason of this is that the shops in such streets usually are old concerns with a well-established connexion, the owners of which find no object in spending their money on making a show. Street rebuilding seems a little quiet at present in Liverpool, but a great deal has been done of late years, and much of it is very good. Classic tendencies prevail in the newer buildings, but it is often Classic with considerable variety and novelty of detail, and we should certainly say that on the whole a better and more dignified taste is shown in the aggregate of the more recent Liverpool street buildings than in the often eccentric and "fussy" Gothic which has been developed in Manchester in similar edifices.

In the *place* which is formed contiguous to St. George's Hall and the Library and Art Gallery, of which the Wellington Column (a parallel of the Nelson Column in Trafalgar-square) is the central object, there is now a fountain, by way of completing the reminiscence of Trafalgar-square; a much better fountain, as a design, however, than the two on that famous site, with a basin supported by figures well modelled, if not suggestive of anything very original or romantic; and the fountain seems to be liberally supplied with water, and makes a very pleasant episode in the centre of the irregular open space. An effort to combine foliage with architecture is made hereabouts; the Art Gallery has its sloping green embankment and some shrubs within its balustrade, and there are shrubs in large tubs round the fountain. Stone-ware vases would look better. The analogous position to that which the National Gallery occupies on "the finest site in Europe" is here occupied only by the rather mean-looking small shops and houses of "Commutation-row," which skirts the upper side of the *place* and faces the spectator ascending the rise between the Library and St. George's Hall. If there could only be a good excuse found for the erection of a really fine building flanking the upper side of the *place* where Commutation-row now stands, forming a background to the Wellington Column and the fountain, and a culmination of the architectural effect in this direction, such an improvement would be more effective than anything, and would give the best finish to what has in it

* See Archives des Missions scientifiques.—2ème série, tom. v.

† See Annali dell' Istituto di Corresp. Archæol., tom. L., 1878, pp. 118—192.

even now the making of an effective and stately architectural combination.

One point in connexion with the Art Gallery, which in general we have previously described, may be mentioned: the has-reliefs in the long panels on each wing of the building have now been completed; the space only was left for them before; and they are worth a word, as they appear to be an attempt to treat subjects of the present day as motivee for architectural sculpture. What is their precise intention we do not too hastily assume to understand, but they would seem to represent the procession to open the Gallery—at least, there is recognisable a carriage-and-four, one of the occupants of which is taking off his hat, presumably to an applanding crowd; and the general movement of other figures, mounted and unmounted, in the composition, confirms the idea of a procession. This is no doubt precisely the same kind of reference to events of the day which characterised the Panathenaic frieze of the Parthenon, and the has-reliefs of the Arch of Titus and of the Trajan column, except that in the Panathenaic frieze we opine that there was rather less of realism and more of conventional treatment than some critics have thought. It certainly seems very like common sense to treat architectural sculpture on the same principle, in regard to the events of the day, which was employed in a good deal of the ancient architectural sculpture which we now admire or feel interested in. We entirely approve of making the experiment, at all events; and yet how is it that, even while commending it in this sense, we find it impossible to escape from a certain sense of the ludicrous in looking at it? Is sculpture, after all, an anachronism in regard to modern life? Are we too practical and self-conscious to look at such things with the simplicity of feeling with which they were once regarded? This would hardly explain our different estimate of the Trajan and Titus basreliefs, either; for Rome when those were done was highly artificial and self-conscious herself. Is it that historical events and the lapse of time impart to the old sculptures an interest and a dignity which are perhaps really adventitious, and which did not belong to them in their own day?

"Or is the Caucasian played out?"

as "Truthful James" suggests in one of Bret Harte's lyrics: are modern life and modern costumes and manners too devoid of dignity or sentiment to have any interest in sculpture, or to look otherwise than semi-ludicrous when so treated? It is to be feared the last is nearest the truth. Anyhow, it may be admitted that for general decorative effect in regard to the architecture of the building this does as well as anything else; considered in detail, it will be perhaps (if it stands well) more interesting to future generations, to whom it will represent a fact in the town's history, than to spectators at present. But we suspect that for present enjoyment, sculpture is an art for idealism, not for realism. The realism of the present day is pictorial, not sculpturesque.

This subject of architectural sculpture reminds us of the omission which still remains, without apparently a thought of supplying it, in the great building of Liverpool, St. George's Hall. We have over and over again called attention to the fact that Elmes's building is entirely incomplete without the sculptural decoration which was intended; and that to leave it as it is is doing the greatest injustice to the memory of its architect and to the building itself, which is certainly the most remarkable effort in reproducing Greek architecture which modern Europe can show. The building was intended to have statues on the screens between the square columns, and has-reliefs on the square panels below, which remain to this day waiting to be worked. There has been great profession of activity about art in Liverpool of late years, and yet the one thing which ought to have been done first has been utterly overlooked, and seems likely to be so still, for it does not appear as if any one either knew or cared anything about it. If the money expended on the colossal statues in connexion with the Art Gallery, the effect of which is very doubtful, had been expended in making at least a beginning of completing the sculptural decoration of St. George's Hall, it would have been much more sensibly and suitably laid out. It is really astonishing that so much should be said, and so much money have been spent, and so many speeches made in Liverpool about the encouragement of art, and that the most obvious claim on the attention of those who wish to promote artistic production there should be persistently overlooked. If the Liverpool amateurs and connoisseurs wish us to believe that they know and care as much about the promotion of art as they say they do, let them "turn to" and encourage the much-neglected and illused modern sculptors, by giving some of them commissions to execute the sculpture for want of which their most remarkable building has been standing all these years unfinished and forlorn, a discredit to the taste and enterprise of the town.

ON SOME POINTS IN THE LAW OF LIGHT AND AIR.

One may fairly doubt whether any subject causes more litigation than does that of the right to light and air. Of course, in many cases the only question in dispute is one of fact: whether, indeed, there has been such a deprivation of these elements as will enable a court of law to interfere, or whether the person who comes to the court for protection has any right to the light and air which he claims, so as to enable him to ask for the protection of the law. Sometimes, however, in spite of the number of decisions which have been given from time to time on this subject which are purely legal in their nature, and set forth some principle of law, others are given of a similar character which show how difficult it is to say that any branch of law can be considered as finally and definitely formed. The questions which were raised in the recent case of the Ecclesiastical Commissioners for England *v.* Kino (19 *Law Journal* Reports, Chancery Division, p. 529), which was decided during the current year, first of all by Vice-Chancellor Hall, and next by the Court of Appeal, can hardly be said to be quite novel ones. But the fact that the Court of Appeal thought it necessary to deliver elaborate judgments on the points submitted to them,—"very interesting points," as they were styled by Lord Justice Bret,—shows that, until this decision, the law on the questions argued could not have been considered as settled, so as to be a firm and undoubted guide for those who might desire to ascertain their rights. More than one point was raised in the arguments touched on in the judgment, but there are two to which we specially wish to draw the attention of those who are interested in the law relating to buildings.

The first was as to the right of the owner of the site of a demolished building, which, before it was pulled down, had a right to light and air through certain windows, to prevent a neighbour from building so as to diminish the light which would have come to those windows if they remained as they were. The point had been before Lord Justice Giffard, in December, 1869, in the case of Staight *v.* Burn (39 *Law Journal* Reports, Chancery, p. 289), and had been decided in favour of the applicant. That case, however, seems by some to have been assumed to have been decided on collateral points, and, indeed, the question of alteration of the premises does not, from the report, seem to have been argued at any length. In the judgment of Vice-Chancellor Hall in this last case the decision of Lord Justice Giffard is not mentioned at all, and the application is characterised by the judge as being "one which has not hitherto been presented to the Court." Accordingly it was dismissed by him, and so came before the Court of Appeal.

The facts of the case, so far as they were required to raise the point of law, were comparatively short and simple. Under the provisions of a certain Act of Parliament, the Church of St. Dionis Backchurch, and the fabric and site, with all its rights, easements, and appurtenances, became vested in the Ecclesiastical Commissioners in fee simple. In the south side of this building there were three windows, each 6 ft. 6 in. wide and 12 ft. high, and another nearly 6 ft. wide and 3 ft. high, occupying the arch over the south door. These had acquired the right to light. Under the Act of Parliament, this church was pulled down, careful plans and measurements of the edifice having previously been taken, so as to preserve a proper record of the position and extent of the ancient lights. The church, it may interest our readers to know, had been rebuilt by Sir Christopher Wren, and we may, perhaps, be permitted to ask once more whether it is advisable to pull down these historical buildings in this summary fashion. But this is only by the way; we are now concerned with the legal rather than the artistic or antiquarian character of this church. Since it had been pulled down, the defendant had begun to erect a new building opposite, and it was already carried up to the height of 30 ft. Hence arose the action. It may also be well to add that the site of the church had been put up for sale in June, 1879, as building land, but had not been sold, and also that after the issue of the writ, but before the motion for an injunction came on, the Commissioners had erected a temporary wooden structure, with apertures corresponding to the old windows. Under these circumstances, as we have already mentioned, Vice-Chancellor Hall considered that the Commissioners had no right to ask the Court to protect the ancient lights. But the Court of Appeal was of a different opinion, and considered that they could issue the injunction which was asked for. The cardinal point of the decision was, perhaps, most clearly expressed by Lord Justice Brett, who pointed out that the question first of all was, whether there was such a right, and next, whether there was evidence to show that it has been abandoned. If it has not been abandoned, then the right still exists, and so existing entitles the owner of it to ask the protection of a court of law. But this general proposition seems to be qualified by the proviso, so to say, that the windows are within a reasonable time to be restored, because if they are not it would obviously inflict great hardship upon an adjacent owner if he were prevented from building when after all he would not interfere with any one's right. In the present case, Lord Justice James remarks, "If the windows should be restored, as I believe they will be;" and Lord Justice Cotton states, "Upon the evidence, and from the position of this property, I should say we must arrive at the conclusion that within a short time, having regard to its situation, not only will the land be sold, but that it will be covered with buildings, and I think we may come to the conclusion that the purchaser will put up his buildings so that the windows may have the enjoyment of the old right of light." It is clear, therefore, that the proviso, as we may call it, is pretty sure yet to come for further elucidation before the Courts of Law, but when it does it will, as it seems to us, be chiefly a question of fact whether the owner of the ancient lights has abandoned his right to them. Thus if it were proved that in the buildings to be erected no provision was made for preserving the windows in the original places it might reasonably be presumed that the right had been abandoned. To those who, like most of our readers, are accustomed to matters connected with buildings, other instances will suggest themselves. It is satisfactory, however, that the law is now clear that by pulling down a building with ancient lights the right to such lights is not *ipso facto* abandoned.

The second question decided in this case is one which, as Lord Justice Brett says, deals with a subject which it is startling "to find relied on either as a kind of legal doctrine, or as a rule of evidence which is to make a *primâ facie* case." That is the angle of 45°. As Mr. Banister Fletcher has pointed out in his little work on "Light and Air" (p. 68), this angle of 45° is of no real value, and the sole question is, has there been a substantial interference with a plaintiff's light? For Lord Justice James points out in vigorous terms that "the rule of 45° is a matter of very slight importance. It may be an element in the case, but it is a very small one indeed. It is only to be used as a sort of test in the absence of any other mode of arriving at a conclusion, but it is no rule of law,—no rule of evidence, no presumption of law, and no presumption of evidence, except of the very slightest kind." That is pretty downright language, and after it no one can rest under the delusion that the angle of 45° is of much value in questions as to the diminution of light. No doubt some of the language of previous decisions, such as that of Lord Selborne, in the City of London Brewery Company *v.* Tennant, has caused the idea to get abroad as to the value of the 45° test: it appears to have arisen, to quote Lord Justice Cotton, "from referring loosely to the Metropolitan Building Acts without looking at the clause." In fact, if the Metropolitan Local Management Act, 1862, s. 85, is examined, we find the foundation of the error, and see the falseness of the conclusions drawn from it. Thus the case we have been discussing is further of service, since it has cleared away the ground in regard to a matter

likely to cause much misapprehension. We have, in fact, in questions as to the diminution of light, only this one point to decide,—is there a real interference with an existing right? If there is, no amount of scientific theories,—of rules taken from legislative enactments,—will suffice, and the plaintiff must inevitably succeed in obtaining the protection of the Court. There can therefore be no question that from the date of the decision in the case of the Ecclesiastical Commissioners *v.* Kino, a more settled state of the law on this point will certainly exist, and the litigation between these parties will have been most valuable in the interests of owners of buildings, and for the assistance of those who have to aid them by their professional advice.

AIDS TO THE STUDY OF ART.

Public opinion, both in the House of Commons and in the Press, has responded with unusual unanimity to the plea that aid should be given to the study of art by the transmission to the various local centres of art-teaching throughout the country of such duplicates or copies of the *chefs-d'œuvre* of our metropolitan museums as can be spared or provided. As to the importance of providing the students with the best available models and examples, there is but little that is new to be urged. The question of duplicates is a more complicated one. It is urged by those who should know what they are talking about, that the duplicates, properly so-called, possessed by the British Museum, are few, and that their money value to the parent institution is greater than their art value to the subsidiary establishments. As to this, however, there is some evidence that the sale of what are called duplicates is a mistake. The market value of such articles is rapidly on the increase. Not only so, but many engravings or rare books which may be roughly described as duplicates, are really distinct states, or stages, of the work of the engraver or of the printer. As such, they not only are of value as illustrating the history and procedures of art, but they greatly enhance the value of those better-known originals to which reference is usually made. Thus, whether we regard it as a purely financial question, or look at it on the broader grounds of art, it may prove a matter of very short-sighted policy to sell these so-called duplicates.

One thing strikes us with reference to this part of the debate. The curators and managers of our museums are at present the only persons who can speak with full information, if even they can do so, on the subject of the treasures in their keeping. The teachers and students of art are naturally desirous of being able to form their own opinions on the subject. This points to the imperative need of accessible catalogues. One man tells you that the vaults of the British Museum are full of priceless and hidden treasures, which might, to great advantage, be distributed through the country. Another man replies that the so-called treasures are little better than rubbish. No one can tell which view is correct, or where the line should be drawn between the two opposite views. The first step, therefore, to enable the educated part of the public to form an independent idea of the subject is to draw up a list of what these treasures are. On many grounds this is desirable, and the fulfilment of this requirement seems to us to be a necessary preliminary to any rational discussion of the subject.

The second part of the debate referred to copies. Here it should be remembered that the most famous works, especially those of sculpture, can only be known to the untravelled Englishman by the medium of copies. Again, the art of facsimile-copying is one that may be said to have been born within the last half or even quarter of a century. For some things, such as goldsmiths' work, bronzes, and medals, the *facsimiles* produced by the electrotype process may be said to deserve the title. There is, it is true, a very curious process of discolouration to which these electrotype works are subject, which may, possibly, in the course of years, greatly deteriorate their value. In cases of silvered or gilt electrotypes of which the substance is of copper, we have ourselves been surprised to witness the effect of this process, although we have not seen it anywhere mentioned. The British Museum now offer the invaluable boon of providing casts or electrotypes of their coins and medals at merely the lowest cost price. We have repeatedly availed ourselves of this advantage. Nothing can be more perfect than the facsimile when sent home. In such cases as the Papal medals, or the noble tetradrachm of Lysimachus, bearing the head of Alexander the Great, he would be a very good judge who could tell the copy from the original, apart from the test of weight. But leave the electrotype in your cabinet, or even carry it about as a trinket. The copper seems to weep through the silver or gold of the coat, and gradually the medal becomes discoloured. A sharp rub with a bit of wash-leather will restore the original beauty. But each time that this is effected a portion of the surface metal is removed. The gold becomes more cupreous, and sooner looks dirty; the silver more and more rapidly blackens. In fact, truth avenges itself, and the facsimile, however clever, is not permanent.

There is thus a limit to the durability and value of the most perfect reproductions,—those of the work of the goldsmith, the medallist, or the jeweller. As to bronzes, the durability may be greater. With regard to marble statues, the use of plaster-casts is familiar to us all. It is not every one, however, who has had the opportunity of comparing the effect of a good cast with that of the original. We do not think that all that is possible is often effected by the caster. The rawness of the white of the ordinary plaster-cast is distressing. In most cases when it has been attempted to obviate this it has been done at the expense of sharpness of detail. What is requisite is to reproduce the tone, colour, and apparent texture of the marble as carefully as the electrotypist reproduces those of his model. The waxlike finish of the finest statues, or the granular appearance of certain marbles, can, no doubt, be produced in apparent facsimile, if it be made worth the while of the skilled copyist to do so. It is idle to expect this from the man who produces casts for sale, or who is limited in his labour by being told that such and such is the outside that his work ought to cost.

With these points of reserve, the labours of the copyist may be made available, with great advantage, for our local museums. There remains the further method of reproduction,—photography. Here, again, there is a special danger. Photography lends itself so readily to effects which charm the uneducated eye,—by the very magic of their artless reflection,—that the offence they cause to the educated eye is but too apt to be overlooked. Take, for example, the fine permanent photographs of Italian sculpture which were originally taken in Rome, and which are now reproduced, we suppose, in London. The effect, at the first glance, is that of the Venus itself. The solid *impasto*,—if we may borrow the term,—of the carbon actually deposited on the paper has all the force, and fifty times the durability, of a chalk drawing. What can be more charming? What, indeed? but for one terrible defect,—the utter want of proportion due to the lens of the camera. The bolder the figure, the more pronounced is the distortion. After a time this distortion becomes so painfully apparent to the eye, that the idea of representing sculpture by photography is condemned by the judge of art. For the guidance of the pupil, at all events, these imposing pictures would be wholly misleading.

And something of the same sort is to be said as to the representation of great paintings by photography. Here, indeed, the laws of perspective are less obstructive to success. In dealing with a flat surface the disproportion due to the various distances of the different parts of a statue from the lens is avoided. The difficulty is not destroyed, but it is greatly diminished. But here arises another check. It is the chromatic difficulty. We may obtain, for example, a full-size photograph of one of the noblest of the Madonnas of Raffaelle. The drawing is perfect,—or nearly so; the expression,—how is it that the expression is not there? That quality which the engraver calls colour is absent from the photograph, or at least it is incorrectly given. The effect of the various pigments used on the light which is reflected from the surface to the camera is quite different from that which it produces on the eye. Roughly, indeed, this is known to all photographers. But how far, and in what direction, the change of aspect is effected is not known. We could produce an example in a proof photograph of a well-known picture in the National Gallery,—secured before the artist had time to "finish it,"—that is to say, to remove the effect which he neither expected nor liked. A visible patch covers the forehead of the Madonna. On observing this, the first thing to be done was to revisit the picture, on which no such blemish was remembered to exist. Neither did it,—or at least did it until a magnifying-glass was introduced. Then it became clear that the restorer had been at work! So well had he done his work, that he deceived the unaided eye. But the optical action of the pigments on the reflected light caused instant detection. In this way, besides the well-known action of the photographic process in refusing some tints and deepening others, the colour of a painting is often wholly misrepresented by the photograph.

There remains, however, one function of photography, especially of permanent photography, of which the value is unquestionable. That is, in the reproduction of drawings and sketches. Here we may look for absolute *facsimile*, if the paper be properly provided; and here, we may add, we have at once the means of preserving and of multiplying the most precious and most perishable portions of that great heritage of art which has come down to our days. As a rule, the sketches of the greatest masters seem to emanate more directly from their genius than do the paintings themselves. The more laboured and successful a painting, the more instructive are the preliminary sketches. And of how many designs have we the sketches alone? Photography fails to give a correct idea of such a painting as the Transfiguration, or as the Madonna di San Sisto. But photography can produce a true facsimile of Leonardo's drawing of the Virgin seated on her mother's lap, which was some years ago on the walls of Burlington House for a short time, and which then struck us as being, all things considered, the most exquisite work of human art on which our eyes had been privileged to dwell.

FROM THE BANKS OF THE SEINE.

We remember to have heard Horatio Greenough (the sculptor who, in the estimation of the Americans, stands only second as an artist to the painter Washington Allston), on his return from the United States, where he had endeavoured to pass through Congress a grant for some expenditure in works of art, remark that the sole interest he met with on the part of those to whom he applied was an antagonistic one, and this, we are afraid, is the interest too often taken by the Governments of Anglo-Saxon countries. Here in France it certainly cannot be said that the Parliamentary interest in art is an antagonistic one; there is a Minister of Fine Arts, and a very large and ungrudgingly-voted Fine-Arts Budget. Though millions may be expended on the army and navy, the Government have long since made up its mind on the political importance of the encouragement of the fine arts. While it would be far from desirable for our Government to take so active a part in the management and conduct, so to speak, of the fine arts, as is the case here in France,—a feature which daily gives rise to sad complaint,—a somewhat wider encouragement and assistance might be afforded by them to the arts. What this encouragement is in France, and of how substantial a nature, may be judged from the number of works of art which the Minister of Fine Arts has recently commissioned out of the budget for 1881, consisting of a long list of statues, busts, medallions, and pictures, the mere enumeration of which, and the towns for which they are destined, would amply suffice to fill a column of the *Builder*. The metropolis, Havre, Rouen, Amiens, Rheims, Versailles, Grenoble, and a large number of other cities, are to be enriched with memorials of their great men; in this manner the golden spur of emulation is industriously kept bright, and a large number of artists are worthily employed. The total amount allowed for these works of art is 430,000 francs, or some 17,000*l.*, the greater part of this expense being borne by the State, though a certain number of the towns mentioned have voted considerable sums to aid the general funds. In addition to these commissions there are a certain number of other works to be executed, but not yet decided upon, for which the Minister of the Fine Arts will ask for an increase of 4,000*l.* in the Art Budget. This, however, is but part of the sums allowed. In 1879 the Fine Art Budget unanimously voted, amounted to no less than 7,579,530 francs, or something more than 300,000*l.*,—53,000*l.* for commissions and purchases of works of art at the annual exhibitions; about 27,000*l.* for the art educational

establishments; about 33,000*l.* to the national museums; another 53,000*l.* to the historic monuments; to the Conservatoire, subsidised theatres, and the encouragement of music, 87,000*l.*; to the national manufactures (the Gobelins tapestry works, the Sèvres porcelain works, &c.), 37,000*l.* When the many thousand pounds annually spent by the Paris Municipality in the purchase of works of art are added to the sums expended by the Government, it will be seen that there is no lack in France of official money encouragement to the fine arts.

Last week the "French Association for the Advancement of Science,"—a somewhat more recent establishment than our own venerable British Association,—held its annual meeting in the antique town of Rheims, under the presidency of M. Senator Krantz, the illustrious engineer to whose energy France owes the Great Exhibition building of 1878. In his inaugural address M. Krantz recalled the objects of the Association: to give to science,—now the source of such universal wealth,—the help which the Government cannot always distribute in an equally efficacious manner; to encourage students, freed from the trammels of official tradition, to seek and to open new ways side by side with the beaten paths on which advance the greater number. The association has assured for its use considerable funds, recently increased by several generous legacies; and in the past year it was able to distribute nearly 60,000 frs. in subsidies for scientific research. The first day's meeting was a busy one, several lectures occupying the afternoon: one on the geology of the district; another on the "Hygiene of the Eye-sight," which attracted much attention; as also a lecture from a member of the French Institute, in which was traced a history of the wool trade of Rheims. Of these lectures, that by M. Javal on the care due to the eye-sight was, perhaps, the most instructive. The important question of the necessity for the consideration of the lighting of school and other rooms, was treated with the seriousness that the subject requires. The rest of the lecture was occupied with a more or less technical study of the use and value of convex and concave glasses; a large share was devoted to the consideration of the widely-spread defect of astigmatism, in reality easily overcome by the use of glasses the surface of which is cylindrical in lieu of being spherical; due credit was given by the lecturer to Thomas Young, the discoveror of astigmatism, as also to the eminent astronomer Airy, the first to urge, some fifty years ago, the use of cylindrical glasses. There are undoubtedly thousands who suffer from fatigue and weakness of their eye-sight, and whose cause of suffering would immediately cease were they to use appropriate spectacles or glasses. In the cases of slight astigmatism, or with those whose profession can be reconciled with comparatively defective visual power, their astigmatism may be neglected without great risk; but when this defect exists in a marked degree with a person who lives, so to speak, by his eyes, the inconvenience becomes intolerable.

Parochial Work in Islington. — The annual report of the Vestry of Islington, lately issued, says that there are 105 miles of roads and 206 miles of footpaths over which the jurisdiction of the Vestry extends. During the year some 60,695 yards of granite, Victoria-stone, flints, ballast, &c., were used on the roads and footpaths, as well as 1,876 ft. of new granite kerbing. All or part of twenty-nine new streets were taken to and paved during the year; a total length of roadway of 17,789 ft.,—the length of pavement being 39,147 ft. Twenty-eight other streets have been surveyed, and estimates prepared for making-up, &c. The cost of dusting and slopping, which is done by the Vestry staff, during the year amounted to 10,893*l.* 11s. 8d. In this amount, in addition to the actual outlay, are included estimated charges for interest on the loan obtained to meet the original cost of the Liverpool-road stables, and for interest on the cost and depreciation in the value of the Macclesfield-wharf and other depôts, and for depreciation of horse stock. Watering the roads cost 2,178*l.*, of which 1,017*l.* was paid for hire of horses. Sewerage works of various kinds were executed at a total cost of 4,139*l.* One thousand three hundred houses were drained at private cost. The total cost was 14,759*l.* 18s. 6d. Plans and sections of sewers, &c., to be constructed at private cost were completed, the cost being estimated at 2,758*l.*

EXISTING ANALOGUES OF STONEHENGE AND AVEBURY.*

RESEARCHES IN THE MEDITERRANEAN.

Among the various matters connected with these strange and impressive monuments to which the learned have given attention, is that of discovering some precedent or authority for the structures, or at least an example of their design or construction; and it must be admitted that these endeavours have so far been unsuccessful. But there seems a generally-received opinion that there is at least evidence in classical writers that temples prior to that of Solomon, and of course, therefore, among many nations long after, were mere enclosures, open alike to the heaven above and the winds around. It must be admitted, however, that no structure like Stonehenge has been described.

There are three points for consideration in connexion with Stonehenge:—

1st. It is a structure of at least two periods widely separated. The materials and dimensions of the earlier structure differ altogether from those of the later and grander erection.

2nd. It is not mentioned by writers of antiquity, unless one passage, very doubtful as to locality, be admitted.

3rd. It must have been fully known to the Romans, as Roman pottery and other remains attest. Yet it is not mentioned by them.

To these points a 4th may be added, viz.:—That it occupies a very central position amongst the great sepulchral memorials of the ancient British people, and possibly of as sacred a locality of a still earlier race.

On the first of these points my opinion is exactly opposed to that of Mr. Cunnington, who considered that "the grand erection was first made, and the smaller circle and oval of inferior stones were raised at a later period, for," he continues, "they add nothing to the general grandeur of the temple, but rather give a littleness to the whole, and more particularly so if you add the too small trilithons of granite."

It is more natural to suppose that as we go back into the times of primitive occupation, the smaller stones would be erected, and the larger when wealth and power were more at command. The material of the smaller stones is that generally used by the earlier settlers.

Roman roads lead to the neighbourhood, and Roman pottery and relics have been found. I will only notice on this point that the silence of Latin writers is remarkable.

It may be observed here that the handling of the stone appears unlike that of any monument of Celtic erection in Brittany or Britain.

I have been led to form some conclusions on Stonehenge and Avebury by an expedition lately prosecuted by me in the Mediterranean, where, in some of the islands, I have found monuments which appear to me, though hitherto quite undescribed, to throw much light on these structures, if not, indeed, to present analogues of construction, with additions, which I believe are as without example as the great Wiltshire monuments themselves.

These consist of enormous *enceintes* of Cyclopean walls, within which are lofty conical erections capable of supporting a vast concourse of persons externally, and many of which are clearly connected with a part in each of such *enceintes* devoted to solemn rites. These reserved parts are always, when the wall has not been destroyed, surrounded by an inner enclosure. Within these latter are the remains of circles of monoliths, in the centre of which, as a rule, is a lofty table or altar composed of a large block resting horizontally on an oblong, placed vertically, and forming the letter T, the *tau*. In some cases a third stone is erected, and this has a rude cap-stone,—it cannot be called a capital; these are rare in the present condition of these remains; they appear eminently symbolic,—in short, this and the *tau* represent the two chief symbols of Phœnician worship.

The stone tables are very remarkable; a vast and heavy cap-stone, frequently 12 ft. long by 3 ft. wide and 2 ft. thick, carefully fashioned, and always in the same form, is poised on a vertical oblong, about 9 ft. wide, and only 1 ft. thick, standing out of the ground 9 ft., presenting a square superficies of a thin slab to the sight; there is no cement, nor any mortise, and yet I ascended, with other persons, on the cap-stone without causing the least oscillation. In one case, however, at what was evidently the grand temple, the cap-stone to the chief table has a mortise, into which the upright is inserted as a tenon, and this is so adroitly done, although evidently not wrought with iron tools, but merely battered with stone implements, that a slight touch of the hand causes vibration, though the stone is perfectly safe, and the natives assert that it vibrates constantly in a high wind. Here we have an approach to the mortise and tenon system of Stonehenge, the only example I am aware of. In several cases, at remote distances in the islands, are found the upright columns, with rude caps, arranged in the form of the trilithons of Stonehenge, though with the cap-stones, and a rude transverse block or lintel above, forming a construction of five stones in lieu of three. Locally these are called dolmens, and, in several instances, there are pure trilithons, or one block resting on two uprights.

The great *enceintes* generally contain three vast conical erections, apparently intended for different purposes: some are solid, with an external ascent,—clearly watch-towers, or serving also, it may be, as places whence the ceremonies in the sacred enclosure might be observed; some are hollow, with doors high up above the ground, indicating places of refuge; there are others, again, the purposes for which are less apparent. The grand temple, surrounded on all sides, and at a distance of some miles, by these lofty cones, is in the form of a pyramid, with the angles rounded off, an immensely strong structure, and not dissimilar in the size of its enormous blocks, and the thickness of its walls, to the well-known Cyclopean works at Tiryns, in Greece; many of the stones are 9 ft. long by 3 ft. to 5 ft. thick. Within the walls is a semicircular chamber, with its base to the south, arranged in tiers of stones, in form of a Greek theatre. The building is about 80 ft. square at the base, has been about 60 ft. high, and the entrance to the hall is about 20 ft. from the ground, to which height the building appears to be solid, the floor being at that level. Whatever purpose Silbury Hill served, any one of these structures would fulfil. East of this pyramidal structure are the remains of an early city, not unlike the walls on the Rivel Mountain, near Snowdon. The defending wall to this pyramid, guarding also the sacred enclosure and the city, is 14 ft. thick and 10 ft. high in its present ruinous condition, and has a number of deep recesses, like the Pelasgic portals at Norba, in Italy, and is formed of stones, some of which measure 15 ft. in length, and resembles in the greatness of its dimensions the vast Cyclopean wall at Samothrace, illustrated by me in the *Builder* by a drawing made in that island. In tumuli near this old city evidences of cremation have been found. There are other widely different but equally remarkable structures, but I confine myself in this paper to the above. In the Island of Minorca alone, although at a distance of thirty miles from each other, and with a range of mountains between, even the extremely remote and all the intervening remains of this kind could have almost instantaneous communication with each other, as tested by me; and I believe a careful survey of the district between Stonehenge and Avebury would show that either by ancient barrows or natural heights, communications could be made between these places. Excavations near these structures have, as at Stonehenge, produced Roman remains, though it need hardly be said the structures are not Roman. It is, however, clear they were known to the Romans. One very curious point arises here. In the Island of Minorca, near to the great port (Mahon, so named from a Carthaginian general named Mago), the stone tables are of larger dimensions, more careful workmanship, and apparently, unlike the others, wrought with metal tools, although the conical structures are not so important. They have all the appearance of later and more careful construction, and it is near these that the largest quantity of Roman remains have been found.

With the politic and conciliatory custom of the Romans in adopting the worship of the respective localities they governed, these later stone tables appear to me identified as restorations of previously existing and possibly of then decaying monuments. In short, on a more magnificent scale, of altars, or deities, or both, as the case may be.

In such case they assume the precise condition of the more vast portion of Stonehenge. The smaller circle and the two small trilithons clearly show the nature of the earlier structure, and the Roman occupation of the locality shows the interest the Romans felt in it. The prin-

* By Dr. Phené, F.S.A., read before the British Archæological Association at Devizes.

ciple of wrought-stone monuments is not British, still less so the mortise and tenon, though the latter was clearly known to the constructors of the ancient monuments in the Mediterranean islands just described, and it is highly probable that rude stone structures, long since removed, in Spain, Africa, or Gaul, may have suggested this method to the Romans.

My impression is that as the Romans consolidated their power by alliance with, and granting freedom to, the nobles of the countries they governed; as they considered the worship of the local deities of other lands meritorious, and no abrogation of or detraction from the honours claimed by their own deities of Rome, they could show this in no more comprehensive way than by restoration or augmentation of that temple in Britain which was in the centre of the deceased nobility of the land, and in the vicinity of what was clearly the great wardmote or gathering-place of the British at Avebury.

On the other hand, there is evidence enough to show, both in the mortise and tenon construction, and in the vastness of the stones (those of Stonehenge are smaller than the great monoliths in Brittany), that the artificers, or at least designers, may have been of Phœnician origin, the monuments of the Balears being Pelasgic of the oldest type. The Pelasgi were a people with whom the Phœnicians were in communication, and all the features of Stonehenge and Avebury have analogues in the islands between the African continent and Europe. In any case that Stonehenge is not a purely British structure is clear.

Dr. James Fergusson, who is not fond of attributing great antiquity to any monuments, allows that the remains on these islands may be coeval with the period of the Trojan War. Having repeatedly examined the route of the ancient traffic in tin through Gaul, I feel clear in stating that they seem to follow a line from Africa, where several trilithons exist, by the Atlantic shore and islands to Britain; a trilithon being found on the coast in Brittany, at St. Nazaire, and one in the Ile D'Ouessant. Dr. Fergusson admits the art of the construction (*i.e.* the design) may have travelled from Africa to Ireland, and thence to Wiltshire; in which I think he is right. The only authors on these remains are the Count de la Marmora and Don Juan Ramis. The former states that ill-health prevented his examining these monuments except in a few instances, of which he gives examples. The latter does not even appear to me to have made personal inspections. To these facts I attribute the very incorrect drawings and deficiency in statements respecting them. The only two Englishmen in Majorca—there are no resident English in Minorca—were the British Consul, son of Dr. Mure, the writer on Greek classical history, and Mr. Waring, an engineer, nephew of Mr. Waring, the antiquary. The latter, in making excavations, had found some curious Roman remains, but neither gentleman had investigated the ancient remains. I received great kindness from both, and much assistance from Mr. Mure; and in Minorca from several of the leading families. The word Talyots, from the Spanish *atalaya*, watch-tower, is admitted by the well-informed on the island to be a modern term applied to these structures by the Minorcans, but to have no significance, though it seems not far from the purpose. My investigations lead me to believe that these places were depôts of valuable articles of commerce, in which the Phœnicians traded, that, in short, they were the great depôts of Carthage, though probably established long before the settlement of that city. The cult of Astarte, under the form of the crescent, is more beautifully illustrated in Minorca than in probably any other place, while the numerous *taus* multiply the three-membered cross (T) of Tyre.

I find a quotation from Homer, and also from Pindar, which I have not had time to verify, that there was a place in the Balearides, supposed to have been the palace of Saturn. I can imagine no place more suitable for this description than what I have called the great temple.

Welsh Slate.—A bed of excellent slate is said to have been discovered near Llanarmon, Mynydd Mawr, which will increase the slate-producing area of the Tanat Valley against the time when a railway shall be constructed in that direction.

GLASTONBURY ABBEY.

Dr. E. A. Freeman, President of the Somersetshire Archæological Society, in the course of his inaugural address to the members of that body at their annual meeting, held at Glastonbury on the 17th inst., elsewhere mentioned, said that the history of Glastonbury was the history of its abbey. Without its abbey Glastonbury was nothing. The history of Glastonbury was not as the history of York or Chester, Lincoln or Exeter; it was not as the history of Bristol, or Oxford, or Norwich, or Coventry. It was not the stirring history of a great city or of a great military post. The military, the municipal, and the commercial history of Glastonbury might be written in a small compass, and it would very largely belong to modern times. The history of Glastonbury was a purely ecclesiastical history,—a history like that of Wells and Lichfield, of Peterborough and Crowland. Again, unlike the history of Wells and Lichfield, but like that of Peterborough and Crowland, it was a purely monastic history. No one who had read the Great Charter should fail to know that there had been bishops of Glastonbury; but Glastonbury looked upon its bishops as only momentary intruders, and was glad to pay a great price to get rid of them. But even the short reign of the bishops did not affect the purely monastic character of Glastonbury. No one ever tried at Glastonbury, as was tried at Winchester, Coventry, and Malmesbury, to displace the monks in favour of secular priests. But, again, among monastic histories, the history of Glastonbury had a character of its own which was wholly unique. He would not insult its venerable age by so much as contrasting it with the foundations of yesterday which arose under the influence of the Cistercian movement, and which had covered some parts of England with the loveliest of ruins in the loveliest sites. Those ruins played but a small part, indeed, in the history of this Church and realm. Glastonbury was something more than Netley and Tintern, than Rievaulx and Fountain's; but it was something more, again, than the Benedictine houses which arose at the bidding of the Norman Conqueror, his house, or his companions; it was something more than Selby and Battle, than Shrewsbury and Reading. It was, in its own special aspect, even more than that royal minster of St. Peter, which came to supplant Glastonbury as the burial-place of kings. Nay, it stood out distinct, as having a special character of its own, even among the great and venerable foundations of English birth which were already great and venerable when the Conqueror came. There was something at Glastonbury which there was not at Peterborough or Crowland, in the two minsters of Canterbury, and in the two minsters at Winchester. Those were the works of their own people; they went back to the days of their ancient kingship, and some of them to the days of their earliest Christianity—but they went no further. They knew their beginnings, their founders, and their history; their very legends did not dare to trace up their historic foundations beyond the time of their coming into this island. But here, in Glastonbury, alone among the great churches of Britain, they instinctively felt that on that spot the name of England was out of place. They walked with easy steps, with no thought of any impassable barrier, from the realm of Arthur into the realm of Ina. Here alone did a legend take upon itself to go up, not only to the beginning of English Christianity, but to the beginning of Christianity itself. Having dwelt with erudition on the history of Glastonbury, Dr. Freeman passed on to make some remarks on the general aspect of the subject, which, he said, directly connected the peculiar character of the buildings with the peculiar history of the place. There was a special character about the church—to be accurate he should have said churches—of Glastonbury, because there was a special character about its history. He conceived that there was a time when Glastonbury was a group of small churches,—the Celtic fashion of building where Roman usage would have dictated the building of one large church. One of these, the oldest and most venerated, the old church,—the wooden church,—lived on, and by living on stamped the buildings of Glastonbury with their special character. It lived on to be the scene of the devotion and the bounty of Canute, and to give way only to the loveliest building that Glastonbury could show, the jewel of Late Romanesque on a small scale, the Western Church, corruptly known since the fifteenth century as St. Joseph's Chapel. That church represented the wooden basilica. But to the west of the ancient wooden church there arose in English times a church of English fashion, a chapel of stone. The wooden basilica and the Church of St. Dunstan had both perished,—not a stick was left of one, not a stone of the other. But both were still there in a figure. Each had its representative. The great eastern church stood for the stone church of English Dunstan; the lesser western chapel stood for the wooden chapel of British Gwrgen, or more likely of some other long before his days. Had the two vanished churches not stood there in the relation in which they did stand to one another, the minster of Glastonbury could never have put on a shape so unlike that of any other minster in England. Nowhere else did they find, as they found there, two churches,—two monastic churches,—thrown together, indeed, in after-times into one continuous building without, but always keeping the character of two wholly distinct interiors; for nowhere but at Glastonbury was there the historical stats of things out of which such an architectural arrangement could grow. Nowhere else did the church of the Briton live on, untouched and reverenced, by the side of the church of the English.

The members subsequently visited the abbot's kitchen. Mr. Parker said this building had been assigned to the reign of Henry VIII., but he believed it could be assigned to the date of Abbot Breinton, 1335-41. A friend of his who had looked round the building was of opinion that it should be termed the abbot's kitchen, not the Abbey kitchen. If they had known nothing of its history they could say at once it was a fourteenth century building. The striking point was the louvre, a very common feature in the common kitchen; but here, inside, the arrangement was absolutely unique, and he knew of no place where there were three or four air holes. The nearest approach to it was Durham. To make it complete there ought to be four chimneys at the four corners, and if the visitors wanted to see something like that they must go to Exeter. Another peculiar feature was the hoards by which they could close one side; many of these were remaining at the present day. If the four corners were taken away they might imagine this to be the Chapter-house.

The Rev. Mr. Fowler, of Durham, who was called on by the President, said in every great monastic building there were three kitchens, the monastic kitchen proper being connected with the refectory in which the monks took their meals. In Benedictine buildings the kitchen was found outside the refectory. In Cistercian buildings the refectory, instead of forming one side of the quadrangle, ran north and south; such was the Abbey kitchen—a building grouped round the quad. Then there was the infirmary kitchen, in which various kinds of food were cooked; and there was a third kitchen, the abbot's kitchen, for the exercise of the hospitality of the abbots to persons outside the monastery. The building before them he had no doubt was the abbot's kitchen, as distinguished from the Abbey kitchen.

The party next proceeded to St. Joseph's Chapel, which occupies the extreme west end of the ruins. This, said Mr. Parker, stands on the site of undoubtedly the first church dedicated to St. Mary, as distinguished from the stone church said to have been dedicated to St. Peter and St. Paul. The great feature of it was that it stood clear and distinct from the church proper. Very many other places had churches and chapels which have been absorbed by the main building. Another peculiar feature was the crypt. The building did not appear to have had a crypt originally, but it appeared to him there must have been some reason for carrying the walls down so far as to allow of the crypt being formed. He thought the little wooden church was at a lower level, and that, disturbing it as little as possible, the architect was able afterwards, in the fifteenth century, to add the crypt. They had actually lined, almost veneered, the walls when they inserted the crypt, so that not one vestige of the masonry of the twelfth century was to be seen. Some details in the mouldings seemed to show it was made at two periods, the first part the eastern, the second the western. They had Norman zigzag mouldings carved out to the fullest extent, and yet they had the great feature of the thirteenth century, the tooth.

The next move brought the party to the place

where the big tower was, and there Mr. Parker pointed out that this large church was like most of the cathedrals, but not filled up with chapels. There was nothing to interfere with a good cross church. It was 400 ft. long, and very well-proportioned. Mr. Fowler proceeded to discuss the place of the high altar, and Mr. Neville Grenville said when Professor Willis examined the ruins he pointed out where it should be, and with a crowbar sounded and got at the foundations.

THE ARCHITECTURAL ASSOCIATION IN EAST ANGLIA.*

The week of the excursion, without storm or showers to speak of, proved well-chosen for the purpose, and the members were carried without the incommodity of fierce sunshine by autumn harvest-fields, with the reapers at their work, and not infrequently made to realise the existence of well-timbered hedgerows along the margins of the decent roads of central and Eastern Norfolk. A little ceremony, according to old custom, took place before the dispersal,—this year under the presidency of Mr. E. C. Lee, the president for the session 1880-81. The excursion always begins the work of a new session, since Mr. Edmund Sharpe showed so admirably the way in which such gatherings could be managed, and left his example in the memories of a sufficient number of active spirits who were all-unwilling to forget the lessons they had learnt, and who could put them to use for the benefit of others. Mr. Fowler (of Louth) received due thanks for his lucid descriptions of many of the buildings, and Mr. F. C. Penrose for acting as guide very pleasantly on the Walsingham and East Barsham day. The clergy showed the party much goodwill, and the good offices of Mr. Lee Warner at Walsingham may also be mentioned, and the charming guidance of the Marchioness of Lothian through and around her wonderful house at Blickling.

The breaking-up of the party—gathered from many parts of the three kingdoms, from thirteen counties, in fact, London supplying the largest contingent, and Ireland the next largest—then set in with vigour, the comfortable head-quarters, the Norfolk Hotel, in St. Giles-street, resuming once again the even tenor of its way. Norwich turned out by no means so bad an excursion-centre as croakers might have imagined. It is true that by some odd chance the old builders hereabouts omitted to recognise so thoroughly as they might have done the requirements of an Association excursion. They put down at Norwich itself a goodly store of notable work, but failed to fill the district immediately adjoining, as such well-intentioned persons would have done without fail if they had known all that was in the womb of the future. An ideal excursion for students should include some interesting town or city as head-quarters, and a thorough scouring of a district near it, girdled by a circle struck with a radius of some fifteen miles. Then the vehicles can leave the hotel-door about nine in the morning and keep in gentle movement from village to village,—making a loop at the end and coming back by another road between six and seven in the evening. After several days of this kind of exploration a plentiful hunting-ground will have been well traversed in every direction, and the spoils stored in note-books, sketches, and memories. Norwich is, however, in a figurative and Pickwickian sense, an oasis in a desert; and thus Mr. Pink, the organising secretary, had to deviate from traditions, and lead the party by a dozen miles of railway journey out and home again to the well-stocked areas in which they were to find sport and take pleasure therein. Such a leap over the less-promising twelve miles to the direct north of Norwich carried everybody to Aylsham on the Tuesday, and the great churches of Aylsham, Cawston, and Salle, and the church and hall of Blickling were reached by road. On Wednesday North Walsham became the starting-point for Trunch, Knapton, Edingthorpe, and the remains of Bromholm (pronounced Broome) Priory, upon the sea in the cliff district of north-east Norfolk,—a lonely run back to Worstead enabling the useful though lightly-spoken-of railway to do service again on returning. Turning from the north to the south-west, Wymondham was reached by rail; and by cross-country routes, Attleborough, Great Ellingham, Hingham, and Deopham were connected in a loop. The district to the south-east of the head-quarters had been proposed for another day, as it affords specimens of Norman at Thwaite, Hales, Gillingham, &c., a class of work not furnished in such plenty by the examples selected from the other districts. The very characteristic church of Beccles—a typical East-Anglian church with continuous clearstory, no chancel arch, with nave and aisles, and two-storied south-porch of rare merit—would have been visited at the end of such a day. In the balance now-a-days, however, church architecture does not outweigh civic and domestic work of merit; and a programme which is to be looked upon as a work of art must contain a proper share of Tudor or Stuart work, and non-ecclesiastical work will be regarded with favour. Censorious people, who have a bad habit of seeing part of a case, have hinted that the great church-restoring movement has gone by,—that town churches in non-Gothic styles will soon be *en règle*, and that the young men are turning their attention to the demands which buildings for trade and habitation will make upon their energies, and meeting half-way the promise of a future which is to lead a few to fame, and one or two to decent competency. The beautiful brick-work of East Barsham need, however, make no one look shamefaced who expresses a wish to visit it, and a secretary's motives in arranging for a visit need not be subjected to very severe analysis. Near by it the Wells and Fakenham Railway now runs, and visitors are not so rare as in the days when Cotman etched the façade, the gatehouse, and the groups of gables and chimneys, and Kepton (in 1811) illustrated them for the publications of the Society of Antiquaries; or, as in the days when the elder Pugin devoted a dozen plates to them in his "Examples," or, as in still more recent days—albeit, forty years ago—when Mr. Penrose sketched, with loving care, this rare brickwork of the end of the fifteenth and the beginning of the next century.

We must be contented just now with a general indication of the scope of the excursion and a note of the districts visited, and congratulate the members of the Architectural Association on the eleventh excursion which they have planned and carried out. As it happens that activity is being shown in visiting the monuments of the past in more than one district,—and it is possible to feel compunction when consuming too much partridge,—considerations less topographical than architectural may be agreeably postponed to a future number.

* See p. 229, *ante*.

THE PROGRAMME OF THE SOCIAL SCIENCE CONGRESS.

A good deal, as it seems to us, will depend on the results of the approaching Congress of the Social Science Association at Edinburgh. It is undeniable that the last meeting at Manchester was not a very successful one, in regard to numbers of attendance and general interest in the proceedings, although the intrinsic interest of the papers and discussions was fully up to the usual mark, perhaps beyond it. The comparative non-success of the meeting was, perhaps, the more remarked because it had been thought that Manchester, more than most places, was a peculiarly advantageous place of meeting, where there was sure to be a great deal of interest in many of the subjects considered, as well as a large attendance. We believe, however, it was well understood that special circumstances, connected with the depression of trade in a manner that peculiarly affected Manchester, had a good deal to do with the rather disappointing result. A really successful meeting is almost a necessity now, after the rather flat meetings at Cheltenham and Manchester, and it may be said that if a successful meeting cannot be realised in Edinburgh it cannot anywhere. There is everything in favour of the rendezvous: a fine city, a society comprising much intellectual vigour, and the probability that some of the questions to be discussed will have new light thrown on them, owing to the different point of view from which some of them are probably regarded in the Scottish capital, as compared with that which is taken south of the Tweed. Under these circumstances we should pretty confidently look for a good meeting at Edinburgh, such as will give a further impetus to the Association at a critical period of its career.

We have already given the heads of discussion in the Health, Economy, and Art Departments. The first question in the Health Section is one which covers a great deal of ground, and, in fact, is concerned with the whole question of the administration of sanitary legislation, and therefore rightly comes first on the list. From the question of legislation in regard to the sub-division of sanitary areas and the appointment of sanitary officials, the second question comes down to the more detailed consideration of the application of sanitary legislation to existing buildings, and also the means of improving their condition with due regard to economy; in other words, the subject includes the questions, What is it best to do to Existing Buildings, and How can we best insure its being done? This combination of two objects in one morning's subject would render the adequate discussion of the question a somewhat complicated affair, and it will be necessary, if it is to be kept disentangled, to keep readers of papers and speakers very close to the point, otherwise the discussion of a question so framed will tend to run a very erratic course. We should have thought there would have been more probability of arriving at a satisfactory and definite conclusion if the question had been subdivided, and the latter half of it made the subject of No. 2 question; and the first half, How to apply or improve legislation for buildings, considered separately as special question No. 3. There is too much matter in the subject to be fully disposed of in one morning's talking if it is to be gone into thoroughly. The third question, as arranged, the Means for the Prevention of the Pollution of Streams, is no doubt a very important one, so important and so large that we can hardly hope it will be fully considered at the last special meeting, which is usually shorter and less fully attended than the earlier ones; and it would probably be much better to reserve a power of adjourning this question for future consideration, and giving the two days to the full discussion of the subjects included under the second special question, which ought to have a peculiar interest for Edinburgh, one of the most picturesque and unsanitary of cities.

In the Art Department, the first subject, in regard to the desirability of a school of dramatic art, subsidised either by private or public funds, is one which takes up the subject which has now been considered at two separate meetings of the Association,—at Cheltenham, where the question of a National Theatre was considered, and at Manchester, where the moral and social aspects of the modern drama were the subject of discussion at a very full and interesting meeting. It is gratifying to find that the improvement of the drama is arousing so much interest, and especially that it does so in the capital of Scotland, a country which has certainly not been hitherto a favourable soil for dramatic art. The second question in the Art Section, the possible or probable advantage of reviving "the old system of master and pupils" in artistic education, and its effect upon the development of historical art in the country, may lead to some interesting conversation, especially if some of the artists will give us their views on the subject, but we very much doubt if it can lead to anything practical. Suppose the meeting decide in favour of "the old system of master and pupils," will that either induce any one painter to take pupils, or induce the Academy to close their school? We do not believe that any system is in fault, or that an old system can be deliberately revived with any good effect. If a large proportion of our leading painters were induced definitely to try the *atelier* system, it would only be a kind of artificial pose, adopted with the view of seeing whether such an experiment would make a revived historical art; and we have certainly no belief that it would. The use of the discussion will be to elicit opinions, and awaken interest in the subject of artistic education, but it can hardly lead to anything definite.

The final question in the Art Section, How can the Musical Education of the Middle-classes be Improved? may be a very practical one, if rightly handled. It should be remembered that there are two ways of looking at the subject. Music may be regarded merely as a means of providing a little innocent recreation for the family circle, or as the study of a great art of expression in sound. Those who regard it in the former light are quite content if people learn enough to amuse them, and some of the apostles of this social view of music have invented, and are continually urging, the use of certain special

methods of notation, &c., whereby the learner may be taken a certain distance with less trouble than in learning the ordinary notation—but *only* a certain distance. Those who take the larger artistic view of the subject know that it is a far greater gain in the long run for any one to master the language in which the whole of music is written, than to learn a little corner of it only by any back-stairs method. The Committee of Council on Education have recently adopted this view, and ruled that the full grant for musical education should only be given for those who have learned the established notation. They have taken, we believe, a wise step, in opposition to a great deal of remonstrance on the part of the upholders of pet theories, and we hope the Art Section of the Social Science Congress will strengthen their hands, and not make the consideration of the subject the occasion of recommending any patent nostrums of musical education.

ANOTHER RAILWAY COLLISION.

A COLLISION occurred in the Bleamoor Tunnel, near Ribblehead Station, on the Midland Railway, on the 19th current, by which, fortunately, no one was seriously injured, but which narrowly escaped being one of the most frightful catastrophes that has occurred on any English line. If anything could add terror to the calamity of the dashing together of two trains, it is that it should occur in a tunnel. The serious character of the collision in question is also enhanced by the fact that the immediate cause,—or rather an immediate cause, was the failure of an air-brake. The machinery of the brake by some means or other got out of order, and the train was stopped by this unwelcome automatic action in the tunnel. The Pullman express was due in a very short time, and was soon heard entering the tunnel. One of the guards of the arrested train ran back towards the mouth of the tunnel, and placed fog-signals on the line. Owing to this the driver of the Pullman train put on his brakes, but not in time to stop before he came in collision with the guard's van of the preceding train. This was completely smashed by the blow; one of the carriages was also much damaged, and thrown off the line, as was also the engine of the Pullman train. But for the notice given by the fog-signals, the catastrophe would have been terrible indeed.

It will, in the first place, be remarked that the brake-power proved, in this instance, a source of danger. It must be remembered, however, that but for the brake-power in the following train, the mishap would have been of tenfold amount. The question as to which is the best system of brake is one on which the occurrence may, indeed, throw some light. The possibility of a brake being so deranged as to stop a train in full course is a very serious one. But the point is not one that throws any doubt on the importance of full and readily-available brake-power. It only, indeed, enforces that necessity.

There is, however, a more serious question in this particular case. The improvement in safety which has of late been so happily remarked on our railways is mainly due to the general introduction of the block system. Without undervaluing the brake, it must be admitted that its utility is secondary to that of the efficient working of the block system. In the present case, the proper use of that system, and the proper observance of the rules for working the line, would have prevented the collision. It is the rule that a train should not be allowed to enter the tunnel until the preceding train has got clear out of it. Whose fault it was that the rule in the present case was broken it will be necessary to ascertain. It is obvious that the safety of passengers is quite illusory if the regulations on which it depends may be thus neglected. The train broke down half-way in the tunnel. It is impossible that the signal that it had left the tunnel should have been given. Under these circumstances it is unpardonable that the Pullman train should have been allowed to enter, and to enter, moreover, at the usual speed. A thorough investigation—first of the neglect of rule, and secondly of the character of the brake used, and the nature of its disarrangement—is imperatively demanded.

We may add that the verdict of the jury in the Wennington accident is in full accordance with the warnings we have given on the subject of the education of the workman. The verdict was to the effect that the speed of the train at the spot was greater than the conditions of the line warranted, and that the brake power was totally inadequate. The jury added the recommendation that special instructions as to speed, &c., should be issued in cases of all curves and crossings at all corresponding with the one at Wennington; and that a more complete inspection, by a duly-authorised person, should immediately follow upon any alteration of levels, &c., made by platelayers. They further added that crossings and guard rails on curves should receive special attention. This is the application, in one especial instance, of the rule of which we have urged the general necessity. When we find that an assistant engineer, on being asked by the Coroner at Berwick on the 19th current, "At what distance would a train without brakes be drawn up?" replied that "He could not tell," it is tolerably clear that practical technical education is not in a satisfactory condition. It is to be hoped that the feeling of satisfaction at the escape of the 19th inst. will not diminish the care with which the lesson thus afforded is laid to heart. We hope that the presence of mind of the guard who applied the fog-signals will not be unrewarded.

ARCHÆOLOGICAL SOCIETIES.

Somersetshire.—The annual meeting of the Somersetshire Archæological Society was held at Glastonbury on the 17th, 18th, and 19th inst., under the presidency of Dr. E. A. Freeman. The Council, in their report (read by Mr. C. J. Turner, secretary), after expressing regret at the death of the late president of the Society (the Rev. Precentor Meade), stated that the Society had maintained its position as regarded numbers, which were nearly the same as last year. The Council, however, found considerable difficulty in meeting the expenses of the Society, and were forced, from want of funds, to abstain from helping many undertakings and making many acquisitions which would be of benefit to the cause of local knowledge. Through the intervention of one of the vice-presidents (Mr. W. Long, of Wrington), the Council had the opportunity of buying for 100*l.* the interesting and valuable collection of manuscripts, books, &c., relating to the county of Somerset, made by Mr. Serel, of Wells. An appeal for subscriptions for this purpose had produced the sum of 85*l.* A committee appointed by the Society had been enabled by private subscription to make extensive excavations at Penpits, and the result of the investigation was embodied in a report in the volume of proceedings for the year. The President then delivered his inaugural address, some passages of which we print on another page. The Bishop of Bath and Wells, on behalf of the Society, thanked the president for his discourse, and Mr. G. T. Clark spoke in terms of eulogy of the address. Mr. J. Parker then read a paper on Glastonbury Abbey. In the afternoon the Abbey buildings,—the Abbey Church, kitchen, barn, and tor,—were visited. In the evening at half-past six there was a public dinner at the George Hotel, and at half-past eight a public meeting was held in the Town Hall, when papers were read. During the year several donations, including some bronze implements, had been made to the museum. The business of the meeting at Glastonbury was resumed on the 18th inst., when a meeting was held in the Town-hall, at which papers were read on "An Ancient Plankway at Shapwick," by Mr. Dymond, and remarks thereon were made by Mr. Boyd Dawkins, the Rev. H. H. Winwood, and others. The society then visited the different places of historic interest, including the hospital in Magdalene-street, the hospital chapel at the rear of the Red Lion Inn, St. Benedict Church, and St. John's Church. After luncheon there was an excursion through the neighbourhood. The first halt was made at Meare, where a building which was originally the residence of the keeper of the fisheries under the abbot, an office of considerable importance in Catholic times, was visited. At the Manor House, the residence of Mr. T. Look, a very fine hall, 60 ft. in length, was inspected; and at the parish church the Rev. W. Hunt stated that the chancel was of the time of Edward III. After driving to Shapwick, the party inspected the Manor-house and the church, and visited on the return journey the Abbot's Manor-house at Sharpham, once the residence of Fielding, the novelist. On the 19th, the society visited the earthwork at Ponter's Ball, where the fosse is still visible. At West Pennard Church is a remarkable octagonal tower of the reign of Edward IV., and a fine west window. The side of the tower had been faced for the convenience of the parishioners playing tennis on Sunday afternoons. The inside of this church appeared to have been extensively recast in the time of Henry VII. West Bradley Church was described as of the time of Henry IV., and contained a curious chancel roof and windows of the domestic character, and the Norman font was well worth notice. Near here was an ancient tump or barrow. At Baltonsborough Church the Rev. W. Hunt pointed out that the nave was broad and without aisles, and that there was an exceedingly good gable cross. The old oak benches, with fifteenth-century mouldings, were looked upon with interest. Here is a curious stool of repentance. Barton St. David Church was remarkable for its octagonal tower, and its chancel arch of the time of Henry III. Butleigh Church was next inspected, and the society was entertained at tea at Butleigh Court, the beautiful residence of Mr. Neville-Grenville. The society finished its proceedings by a visit to Street Lias Quarries.

Essex.—The annual meeting and excursion of the Essex Archæological Society recently took place, Saffron Walden being the *locale*. The annual report, read by Mr. H. W. King, called attention to the frequent loss and destruction of sepulchral monuments and painted glass during the progress of modern church restoration. The last *Journal* of the Society contained a record of the abstraction of valuable (fourteenth and fifteenth century) glass from Rochford Church. Some years ago a much larger quantity was removed from the Churches of North Ockendon and South Shoebury; while the record of the loss of sepulchral monuments which has taken place during the last forty years is much larger and far more serious, and, were a catalogue prepared, would prove somewhat startling. There are reports of churches where the whole of the sepulchral slabs have been buried. Such is stated to be the fate of the memorial of Strype, the historian. Recently the attention of the Council has been called by public correspondence to similar losses at South Weald, one of the abstracted brasses having been publicly advertised by a private possessor. This, it is believed, will be restored, and the present vicar has signified to the Council his desire to replace any that can be recovered. The historical value of sepulchral heraldry and inscriptions cannot easily be over-rated. They serve as ready indices of names and dates to the public records, and valuable discoveries have been made by their sole aid, and are daily depending upon them. The existence of such a learned society as the Harleian alone proclaims their importance to the historical genealogist. Mr. G. E. Pritchett, architect, and others endorsed these remarks. It was decided to hold next year's meeting at Chipping Ongar. The parish church was described by Mr. C. F. Hayward, F.S.A.; and Mr. H. Ecroyd Smith, having read a paper entitled "Notes on an Ancient Cemetery at Saffron Walden," a visit was paid to Audley End, by permission of Lord Braybrooke.

AN ARCHITECTURAL MEDLEY.

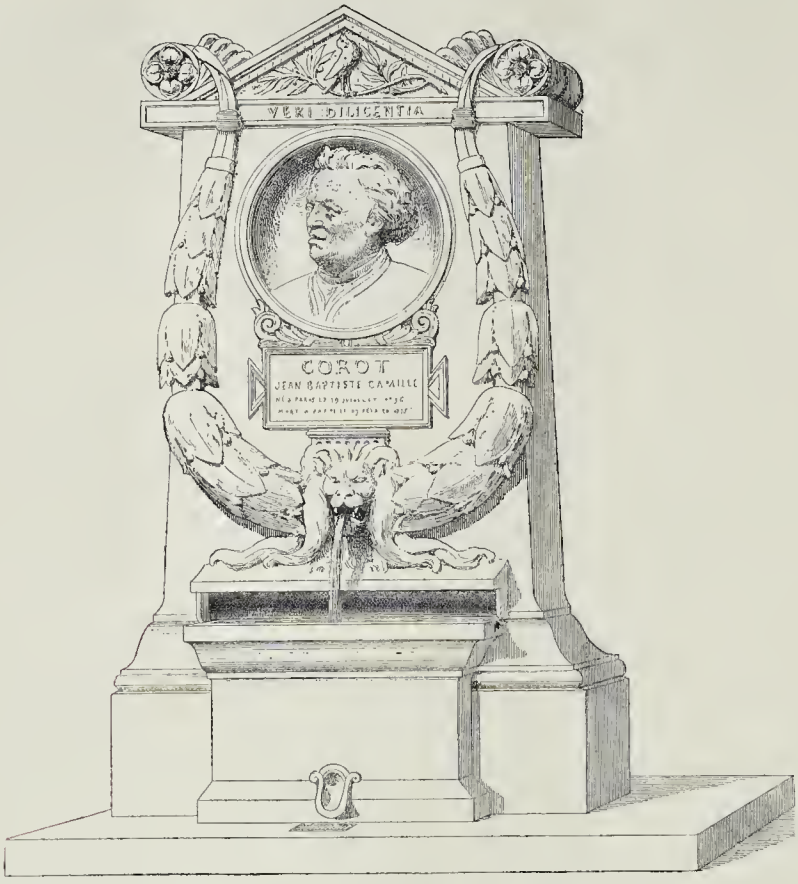
NOTWITHSTANDING the prosaic nature of our every-day life, there lingers amongst the members of the profession and the friends of architectural art a strong regard for what may be termed romantic and picturesque architecture. Of the former class there are several leading architects who work in this style, producing some most charming half-timbered domestic buildings, with quaint chimney-stacks, and studied irregularities.

Of the purely picturesque style, many of the "Queen Anne," or "Free Classic" buildings are good examples. Whilst admiring the beauties of this class of work, our better understanding will not permit us to subscribe to that excessive indulgence in architectural patchwork which is characteristic of some recent structures. We cannot approve of the desire to ape antiquity; to make a new house look like the "patchwork of centuries," with all the quaint conceits of Mediæval buildings, not growing out of necessities, but stuck on.

Many of our architects can and do produce good substantial nineteenth-century edifices, characteristic of modern requirements, modern advancement, and modern thought, while

> "Some by old (forms) to fame have made pretence,
> Ancients in phrase, mere moderns in their sense."

In the accompanying illustration an endeavour



MONUMENT ERECTED AT VILLE D'AVRAY, FRANCE, IN MEMORY OF COROT.

bas been made to incorporate some of the peculiarities of style advocated by several architects whose works are prompted by adoration for the romantic, picturesque, and antiquated. The drawing is intended to display the vagaries sometimes indulged in, at the same time that it conveys a not untruthful representation of what a building might ultimately become with the varied additions of several generations.

Whatever may be its merits as a drawing and fanciful composition, the author of it desires it should be looked upon as a warning against the too-free indulgence of individual whim, constituting, as it does, a gentle satire upon designs, whereof it may be said,—

"Such labour'd nothings, in so strange a style,
Amaze the unlearn'd, and make the learned smile."

Jas. Geo. Buckle.

COROT'S MONUMENT.

In May last, as we mentioned at the time, a monument to the memory of Corot, the French landscape-painter, was set up at Ville d'Avray. The body of the artist rests in the cemetery of Père La Chaise, where there is a fitting tomb. The monument we illustrate is set up on a triangle of turf near the late residence of the master. An inclosure of trees isolates it from some neighbouring houses which form the termination of Ville d'Avray, and affords a fitting background for the structure. It is wholly of white marble, and takes the shape of a fountain. On the face of the main block is a medallion of Corot, by M. Geoffroy Dechanme, and in the tympanum of the small pediment that surmounts it is a dove in bas-relief above these words, "*Veri diligentia.*"

CREWKERNE GRAMMAR-SCHOOL.

This building is now being erected under a scheme of the Charity Commissioners, and will take the place of the old school-buildings, the foundation of which dates from about the year 1499.

The present buildings, situate close to the church, almost in the centre of the town, afforded no scope for extension or improvement, and the governors resolved to acquire a fresh site. The spot selected is just outside the town on the road to Yeovil, and is perhaps as fine a site as could be obtained in any locality, including splendid views of the surrounding country; and the buildings will form, when completed, a prominent feature from the London and South-Western Railway as the town is approached.

The school is designed to accommodate about sixty boarders and ninety day boys, and is arranged so as to be capable of extension. The master's house is entirely self-contained, the dormitories being arranged over the school, class-rooms, &c., with bedrooms for the assistant-masters adjoining.

Provision is also made for the sick and convalescent and matron's and nurse's rooms, and a detached building for infectious cases is to be erected.

The baths, lavatories, and sanitary arrangements are provided for in a distinct block outside the main building, attached by a lobby with cross ventilation, and arranged on sanitary principles.

There is a large basement for cellarage, and a laundry and fives courts, plunge-bath, &c., are to form part of the scheme. The recreation grounds are of large extent.

The water supply is obtained from a well sunk on the site to a depth of 100 ft., and the drainage will be connected with the main drainage of the town.

The buildings are being constructed of Crewkerne stone, with dressings of Ham Hill, and the roofs are to be of slate. All inside woodwork is to be of pitch-pine, varnished.

The architects are Messrs. John Giles & Gough, of Craven-street, Charing-cross, London, whose designs were selected in competition.

The builder is Mr. Trevena, of Plymouth, whose contract amounts to between 6,000*l.* and 7,000*l.* He is rapidly carrying out the works, under the supervision of Mr. Mansel, the clerk of works. It is hoped that the buildings will be ready for occupation in twelve months.

VICARAGE HOUSE, CUDHAM.—Mr. Charles Innes, Architect.

NEW HOUSE AT CUDHAM, NEAR SEVENOAKS.

The house illustrated in our present number has recently been erected, as a residence for the Vicar of Cudham, by Mr. Sampson Copestake, the patron of the living. It is built on an elevated site at the back of the church, and commands extensive views of the country for miles round. Owing to the situation being so much exposed, the external walls are built hollow, connected together with bonding bricks; and they are faced with white gault bricks from Dunton Green, and red brick arches and bands. The oriel window, front doorway, chimneys and other dressings are of red and white terra cotta, from Messrs. Johnson's Works, Ditchling, Sussex, who also supplied a great part of the red bricks. The central hall is two stories in height, lighted from the top by a lantern light, with a gallery on the first floor from which the bedrooms open. Stabling and farm-buildings are built at a short distance from the house, and correspond in style; also a gardener's cottage overlooking the walled kitchen-garden.

The works were carried out from the designs and under the superintendence of Mr. Charles Innes, architect, of Queen-street, City; Mr. Read acting as clerk of works. Messrs. Payne & Balding, builders, of Bromley, Kent, executed the foundations and basement story of the house, the gardener's cottage, and the boundary walls. Mr. Deards, of Webber-row, Blackfriars, built the superstructure of the house; Messrs. Simpson & Sons executed the tile pavings, and Messrs. Homfray & Co. the pneumatic bells.

The total cost of the works, including stables, gardener's cottage, and walls, is about 9,000*l.*

THE BRITISH ARCHÆOLOGICAL ASSOCIATION AT DEVIZES.

In the account which we published last week (p. 229) of the proceedings of the first three days of this conference, we mentioned that on the opening day the visitors inspected the churches and Castle of Devizes. At St. John's Church, after examining the outside of the structure, the party seated themselves in the nave whilst the rector, the Rev. J. Hart Burges, D.D., read a paper on the origin and architectural points of the edifice. He said it was one of the most interesting specimens of Norman architecture that existed; the chancel, tower, and transept were built about the same time as the castle, and probably by Roger, Bishop of Salisbury, whose beautiful structures were the wonder of the age. So solidly were his courses of stone laid together that his contemporary, William of Malmesbury, had said that the stones looked like one block of masonry. The tower was perfect in construction, and the inside was covered with the most florid intersecting Norman arches. The chancel he hoped to improve ere long by altering the painting which existed there, but before that was done he intended to place a coloured window over the west door.

Mr. Loftus Brock returned thanks to Dr. Burgee for his paper. He said the churches in Wiltshire were very different from those which they visited last year in Norfolk, and were nearly all of cruciform type. He differed a little from Dr. Burges as to the age of the church. He thought that in the troubled times during which Bishop Roger lived they would not have had time for building such a structure. He thought between 1152 and 1160 was the time in which the church was built. Under the tower there were pointed arches on the narrow sides, and semicircular arches on the longer sides. They did not know of pointed arches being used earlier than 1150. It was a very rare thing to see a tower which was not square. He only knew of two or three in the South of England besides this one.

The party next proceeded to St. Mary's Church, and then to Devizes Castle.

At the evening meeting in the Town-hall, on Tuesday, the 17th, the first paper was read by Dr. Stevens, on "The Discovery of Palæolithic Flint Implements, with Mammalian Remains, in the Reading Drift." Dr. Stevens said he had well examined the drifts at Ealing, Ealing Dean, and Acton, but had never found so many and such interesting implements as at Reading. In September, 1879, he visited the north side of the Reading valley, but had not found anything. In the following month he searched in the south side, and there found a very interesting hatchet and a curious pointed tool. He next examined the Grovelands, Redlands, and Westlands drifts, and in the latter found a splendid hatchet of quartzite. Of the implements some were not worn, and could not have travelled far; while others were water-worn, and must have been washed down from the higher levels. On the 6th of February, 1880, he found, 5 ft. down in the gresnsand, part of a mammoth's bone, and also a well-pointed instrument. This was an important discovery, and established the fact that the deposits were made at the same time, and that the mammoth and the race of men who made the instrument were contemporaneous. Near the same spot he found also a bone of a carnivorous animal, which proved that lions and other tropical animals then inhabited these regions, but were driven southward, before the intermediate seas had been formed, to reach the more congenial climate of Africa. He was persuaded that the inhabitants were a race of fishers, like the Esquimaux, who were driven by the floods and ice of winter to seek the higher lands. This would account for the finding of similar flint implements in the higher districts, and which the pick and shovel of 1880 had succeeded in bringing to light. Dr. Stevens was warmly thanked for his interesting paper, and Mr. G. R. Wright, F.S.A., said he should like to ask him if he had formed any opinion as to the time and the physical character of the men who lived at that time. Dr. Stevens observed that Sir John Lubbock had said the skulls of those men were smaller than now. With the progress of civilisation the skulls had been enlarged.

The next paper was by Mr. J. A. Picton, F.S.A., on "The Ethnology of Wiltshire as illustrated by its Place-names." Mr. Picton said he proposed to consider what light the study of place-names would throw upon the nature of districts and the style of man. Hitherto most astounding guesses had been made as to the meanings of names and words hung together on account of the merest superficial resemblance. It was only lately that anything like a systematic way of going to work had been established. Names of places were often derived from their geological nature or from their geographical position. In the northern counties the names were of Norwegian derivation, and in the west Celtic. In Wilts they were nearly all Anglo-Saxon. Places were often really described in the affixes, and these qualified by their prefixes, thus—"*Winterbourne*," &c. It was often supposed that the ancient Britons were the aborigines of this country, but they were really only immigrants. No county was richer in pre-historic remains than Wiltshire. They had the primitive pit dwellings, the harrows, and later on the splendid monuments of Avebury, Silbury, and Stonehenge. Many Wiltshire names, such as "Kennett," were utterly inexplicable. Some places, as Longstreet, Stratford, &c., were so called from the Saxon "street," a Roman road. The Romans came to Wiltshire about fifty years after their landing in Kent. The name *Wansdyke* was from the Saxon god "Woden." The name Devizes was from "*Castra ad divisse*" the "camp at the division" of three manors which then existed.

At a meeting in the Town-hall, on Wednesday, the 18th, Mr. Brock read a paper on "The Discovery of a Viking's Ship in Norway." He said they were now assembled in a district remarkable for its numerous tumuli and ancient monuments. Each of the barrows on the downs was the burying-place of a family who had wished to lie near the great temples of Stonehenge or Avebury. In a county where the interments of ancient people are so diverse, he needed no apology for broaching the subject of a remarkable discovery recently made in a distant country. It related to one of the formidable sea kings who were then the terror of our Saxon forefathers, and one of a race whose bones may yet be found on our soil, having fallen before the English in battle. This discovery might be compared with the discovery of a ship at Dundalk, in 1785. There were some differences, however, in the construction of the two ships. There is every indication that the ships were used for sepulchral purposes, for ancient naval heroes were often buried in their ships, with their spears and accoutrements. King Frotho II., of Denmark, made a law that if any admiral died he should be buried in his own ship, as also should the principal commanders. The ancient Saga writers said that many heroes were buried in their own ships. In 1852 the first vessel of the kind was found. In 1863 another was discovered, and in 1867 another, which is to be seen at Christiania. The one just found enabled them to tell positively the manner in which the Norsemen were buried. Near the little village of Sandefjord there was a legend to the effect that a sea king was buried near, and that lights might sometimes be seen near the grave. On examination, a buried ship was found, supported by timber logs, at about 5,000 ft. from the sea, though probably the water was then nearer. The figure-head was beautifully carved, and represented a dragon, which was the usual figure-head on Viking ships. Three small boats were found, and some oars beautifully carved. In front of the mast was the burial-chamber. In the after part of the vessel some bones were found wrapped in silk. They heard in Sagas of burial-places being broken into by thieves, and as this one was disturbed they had a sad illustration of that truth. The length of the boat was 79 ft., and he attributed the date of it to A.D. 800. The ship was placed with prow towards the sea, so that the great chief might sail out to sea when called by Odin.

Mr. Mayer said that a similar ship had been found at Iona, in Scotland, in a manor, but it was the ship of a missionary, and not of a Viking.

The subject was also commented upon by Mr. Morgan and Mr. Picton, who said that the naval supremacy of England was due to the Viking blood in our veins. The Vikings were a race born to rule and conquer.

Earl Nelson said that his great-uncle at Copenhagen had remembered his Viking descent, for he had signalled to the Danes, "Danes, we are brothers."

Thursday, the 19th, proved a very enjoyable day. Favoured by fine weather, a large number of the members and visitors started at an early hour by special train to Chippenham, where carriages were in waiting to convey the party to Bradenstoke Priory. Passing along through lovely country, with the harvest in full swing on every hand, Langley Burrell was reached. This is a very ancient village, the church being partly of the Norman period, although the original fabric was much older. On the east end of the ridge of the nave is a stone crucifix, which attracted great attention, and on the west front of the tower (which stands on the south side of the church), is a monumental effigy comprising two figures (probably the founder and his wife), which it was suggested should be preserved with greater care. The next village reached was Draycot Cerne, the manor of which was transferred from Ralph de St. German in 1196 to Robert de Venuz, for fifty marks. It is at the present time the property and residence of the Earl Cowley. The old house at Draycot bears a date over the hall chimney of 1574. The church is supposed to have been built by Henry de Cerne about the year 1260, and is partly Early English in style. In the chancel floor is a monumental brass, with the effigies of Sir Edward Cerne, who died 1393, a monument of great beauty. The original font has been transformed into a garden-pot (so says the *Wilts and Gloucestershire Standard*, to which journal we are indebted for some of these particulars), and stands outside the church. The chancel was noticed as being on a lower level than the nave, a peculiarity found only in Saxon churches. Sutton Benger Church Mr. Brock considered to be one of great interest to all architects and archæologists. It is of the Late Decorated period (about the fourteenth century), the tower of Perpendicular date, having an embattled parapet, enriched with panelling, four pinnacles at the angles, and in the centre a very pretty open-work spirelet. The font was Norman, and the nave contained some fine specimens of Norman work. In 1330 an aisle had been added, and the work had been carried out in no niggardly spirit; the windows being beautiful and artistic to the last degree. The east-window of the aisle was enriched with hall-flowers all round, and was of very beautiful composition. A niche inserted in the lower portion of the window contained a sculpture of the Virgin; close by them being a piscina, and on the back of the niche (externally) was a miniature representation of the entire window itself. A very good piece of tapestry, supposed to be a portion of an altar-cloth, is now spread over the reading-desk. The parish register dates from 1653. Christian Malford, the next village, has still the remains of the steps and shaft of an old stone cross. The manor was given in 940 by King Edmund, to

Dunstan, Abbot of Glastonbury. The manor now belongs to the Earl of Carnarvon. The church, of very ancient date, does not present any particular features, but there are some old monuments and brasses. The next halt was at Bradenstoke, and here Mr. Brock acted as guide to the party, and gave an account of the Priory. It appears that this was founded on the 13th of April, 1142, by Walter, son of Edward of Salisbury, a valiant Norman soldier, who had accompanied the Conqueror in his invasion of England, and received the lordships of Salisbury and Amesbury in return for his services. It was dedicated to the Virgin Mary, and its inmates were canons of the order of St. Augustine. William, Earl of Salisbury, grandson of the founder, who died in 1196, is said to have been buried in the Priory Church. In one of the apartments, known as the Prior's room, is a chimney-piece of stone, richly carved and painted with five plain shields in the centre of quatrefoils, the lower part being beautifully worked in lozenged panels, containing, raised on foliage, four golden letters, "W.A.L.S." This beautiful chimney-piece, which is crowned by an elegant cornice of leaves and a central bracket, is of the age of Henry VI. The Priory now belongs to Sir Gabriel Goldney, Bart., M.P., who was represented by his son, Mr. Prior Goldney, who entertained the company with refreshment.

Having continued the journey to Malmesbury, the company were quite prepared to accept of the hospitality of Mr. W. Powell, M.P., who entertained them at luncheon in the suite of reading and recreation rooms which he has established in the town. One portion of the company was presided over by Mr. Powell; Mr. Swayne, deputy chairman of Quarter Sessions, occupying the chair in another apartment. The health of Mr. Powell was proposed by Mr. Geo. Wright (in the absence of Earl Nelson, the president).

Mr. W. Powell, in reply, said it not unfrequently happened that those who lived near a place were less well acquainted with the objects of interest in that place than those who came from a distance, and therefore it was that they were looking forward with great eagerness to the account they were to have of their ancient abbey,—that magnificent structure which the historian told them rivalled in architectural beauty the nave of Winchester, the choir of York, the spire of Salisbury, and the majestic towers of Lincoln.

The company then visited the Cross and the Abbey, the latter being commented on by Mr. G. Patrick, Mr. Brock, and Mr. Ewan Christian. In 1541, the parish church of St. Paul having become ruinous, the nave of the abbey church was given by Stumpe to the parishioners, who obtained from Archbishop Cranmer a licence to convert it into a parish church, for which purpose it continues to be used to the present day. The valuable documents which formerly belonged to the abbey have been lost, to a very great extent. The features of the architecture of the abbey church were pointed out and commented upon. When perfect it must have claimed a high place amongst the ancient ecclesiastical edifices of this country. The fabric consisted of the usual parts of a great English minster, the four limbs of the cross and a central tower. Of these portions the present parish church includes only two-thirds of the nave and aisles used by the monks. The style of its architecture is Norman, pure in its details, but with the pointed arch, erected probably about the middle of the twelfth century. Subsequent additions and alterations have been made, one of which was the erection of a western tower. The central tower fell some time in the sixteenth century, carrying some of the building with it, and was never afterwards rebuilt. The western tower also fell subsequently, and it is said that during the rejoicings for the return of King Charles II., 29th May, 1660, the noise of artillery so shook the old buildings that one of the remaining pillars of the central tower and the parts above it fell the same night. The south porch and doorway, with its elaborate series of Norman sculptures, is one of the richest specimens of its kind in England. Within the porch, in two groups on either side, are seated figures of the twelve apostles; and over the inner doorway is a figure, also seated, of the Saviour, on a throne between two cherubims. There is also a series of sculptures in medallions, illustrative of both Old and New Testament history. There is a tomb, with recumbent effigy, in royal robes, ascribed to King Athelstan, but it appears to have been erected several centuries later than his death in 941, and was probably put up by the monks. All these and many other (which our space will not allow us to enlarge upon) interesting features were described and commented upon by Mr. T. Blashill, Mr. G. Patrick, and others. The cross, which stands near the centre of the town, was built about the reign of Henry VII. It consists of eight great pillars and eight open arches, one large pillar in the centre bearing up the whole. It has flying buttresses, and an octagonal turret with a small niche on the end encloses a representation of the Crucifixion. The cross was repaired at the commencement of the present century. After all these points of interest had been duly noted, the party, having taken tea with Dr. Jennings, returned to Devizes.

In the evening a meeting was held in the Town-hall, for the reading of papers, Earl Nelson in the chair. The first was by Mr. Thomas Morgan, F.S.A., on "The Gewissens in Wiltshire." He said that, having traced (at the last Congress) the East Angles in Norfolk and Suffolk, he now wished to speak of the "Gewissens" or "Westerners." The term seemed to have been used in opposition to the "Easterlings," just as on the Continent the Eastern Goths were opposed to the Visigoths or Western Goths. It was necessary to go back to the Roman times to trace the rise of the kingdom of Wessex and its vicissitudes until swallowed up in the smaller kingdoms. Out of the 500 years during which the Romans were in supremacy in Britain, no less than 300 were without any record whatever of Britain. Records of the revolutionary Roman times were the milestones found at Bitterne, near Southampton, recording the names of Gordian the younger 238 to 244 A.D., and other celebrities. The materials for history were very sparse, neither had any satisfactory explanation been given for the absence of all literature of the period.

The paper was commented on by Mr. Karslake and Mr. Swayne, after which Mr. Morgan was heartily thanked for his learned paper.

Dr. J. S. Phené then read a paper on "Existing Analogues of Stonehenge and Avebury, from Researches in the Mediterranean," which we print on p. 257.

The paper was commented upon by Mr. Mayer, F.S.A., Mr. Picton, the Rev. Sir Talbot Baker, and others.

At nine o'clock on Friday, the 20th, about 150 members and visitors drove through the beautifully wooded and fertile country between Devizes and the foot of Salisbury Plain, passing through the prettily-situated villages of Enford and Netheravon. About twelve o'clock they arrived at Amesbury, where the church was examined and commented upon. It is one of the finest edifices in the district, cruciform in plan, with a square central tower. There are remains of Norman windows and arches. After this, luncheon was partaken of at the George Inn. At Ameshury the party was joined by the Newbury District Field Club, whose members had taken advantage of the British Association being in the vicinity to have a united excursion. The whole party then proceeded from Amesbury across the plain to Stonehenge.

The Rev. A. C. Smith, in describing the temple, said that when perfect it consisted of two circles, and two ellipses of upright stones, concentric, and environed by a bank and ditch, and outside this boundary, of a single upright stone, and a *via sacra census*. The entrance to the cluster faced the north-east, and the avenue to it is still traceable by banks of earth. One stone, called the "Friar's Heel," 16 ft. high, is supposed to have been a gnomon. The outer circle consisted of eighty stones, fixed upright at intervals at 3 ft. 6 in., but connected at the top by imposts which formed a continuous corona, or ring of stone, at a height of 16 ft. Within this was the grandest part of Stonehenge, the great ellipse, formed of five, or, as some think, seven, trilithons, the largest attaining an elevation of 25 ft. Lastly, within the trilithons was the inner ellipse, consisting of nineteen granite posts; and in the cell thus formed the altar-stone, or the stone of astronomical observation. Now the outer circle consists of sixteen uprights, and six imposts; the inner circle of seven uprights; the great ellipse of two perfect trilithons, and two single uprights; the ellipse of six blocks, and within the cell the so-called altar-stone. The origin, date, and use of Stonehenge are equally unknown to us. It has at different ages been called by different names, and even now many different opinions exist upon the subject. Some antiquaries beheld in Stonehenge a work of the antediluvians, others a sanctuary of the Danes, and others a temple of the Romans; but a numerous and learned band consider Stonehenge to be a Druidic temple.

Dr. Phené said that it was obvious that the remains were the work of two different eras.

Earl Nelson said he should like to see those stones replaced that had fallen within the memory of man.

The temple was also commented upon by Mr. T. Morgan and others.

Vespasian's Camp, an interesting Roman relic, was also visited, and the party returned to Devizes over the plain, *viâ* Redholn.

In the evening a meeting was held in the Town-hall, Earl Nelson in the chair. The first paper was by Mr. J. Tom Burgess, F.S.A., on "Ancient Fortifications, especially with reference to the Devizes Castle." Mr. Burgess said he had not come to Devizes with the intention of reading a paper on the castle, but the idea was suggested to him on learning how little really was known of it. The castle struck him as an embodiment of the successive ideas of a military defensive position. There was no county in England which possessed so many features of interest to the student of the past as Wiltshire. It is studded with so many ancient monuments as to offer almost an unrivalled field for the study of antiquity. Devizes Castle stands on a huge mound, and it presents many points in common with other castles erected about the same time by Bishop Roger, of Salisbury, who reconstructed old castles on the plans adopted by the Norman military architects. It was too much the fashion to describe the entrenchment as British, Roman, Saxon, or Danish, as the case might be; but the fact was, the commanding position would commend itself at any period to those who had to defend themselves. Such a castle was probably the stronghold of a nation and the residence of its king. Kent had four of these strongholds. Mr. Gordon Hills had a theory that these mounds were merely Roman works thrown up for general survey, but many mounds were found in very low-lying positions surrounded by a wall, which showed that they were intended for habitation. All the old Mediæval castles had not a donjon or keep like Devizes. He then alluded to many other Danish and Saxon castles in England, and compared them with Devizes Castle. Many of them were placed by the banks of rivers, and most of them on artificial mounds. Fortified mounds were found of many types, and they showed the exigencies of the people who inhabited them. The natural mound in some places was surrounded by a ditch and valla, which, in their turn, were fortified with stockades and palisades. They were also supplied with means of retreat. On the weaker side of the mound the ramparts were erected. There were many instances in which the original fastness was enlarged, as at Old Oswestry, Dorchester, &c. When Vespasian came to subdue the great western land, he found that it bristled with earthworks of the most formidable kind, and which had to be stormed before the Roman legions could pursue their march westwards. They might now fairly surmise that on this march Vespasian came across Devizes, and from the discoveries it might be assumed that that great soldier occupied it long as a commanding and strong post. Subsequently the adjacent forests sheltered the great Alfred; but those forests were now gone, and the chalk bluffs that witnessed his victories, and which still bear the ensign of his country, now fringe smiling cornfields, orchards, and fertile pastures.

A paper was also read by Mr. G. R. Wright, on "The History and Hardship of the Present Law of Treasure Trove."

On Saturday last a large party set out in carriages for Bromham. Passing through the villages of Dunkirk, Rowde, and St. Edith's Marsh, the first halt was made at Bromham. The especial point of interest there was the fine church, which was described by the rector, the Rev. E. B. Edgell. It consists of chancel, central tower, south transept, nave with south aisle, south porch with parvise, and a chantry forming a south aisle to the chancel. The nave is in the Perpendicular style of architecture, and the chancel Early English. There is a beautiful chapel on the south side of the chancel built by Richard Beauchamp, afterwards Lord St. Amand; it is Late Perpendicular in style. There are also some beautiful tombs and brasses

in the church and chapel, to the memory of Elizabeth Beauchamp, John Baynton, Sir Edward Baynton, Anne Pakyngton, and others. The party then inspected "Old Bromham House," which was formerly one of the principal halting-places for the nobility on their way to Bath. It was visited several times by James I., who hunted in the park. Close to the house are the remains of an old Roman villa, which were examined with much interest. Several hones and coins have been found there from time to time. Wans house and the Roman road were then visited, and the party next drove on to the mansion of Bowood, the princely residence of the Marquis of Lansdowne. Many of the historical pictures were viewed with very great interest. After luncheon at the Lansdowne Arms, the drive was continued by Keeper's Lodge to Spye Park, the residence of Major Spicer, and from thence past the conduit at Bowden Hill to Lacock Abbey, by Bewley Court. At the abbey the party were received by the owner, Mr. C. H. Talbot, who conducted them through the building, of which he gave the history and described the leading architectural features. It was founded by the Countess Ela in 1232. The abbey surrendered in 1539, and its site was granted to Sir William Sherington, and from his heirs came into the possession of the present family. It was strongly fortified during the Civil War for Charles I., but it surrendered to Fairfax immediately after Bristol and Devizes had fallen. The cloisters, which were greatly admired, are built in the Late Perpendicular style. On the stone groining of the roof are a series of shields of arms, including those of many old families, and several others not satisfactorily identified. In the pavement are the remains of several interesting monumental memorials, including one of the foundress, Countess Ela. The remains of the refectory, dormitory, and sacristy were also visited and commented upon, as also were the Nuns' kitchen and Chapter-house. The parish church and village cross were then visited, and the party returned to Devizes.

At half past eight p.m. a meeting was held in the Town-hall, when an inspection of the ancient deeds and charters of Devizes was made by Mr. W. de Gray Birch, F.R.S.L. (British Museum). Mr. Lambert, F.S.A., described the borough maces and regalia.

Earl Nelson, in a brief closing address, summarised what had been done during the week. Besides getting a view of the wonderful beauties of the county of Wilts, they had obtained a fair idea of the earthworks it contained, and how vast they were. He particularly noticed that what were formerly accepted as being Roman camps were now called British; and in the same way as these ground-works had been ascribed to the earlier inhabitants, so also many of the churches which had been called Norman were now called Saxon. This, he thought, was most reasonable, because the Norman style of architecture first came into use under Edward the Confessor, and surely William I. would not have pulled down every scrap of Saxon building. Something had been done by Dr. Phené's excellent paper to elucidate the mystery which had for ages hung over Stonehenge. He thought the outer entrenchment ought to be preserved from public mutilation, and he hoped something would be done to keep those stones upright which were now falling. He should also much like to see the trilithon replaced which fell in 1797.

Mr. Picton, F.S.A., proposed a vote of thanks to the noble chairman, who responded, and after several other complimentary votes of thanks had been passed the company separated.

Although the business of the Congress formally closed with this meeting, on Monday morning a number of members started for Warminster *en route* to Longleat, the famous seat of the Marquis of Bath. The picture-gallery was visited, and some of the old paintings greatly admired.

The arrangements have been most satisfactorily carried out by the honorary local secretaries, Mr. J. Reynolds, of Bristol, and Mr. W. H. Butcher, of Devizes.

The Lord Lawrence Memorial.—The committee have determined upon the erection of a standing statue of Lord Lawrence at the south-east corner of Waterloo place, just opposite the statue of Sir John Burgoyne, to which, as regards size and effect, it will bear a considerable resemblance. Mr. Boehm is executing the work.

ARCHÆOLOGICAL DISCOVERIES.

Carchemish, the Capital of the Hittite Kingdom.—The *Times* of the 19th inst. contains a long and interesting account of recent discoveries made at Carchemish during excavations conducted for the authorities of the British Museum, under the supervision of Mr. P. Henderson, the British Consul at Aleppo. At one point there was brought to light a large chamber, the walls of which were decorated with sculptures. The chamber is in the form of a corridor, such as those in the palaces at Nineveh; its length is 60 ft., with a breadth of about 18 ft. The floor of this corridor being uncovered, it was found that there was a flight of broad steps leading from the lower city in the direction of the palace mound. The west wall of this corridor only remains *in situ*, and along it have been ranged a series of Hittite sculptures in bas-relief. In concluding his account of the discoveries, the writer expresses the hope that the time is not far distant when the British Museum authorities may learn, perhaps from their German colleagues at Olympia, that digging and archæological exploration are two different things, and also that if excavations are to be any credit to those who undertake them they must be conducted by those who can bring a knowledge of the subject and an unvaried attention to bear on the works, so that all that is found may be secured. Such necessary attention cannot be expected from a consul whose seat of jurisdiction is more than ninety miles from the excavations, and who is rendered dependent on the honesty of a native overseer.

Winchester.—During the last few weeks workmen have been employed in laying down drainage pipes throughout the cathedral enclosure at Winchester, and some interesting relics of Roman handiwork have been discovered. In Canon Warburton's garden, situated on the north side of Dome-alley, was found a portion of a Roman pavement, which was slightly damaged in its removal to the Deanery; and a subsequent search revealed a further portion of the remains, which were embedded about 6 ft. below the surface, a short distance to the east from the first discovery. The pavement represented a border turning at right angles, but the centre portion was missing, its absence being accounted for by the fact that a tree had been planted over it. The spot in which this relic was discovered is situated about 120 yards south-east of the Roman pavement discovered in 1878 in Minster-street, and which now occupies a conspicuous position in the public museum in the city.

Orkney.—The *Scotsman* says that some workmen, while trenching a mound in the island of Sanday, Orkney, the other day, after disclosing two solidly-built circular walls, 4 ft. thick, and about the same distance apart, came upon an underground passage 35 ft. long, and varying in width from 2 ft. to fully 4 ft., cut out of soft rock, and covered with broad heavy stones. The bottom is covered with clay, and does not seem to have been laid with stones. A number of bones have been found.

SCHOOLS OF ART NATIONAL COMPETITION.

The Science and Art Department have issued the report of the Examiners in the National Competition, 1880, of works sent up from schools of art. It states that the number of drawings sent up from the schools of art for examination this year was 169,147, from 151 schools. Of these works, 989 were referred to the National Competition, being 406 less than in 1879, when the number was 1,395. The following are among the students rewarded in the National Competition, 1880:—

Gold Medals.—Alfred W. Bowcher, South Kensington, model of figure from life; John W. Bradburn, Coalbrookdale, design for a ceiling suitable for a synagogue; Francis Gibbons, Cirencester, design for a mosaic pavement; William Kitson, Westminster (Royal Architectural Museum), modelled design to fill a given space; Evangeline Stirling, South Kensington, model of a head from life.

Silver Medals.—Frank Brown, Westminster (Royal Architectural Museum), design for a country house (four sheets); George F. Catchpole, Westminster (Royal Architectural Museum), design for a soup tureen, candelabrum, and dinner plate; Gilbert S. Doughty, Nottingham, design for a church (four sheets); Thomas Datton, Nottingham, design for wall paper (two sheets); William S. Frith, Lambeth, model of a head from the life, model of a figure from life, seated; Alfred Hall, Cirencester, design for a cup (two sheets), design for a portion of a side of a ball-room; Cecilia Jacques, South Kensington, design for surface decoration; William Kneen, Manchester (Grammar School), design for wall paper; Fred. Marshall, Bloomsbury (Working Men's College Art Class), chalk drawing of figure from antique; Alonzo Middleton, Nottingham, design for wall paper; John Smith, Coalbrookdale, design for a loving-cup; William G. Thomas, Westminster (Royal Architectural Museum), design for iron gates (for two); Henry Tidmarsh, West London, design for a shield; Alfred Williamson, Leeds (Young Men's Christian Association Art Class), design for a church (five sheets); Austin Winterbottom, Sheffield, studies of the sycamore and chestnut in their different stages.

The Examiners were as follow,—

Figure-drawing and Painting.—Mr. P. Calderon, R.A., Mr. G. D. Leslie, R.A., Mr. W. F. Yeames, R.A.; Mr. E. J. Poynter, R.A., director for art; and Mr. H. A. Bowler, assistant director for art.

Design, with Architecture and Modelling.—Mr. J. E. Boehm, A.R.A., Mr. William Morris, Mr. J. J. Stevenson, and the director and assistant-director for art.

Design.—Mr. H. S. Marks, R.A., Mr. W. Morris, Mr. J. J. Stevenson, and the director and assistant-director for art.

Painting in Oil and Water-colours.—Mr. W. F. Yeames, R.A., Mr. H. S. Marks, R.A., Mr. Val Prinsep, A.R.A., and the director and assistant-director for art.

The Examiners in the Architectural Section say,—

"Some designs for panels were skilfully executed, though not in a sound method of ornamentation, the ornament being too cut out from the ground, and the treatment of the flowers too naturalistic and minute for proper combination with architectural forms. Some elaborate and well-executed drawings were submitted by the architectural classes, many of them by young students; their subjects were somewhat ambitious, but their treatment fairly justified the attempts to design important buildings. The examiners recognised these attempts by numerous awards, but they hope that instruction in this class will be extended in future, as it seems at present to be limited to the exclusive study of Gothic ecclesiastical architecture. Some designs for half-timbered houses were good, exhibiting sometimes, however, a straining after picturesqueness by needless irregularity of plan and complexity of roofing instead of order and symmetry, which would be the first aims of architectural design. Irregularities should not be sought for their own sake, but should arise from and give evidence of some necessity for their occurrence. A panel for a room competing for the Plasterers' Company's prize, and designed for execution in relief, showed much fine sense of the proper distribution, relative projection, and variety of surface of the elements of which it was composed, but lost some of its effect owing to a want of knowledge of the human figure on the part of the student, who otherwise exhibits great capacity for designing. A good design for a mosaic pavement, with correct classical feeling, sent from Cirencester, was awarded with a gold medal; as was a design for a ceiling suitable for a synagogue from Coalbrookdale."

UNHEALTHY DWELLINGS IN LIVERPOOL.

At the meeting of the Liverpool City Council on the 4th inst., the Health Committee called attention to a report of the medical officer of health, presented in pursuance of the Liverpool Sanitary Amendment Act, 1864, as to premises which ought to be demolished or structurally improved, and which will be submitted to the grand jury at the Quarter Sessions as the sixth presentment under the Act.

Alderman A. B. Forwood said that about eighteen months ago the Health Committee promoted the obtaining of a provisional order to amend the Sanitary Act of 1864, whereby they could take measures to improve the sanitary condition of the courts and alleys of the town in a less expensive mode than they had hitherto been able to do under the Act of 1864. Under that Act the medical officer was all-powerful; if he certified that certain premises were injurious to health, they had no control over that certification; but if it went to the grand jury, and they inspected the premises, and if they were of opinion that the medical officer was right in his statement, they authorised the taking of these premises under the conditions of the Act of Parliament. The medical officer had drawn up this presentment, and prepared his plan, which would be submitted to the grand jury at the next sessions. The general plan adopted by the medical officer was to remove the houses at the entrances of those closed-in courts that existed in the town. There were many courts in the town which were approached by passages; all chance of ventilation or air was prevented by these houses in front. In most cases the medical officer had proposed to demolish these houses in order to throw air and light into the courts. It was also proposed to remove premises to the rear of the front houses which were obstructing ventilation; and he thought from the care the medical officer had shown in going through the different districts that he would be able to make these streets and houses quite habitable without their having to

go to the great cost of taking them all nnder the Artisans' Dwellings Act. The change effected hy the provisional order had more particular reference to arbitration. Instead of the owners of each individual property having any right to ask for arhitration, the local Government Board would appoint one arhitrator, who would hear all the cases and give a decision in each case, hy which they would save a great amonnt of expense. Instead of having an average of 130*l.* or 140*l.* to pay for these miserable houses, which involved a large amount of legal expense, he hoped they would he ahle, nnder the provisional order, to do it for half the amount.

NEW BUILDINGS ON THE THAMES EMBANKMENT.

A Bill is at present hefore Parliament to enable the Corporation of London to enter into certain arrangements with the Government as to the sale of land on the Thames Embankment (on part of the site of the City Gasworks), for the erection of a new Mint. The City Lands Committee reported, at a recent meeting of the Conrt of Common Conncil, that in pursuance of a reference to them in February last, they had proceeded with the negotiations for the acqnisition hy the Government of a portion of the land helonging to the Corporation on the Victoria Embankment, consisting of ahout three acres, for the erection of a new Mint; and for the acquisition, hy the Corporation, of the premises in Basinghall-street, formerly nsed for the purposes of the Bankruptcy Conrt. Mr. George Pownall was appointed hy the Government to meet the City Architect for the purpose of determining the snm to he paid by the Government for the fee simple of the land to he purchased, as well as the snm to he paid by the Corporation for the old Bankruptcy Court premises, with the nsual power to appoint an nmpire. Mr. Pownall and the City Architect not having heen ahle to agree as to the amounts to he paid for the said properties, they referred the determination thereof to Mr. E. N. Clifton, who had since made his award, settling and determining the value of the fee simple in possession of the land in Basinghall-street at 93,500*l.*, and the value of the fee simple in possession of the land on the Victoria Embankment at 254,475*l.* These arrangements were conditional on the Act heing obtained. As onr readers know, the new buildings for the City of London School are ahont to be erected on the west side of De Keyser's Royal Hotel; and westward of the school buildings a new street running northwards to Whitefriars-street is ahont to he constructed. The proposed new huildings for Sion College, the new hall for the Grocers' Company, and the new Mint, will fill np the remainder of the large area now vacant. The works for the extension of De Keyser's Hotel eastward into New Bridge-street are now in full progress, so that we may hope that hefore very long the City-end of the Victoria Embankment will asenme a finished aspect. The site of the Bankruptcy Court in Basinghall-street will probahly he devoted to the erection of a new Conncil Chamher adjoining the existing Corporation huildings at Guildhall.

THE TREES IN KENSINGTON GARDENS.

For several years past we have from time to time called attention to the urgent necessity of removing the many decaying and decayed trees which have so long disfigured this sylvan retreat, and we are glad to note that the work is now heing energetically taken in hand. The work of tree-felling must now of necessity he much more extensive than would have been needful had timely heed heen given to advice and remonstrance. It is satisfactory to he assnred that the axe will he wielded warily as well as holdly.

AN APPRENTICESHIP SCHOOL IN ROUEN.

This institution was fonnded hy the Municipality of Rouen in May, 1878. The trades tanght are those connected with the working of wood, metal, and leather. There are, at the present time, ahont forty pnpils. They are admitted at twelve years of age, when they leave the primary schools, and the term of apprenticeship is three yeare. Our informant says the results promise to be satisfactory.

SONNET.

LILIAN ADELAIDE NEILSON.

An exit, and re-entrance death-debarred:—
Gone Lilian Neilson, with steps of fleetness!
Silent now thy voice's rhythmic neatness;
Thy careful, bright career too early marred.
Howe'er to thee the problem might be hard,
Well didst thou present in due completeness
The fine human warmth and southern sweetness
Of him, the world's dear sympathetic bard.
Much moved to mourn in verses over thee,
My trembling lute I sadly took, this plaint
To sing of Juliet we no more shall see:
In hope that tones here struck without constraint,
Might for others also tell in melody
The grief for one, who many griefs could paint.

E. C. I.

THE LATE MR. BENJAMIN FERREY, ARCHITECT.

We record with extreme regret the death of Mr. Benjamin Ferrey, F.S.A., which took place on Sunday last at his residence, 55, Inverness-terrace; the cause was weak action of the heart and general decline. Few men in the profession have heen more generally popular, and his departnre will he lamented hy many friends. We shall give some account of his life and works in our next. Mr. Ferrey wae in his seventy-first year, having heen horn April 1st, 1810.

EMPLOYERS' LIABILITY BILL, 1880.

The Master Builders of Great Britain have petitioned the House of Lords, praying that their Lordships will make such alterations in the Bill as will hring it into accord witb the following objections:—

OBJECTIONS

Of the Master Bnilders of the United Kingdom to the Employers' Liability Bill, 1880, as passed by the Hon. House of Commons.

We beg to Submit,—

1. That the Master Bnilders of the United Kingdom employ a larger number of hands than are employed in any other branch of industry proposed to he affected by the present Bill.

2. That, while many other clanses of the Bill are open to objection, Sub-clause 3 of Clause 1 is the most objectionable, as the one which entails the greatest hardship upon employers, and especially those engaged in the building trade.

3. That it appeared from the observations of H.M. Government, that the object and scope of the Bill was only to render the employer liable for the acts of a person "to whom the employer distinctly delegates his own authority," and the definition introduced into the Bill, of a "person who has superintendence entrnsted to him," is "a person whose sole or principal duty is that of superintendence, and who is not ordinarily engaged in manual labour."

4. That Sub-clanse 3 is in direct contradiction to such definition, and therehy (so far at least as builders are concerned), almost abolishes the defence of common employment, nearly every one employed being nnder the direction of some other. For the above reasons it is humbly submitted that it will be just and expedient that Sub-clause 3 should be omitted from the Bill, which would then leave every employer liable for the acts of his authorised superintendents.

5. That in regard to Sub-section 4 in Clause 2, it is submitted that it would be impossible in most cases to prove that the workman *knew* of the defect or negligence which caused his injury, and it is therefore desirable to alter the clause as follows, by inserting the words hereinafter put in italics:—

In any case where the workman knew, *or with ordinary care would have known*, of the defect or negligence which caused his injury, *or was aware of any improper conduct on the part of others in the same employ which tended to cause his injury*, and failed within a reasonable time to give, or cause to be given, information thereof to the employer or some person superior to himself in the service of the employer, unless he was aware that the employer or such superior already knew of the said defect or negligence.

Benjamin Hannen,
President of the Builders' Society.
Geo. F. Trollope,
President of the Central Association of London Builders.
Stanley G. Bird,
Vice-President of the National Association of Master Builders of Great Britain.

London, August 20th, 1880.

The Cathedral at Truro is steadily making progress. Attention is centralised on the foundations, and these are heing got in. The excavating is going on down to 5 ft. helow the line of the crypt-floor line. The concrete footings for the east-wall are finished, and up to that level. The foundations all rest npon the solid rock 10 ft. 6 in. helow the grond at the east end, and 16 ft. 6 in. helow the nave floor line. A scaffold is up aronnd the old spire, which is some 120 ft. high, and it is being removed.

THE ROYAL MANCHESTER INSTITUTION.

The proposed scheme for the transfer of the Royal Manchester Institution, Mosley-street, to the Corporation of Manchester as a public gift, has been issued, with an explanatory letter to the governors of the institution, the committee to whom the matter was referred having delayed action until the question of the Manley Hall purchase was settled.

The proposed scheme is drafted as follows:—

1. The Royal Manchester Institution, as at present constituted, shall be dissolved, and the entire landed property, and the pictures and other effects in the building helonging thereto, shall he conveyed and transferred to the corporation of the city of Manchester as a public gift from the governors of the Institution, to be held by the corporation upon trusts to be mutually settled for public purposes.

2. The corporation shall provide an endowment of 2,000*l.* annually, to be devoted to the purchase of works of art, by which in time a permanent art-gallery for the city will he formed.

3. The chief rents shall be paid by the corporation.

4. The corporation shall maintain the institution in a state of efficiency; and if any surplus arise from exhibitions or other sources, such surplus shall he expended from time to time in the development of the permanent art-gallery.

5. The governing body shall be a composite committee, consisting of members of the corporation and members selected from the governors of the Royal Institution, in such proportions as may he mutually agreed upon.

6. All existing privileges of governors and their families shall he reserved.

7. The art-gallery shall be open free to the public on such days of the week as the governing body shall determine, and they shall also have the power to decide on the terms and conditions of admission on other days.

8. The above are proposed as the general principles, subject to such modifications as may be fonnd necessary.

By order of the council.

R. F. Ainsworth, M.D., Chairman.
E. Salomons, F.R.I.B.A., Hon. Secretary.

Manchester, August 4, 1880.

The approval of the governors of the Institution has yet to be obtained.

ARCHITECTURAL ASSOCIATION.

SURVEYING CLASS.

Among the many and great advantages offered by the Association to the junior members and students of the architectnral profession is the Surveying Class. This year's course of lessons has just heen hronght to a cloee.

Arrangements were made with Mr. A. T. Walmisley (civil engineer), of 5, Westminster-chambers, Victoria-street, to give twelve lessons (six indoor lectures and six field lessons), which should embrace surveying with chain only; with chain and theodolite plotting; various methods of setting out curves with and without the theodolite; explanation of rules and tables connected therewith; the box-sextant and optical square protractor and vernier explained; levelling, adjustment for reversion and collimation explained and illustrated practically; calculations of areas by the planimeter; contours; calculation of drainage areas and capacities of reservoirs; calculation by Bidder's tables of earthwork in banks and cuttings from railway sections; the eidograph explained. In short, the instruction included every branch of land-surveying likely to fall within the experience of an architect, and Mr. Walmisley certainly spared no pains to make it thorough as well as comprehensive.

It is to be hoped when the class is more regularly established and more widely known the members of the Association will more numeronsly avail themselves of its invaluable help.

PARLIAMENTARY JOTTINGS.

Employers' Liability Bill.—This Bill was hrought up and read the first time in the House of Lords on the 19th inst., and was read a second time hy their lordships on Tuesday.

Lower Thames Valley Drainage.—In the Honee of Commons, on the 19th inst., Mr. Brodrick asked the President of the Local Government Board whether, considering that the inquiry of the inspectors into the Lower Thames Valley Drainage scheme terminated nearly three months ago, and that the scheme was condemned by a vote of the House of Commons last session, he could give a guarantee that the decision of the Local Government Board shonld he announced at a time when the attention of Parliament might he called to it. Mr. Dodson, in reply, said: I cannot guarantee that the decision of the Board shall he announced before the close of the session, as I must have time to master the volnminous evidence, and it would not he fair towards the parties interested to keep them in suspense until next year. If, however, the Board should decide to grant the provisional order applied for, the order would have no validity nntil confirmed hy an Act, so that ample opportunity will be afforded for its consideration by the House.

The British and Natural History Museums.—In the House of Commons, on the 19th inst. Mr. Gibson asked the Right Hon. the senior member for Cambridge University, one of the trustees of the British Museum, whether the

original estimate for the furniture and fittings of the new natural history museum was 177,570*l.*; whether of that sum there had only been actually granted the sum of 60,000*l.* in three successive instalments, leaving yet to be granted the sum of 117,570*l.*; whether, if the grants on account of original estimate were not in future largely increased, the removal of the Natural History collections might not be much retarded; and, whether the trustees of the British Museum would again bring the matter under the notice of the Treasury, and thus secure the speedy realisation of the advantages for which the public had already paid considerable sums.—In reply, Mr. Walpole said, the question involves four queries. In answer to the first, it is the fact that 177,570*l.* was the original estimate for the furniture and fittings of the new Natural History Museum. In answer to the second, the sum actually granted this year is only 60,000*l.* In answer to the third, it is obvious in that state of facts the removal of the national collections must necessarily be retarded if the grant of 20,000*l.* is not largely increased next year. In answer to the fourth, when the trustees meet next November to consider the estimates, I have no doubt they will bring this matter under the notice of the Treasury, in the hope that they will be able to accede to a much larger grant for the ensuing year, otherwise the exhibition of the zoological collections must necessarily be postponed.

National Portrait Gallery.—In the House of Commons on Monday last, Lord F. Cavendish, in reply to Mr. Beresford-Hope, stated that authority had been given to the Board of Works to make the alterations which were considered necessary for the protection of the National Portrait Gallery from fire. These works will be proceeded with at once.

SANITARY MATTERS.

International Conference.—A telegram from New York, dated the 19th inst., says that Mr. Evarts, Secretary of State, has sent a circular through the American Ministers abroad inviting the maritime Powers of the world to send representatives to an International Sanitary Conference to be opened at Washington on the 1st of January, 1881, with a view to securing a system of notification of the actual sanitary condition of the ports under the jurisdiction of the respective Powers, and of vessels sailing from those ports.

Sewer Ventilation at Portobello.—Serious complaints having been made of a nuisance caused by the ventilation of the sewers of Portobello by means of gratings opening into the middle of the streets, Mr. Malcolm M'Neill and Dr. H. D. Littlejohn have held an official inquiry into the matter. Their report, just published, says that there can be no doubt that in theory the system of sewer ventilation adopted in Portobello is a good one, and is advocated by eminent sanitary authorities. But, the reporters add, "In any plan of free ventilation of the sewers of a town by openings in the roadway, if a nuisance from the escape of offensive odours from the drains is to be avoided, it is absolutely necessary that the drains themselves must be properly laid, and at the same time be of the best construction. . . . . The plans of short air-shafts from the drains opening on the roadway were obtained from the neighbouring burgh of Leith, where the system had been partially introduced, and, without availing themselves of the experience of the Leith Burgh Surveyor, the Local Authority proceeded to carry out the system of open street sewer ventilation in Portobello with the assistance of an ordinary tradesman. If a practical engineer had been consulted, and if he had strongly recommended the system in question, there can be no doubt that the whole sewerage of the burgh would have been overhauled and in part reconstructed. After this had been done, at points which would be determined by careful engineering experiments, the best sites for the street openings would be selected, and the ratepayers would thus have the satisfaction of knowing that the Local Authority had availed themselves of sound engineering skill, and that the system was being tried under the best possible conditions." But Portobello, in addition to imperfect construction of drains, has special difficulties connected with its site as a town which rendered great care necessary in the adoption of this system of sewer ventilation. Its drains are tide-locked for a considerable portion of the twenty-four hours, and the sewage is thus accumulated for several hours in the drains, which, wherever imperfect, are thus subjected to the agitation of deposits along their course, and to the consequent escape of offensive odours."

THE NUDE:

ANOTHER THEORY.

In Eve's happy time there was no "society,"
For all the world knows poor Adam was none,
That when he went out he seldom came home to tea,
And so her best muslin was never undone.

You talk of the nude,—of this they'd satiety,
Where there's no Mrs. Grundy the nude is full dress;
Flounces of fig-leaf would have been impropriety,
Things that grave Adam would have had to repress.

But stay! you forget, there was then no occasion,
For jerseys, for lacing, for flounces at all,
These didn't come in till the serpent's persuasion,
These didn't come in till after the fall.

The apron, 'tis clear, came in with bad morals,
Your social arrangements all came in with sin,
Eve's daughters by dressing no longer seek laurels,
We may therefore conclude the nude has come in.

The hall-room is platform for groups of poses plastiques,
And damsels of flesh with the marble will vie,
Whilst the stage is the scene of naked gymnastic,
And Venus displays her limbs next to the sky.

Days of pure thoughts must be surely returning,
We shall see native Eves in the Park, in the Row,
Whilst a crowd of young athletes with genius burning,
Will pass with lids drooping, and seem not to know.

METER.

COMPENSATION CASES.

Value of 14 ft. in Gracechurch-street.—An action was tried last week before a special jury and Sir Thomas Chambers, Q.C., M.P., the Recorder, to assess the compensation payable to Mr. John Wilkinson, in respect of his freehold premises, No. 90, Gracechurch-street, possessing a frontage of 14 ft. to that thoroughfare, and covering a superficial area of some 640 ft., in consequence of the land being required by the Corporation of London for the improvements and approaches to the new Leadenhall Market. The evidence as to the value of the freehold on the part of the claimant exceeded by one-third that of the valuers for the Corporation. For the former, Mr. Edmond F. Fuller (Fuller & Fuller), Queen-street, City, who had prepared the claim, submitted 600*l.* a year as the annual value of the premises to an ontsider, and some 10 per cent. more to the tenant in possession. On the part of the Corporation, the highest estimate was 450*l.* a year, or 10*s.* a foot rental for the land at twenty years' purchase, and cost of the buildings added thereto. The claimant stated that he rented the premises some twenty-six years ago at 90*l.* a year, and that he purchased them about twenty-three years back for 1,800*l.* In the end a verdict was returned for 16,500*l.*, including the fixtures, agreed at 418*l.* This result was, it is said, arrived at by the jury assessing the rental value at 550*l.* a year, or 12,100*l.* for the freehold, being about 18*l.* 18*s.* a foot, or 823,284*l.* per acre, as against about 2*l.* 15*s.* per foot, the purchase-money paid in 1857, to which they added upwards of 3½ years' purchase of the profits made out of the business as compensation.

Birnbaum v. The Corporation of London.—On the 19th inst., the claim of Mr. Bernard Birnbaum, of 89, Gracechurch-street, was heard before the Recorder and a special jury.

The plaintiff, a manufacturer of waterproof and gutta-percha goods, some years ago purchased the residue of the lease of his premises, which were not only valuable for the purposes of his business, but for letting. The lease had to run for five years and a half, and Mr. Birnbaum expected a renewal. Being at a corner, the position was rendered more valuable for such purposes as advertising. The yearly rental, when the lease was acquired by the claimant in 1868, was 320*l.* It was now considerably in excess, and it was estimated that at the present time the improved net rental was at least 290*l.*, or 600*l.* altogether.

Mr. Collins was called, and deposed that he had examined the property. Part of it was let off at very low rentals. He estimated the net improved rental at 290*l.* per annum, which, calculated on the 6 per cent. table, and multiplied by five and a-half years' purchase, gave a total of 1,595*l.* Adding the 10 per cent. for compulsory purchase and the sum allowed for fixtures, he arrived at a total of 1,946*l.* 10*s.* as the value of the building, without taking into account loss of trade, &c.

Mr. Farmer stated that he considered the net improved rental to be 280*l.* per annum, and he considered that the value of the building was 1,886*l.* In cross-examination, he said that the premises were in a dirty condition, and would require the expenditure of 100*l.* to put them in repair.

Mr. Fuller and Mr. Eason gave confirmatory testimony, whilst Mr. Davids (of Messrs. Harvey & Davids) estimated the improved rental at 440*l.*

For the Corporation, Mr. Trist and Mr. Driver were examined, and these gentlemen valued the improved rental at 209*l.* and 190*l.* respectively.

The jury, after a short deliberation, awarded the compensation as follows: 1,512*l.* 10*s.* for lease, including the 10 per cent. for compulsory purchase; 192*l.* 10*s.* for fixtures; 365*l.* for goodwill; and depreciation of stock, 250*l.*: total, 2,320*l.*

THE COLLEGE FITTINGS AT YEDO, JAPAN.

SIR,—I have seen the letter of M. De Boinville, taking exception to the good opinion I have formed of the Physical College fittings at Yedo, which were suggested by Professor Ayrton, and ably carried out by the architect.

Dr. Williamson, of University College, who took the chair at my lecture (but who is not a professor of King's College), admitted the original character of the fittings to which I referred, so far as he knew, and I have said no more.

I am not aware that I have given any privileged information, or described anything not justified by the subject under discussion.

I certainly did not wander away into a description of the architectural excellences of the buildings forming the College at Japan, nor did I allude to any defects; but I simply drew the attention of the audience to a class of specially-designed fittings in one department only, the particulars of which were given to me by their originator, though not their executor, and I still think them highly creditable to both, and to the enterprising founders of a technical college the like of which is scarcely equalled out of Japan.

EDW. C. ROBINS.

SEWAGE AND THE THAMES.

SIR,—Observing in the *Builder* of the 7th inst. the trouble the London sewage is occasioning in the neighbourhood of Woolwich, let me ask,—is it impracticable to treat this large mass on the same principle as the smaller volume flowing out of the sewers at Taunton is treated? There I was recently shown by the surveyor a perfectly clear and pellucid stream of water passing from their sewage works, and causing no nuisance whatever in the river. Whereas, before the establishment of these works, fish could not live in the river, they now are to be seen, not only above the sewage works, but in all parts, even to the very outlet from the works.

Clearly, therefore, the only difficulty would be an engineering one, in applying the same system on a large scale to the London sewage. It would be difficult to conceive that engineering skill is not equal to such a task.

FELDSPAR.

PIN DOVETAILING MACHINE.

HAVING paid a visit a few days since to the Bow and Bromley Institute (above the North London Railway Station, Bow, E.), where a Workman's Exhibition is now being held, amongst the many models shown there my attention was particularly attracted to a good specimen of pin dovetailing, in the form of a square pedestal produced by a machine on an entirely new principle, invented by Mr. P. Hackworth, foreman machinist to Mr. W. Brass, contractor, Old-street, St. Luke's. Being allowed by Mr. Hackworth to inspect the machine, I consider the simplicity and ingenuity of its construction, coupled with its low cost, should recommend it to the notice of those interested, namely, builders, cabinet and pianoforte makers, box and drawer makers, shop-fitters, and many others where it might be employed to great advantage.

JOHN RENNIE.

"BUILDING LINE."

SIR,—Will some of your correspondents kindly reply to the following questions:—

1st. Is there any authority, urban or suburban, can compel me to build up to my building line? I want to go 9 ft. behind it.

2nd. What steps can I take when the local authorities refuse to pass my plans because of my setting-back?

W. H.

Lambeth Palace Library will be closed for the recess for six weeks from the 30th inst. The new collection of pamphlets on the monastic literature of England and Wales is rapidly increasing by the gifts of authors and societies.

GAS JOTTINGS.

Lancaster.—The Gas Committee of the Lancaster Corporation, who came into possession of the Lancaster Gas Company's concern in July, 1879, report that, after allowing for interest on capital, the net profit on the first year's working amounts to 2,335*l.* They have resolved to reduce the price of gas to small consumers from 4s. 2d. to 3s. 8d. per 1,000 cubic feet, and to large consumers from 3s 8d. to 3s. 6d.

Oldham.—The gross profits of the Oldham Corporation Gas Works on last year's working were 25,800*l.* The sum of 13,500*l.* was handed over to the borough fund, to he applied in aid of the rates. The price of gas is 4s. 2d. per 1,000, with discounts for ready money.

Books.

British Bee-Farming: Its Profits and Pleasures. By Jas. F. Robinson. London: Chapman & Hall. 1880.

There are many ways in which, with much pleasure to themselves, people with a head on their shoulders and a fair amount of energy may make money, who now merely moon about and *wish* they could do so. As our author quotes,—

> "The wise and active conquer difficulties
> By daring to attempt them. Folly and sloth
> Shiver and shrink at sight of toil and trouble,
> And make the impossibilities they fear."

Among these ways, at any rate with persons living out of town, should he placed bee-keeping, or, as it has come to be termed, bee-farming, concerning which Mr. Robinson has "no hesitation in saying, that in proportion to the capital expended, bee-farming will be found the most profitable business known." From 6*l.* to 9*l.* per annum may he made per hive, and twenty hives may he as easily looked after as one. Moreover, we import hundreds of tons of honey annually from Italy and elsewhere, which might he as well produced in heathery England. To get the most out of a hive some knowledge is, of course, necessary, and this Mr. Robinson's hook now before us supplies. It is clearly written and full of practical information.

Breweries and Maltings; their Arrangement, Construction, Machinery, and Plant. By Geo. Scamell, F.R.I.B.A. Second Edition, enlarged, by Fredk. Colyer, C.E. London: E. & F. N. Spon. 1880.

We need merely mention the issue of a new edition of Mr. Scamell's book. On its appearance we made its contents fully known, and assisted in obtaining for it a considerable circulation. The new edition has been partly re-written by Mr. Colyer. It contains twenty pages of plans and sections. It has been published a little too soon to include the alterations which will he required by the recent changes in the Exciso Laws.

Views of Ancient Buildings Illustrative of the Domestic Architecture of the Parish of Halifax. By John Leyland. Halifax: R. Leyland & Son. 1879.

Halifax is rich in residences of the fifteenth, sixteenth, and seventeenth centuries, and it was most desirable that some record of them should be preserved before time or further restorations should make the task more difficult. When we read in the first page of the introduction that, "Though diversities of taste may still exist, there can he no doubt that already the general opinion of this country is in favour of a return to the architecture of our forefathers of Mediæval times, both in ecclesiastical and domestic buildings," the impression is given that it must have been written much longer ago than 1879, though only just now published. And yet, on the other hand, it would seem obvious that Mr. Leyland's antiquarian studies have not been carried very far back, or he would scarcely have commenced his book with the assertion that, "It was the late Augustus Welby Pugin who first pointed out the perfection and grandeur of the cathedrals, abbeys," &c., of the great architectural agee of England. The work is of folio size, and includes twenty-five plates. There is not much art in the drawings, reproduced by the now inevitable photo-lithographer, but they serve to convey with exactness the aspect and style of the various structures, so we have reason to be obliged to Mr. Leyland, and we hope his example will he followed by dwellers in other localities.

Notes on Sketching Tours. By an Architect. B. T. Batsford, 52, High Holborn. 1880.

This is an able and a charming little book, and is likely not only to lead those who always sketched to sketch the more, but to make many sketch who ne'er did so before. The "architect" is Mr. Henry Taylor, of Manchester, who sketches very well himself, and gives numerous examples. Good lines of country are pointed out both at home and abroad, and the author gives references to a large number of books, as he goes along, in a simple and natural manner, calculated to lead the student to look them up, and make the most of them. *Nota bene.*—It is not necessary to be an architect to derive advantage from these "Notes."

Miscellanea.

Chemical Ventilation.—On the 18th inst. Dr. Richard Neale, in the presence of a number of engineers, gave a demonstration of a scheme to purify the foul air of tunnels, mines, cabins, churches, theatres, hospitals, and other buildings. The *Lancet* says:—The proposal promises to create a new era in ventilation. Nearly all attempts hitherto made to purify the air in crowded buildings have been mechanical, and have consisted of driving out the foul air by currents of fresh air. Dr. Neale's proposal, on the other hand, is a chemical one, and is designed to destroy the poisonous gases. It is not, of course, intended to supersede ordinary ventilation hy currents, hut rather to act as an auxiliary. The essence of the scheme is the adoption of some simple chemical facts. As the lungs of living beings appropriate oxygen and give off carbonic acid gas, Dr. Neale proposes to make a "chemical lung" which will appropriate carbonic acid and sulphurous gases from the air containing them, without yielding any products in exchange. The air in the tunnels of the Underground Railway was referred to as a conspicuous and well-known example of impurity irremediable by mechanical means. The principal deleterious gases in this instance are carbonic acid and sulphurous gases and carbonic oxide. All these, but especially the two former, may, Dr. Neale maintains, he easily got rid of by chemical means. By mixing a solution of sulphurous acid and water in a flask, Dr. Neale made an excellent imitation of the air at the Baker-street or Portland-road station. He then added a small quantity of solution of caustic soda, and agitated the flask briskly for a few seconds, and immediately the sulphurous smell was abolished. Into the same flask a current of carbonic acid gas was next passed, so that a lighted taper introduced into the flask was at once extinguished. After a few shakings a lighted taper was again introduced and burnt with a bright steady flame, showing that the soda had taken up the acid. Similar experiments were made with solutions of caustic lime.

Burning of the Lyceum Theatre, Sunderland. — This structure has gone the way of all theatres. It was designed by Mr. Thomas Moore, architect, Sunderland, and was opened to the public for the first time on the 29th of September, 1856, its erection having occupied just twenty weeks. The building was 106 ft. 9 in. in length, and its original breadth was 48 ft., but some time after it was finished the house adjacent to it on the northward was added on to it, and its width then became 72 ft. 6 in. The front is about 55 ft. in height, and from the floor of the pit to the ceiling the measuring line gives a record of 38 ft. The auditorium was of semicircular shape, and it measured 44 ft. in width at the proscenium, whilst from the edge of the stage to the front of the dress circle the distance was 30 ft. The stage was 55 ft. deep. The fabric of the building cost within a trifle of 7,000*l.* The carpenters' shop was situated close to the roof of the theatre, and it was here that on Thursday night in last week the fire broke out. No one was in the building at the time, and it is quite impossible even to hazard a guess at the cause of the outbreak.

Mr. Joseph Newton, C.E., who as president for twenty-four years has promoted the welfare of the London Association of Foreman Engineers and Draughtsmen, has been presented with 100 sovereigns and a timepiece.

Mr. Robert Charles Ransome, the senior partner in the firm of Ransomes, Sims, & Head, Orwell Works, Ipswich, one of the oldest agricultural engineering works in the country, returned to the works on the 9th inst., after a nine months' tour round the world, taken for the benefit of his health. His return was the occasion of a remarkably congratulatory gathering of the whole of those engaged in the works, and the presentation of an illuminated address, and a handsome album containing the signatures of the 1,150 persons employed by the firm. These, in a neat and very appropriate speech, were presented by Mr. Henry Alexander Byng, C.E., and as suitably acknowledged by Mr. Ransome. Mr. G. A. Biddell, C.E., then made a characteristic speech, in which, after re-echoing the welcome of the address, he took occasion to refer to foreign competition, which, he said, was not so much in the hands of the masters as of the men, and that the performance of thoroughly good, honest work in every respect was most necessary, and the strongest means of defying it. Mr. W. D. Sims, many years a partner in the firm, and Mr. J. E. Ransome made some remarks on the occasion.—*Engineer.*

Death by Lead Poisoning.—Last week Mr. Payne, the City Coroner, held an inquest at the Mortuary, Golden-lane, Barbican, on the body of Mary Ann Donovan, aged thirty. Evidence was adduced showing that the deceased, a single woman, earned her living hy working at a white-lead factory in Hoxton. On the 13th inst. she was seized with what appeared to be a fit, and was removed to St. Luke's Infirmary City-road. The next day being Saturday, she left the infirmary to go and take her wages. The following day she complained of being ill and of having severe pains in the head, which continued until the morning of the 17th inst., when her landlady went for a medical order for the parish doctor. That was at ten o'clock in the morning, hut owing to the doctor and his assistant being out on professional business, no doctor attended until about one o'clock, when Donovan had been dead an hour or so. Dr. Reed deposed at the inquest that there were distinct marks of lead poisoning to he seen between the teeth and gums of the deceased's mouth, the effect of the employment she had followed. The cause of death was an apoplectic or epileptic fit, produced hy the lead poisoning. A verdict in accordance with this evidence was returned hy the jury.

The Ruins of Conway Castle.—A Shrewsbury paper says,—Visitors who approach Conway hy rail from the Chester side are often surprised, and doubtless alarmed, to see, upon emerging from the tubular bridge, the vast fragment of one of the towers of the old castle suspended some 40 ft. above them, and clinging to the picturesque ruin in a way which awakens fears for its security. The peculiar position of this ruined tower, which is known as Twr Dain, is said to be due to the avarice of some of the old inhabitants of Conway, who, hy excavating the rock at its base, caused a vast fragment of the building to fall, leaving the upper portion, however, in a state of perfection which suggests comparison between the builders' workmanship of the thirteenth century, when Conway Castle was completed, and that of the present day. Although there appears to he no immediate danger of the old ruin giving way, the London and North-Western Railway Company are taking precautions for the safety of their line, which runs almost underneath it, and have determined upon giving the ruin a substantial support.

Accident.—At Cradley-heath, Staffordshire, an inquest has been held on the body of a woman named Ann Heath, who was killed by the fall of a portion of a building. It appeared that a chainmaker named Joseph Billingham let a shop to other chainmakers. On the 10th inst. a portion of the building fell down, killing the deceased, and seriously injuring other persons. Several witnesses swore that they had called Billingham's attention to the dangerous state of the building in question, but he neglected to have any repairs executed. The jury returned a verdict of "Manslaughter" against Billingham.

A Stupid Practice.—Steps are being taken to put a stop to the practice frequently indulged in, hy a certain class of visitors to the Cathedral of Canterbury, of carving their names and initials upon the walls and columns of that edifice. A prosecution has been instituted hy the Dean and Chapter against an excursionist from London, who was found guilty, and fined by the magistrates for the offence.

The New Clock, Chimes, and Bells for Dunedin Town Hall.—The new clock and bells for the Town-hall of Dunedin, which have only recently been sent out, have been entirely manufactured by Messrs. Gillett, Bland, & Co., of Croydon. The clock strikes the hours upon a bell weighing about 30 cwt. (note D), and chimes the four quarters on four other bells in due proportion of the following notes, A, F sharp, B, G; the five bells weigh altogether 3 tons 16 cwt. 2 qrs., the chimes being similar to those at the Westminster Palace. The four illuminated dials are each 7 ft. 6 in. in diameter, the figures, minutes, and circles being of cast iron, all in one piece, glazed with patent opal glass, and painted and gilt. The main frame is made, on the horizontal plan, of solid cast iron, planed top and bottom on an engine, and is so constructed that any wheel can be taken out separately without disturbing the other parts, and the clock over all is 6 ft. 6 in. long, 3 ft. 6 in. wide, and 3 ft. high. All the wheels are of the best gun-metal, turned, cut, and polished in an engine, the main wheels being 18 in., 18 in., and 16 in. in diameter. The escapement is the "double three-legged gravity," which the makers have from long practical experience found to be much superior to all ordinary kinds for perfect time-keeping. The pendulum (instead of the ordinary wooden rod) is a compensation one, made of zinc and iron tubes, and to beat two seconds of time, with a cylindrical bob at the bottom, weighing about 2¼ cwt. It also has a collar fitted on the rod for small weights for regulating, and a degree plate; it will, therefore, not be affected by any variation of temperature. There are two engraved and silvered dials on the clock, showing minutes and seconds, for the purposes of adjusting the outer hands and taking observations. All the bushes for the steel pivots to run in are made of gun-metal, screwed into cast-iron frames, so that they can be easily removed when required. The motive power is given to the clock by weights, weighing 1¼ ton, suspended from the three wrought-iron barrels by steel wire, altogether 500 ft. in length. The chime-barrel is constructed on Gillett, Bland, & Co.'s improved principle, with movable steel cams, so that the chimes can be adjusted to the greatest nicety, or changed at any time if required.

The Princes of Wales and Carnarvon Castle.—A suggestion made some time ago respecting the desirability of placing in Carnarvon Castle a tablet commemorative of the birth of the Princes of Wales has at last been carried out. Through the liberality of Mr. R. Sorton Parry, formerly High Sheriff of Carnarvonshire, a tablet, containing the names of the seventeen Princes of Wales and the dates of their birth, has been fixed in a prominent part of the noble pile. The memorial, which was executed by Mr. Hugh Jones, marble mason, Carnarvon, is surmounted by the Cambrian plume.

Manchester Industrial Exhibition.—Owing to the great demand for space at this exhibition it has been found necessary to postpone the opening until September 1st, in order to allow of the proper arrangement of goods, &c. The exhibition will be the largest of the kind that has been held in the North of England. Nearly all the space covered by the Agricultural Hall (two acres), with the exception of what has been retained for passages, will be covered by exhibits. The manager (Mr. Fred. Scott) has been assisted in the arrangement of exhibits by Mr. Joseph Corbett, engineer, Bartou-arcade.

The Patent Office.—From the annual report of the Commissioners of Patents it appears that during 1879 there were 5,388 applications for patents. This is a decrease of five upon the returns for the previous year, when the number of applications was 5,393, being the highest ever recorded. Of the first-stated number no fewer than 1,877 applications, or a little over one-third, were abandoned, so that only 3,461 proceeded to the final stage, and arrived at maturity. From the report we learn that a new edition of the index to the patents granted from 1617 to 1852, under the old law, is in progress.

Melbourne Cathedral.—A letter from Melbourne says,—"A gentleman here has just given 10,000*l.* towards the new cathedral, which I am sorry to say they are going to build in a hole, simply to be near the railway station."

Social Science Congress, Edinburgh.—The presidency of the Art Department has been accepted by Mr. W. B. Richmond, Slade Professor of Fine Art at Oxford.

The Tower of London.—We are glad to hear that in consequence of the many complaints of the delays in admission to the Tower which visitors have hitherto been subject to, it has been decided to abandon the system of visiting by batches of twenties, and to throw the rooms open as in other museums. The "beefeaters" will no longer act as guides, but as custodians and sentries at various places throughout the building. We urged the desirability of the change long ago, and the proposition was backed up in our pages by the late Mr. Planché, who had the improvement of the Tower Armoury much at heart. It was stated by Mr. Childers, Secretary of State for War, in the House of Commons on Monday last, that the new arrangements are to be made experimentally. An improved catalogue is to be issued, and the various objects of interest will be labelled. A committee has been appointed to work out the details of the new plan, which will be brought into operation as soon as possible. The possibility of showing to visitors additional places of interest will be considered by the committee, and also the question of an additional free day.

Pictures at Bristol.—The Committee of the Bristol Fine Arts Academy have decided to establish an exhibition of pictures which shall be of a permanent character, and free to the public for four or five months in the year. The spring exhibition will be held as usual, but it has been decided to discontinue the loan exhibitions that have for several years past been opened in the autumn. The encouragement given to these latter has not been sufficient to induce the committee to again undertake the great labour and responsibility involved, and in place of exhibitions of this kind an attempt will be made to form a permanent art gallery. The works already in the possession of the Academy enable them to make a start in this direction, and it is hoped that in time many more valuable works will be presented, so that a gallery worthy of the city may be formed. Should the committee meet with the encouragement they hope for, a new gallery will be added to the building for the reception of the pictures.

Messrs. Child's New Banking House, Temple Bar.—On the 23rd inst, the new buildings, partly in Fleet-street and partly in the Strand, which have just been erected as the banking premises of Messrs. Child, consequent on the demolition of Temple Bar, were opened for business. The elevation, which is in Portland stone, carved and decorated, contains three lofty floors. The ground-floor portion, which is wholly appropriated as the banking-house, is elaborately rusticated, with a massive entrance at the east, or Fleet-street, end of the frontage, surmounted by a frieze and an overhanging cornice and balcony. Above this is an ornamentally-carved shield with the arms of the Marigold Tavern, which, according to tradition, stood upon the site some 300 years ago. At the west or Strand end of the frontage there is a corresponding balcony, with Messrs. Child's arms and crest. Mr. John Gibson is the architect, and Messrs. George Smith & Co., of Pimlico, are the builders.

Art-Metal Work.—Messrs. Hart, Son, Peard & Co., have issued many trade-books in their time, quite up to the demands of the day, and very useful to those who wished to know where to obtain what they wanted without the extra cost of fresh designs and isolated workmanship; but they have not before sent out anything so complete as that which they have just now issued under the title "Examples of Art-Metal Work for Ecclesiastical, Public, and Domestic Use." It is divided into six sections. Prices are given, and the designs, which are of very varied character, are so well classified, that articles or specimens of work needed can be found at once. For designers, too, the book is suggestively valuable, and enables them to know for about what cost the firm would produce what is proposed.

Victoria Docks.—An improved form of jetty, fitted with hydraulic cranes for discharging coals from steamers, is being erected at the Victoria Docks, for Messrs. W. Cory & Son, from the designs of Mr. Henry Adams, C.E., on the site of one of the old coal-berths recently burnt down. Another of the jetties is also to be extended and fitted with a fourth crane, in order that the large steamers now being built for the coal trade may be discharged in one tide. When this extension is completed, a steamer, with suitable hatchways, will be able to discharge 2,000 tons of coal in twelve hours.

St. Paul's, London.—Some time ago, on a survey being made by the cathedral architect (Mr. Penrose) it was discovered that a portion of the stonework in the upper part of one of the lofty fluted columns of the west portico at St. Paul's had given way. It was found that nearly one-half of the upper course of the column, immediately under the capital, and upwards of 3 ft. in length, had cracked and parted from the other portion, rendering the condition of the structure dangerous. Its removal was a ticklish piece of work, and has been accomplished successfully.

Destruction of Whitechapel Church by Fire.—We regret to learn, as we go to press, that the parish church of St. Mary, Whitechapel, was totally destroyed by fire on Thursday afternoon. The fire is believed to have originated in the organ-loft. The church was only rebuilt a few years ago, at a cost of about 70,000*l.*, from designs by Mr. Ernest C. Lee, now President of the Architectural Association.

Surveyorship, London and North-Western Railway.—Mr. F. Wood, of Rugby, has resigned the post of Surveyor to the London and North-Western Railway Company, which he has held for many years, and is succeeded by Mr. Charles Hull, of Liverpool.

Roof Varnish.—A varnish for roofs has been recently patented in Germany which is composed of 35 parts of clay slate, 30 parts mica slate, and 35 parts rosin, all finely powdered and heated with 50 parts of tar.—*Bay. Ind. und Gewerbeblatt.*

TENDERS

For the erection of residence, at Hayes Common, Kent, for Mr. De Zoete. Mr. Somers Clarke, architect:—

Nightingale	£5,387	0	0
Coney	5,331	0	0
Hull	5,274	0	0
Manley	5,139	0	0
Dove, Brothers	4,295	0	0
Gammon	4,199	0	0
Funnett (accepted)	4,110	0	0

For alterations and new stables, at St. James's Tavern, Westminster, for Mr. J. Smith. Quantities not supplied. Mr. H. J. Newton, architect:—

Anley	£2,575	0	0
Goddon	2,493	0	0
Wagner	2,359	0	0
Beale	2,333	0	0
Gritten	2,327	0	0
Lamble (accepted)	2,257	0	0

For pewterer's work, at same:—

Paddon	£146	0	0
Angliss	145	17	6
Richards	140	0	0
Hellings	132	0	0
Warne	129	0	0
Heath	125	0	0
Sanders (accepted)	110	7	0

For Patrick Stead Hospital. Mr. Henry Hall, architect. Quantities supplied by Mr. S. J. Thacker:—

Watson	£5,630	0	0
Garrud	5,483	0	0
Garlick	5,377	0	0
H. B. Smith	5,182	0	0
Girling	5,175	0	0

Green, Brothers	2,479	0	0
Heap	2,449	0	0

Tenders, with schedule of prices combined, for constructing new roads and sewers, to form "The Avenue," on the new Cliftonville Estate, Northampton, for Mr. P. Phipps. Mr. Matthew Holding, architect. Quantities supplied:—

Chapman	£1,243	15	11
Finnegan	1,089	18	6
Ireson	1,035	10	9
Martin	914	0	0
Wingrove	886	11	6
Hames	782	2	11
Barlow	761	10	9

For alterations at the London Alehouse, Exeter, for Mr. William Davie. Mr. C. Pinn, architect. Quantities not supplied:—

Westlake	£275	10	0
James & Inch	265	0	0
White (accepted)	250	0	0

For converting two houses into one, at Exeter, for Mr. W. Snow. Mr. C. Pinn, architect. Quantities not supplied:—

Westlake	£300	0	0
Brook	215	0	0
James & Inch (accepted)	147	0	0

For two hydraulic lifts, tank, pipes, and other apparatus, for the Royal Hotel, Blackfriars. Mr. E. A. Grüning, architect. Mr. F. Colyer, engineer:—

Contract No. 1.—Wells.
Baker & Sons (accepted)

Contract No. 2.—Lifts, &c.
Simpson & Co. (accepted).

Contract No. 3.—Heating apparatus.
Siehe, Gorman, & Co. (accepted).

For additions to the Palace Brewery, Anerley-road, Crystal Palace, for Messrs. Edie, Brothers. Mr. C. J. C. Pawley, architect:—

Flynn & Sons, Anerley	£350	0	0
Smith & Sons, South Norwood	260	0	0
Fox, Anerley	250	10	0
Hollidge & Stuart, South Norwood *	233	0	0

* Accepted.

For painting and decorating house at Highgate, for the governors of the Cholmley School. Mr. Herbert Winstanley, architect;—

Phillips & Son	£334	0	0
Harrison & Wood	294	0	0
Wheeler	288	0	0

For new roads, on the estate of the Right Hon. the Earl of Yarborough, at Great Grimsby. Messrs. Maughan & Curson, surveyors:—

Brown (accepted)	£836	9	2

In the list of tenders for Colchester drainage, for "Wickerson" read C. Dickinson.

NOTICE TO SUBSCRIBERS.

THE INDEX and TITLE-PAGE for Volume xxxviii. (January to June, 1880) was given as a Supplement with our Number for July 10.

A COLOURED TITLE-PAGE may be had, gratis, on personal application at the Office.

CLOTH-CASES for binding the Numbers are now ready, price 2s. 6d. each; also

BEADING-CASES (Cloth), with Strings, to hold a Month's Numbers, price 2s. each.

THE THIRTY-EIGHTH VOLUME of "The Builder" (bound) is now ready, price Twelve Shillings and Sixpence.

SUBSCRIBERS' VOLUMES, on being sent to the Office, will be bound at a cost of 3s. 6d. each.

TERMS OF SUBSCRIPTION.

"THE BUILDER" is supplied *direct* from the Office to residents in any part of the United Kingdom at the rate of 18s. per annum, *prepaid*. Remittances payable as above.

The Builder.

Vol. XXXIX. No. 1961. SATURDAY, SEPTEMBER 4, 1880.

CONTENTS.

The Late Mr. Benjamin Ferrey, Architect.

BENJAMIN FERREY was born at Christchurch, Hants, on April 1st, 1810, the youngest son of Mr. Benjamin Ferrey, of that town. They were a French Huguenot family, their ancestors having come over to England at the time of the Revocation of the Edict of Nantes, some 200 years since. When quite a little lad, Benjamin Ferrey evinced a taste for drawing, and loved old buildings. Close to his own home he could see a glorious example,—the grand old Priory Church. The sketches he made at the age of thirteen of the interior are very correct in their perspective, and good in touch for one so young. It may as well be said at once that Ferrey eventually became one of the best draughtsmen of his day, being, moreover, very accurate and painstaking. In his two months' tour in 1833, through France, Italy, Switzerland, and Germany, he made many sketches (some of them lithographed subsequently for the Architectural Publication Society). All through his life he was very fond of drawing. Benjamin Ferrey received his education at the Grammar-School at Wimborne, Dorset, where his genial disposition made him a great favourite with the head master (the Rev. James Mayo) and his schoolfellows. He astonished them at times by drawing for hours in the Minster, and the boys were always glad to have a sketch by little Benjamin.

The father wisely resolved to follow the bent of his son's inclination, and placed him with Augustus Pugin—himself, it will be remembered, a French Protestant, who had fled over to England on account of religious persecution. Mr. Pugin had not practised much as an architect, but was a clever draughtsman, and possessed a good knowledge of architecture. He was in the habit of making long tours, and diligently drawing and measuring mediæval buildings, accompanied by several pupils, who assisted him.* In this manner many parts of England and Normandy were visited.

The following letter, addressed later in life to the conductor of this journal, gives some interesting information concerning Ferry's trip to Normandy. It was written with reference to the Lady Chapel at Caudbec:—

"I think I can afford you some indisputable information respecting the construction of the great pendant of this chapel, which may set doubts at rest. I, with Mr. Talbot Bury and others of Mr. Augustus Pugin's pupils, many years ago accompanied that gentleman and assisted him by sketching and measuring the various portions of buildings published by him in his work entitled 'Specimens of the Architectural Antiquities of Normandy.'

I have a most vivid recollection of the intense interest which the elder Pugin felt in the construction of the remarkable pendant of this chapel. I can answer for it that there is nothing in his illustration of it, as shown in Plate 64, but which is perfectly correct. An opening being made through the tufa of the groining at the top, some of us got in, and no little trouble was it to get out again: but with a light there was no difficulty in ascertaining the size of the voussoirs resting upon the huge keystone of the groining,

* Most of these distinguished themselves in after-life, not as architects, but otherwise. For example, the late E. W. Cooke, R.A.; the late Joseph Nash, the painter; the late Charles Mathews, the actor. Mr. F. T. Dollman was another pupil who did not forsake architecture, and whose excellent architectural works are well known and appreciated. Another pupil who still survives in the active exercise of his profession is Mr. R. B. Grantham, the eminent C.E.

a monolith of upwards of 17 ft. long. There may probably be some conjecture as to the sizes of the voussoirs built into the external angular buttresses, but in all probability they would correspond with those visible to the eye.

The striking feature, however, of the Lady-chapel, both in execution and effect, is the surprising pendant; its appearance looks quite perilous, and until Pugin with his wonted energy had a hole made and found out the exact nature of the construction, all sorts of notions were prevalent, many believing that iron suspension rods, &c., were employed.

A careful description of the construction ought to have accompanied the plan and sections. Britton, who never saw this chapel, or any of the buildings he describes, could only give meagre accounts, wholly insufficient to exhaust the constructional interest which attaches to them. This was through no fault, but an unexpected illness, which prevented his accompanying Pugin."

In Ferrey's "Recollections" of A. Welby Pugin are many interesting anecdotes of Mr. as well as of Mrs. Pugin. The latter was more severe than the former, and kept the youths in good order. Mr. Ferrey had a keen sense of humour, and in his graphic, animated manner (he was a good mimic) could recount some of the rather severe practical jokes which some of the young men at times used to play on benevolent old Mr. Pugin.

Mr. Pugin, instead of taking all credit to himself for the assistance his pupils rendered him, was in the habit of allowing each one who made the drawing for the lithographer to fix his name, as "So-and-so *delt.*," with A. Pugin *direxit.* in the other corner. In Pugin's "Ornamental Bargeboards," and in his "Gothic Ornaments," a large proportion bear the inscription, "Benj. Ferrey *delt.*" in one corner. There is no doubt that this practice in measuring and closely examining old buildings was of great service in after-years to Ferrey and his fellow-pupils. The knowledge of detail and the good eye for proportion which always distinguished him may be said to have been partly the outcome of his travels with the elder Pugin.

After studying several years in this way, Mr. Ferrey entered the office of Mr. Wilkins for a short time as assistant, and worked at the detail drawings for the new National Gallery. To this association, perhaps, may be attributed the fact that Mr. Ferrey, though originally brought up in a Gothic school, and known as one of the early workers in the Gothic Revival, was never bigoted as regards the Classic styles, with which his pencil was always quite familiar. He never took the strong line that Sir Gilbert Scott did in that respect, though he undoubtedly preferred Mediæval architecture, with which he was more at home.

In 1834 Mr. Ferrey brought out "Antiquities of the Priory Church of Christchurch, Hants," the perspective and measured drawings of which he had been engaged upon for some time. In the literary portion of this work he enlisted the services of Wm. Brayley, and fortunately secured able engravers for the plates. About this time Mr. Ferrey commenced practice in Great Russell-street, Bloomsbury (on the site now occupied by the British Museum). He was soon commissioned by the late Sir George Gervis, Bart., to lay out his estate at Bournemouth (then a place consisting of but a few houses in the midst of fine woods and heath). Though Sir George Gervis, in a prophetic spirit, said that one day Bournemouth would be a great town, few people at that period believed it would develop as it has done. The Bath Hotel and several rows of villas, among them Westover Villas, on the east side of the Bourne, were designed and built under Mr. Ferrey's superintendence. So keenly did he enter into the scheme that he took a house at Bournemouth, and resided for some time there.

In 1836 Mr. Ferrey married Ann, the daughter of Mr. William Lucas, of Stapleton Hall, Stroud-green, Hornsey. One of Mr. Ferrey's first clients was the Rev. Thomas Thurlow, nephew of the great Lord Chancellor Thurlow, of Baynard's Park, near Cranleigh, Surrey. He made extensive additions to his old Tudor mansion. In 1839 he carried out a portion of Dorset County Hospital, Dorchester. In 1841 Mr. Ferrey was appointed Hon. Diocesan Architect, Bath and Wells, a post he held up to the time of his death. His connection with this diocese was seemingly quite fortuitous, as he had no relatives or particular interest in the county, but was introduced there by his friend the late Archdeacon Brymer, Rector of Charlton Mackerel, Somerset. He also obtained work in Dorsetshire through his friend the late Mr. C. Acland Troyte,* a country gentleman and a member of the good old Devonshire family of Acland.

In 1842 the subject of our notice was employed as the architect to superintend the restoration of the nave and transepts, and of the Lady chapel, Wells Cathedral. While this work was in progress Mr. Ferrey took one of the canon's houses for several months. He subsequently carried out for Bishop Bagot extensive additions and restorations to the Palace at Wells (and in later years for Lord Auckland and succeeding bishops, including Lord Arthur Hervey, the present prelate), as well as the restoration of the beautiful chapel there. The additional story to the principal front of the palace is a feature often thought by strangers to be a part of the original design.

Mr. Ferrey was one of the original members of the Architectural Society, and in 1839 became a Fellow of the Institute of Architects (he was one of its oldest members). He afterwards served on the Council and was twice a vice-president.

In the competition for the Houses of Parliament, Mr. Ferrey acted as honorary secretary to the Committee of Architects, and was himself a competitor. In 1843 Mr. Ferrey designed the costly Church of St. James, Morpeth (as well as schools), in the Norman style, a building well thought of in the North of England as a successful adaptation of the grander features of that style.

In 1845 Mr. Ferrey, then considered one of the rising church architects of the day, was commissioned by the Baroness (then Miss) Burdett Coutts to design the Church of St. Stephen, Rochester-row, Westminster. It was a poor neighbourhood, and a church was much wanted there. Handsome schools and a vicarage were also erected about the same time; the whole of these works, carried out at great cost, were due to the munificence of Lady Burdett Coutts.

At this period (about 1847) he had many works in hand, as this note to us will show:—

"As I think you said you would be always glad to have hints of what I am doing in the country, let me say:—

1. I am building a new Governor's house to the Oxford Gaol. It has been designed to form an angular tower in keeping with the rest of the structure.

2. I have reported upon the condition of the fine abbey church at Sherborne, Dorset, in reference to removal of all the existing pewing, and, indeed, the general restoration of the interior.

The noblemen and gentlemen in the neighbourhood take great interest in the work.

3. I have just completed some extensive alterations to the Palace at Cuddesden, for the Bishop of Oxford,—suites of bedrooms, new offices, &c.

An entirely new Decorated chapel, fitted up with good oak dressings and roof; the east window presented by Prince Albert, beautiful glass by Willement; the other windows, presented by the Archbishop of York and others, are by Werrington, Wailes, and O'Connor.

4. Several additions are now going on at the Palace at Wells. In this instance, as above, the Ecclesiastical Commissioners find the money.

I have mentioned these as being *public works.*

In the course of this month [October] there will be three of my churches consecrated,—St. Mary Magdalene, Barnstaple; Melsland Church; St. James, Norfolk.

The Town-hall at Dorchester, which was noticed some time since, is my work."

From 1846 to 1853 Mr. Ferrey principally resided at the Grove, Fair Mill, about a mile from Henley-on-Thames, though still having his offices in town. He always considered this one of the happiest periods in his life, as the society in the neighbourhood was very congenial to him.

Mr. Ferrey had now got into the full swing of practice, and among other works (a list of which is given below) he carried out Penn Wood Church; St. Peter's, Elsted, Hants; Diocesan Training Schools, Saltley, near Birmingham; St. John's, Eton; Buckland St. Mary Church (this is generally considered one of the most successful of his churches, though not the largest); Esher Church; Wynnstay (Sir Watkin Wynn); Bulstrode (for the Duke of Somerset). In 1861 Mr. Ferrey published his "Recollections of A. Welby Pugin," a work which received very favourable notice from the Press, and was read by the public with great interest. He had been engaged on the task for some time, and had long entertained the idea of writing his "Recollections" of this eminent man. About 1870 Mr. Ferrey prepared designs for a proposed cathedral, Victoria, British Columbia, which will probably be carried out before long. In this year he was the recipient of the Royal gold medal, as recommended by the Institute. The last work of Mr. Ferrey was the mansion for the Duke of Connaught, at Bagshot Park, which was commenced early in the spring of 1877. In October of that year he had a slight attack of paralysis, since which he has been in delicate health, though up to the commencement of the present year he had been able to spend three or four weeks occasionally in the neighbourhood of Bagshot, so as to superintend the work, as well as to have the benefit of pure bracing air. Within the last few months, though, mercifully, there was no return of paralysis, weak action of the heart rapidly exhibited itself, with other complications, and at half-past two o'clock on Sunday afternoon, August 22nd, after having lingered several days, he expired quite peacefully and painlessly.

Mr. Ferrey took a great deal of interest in the formation of the Royal Architectural Museum. He also has contributed papers to the Institute of Architects. He was one of the consulting architects of the Incorporated Church Building Society. We have already spoken of him as an architectural draughtsman. He was equally skilful at landscape, and in water-colours could use his brush with much skill. In his holidays he was wont to delight in the latter as a relaxation after his architectural work. He was also extremely fond of music, particularly church music, and had a pleasing baritone voice. Mr. Ferrey, about twenty years or so since, invented and patented a mode of stamping plaster which was inexpensive and very effective. He adopted this process at Macclean Church, near Ampthill; All Saints', Blackheath; Streatham Parish Church (in the chancel), and at other churches.

Mr. Ferrey has had many pupils, several of whom have since become well-known architects.

In 1863 he was elected a fellow of the Society of Antiquaries, and was always proud of the title.

A letter now before us, written early in his career, and which may be usefully printed, refers to a state of things in the profession which is less commonly found now:—

"As a mere matter of fact, you can mention whenever it may suit, that large additions and the erection of a new Episcopal chapel are now going forward under me for the Bishop of Oxford, at the Palace, Cuddesden, near Wheatley, Oxford.

My object, however, in this communication is to suggest whether you may not do a great service to the public and the profession by a temperate statement in one of your *leaders* of the *inconvenience and disadvantages* arising from the union of *architect and builder* in the same person. I could give you many illustrations which I have met with in the course of my own practice; and I could, if I had time to write a long article, point out the many evils of the system. At this time I have three *country* architects who have tendered, and are executing contracts as builders under me. Their position is most anomalous, viz., they proclaim themselves architects and builders, and I have had opportunities of detecting their malpractices in cases where they have acted in the twofold capacity. Indeed, it stands to reason that one of the principal functions of the architect must be sunk when he becomes the tradesman. As to checking expenditure, &c., it is absurd. I believe that the intelligent public are beginning to see this, but I know the influence of the *Builder* is very great; I see it upon every gentleman's table in the country, and they would at once see the force of the arguments which might be advanced, if you think it would be consistent to say something upon the subject. In the case of a respectable builder, I have no hesitation in permitting him to trace any drawings he pleases, because they are essential to him in the performance of his duty; but it is too bad that the architect and builder should take his copies for carrying work into execution, and then, as *architect* only, at some subsequent day, make use of others' designs.

I do not make these remarks in disparagement of the builder. I respect him in his position as much as anybody, but upon principle I feel annoyed when I see him *acting two parts.* A man should be either a builder or an architect, but the joint pursuits is highly objectionable. The practical part and the occupation of building is an ample pursuit for one man, without his meddling with the artistical and theoretical branch. It is however, unnecessary that I should say more upon this point. I am led to advert to it now because I have found it necessary to refuse the *tender* of a man who calls himself an *architect.* I feel that I cannot exercise proper control, and am fettered when dealing with such a person.

I am confident that the *Builder* may advocate right principles without any fear of losing support from a class, and indeed all the respectable builders with whom I am acquainted deprecate strongly the course I have adverted to. They rightly believe that it is for the benefit of the employers themselves that they are under the superintendence of an architect, as relieving them from *much responsibility*, independent of the many other objections that could be named.

P.S.—I should be glad on some opportunity to give you a few facts bearing on the above topic; I am sure that a great saving is effected by the employment of an architect; some employers fancy they save five per cent. by dispensing with a professional man,—this is a great delusion."

Benjamin Ferrey, with his pleasant countenance and winning manners, gained many clients, and in most cases his clients became afterwards his personal friends. With young architects he was always very popular, and many could bear testimony to his good nature and willingness to help them in any difficulty by the aid of his experience. In domestic life his evenness of temper was characteristic. In December, 1872, Mr. Ferrey married Emily, daughter of the late Mr. William Hopkinson, who survives him. By his first wife he leaves three children, a son and two daughters. The son, Edmund Benjamin, who has been in practice for about ten years, jointly with his father, and on his own account, has taken the prin-

* Whose name is well known as author of several of the "Hymns, Ancient and Modern."

cipal part in the business since Mr. Ferrey's illness in 1877, and promises to be an efficient successor. Mr. Ferrey was buried in the same grave as his first wife at Highgate Cemetery, on August 27th, the funeral, in accordance with the wish of the family, being kept private.

List of the principal works carried out by Mr. Benjamin Ferrey since the year 1834 (in the later ones his son was associated with him) :—

Mansions.—Bagshot Park (Duke of Connaught), Wynnstay (Sir W. W. Wynn, bart.), Bulstrode (Duke of Somerset), Huntsham Court, Devon (Mr. C. A. W. Troyte), Datchet House (Mr. W. Good); Bude Haven House (Mr. Arthur Mills); Streatham (Mrs. Hamilton); Park Side, Wimbledon (Mr. W. Williams).

Mansions (Alterations and Additions). — Luton Hoo (Marquis of Bute); Baynard's Park, Horsham (Rev. Thomas Thurlow); Brogyntyn, Salop (Lord Harlech); Bridehead, Dorchester (Mr. Robert Williams); Bishop's Palace, Wells (successively for Bishop Bagot, Lord Auckland, and the present bishop, Lord Arthur Hervey); Brandon Lodge (Lady Beresford); Cefn Park, North Wales (Sir Roger Palmer, bart.); Putney Heath (Mr. R. Williams); Fitzroy Farm, Highgate (Earl of Dufferin); Killadeagh Castle, Ireland (Earl of Dufferin); Frampton Court, Dorchester (Mr. R. B. Sheridan); North Aston, Oxon (Mr. W. H. Foster-Melliar); Hatch Park (Mr. W. H. P. Gore-Langton, M.P.); Knowle, Surrey (Sir William Hanham); Herbert, Hon. Sidney; Penlarth House, North Wales (Mr. W. W. E. Wynn); Poltimore Park (Lord Poltimore); Park Hill, Henley-on-Thames (Mr. Rhodes); Riby Grove, Lincolnshire (Colonel Tomline).

Public Buildings, &c.—Saltley Training Schools, near Birmingham; Ascot Grand Stand (dining-room, booking offices, &c.); Cambridge Mausoleum, Kew-green; Royal Cambridge Asylum, Kingston-on-Thames (commenced by the late Mr. Allom); Dorset County Hospital and Chapel, Dorchester; Schools, Vicarages, Railway Stations, on Lord Dufferin's Estate, Ireland; Almshouses, Kirtling, Oxon; Diocesan Schools Oxford; St. John's Foundation School, Leatherhead, and Chapel (jointly with Mr. J. H. Good, architect); Luton Town-hall; Grammar School, Henley-on-Thames; Shepton Mallet Almshouses, Somerset; Almshouses, Dorking; Town-hall, Dorchester.

Schools.—Beaulam; St. Mary's, Battersea (Wandsworth-common); Buckland Newton, Dorset; Bala, North Wales; Ceddington; Linslade; Chetwynd, Salop; Cuckfield, Sussex; Llanuwchyn, North Wales; Darshill, Somerset; Dowlish Wake, Somerset; Geddington; Henley-on-Thames; Lower Slaughter, Gloucestershire; Llanfachreth, Merioneth; St. Mark's, St. John's-wood (jointly with Mr. J. H. Good, architect); Netherton, Northumberland; Overton, Oxon; Otterton, Devon; Romsey, Hants; Sidlesham, Sussex; St. Stephen's, Rochester-row, Westminster; Oakhill, Somerset; Taunton (St. Mary Magdalene); Upper Tooting, Surrey; Esher, Surrey; Westbourne, Sussex; Wargrave, Berks; St. John's, Angell Town, Brixton; Morpeth, Northumberland; Great Bedwyn, Wilts.

Parsonages.—St. John's, Angell Town, Brixton; Compton Vallence (jointly with Mr. Crickmay, architect), Grasley; Cuttislock, Dorset; Charlton Mackerel; St. Paul's, Dorking; St. John's, Eton; Elsfield, Somerset; Hounsdown, Hants; Henley-on-Thames; Kirtling, Oxon; Keresley and Coundon Vicarages; Little Milton, Oxon; Mentmore, Bucks; Maiden Newton, Dorset; Melrose, Scotland; New Shoreham; Nuthurst, Sussex; Overton; Pishill, Oxon; Penn-street, Bucks; Romsey, Hants; Stanton, Wilts; St. Stephen's, Rochester-row, Westminster; Stanford; Lower Tooting; Tarrant Hinton, Dorset; Wheatley, Oxon; Warkton, Northants.

New Churches.—Shepherdswell, Kent; Brighton, St. Ann's; Coldharbour; Ascot-heath; All Saints, Blackheath; Ashurst, Sussex; Burton, Hants; Brightwell; Barcombe, Sussex; St. John's, Brixton; Brockhamgreen, Sussex; Bengeo, Herts; Birlingham, Worcestershire; Bala, North Wales; Buckland St. Mary, Somerset; Christ Church, South Banbury; Cefn, North Wales; Christ Church, Clapham; Christ Church, St. Giles's; Christ Church, Kensington; Christchurch Cemetery Chapels, Hants; Chetwynd, Salop; Dogmersfield, Hants; St. Mark's, Old-street, London; St. Paul's, Dorking; St. John's, Eton; Esher, Surrey; Christ Church, Eastbourne; Cemetery Chapels, Eastbourne; Faulk-green, Salop; Guernsey; Hillingdon Cemetery Chapels, Middlesex; Hale, near Farnham; Hounsdowe, Hants; Holdenhurst, Hants; Harpsden, Oxon; Kilgerran, Pembrokeshire; Lower Slaughter, Gloucestershire; Linslade, Herts; Llanfachreth, Merioneth; Llangedwyn, North Wales; Little Briddy, Dorset; West Lydford, East Lydford, Somerset; Lufton, Somerset; Episcopal Church, Moscow; Melplash, Dorset; St. John's, Morpeth; Otterton Devon; Pett, Sussex; Penn-street, Bucks; Holy Trinity, Roehampton; Slinfold, Sussex; Sandbeck Private Chapel Yorkshire (Earl of Scarborough); Sambrook, Salop; Immanuel Ch., Streatham-common; St. Stephen's, Rochester-row, Westminster; Volster, Somerset; Whitchurch, Hants; West Hatch, Somerset.

Church Restorations and Additions.—Wells Cathedral: nave and transepts and lady-chapel, 1842; west front and towers, 1870-74; St. Mary Magdalene, Taunton (tower rebuilt—G. G. Scott and B. Ferrey, joint architects); Christchurch Priory Church, Hants; Ackworth, Yorkshire; Abbotsbury, Dorset; Binfield, Berks; Brislington, Somerset; Babcary, Somerset; Barkway, Herts; Braisgrove, Hants; East Coker, Somerset; St. Lawrence, New Brentford; Chipstable, Somerset; Chobham, Surrey; Romsey Abbey (north transept, &c.); Cookham, Berks; Castle Cary, Somerset; Craich, Derbyshire; Corwen, North Wales; Corston, Somerset; Chiselhurst, Kent; Charlton Mackerel, Somerset; Down Ampney, Gloucestershire; Dowlish Wake, Somerset; Eling, Hants; Enlish Episcop, Somerset; Enmore, Somerset; Trinity Church, Eastbourne; Frampton, Dorset; St. George's, Hanover-square; Highclife, Hants; Henley-on-Thames (parish church); Huxham, Devon; Isle Abbot (rebuilding of tower), Somerset; Keresley, Staffordshire; Kelston, Kingswood, Hants; Limington, Somerset; Llanfair, North Wales; Langford Budville, Somerset; Long Ashton, Somerset; Martock, Somerset; Meifodd, Merioneth; Merriot, Somerset; Merton, Surrey; Maulden, Beds; Ruabon, Denbighshire; Sotherton, Suffolk; Scropton, Derbyshire; Southbourne; Stamfordham, Northumberland; Streatham (parish church), Sopley, Hants; Sandymount, Ireland; Crom Church, Ireland; Tyneham, Dorset; Thames Ditton, Surrey; Upton, Bucks; Up-Ottery, Devon; Wichnor, Staffordshire; Westbourne, Sussex; Warmington, Northants (chancel), Wingham, Kent; Wrexham, North Wales; Wanstrow, Somerset; Ystrydgynlais, South Wales.*

HEALTHY DWELLINGS.

THE book published under this title† by Captain Galton seems calculated to fill a special place in the literature of the subject. It is not a book giving details and diagrams of methods of drainage, trapping, &c.; it is one in which the principles to be considered, and the best methods to be employed in regard to the whole subject of the sanitary conditions of dwellings, are generally treated of in one volume and in relation to one another, giving a kind of *coup d'œil* of the subject of sanitation. While in other practical treatises we have the subjects of drainage, of water supply, of ventilation, &c., separately gone into and illustrated in detail, we have here the outlines of all these various branches of the subject considered in relation to each other, and within the compass of a comparatively small volume.

Practical sanitary science, says the author in his preface, is embodied in the words "pure air, pure water," and these include a pure subsoil. This latter is, therefore, to be regarded as the basis of the whole, and receives the first consideration in a chapter on the conditions which regulate the healthiness of a site. There is a great deal of information collected in this chapter; some of it of course is familiar to everyone who has paid any attention to the subject, some of it may be new to a good many readers, even among those who are not unacqnainted with sanitary matters. This is followed by a chapter on the effect of soils and local conditions on the healthiness of site. The author commences by quoting Dr. Parkes's scale of relative healthiness of various classes of site; "primitive rocks, clay slate, and millstone grit," standing highest, and marshy land lowest. But he is careful to point out that the advantage of a naturally healthy site may be all thrown away and become practically non-existent. "During the first visitation of cholera, one of the places which suffered most severely, owing to its filthy local conditions, was Megavissey, on the granite formation of Cornwall." This fact as to the influence of the habits of a population on the prevalence of an epidemic, is, of course, almost proverbial now. Another example given is, however, more out of the way of ordinary experience. This is the case of the erection of a military sanitorium on the granite peninsula of Kowloon, in China, which seemed to possess every requisite for health in its geological formation and its free exposure to winds; yet the troops on being moved into the huts there suffered severely from fever. "This arose from the disturbance in a tropical climate of the surface soil impregnated with decaying organic matter. Until soil of that nature has been opened and oxygenised it is in the highest degree deleterious." For similar reasons the removal of brushwood in the vicinity of a camp, though highly desirable in the long-run, has been found to cause fever in the first instance, owing to the disturbance of decaying organic matter. In this and some other points in the book, Captain Galton's experience as a military engineer comes in usefully, and leads to the suggestion of conclusions from facts which are less within the range of the civil sanitary reformer's usual experience. An instance from the experience in the camp at Balaclava as to the relative healthiness of two methods of placing dwellings on a slope (illustrated by sections) is one of the most direct and practical examples that could have been brought forward of the influence of site and drainage on health, and one that can be understood and appreciated by every reader. Another point brought forward in this chapter, and which is certainly sometimes overlooked, is that a hilly site, even with good subsoil and exposed to breezes, is not necessarily healthy if the wind comes to it over a stretch of plain deficiently drained or otherwise unhealthy in its conditions. The elevation of the site does not raise it above the risk of contamination from the lower ground.

In the chapter on the healthy arrangement of buildings on a given area some interesting comparisons are drawn between the conditions of eastern and western towns, and the conditions of camp life as compared with life in built towns. The density of population in a camp area on active service is very greatly in excess of even the highest densities of population in London and other large towns, and this without either drainage or paving. The difficulty of preserving sanitary conditions under such a state of things when the camp is anything more than a merely temporary one, is, of course, obvious, and the conclusion that no one site should be occupied for more than a limited period is inevitable. The author considers that the continued occupation of Aldershott as a camp, on a porous soil, without paving or adequate drainage round the tents, is leading to a gradual deterioration of the health of the camp. He does not give the density of population of Aldershott Camp, but we presume it is considerably below that which is frequent in camping on active service. A good deal more attention, however, is now paid to the sanitary arrangement of camps than used to be the custom; and those who read General (then Colonel) Pearson's letter from his camp at Ekowe, detailing its arrangements to the Commander-in-chief, must have been struck by the practical care which was given by this prudent as well as spirited officer to the arrangement of his camp so as to get the best sanitary conditions attainable under unavoidably unfavourable circumstances, where a number of men were put in a comparatively small area without the possibility of change of place or change of air.*

The remarks on the purity of air in an occupied dwelling, and the various influences which may interfere with it, should be read with attention, and suggest a great deal. In London it is observed there are special conditions arising from the large amount of suspended organic matter in the air; an important factor in which is the ammonia given out by the manure from the enormous quantity of horses kept in London, and continually traversing the streets during the day. The author tells us that the mud from a paved street in London was found on analysis to contain nearly 90 per cent. of horses' dung, and that the mud on the new wood pavements consists of it almost entirely: but in a macadamised street there surely must be a very large amount of mere detritus arising from the grinding down of the material by the wheels. A fact in regard to wood pavement is brought up again which is of some interest now that this pavement has come again so much into use. It is that the wood pavement laid down in Regent-street about thirty years ago was taken up because it had become so saturated with ammonia that the emanations tarnished the plate in the silversmiths' shops. Captain Galton does not give the time which the paving had been down before arriving at this state. The same evil has been pointed out in America.

The chief difficulty of ventilation is summed up in the course of a chapter on cubic space and floor space, as consisting in the necessity of avoiding draughts. "Everyone approves of ventilation in theory; practically no one likes to perceive any movement of air." Thus a great deal of our ventilation in ordinary houses is really done accidentally, through crevices around doors and windows which theoretically in many cases should not exist, and which are not taken account of, but without which a sleeping room, under the usual conditions of closed windows and drawn curtains, would be unbearable, and positively injurious before morning. This is a point to be considered, we may observe, in reference to the employment of concrete houses with a finished and close outer skin, as described in a recent article in our columns. The experience there mentioned of one who had resided in such a house on an exposed situation, that a gale of wind might be blowing outside, and the inmates hardly be

* Of the above-mentioned works, the following have been illustrated in the volumes of the *Builder* for the years indicated, viz.:—Christ Church, Endell-street, Long-acre (1845, p. 114); St. Stephen's Church and Schools, Rochester-row, Westminster, built at the cost of the Baroness Burdett Coutts (1847, p. 359); interior of St. Stephen's Church, Westminster (1850. p. 516); St. John's Church, Angell-town, Brixton (1853, pp. 296-7); St. John's Schools, Canterbury-road, Brixton (1853, p. 303); St. Paul's Church and Parsonage, Dorking (1857, p. 755); Bulstrode, Buckinghamshire, one of the seats of the Duke of Somerset (1861, pp. 860 61); Pulpit, Church of St. Mary Magdalene, Taunton (1867. p. 688); mansion, Bagshot Park, Surrey, for H.R.H. the Duke of Connaught (1877, pp. 1198-1200).

† Observations on the Construction of Healthy Dwellings, namely, houses, hospitals, barracks, asylums, &c. By Douglas Galton, late Royal Engineers, C.B., &c., &c. London: Henry Froude; Oxford: Clarendon Press. 1880.

* Since these words were written, a letter has appeared in the *Times* giving an extract from the correspondence of a young officer serving in the present Afghanistan campaign, from which it appears that a camp was pitched on one occasion among the carcasses of dead and putrefying camels. We imagine, however, that this is quite an exceptional instance of carelessness or stupidity.

conscious of it, shows that there was very little of what we may term natural ventilation in such a building, and that with impervious wall-material and tight fitting of windows and doors comes the increased necessity for sufficient systematically-arranged ventilation.

Captain Galton's remarks on the details of ventilation are preceded, very logically, by the consideration of the movement of air, a subject which people who are speculating in ventilating processes would do well to consider more fully than they usually do. The author is not in favour of mechanical means of propulsion or expulsion of air, except in special cases, and points out that not unfrequently propulsion of air into an apartment in this way results in a strong current towards the nearest outlet, leaving stagnant portions of unchanged air in the sides and angles of the apartment. It is just as well that some one should draw attention to the fact that inlets for ventilation should be so arranged as to disperse the introduced current throughout the room as much as possible; for this self-evident fact (as one would think it) seems to be beside the comprehension even of some people who professedly deal in ventilation; and not long since we saw an arrangement for ventilating recommended on the ground (partly) that it sent the current as direct as possible from the inlet to the outlet. Captain Galton has no special panacea in ventilation to recommend; he examines and states briefly the principles on which ventilation should be based, and has various suggestions to make in regard to what may be called the common sense of the subject. The channels that admit air should, he observes, be short, direct, and accessible; "long channels collect dirt, and form a refuge for insects; but if it is necessary to make them long, they should be easily accessible for cleaning;" a very simple and obvious consideration, often entirely forgotten. This, we may observe, is one drawback to the upright tubes for ventilation which were re-invented a little while ago, and the idea of which was suddenly seized upon with such avidity and unanimity by a press and a public who seemed never to have heard of ventilation before, and imagined that this expedient was the be-all and the end-all of the science. The author is in favour of the Sherringham ventilator as a simple but effective form, capable of being used both as inlet and outlet. Another point on which he is particular is in regard to drawing the air for inlet ventilation from a quarter where it will be found as pure as possible: another simple consideration, often absurdly overlooked, people seeming to think that air is air, wherever it is drawn from, and that they may let impure air in as ventilation (because they cannot see its impurity), though they would not think of putting dirty water in their washhand basins or baths. One point which the author alludes to especially is that, as a general rule, air drawn from a high level is better than that drawn from near the ground; he instances the Houses of Parliament as a case in which the opportunity afforded for doing this by the lofty tower has been neglected. The House would be supplied with better air if it were drawn down from the top of the Victoria Tower, and the tower would be useful as well as beautiful. We may note that the French Chamber is so ventilated, the air being drawn down from a height of nearly 100 ft.

In the course of observations on warming we have the mention of the system experimented on at Lockport, U.S, by which 200 houses were heated by steam from a central boiler, the steam being arranged so as to be turned on or out off in each house and (if we understand right) in each apartment, as wanted, in the same manner as gas laid on to the houses. The idea of laying on heat in a town, just as gas and water are laid on, has not infrequently tempted the imagination of scientific socialists, but we fear that, however convenient in certain circumstances and over a limited area, the idea of a general application of heat in this way on a large scale is chimerical. It is beset by a difficulty of the same kind, in the first place, as that which at present affects the general use of electric light, viz., the diminution of power in proportion to the distance from the point of origination. Gas and water are gas and water still, and unchanged in their composition and utility, at any distance at which pipes can deliver them; but steam and hot water are parting with their heat all the time of their passage from the boiler to the point where it is to be utilised. But besides this, there is the difference in the way in which their heat can affect the apartment to which it is introduced, which must put such methods at a disadvantage in comparison with ordinary fuel and fire. Captain Galton puts this very plainly at the conclusion of his general observations on warming: "Where a room is heated by warmed air passed through flues into the room" (and this practically includes the case of pipes placed in hot-air chambers and sending warm air from them), "the air imparts its heat to the walls. The air is thus warmer than the walls. When a room is warmed by an open fire, on the other hand, the warming is effected by the radiant heat from the fire; the rays from the fire pass through the air without sensibly warming it, the radiant heat warms the walls and furniture, and these impart their heat to the air. Therefore the walls in this case are warmer than the air." The consequence is that the walls and furniture cannot, by conducted heat, be kept in cold weather as warm as is desirable without raising the air to a temperature both unpleasant and unhealthy. The author thinks, however, that in a room warmed by steam-pipes heated to a high temperature, the effect on the walls would tend to approximate in some degree to that produced by the open fire, in proportion as the temperature of the pipes is raised. We may suggest that the same result might be attained by the systematising of a plan which has once or twice been tried, namely by fire-clay lumps heated by a gas-flame. If the supply of every house in a town with heat from a common source, in the same way in which gas and water are supplied, be ever accomplished on a large scale, it would be more likely to be done through the medium of inflammable gas than by any other medium now known to us, but a supply from such a source would not be healthy unless the fumes of the gas could be kept out of the room. To make gas the means of heating some slow-conducting substance, through which heat would be imparted to the room while the gas-flame itself would be kept from all contact with the air of the room, seems an idea that offers more chance for the working of a system of heat supply than any other; and if the electric light be destined, as we believe, ultimately to supersede gas as a means of lighting, it may perhaps come to pass that coal-gas, superseded for this purpose, may turn out a valuable means of heating, and be thus utilised to even better purpose than it has been hitherto, and in such a way that its more disagreeable qualities may be kept out of sight. The bearing which such a system would have on the prevention of smoke is obvious.

But the method of warming a room affects also the working of its ventilating system, if it has any; or may even be said to produce a ventilating system where there is none. There is therefore the more advantage for general readers in a treatise in which the two subjects of warming and ventilation are considered almost simultaneously and in connection with each other. The difficulty with the open fire is that while it assists ventilation when in operation, the fire-place may, when not in use, entirely change its function, become an inlet instead of an outlet, and throw all the arrangements for ventilation out of gear. It is in respect of such a condition of things, again, that gas in connection with the heating apparatus might become so useful, being so easily regulated, in securing a sufficient heat at any required moment to create an up-draught for ventilation without producing more heat than is wanted. But this is by the way. In dealing with the open fire-grate while in operation the question is how best to produce and to radiate heat economically, to prevent smoke, and assist ventilation. The idea of feeding the ventilation of the room by air warmed in its passage into the room by contact with the fire-place is of course quite a common-place now, but the whole object is not accomplished so well or in so compact a manner in any invention that we know of as in Captain Galton's fireplace, figured in the plan, section, and elevation on page 126. The excellence of this fireplace is well known to those conversant with the subject, yet we believe it has come comparatively little into use, perhaps for the reason mentioned by its inventor—it has never been patented, and therefore manufacturers do not care to suggest its use. There is another reason, however, and a strong one, the impression (too much founded on fact) that it is scarcely possible so to cleanse the entering air in towns as to prevent it from soiling and spoiling the apartment. The principle (to mention it once again) is that of introducing air to a chamber at the back of the fire, where it is warmed by blocks of fire-clay, which form the sides of the chamber and the back and sides of the fireplace, and thus warmed, ascends a shaft, which delivers it into the room, as air-supply, near the ceiling, from whence it circulates through the room, and eventually comes to the grate to feed the fire, and go off up the smoke flue, or what may, for the most part of the time that the fire is burning, be called the hot-air or extraction flue, for the prevention of smoke is facilitated by the introduction of air through a slit in the back lining of the fireplace, so as to give an extra supply of air at the point of combustion, on much the same principle as the "split-bridge" in larger furnaces, which in one or another modification has proved the most effectual means of preventing smoke in such furnaces. This fireplace we take to be, for the combined purposes of heating, smoke prevention, and ventilation the best that has been invented. We looked with some curiosity to see what the author had to say about the functions of his fireplace when not in use, in regard to ventilation. From the passing suggestion that "the inlets for warmed air may be provided with valves, to be closed when the fireplace is wanted rather for ventilation than for warming," it is evidently calculated that when windows are open in warm weather the fire-place flue is to act as an outlet, as before. We should imagine the provision for a gas-jet at or in the chimney opening would be necessary to insure it thus acting. We will sum up, however, in the author's own words, the advantages which he claims for his grate, and all which we believe to be justly claimed:—

"1. That it ventilates the room.

2. That it maintains an equable temperature in all parts of the room, and prevents draught.

3. That the heat from radiation is thrown into the room better than from other grates.

4. That the fire-brick lining prevents the fire from going out, even when left untouched for a long time, and prevents the rapid changes of temperature which occur in rooms in cold weather from that cause.

5. That it economises fuel partly by making use of the spare heat, which otherwise would all pass up the chimney, and partly by ensuring by its construction a more complete combustion, and thereby diminishing smoke.

6. That it prevents smoky chimneys by the ample supply of warmed air to the room, and by the draught created in the neck of the chimney."

Clause 2 seems, by the way, to be sufficiently included in the terms of clause 4. In considering the ventilation of rooms without open fire-places, and in combination with a warm-air system, the author gives a great many useful and suggestive hints. In regard to theatres he draws attention (for which unfortunate actors will thank him) to the facilities which the necessarily large employment of light in connexion with the stage affords both for warming and ventilation, light being at present necessarily connected with heat, which on the stages of most theatres is probably not utilised at all either for warmth or ventilation; adequate ventilation of a theatre will, however, he thinks, be more satisfactory if some mechanical appliance be used to force in the fresh air as well as to remove the vitiated air. A good while since we published a translation of a complete plan proposed by a French architect for the treatment of theatre ventilation, in which the air was to be kept slightly in a state of compression in the house, so that all draughts (if any) on the opening of doors would be outward rather than inward, and the dangerous effect of draughts on people clad in evening dress, or even with better protection in the way of clothing, would be obviated. This was suggested as an extra and accompanying advantage in the employment of propulsion in theatres: another advantage, as recent experiments in the States seem to have decisively shown, is in the better acoustic properties of the house, or rather the marked assistance to its acoustic properties realised when the incoming current for ventilation is propelled from the stage towards the spectators. In the most costly and elaborate of theatres, the Paris Opera House, however, mechanical propulsion is not made use of; hot-water apparatus is used behind the stage, "on the assumption that this method does not dry the air so much" (a very gratuitous assumption, we should say, when the water has no connexion whatever with the air to be warmed, unless it was thought that aqueous vapour percolated through the substance of the heating pipes), "and the part of the house occu-

pied by the public is warmed by stoves, as being quicker in operation." In saying that it is warmed by stoves, Captain Galton of course means that the air is thus warmed in chambers before admission to the house. The description of the ventilation and warming in the Herbert Hospital is worth attention, as it seems to be very efficient, complete, and simple in working; but we can merely refer to it. One observation at the conclusion of the ventilation chapters should be noted:—"No system of ventilation or warming in a large building or establisbment can be satisfactorily conducted unless some person is charged with the duty of seeing that it is maintained at all times in effective action."

To say that "the laws regulating the movement of air should govern the form of buildings," is perhaps rather too round a statement, though the chapter on "the internal arrangement of buildings" recapitulates some points in which this is more of a logical sequence than many readers would suppose. To say that a building must be so planned that air may have free access to every part of it is of course a truism, though one which is not unfrequently forgotten. We have been frequently struck, for example, with the want of ventilation in the central staircase even of recently built and costly houses, especially among some of those numerous houses in flats which have come into use in the Pimlico district and elsewhere. Many of these are built with the stairs, from which all the various tenements open, closed by a fixed skylight at the top, so that in hot weather especially there seems not only an absolute stagnation of air in the upper stories of the staircase, but even an accumulation of fouled air which has risen to the top of the staircase shaft and has no exit; and it must be remembered that change and circulation of the strata of air are much less liable to go on spontaneously in a high narrow funnel like a staircase shaft than in a space of the proportions of an ordinary room. A point to which our author alludes, and which is not so familiar, is that fires frequently spread with greater rapidity than they otherwise would do in English houses through the facility afforded for currents of air to pass from one floor to another behind the boxing of windows, the battening on walls, &c. He urges that "the free passage of air should be stopped as far as possible between every room and the room under and over it, by means of some substance difficult of combustion." Among other means of checking the spread of combustion he recommends especially a course of fire-clay slabs below each floor level projecting 6 in. into the rooms and receiving the ends of the beams carrying the floor above; the under side of the fireclay (or terra-cotta) being moulded and occupying the place of the sham plaster cornice which now forms the usual connexion between the wall and the ceiling of a room. Captain Galton apparently contemplates only double-framed floors, with beams carrying joists above and ceiling joists below, with an air space between. This is all very good, no doubt, but it must be remembered that this means a great deal of expense, and it could hardly be carried out in buildings where economy in both money and space must necessarily be consulted. In the course of the remarks on the internal arrangement of buildings, in which we concur in the main, some special attention is given to the sanitary construction of stables, and the entire want of attention, often, to the provision of adequate ventilation and fresh air for the horses, both in sufficient quantity and in the places where it is wanted. The entirely accidental way in which some new stables are constructed, or old ones left unaltered and unimproved in this respect, would lead one to conclude that horses were not supposed to live by respiration in the same way as human beings. Captain Galton gives small-scale plans (by the way, there is no scale to them) showing where he considers air should be especially introduced to provide for every horse having pure air to breathe both when he is standing and lying down, which we recommend to the reader's attention. Perhaps some of the diseases to which horses are subject, and which are the dread of the horse-owner and the puzzle of the "vet.," may be traceable, if the truth were known, to nothing more far-fetched or mysterious than the want of proper air to breathe.

There are one or two points we rather question in the remarks on "conditions affecting materials and construction." Damp courses of slate (recommended among other means for preventing damp rising) are liable to breakage with the slightest unequal settlement of the wall, and are therefore not to be trusted. Further on, "a floor of wooden blocks laid on and bedded in asphalte combines dryness with warmth for the feet." It may do so, but it almost certainly ensures the rapid decay of the wood so imbedded. These, however, are minor points. Some statistics as to the amount of water which is held in new walls will startle some readers, and explain pretty forcibly to those who are going into new houses why it is not wise to be in too great a hurry to commence occupancy. According to Captain Galton's calculation, a house in which 100,000 bricks have been used, contains in the bricks and in the mortar combined about 10,000 gallons of water, which must be removed from the walls of the house by evaporation before it becomes habitable. Some of this will be escaping, no doubt, from the lower part of the wall while the upper is in process of building, but not much; the greater part will still have to be accounted for when the roof is put on. Another fact mentioned about plaster is suggestive: it was stated in a discussion at the French Academy of Medicine in 1862 that in a case in which an analysis had been made of the plaster from the wall of a hospital, this was found to contain 46 per cent. of organic matter. It ought to be stated, however, to what depth the plaster was cut for the analysis. We can well imagine the plaster being loaded with organic matter in this proportion to a depth of $\frac{1}{8}$ in. or even more, but not throughout its thickness; the question is, how far did the organic substances actually permeate? This is the more important, because some leading sanitary authorities have suggested that the best internal wall-finish for a hospital ward is not a hard and washable material, but an ordinary plaster coating, which should be scraped and resurfaced from time to time; but the efficacy and suitability of this treatment depend, of course, on the degree to which the impurities penetrate into the plaster: if they are merely superficial, the process is easy and satisfactory; if they penetrate deep, the renewal of the plaster throughout would be necessary,—a by no means convenient necessity. We should have more faith ourselves in a smooth wall-facing which would hold far less of organic matter at all times than plaster, and which could be thoroughly cleansed by washing, while the ward was empty, as every hospital ward should be, by rotation, for about a month in each year. The great thing to remember in regard to impervious materials is, that the more completely impervious they are, the more complete must be the provision for cleanliness and ventilation. Captain Galton comments on this again in regard to impervious roofs or ceilings. Experience, he says, shows that it is unhealthy to live under a ceiling impervious to air. "Air heated by contact with the human body carries up emanations which when they rest on a pervious ceiling are retained there, while the moisture passes off through the ceiling; on the contrary, if these emanations come in contact with an impervious ceiling, they are not absorbed, and may be again brought into circulation in the air of the room. Consequently, if circumstances render it necessary to have a ceiling impervious to air and moisture, this must be discounted by providing under such impervious covering additional facilities for change of air in the upper part of the room." For ourselves, we should decidedly prefer and recommend the impervious ceiling with the thorough ventilation; but we admit that it is more difficult to carry this out satisfactorily. But to trust to the pervious ceiling for retaining what we do not want to have returned upon us, seems rather like shirking a difficulty than fairly meeting it.

The author commences his remarks on "Removal of Refuse," by saying that "a theoretically perfect system of refuse removal would be one where a large volume of rapidly-flowing water received the whole refuse, and carried it away, before it had time to decompose, to a large river not used for drinking purposes, and thence to the sea; but this is generally unattainable, and it would leave the waste matter unutilised." As this latter objection is made in the same sentence, it seems rather odd to call this a theoretically perfect system; and it is so desirable to emphasise in this country the danger and folly of sending sewage into rivers, that it is a pity that the author should have seemed to countenance it even under the restriction which he makes. In fact, the restriction is not sufficient, for it is a great evil to the dwellers on the banks of a river to pollute it with sewage, even if they are not going to drink the water; and the whole sentence, so prominently placed, surprises us. We should say a theoretically perfect system was that which conveyed away refuse matter as quickly as possible to where it would be useful, and we have to find out where or in what conditions that is. Chemistry will tell us in the long run, no doubt, but we have not mastered the subject yet. Captain Galton's military experience enables him to give some useful suggestions for the management of extempore latrines, &c., in circumstances where rough-and-ready methods alone can be used; for the rest, the principal systems of removal of house-refuse, by water-closets and sinks, by the dry-earth midden system, and the pail system, are briefly explained, and some of their respective advantages and drawbacks mentioned, but the author does not positively recommend any one system or apparatus, except that he decidedly prefers the pail system (two or three modifications of which are described) to any more wholesale system of removal without water-carriage. The Liernur system is described, and some probable drawbacks to its working suggested; but one obvious objection might be added, that of compelling the employment of yet another elaborate system of underground piping in large towns. Most towns have already three systems of pipes,—gas-supply, water-supply, and drains; and these are enough, in all conscience, to keep in order and provide for, and rather too much in some cases.

This portion of the book, considering the great difficulty, elaboration, and importance of the subject, must be considered but very brief and rudimentary, but it will serve to give general readers an outline of the main difficulties and the principles on which they are to be met. The value of Captain Galton's book is most apparent as a whole, in giving a general and trustworthy view of the subject of sanitation, such as ordinary unscientific readers can understand and take interest in; and in this way it may conduce much towards the enlightenment of the unscientific public, while it contains every here and there hints and experiences which may prove very suggestive to the scientific specialist in sanitary reform.

THE EXHIBITION OF METAL-WORK IN PARIS.

FROM the slight glimpse that we have had within the last few days of the retrospective museum which was announced to be opened three weeks since, we certainly have no reason to regret the delay that has been occasioned by the arrangement of a collection of a series of works of art the like of which has not before been brought together through the long annals of great exhibitions. With the knowledge of the treasures that have been reposing in their cases in the rooms on the first floor of the Palais de l'Industrie, it has been so far sorry work, however instructive, to have to inspect the modern productions down below. Not but what they supply ample matter for inquiry and study,—they indeed should form the chief interest of the exhibition,—but without the means of comparison with older works, such as the museum is purposely intended to facilitate, it is difficult to form a correct estimate of the merit of the modern French metal-workers, whose art is very completely represented here; in this respect every credit is due to the management of the exhibition, which has gathered together such a characteristic show, and one so essentially connected with the industrial application of art. The marvels of modern ingenuity, such as iron has enabled the manufacturer, the engineer, and the architect to carry out, are here unrepresented, a feature, the absence of which is not to be regretted in an exhibition organised by a society avowedly devoted to the application of the arts to the needs of industry. Last year was held in Paris an exhibition in which the applications of science to industry were admirably shown; this year it is the industrial value of the arts which is more prominently put forward. The directors cannot be too warmly complimented on the success of their efforts; it is rarely that an exhibition is marked so plainly with the stamp of unity, and though "the free exhibition," as the class to which have been admitted a variety of the various attractive objects which seem in Paris the necessary complement to every public show, may to some extent be over large, the

general effect of the Palais de l'Industrie exhibition is very "metallic."

Paris can certainly boast of an unusually large number of men who must be termed, for want of a better word, artistic iron and metal workers; and their emulative efforts, though they may strikingly seem to lead in the same direction, show plainly the effect of the endeavour to revive within the last few years the spirit that animated the sturdy work of the past. It is true this effort is strongly influenced by the taste of the eighteenth century, which in France has prevailed for some years, as it promises yet to continue to do.

In the artistic products of the Paris metal-workers,—we are speaking more particularly of the wrought-iron-workers,—the seventeenth and eighteenth centuries chiefly supply the models, and certainly very attractive are the results of this adaptation of the work of the past to the needs of the present. Each exhibition seems to show us that it is hopeless to ask for so-called original design. The discoveries of the scientific man of one age render useless those of his predecessors, but the creations of the artist never make us forget the creations of those who have gone before. The cry, then, that we do but repeat the work of the past finds some excuse in this theory, apparently comfortably accepted by a large number of artistic workers in the present day, and whose productions are satisfactorily represented, in, as regards France, the present Exhibition in the Champs Elysées.

Purists will doubtless shudder at the finely-wrought scrolls and foliage which decorate the iron railings, the tripods, and the chandeliers exhibited, as the sad emblems of a period when art was in its decadence; it is unfortunately true that the Middle Ages, that period when unquestionably the noblest creations of the metal-workers' art were produced, can scarcely be traced as the suggestive source of study taken by the manufacturers. Though relegated to a dark corner, may be seen in one of the most attractive stalls a humble member of the gorgeous railings that surround the tomb of the Scaligers at Verona; it is from the so-believed more graceful creations of later centuries that the designers have drawn their inspirations, and this being a French Exhibition it is the taste of the eighteenth century,—that typically French age,—which is most conspicuous. Had we been in Germany we should doubtless have seen more than one specimen inspired by the work of the Renaissance and the Middle Ages, when in the hands of the humble artist the plastic iron was forged and welded into work that rivals the delicacy of the goldsmith's productions.

The whole metal industry is well represented in this exhibition, from the rough ore to the finished production of the united labour of designer and workman, whose models, drawings, and working-studies are also to be seen here; a large share is naturally devoted to the bronze trade, so important a branch of the metal-worker's art in Paris, which has long been the head-quarters of the manufacture of all the wretched "ironmongery," as it has not too charitably been termed by a French critic, and so long abhorred by all people of taste, that has bedecked for three generations and more the mantel-pieces of households in every part of the civilised world. While this deplorable branch of industry seems still to be in a vigorous state of health, it is satisfactory to feel that its products find the market growing smaller and smaller every day in those countries where art education has been extended, but it still remains to the thoughtful observer a mystery, what outlet the manufacturers find for all this glittering rubbish; and yet only its more respectable productions are here exhibited. The cast gilt-zinc clocks that crowd the showy watchmakers' shops in the more popular neighbourhoods of Paris and the numerous provincial towns, show sufficiently how large a sale there is for a cheaper object than the expensive "*objet de luxe*," as it is pomposuly termed by the polite shopman or the elegantly-printed card of the firms whose products figure under the glass roof of the Palais de l'Industrie.

The gold and silver smith are largely represented, and all the well-known names are to be found; the jewellers are also well represented; the diamond-polishing forms, as it did in 1878, a never-failing source of attraction.

The usefully decorative services of metal are well shown by numerous exhibits of ornaments, cast or *repoussée*, for architectural decorative purposes, and certainly it must be tempting to the professional eye to see a whole Jarret or Mansard window, with its mouldings, its pediment and its details, well studied, an architectural model, in fact, all ready-made for use; weathercocks, finials, and many other decorative objects, are to be found here, and when their use is known, great aid do they afford to the architect. But perhaps the most characteristic feature of the whole show, and one remarkable when we consider that it is devoted to the display of metal-work, is the absence of all noisy machinery, a feature admirably calculated to induce long hours being spent in the exhibition. What the pecuniary success of the show has already been, may be judged from the fact that on the Sunday following its opening, when all was still in disorder, no fewer than 8,000 visitors poured into the Palais de l'Industrie. The management may fairly expect an even larger crowd when the retrospective museum is thrown open, this additional feature promising to be very complete. Among numerous contributions from famous collections, the South Kensington Museum has, we learn, liberally lent a considerable number of their marvels of the metal-worker's art.

THE ROYAL SANITARY COMMISSION AND THE *BUILDER* ON DUBLIN.

IN our notice recently of the Royal Sanitary Commission we almost allowed the report to speak for itself, and we summed up by giving the more important conclusions of the Commissioners. The "Sanitary Condition of Dublin" is a heading of old standing in the *Builder*, as a reference to our volumes for the last twenty years will show. Some journals have been of late taking credit for having pointed out such and such wants and such and such blots in respect to Dublin, whilst quietly ignoring or altogether ignorant of the fact that all the ins-and-outs of the unsanitary condition of the Irish capital were fully treated of long years ago in these pages. Indeed, we might say, without fear of contradiction, upwards of a decade since we anticipated almost every one of the conclusions of the Commissioners, in substance, if not exactly in the same words. Coming down to more recent dates we would particularly direct the attention of our old readers to the series of articles which appeared in the *Builder*, running through nearly every year between 1869 and the present year. The condition of the Liffey and its tributaries, the Poddle, the Dodder, the Jolka, and the other reeking though minor streams, was described. The homes of the people in the tenement houses, and the circumstances of these houses when private mansions and when they had degenerated into rookeries for several separate families, were depicted over and over again. The state of the old markets, meat and vegetable, the old sewers and their construction, the bad house-drainage and its complete absence in several districts, the scavenging under the old contract system, and when taken over by the Corporation, the back streets and the back yards rarely cleaned, unpaved streets, and bad road metalling, the drinking habits of the lower orders, the want of building bye-laws and improved dwellings for the working classes,—these and kindred other matters were fully pointed out by us and the ground again and again travelled over. Respecting that often-debated subject, the purification of the Liffey, and the need of an efficient system of main drainage, a scheme suited to the financial circumstances of the City, we long since advocated the amended scheme which is now about being adopted after a wanton expenditure of money and an utter failure to force an ill-advised and enormously expensive scheme upon the citizens.

In 1870, but not for the first time, we wrote: "Putting aside other plans, we boldly say there is no salvation for Dublin but in a thorough system of parallel main drainage and intercepting sewers on both sides of the Liffey. Until the river is saved from city sewage pollution on its north and south banks, there can be no proper purification of the Liffey. The treatment of the sewage in its final distribution is another question for which more than one method can be adopted, as it pleases those whose chief business it will be to carry it out with profit and advantage to the city and country at large. The Poddle river, rushing over and emptying hourly its avalanches of solid slime into the Liffey, in the most central part of the city, is a frightful picture to contemplate. What it was a quarter of a century since, a mother of dead dogs, night soil, and butcher-shamble's offal, it is still, but multiplied in beastly enormity. Is it possible that the corporate authorities of Dublin can pretend to be ignorant of this frightful stream of rolling filth that passes but a few yards off, under their very noses, while sitting in their town councils? The effluvium of the Poddle wriggles itself through the street sewers, and the malaria of the Liffey is daily wafted into Parliament-street to the City-hall, acting as a due monitor and avenger of corporate negligence and imbecility!"

The Corporation have done a little service in the way of public improvements, but the state of the Liffey is still the same foul blot, the tenement houses are growing worse, the majority of the back streets are brimful of dirt, back yards are an abomination, and proper privy accommodation in the same quarters is absent. We pointed out in 1870, as previously and since, that there were districts north and south of the city that never witnessed a scavenger's cart in their neighbourhood, and that the watering-cart was only reserved for fashionable localities. The picture is still true. Long before the rebuilding of Essex and Carlisle Bridges, we suggested their remodelling to meet the greatly increasing passenger and vehicular traffic between the north and south of the Liffey, and the provision of a new bridge further down the river was advocated at the same time to meet the necessities of the growing northern district. Well, the two former bridges have been rebuilt, and a new swivel bridge was opened last year, built on the site we indicated. Ever since the water supply of Dublin was taken from the Vartry, we admitted that it was fairly good, but we repeatedly said that the poor often suffered from the want of a continuous supply in the poorer districts, and that the receptacles for holding the water in most of the tenement houses were out of repair or in a foul state. In our articles on the sanitary state of Dublin during the last twelve or fifteen years it will be found that we have discussed most of the points bearing upon the question of public or of personal health. Baths and washhouses, ship nuisances in the river, ambulance, and hospital accommodation, the floating hospital in the river or harbour, swimming-baths in the city, and along the sea-shore in the northern and southern marine townships, the state of the old city graveyards still unimproved, the free opening of the public squares, the inspection and disinfection of houses and cabs in times of epidemic, these were some in addition to the other matters already alluded to that we have discussed in our several articles on the sanitary state of Dublin from time to time, and, as we said, extending over several years. The very picture we drew in 1870 and 1871 of the haunts of wretchedness in certain districts north and south of the Liffey, of vice brought on by dirt, and disease and crime by drink, with punishment or death as the outcome, have been on two occasions lately reproduced in other words by the Recorder of Dublin, who directly traces the evils to their true source, the unsanitary condition of the homes and surroundings of the poor and working classes. The Borough Engineer of Dublin traces more evils to the defective condition of the house-drains and the state of the tenement houses than to any other causes, and he is not inclined to admit (indeed he never was) that the main sewers of the city are in a bad condition. Certainly for the last quarter of a century a good amount of new main sewer work has been executed to meet the growing extension of the city; but in the older portions of the city, and between the older and the newer portions, the sewers are as we have several years ago described them, "a patch work system," thus anticipating, as in other matters, the conclusions of the Commissioners.

We witnessed the execution of not a little of this patchwork north and south of Dublin, and the work as a patch was good enough in its way, but the work as a whole, old and new, could never be expected to hang together. The sewers are, to a large extent, irregular in line and gradient, and defective in sundry other ways, and a patch-work they must always remain, until the old work drops away from the new, or new work replaces the old all along the line. Several years ago we wrote,—"The drains connected with the old houses of Dublin lead nowhere, or are choked up; and the house drainage of some of the modern cheap buildings on the skirts of the city is a mere make-believe."

During the fifteen years between 1865 and

1880 we have had occasion at times to say some cheering words about many matters in Dublin and elsewhere throughout the provinces, because it has been our duty to chronicle progress and improvement as well as to point out the obstacles to it and to aid in their removal. The unsanitary state of Dublin has, however, supplied us much material for pleasant thought, notwithstanding the somewhat saddening nature of the subject. To have paved the way to a reform by persistently and consistently advocating the one line of policy in the interest of the few and the many alike,—health and home, and health at home and without, was to preach saving principles which must be recognised on the banks of the Liffey as well as on the Thames, and, indeed, everywhere amongst civilised people. There is a sad want of healthful dwellings for the working classes in Dublin, and a number of these erected by a public company, and which were visited for us some months ago, are deficient in accommodation, lack proper space and appliances, and in most instances we think the rents are too high for the class of persons they were intended for, but which in many cases inhabits them not.

In conclusion, we may say in respect to the main drainage of Dublin the Corporation some days ago resolved to refer the matter to the Main Drainage Committee, with a view to agreeing upon some plan of action for carrying out the recommendations contained in the report of the Commissioners. Procrastination, however, in municipal circles in Dublin is proverbial, and the exercise of a respected public criticism is still necessary to force action and ensure anything approaching towards expedition, even in a life and death question.

The *Builder* collected its own evidence, and its many articles were the result of visits and personal inspection. Yet the outcome of a Royal Commission sitting for many days scarcely carries the subject of the sanitary condition of Dublin further, and in all its essential features it is identical with the conclusion and recommendations long since expressed in this journal.

METROPOLITAN RAILWAY TRAFFIC.

MUCH as is the position of the heart to the body is that of the metropolis to Great Britain; and of nothing is this truer than in regard to railway traffic. If a map of the railways of the country be taken it will be seen that the lines that represent the railways grow blacker and thicker and more numerous as London is neared, and that there is a convergence of lines thereto. But these do not all enter the heart of the city, and hence the idea of a railway which would traverse the most populous part, and also join the great stations where railways ceased, was one which could not be otherwise than acceptable. The passenger who was put down at Paddington, for instance, and wished to travel from King's-cross, had the mild horrors of a middle passage,—long, comparatively costly, and inconvenient often,—to endure. But when the underground railway was commenced it not only gave a quick and cheap means of transport between parts of the great city, but it became also a means of junction between some of its great railways. The public need it met is known to have been great, but not many know the extent of that need, or the manner in which it has been met. Nor is the vastness either of the amount that has been spent in providing the great lines that traverse the metropolis, nor the largeness of the passenger traffic thereon known. It may, therefore, be of interest at this juncture, when another extension of the Metropolitan line has been so recently opened, to give from official sources statistics which show the cost of what has been done, and the extent to which the public avail themselves of the facilities for travel on the chief of the lines that now specially and almost solely serve the metropolis.

In round numbers, nine millions sterling have been spent in forming the Metropolitan Railway, in fitting up with appliances for travel, and in subsidiary works in connexion with the great line that traverses London. With the exception of about a quarter of a million,—expended in providing the working stock of the line, and of one or two smaller sums subscribed to other related London railway companies,—the whole of this vast sum has been spent in purchasing land and buildings, in adapting these for the purposes needed, in forming the line, the works, and the stations, and in the needful expenditure in other methods to create the line. That working stock to which reference has been made is small beside that of the great companies; but it is probable that few of the latter find their passenger accommodation so much used. There are not 300 engines, wagons, and carriages on the Metropolitan; but we shall soon see how large is the volume of passenger traffic that travels over the line. Before leaving the question of cost, however, it is needful to state that the Metropolitan Railway holds a quantity of surplus lands and buildings,—so large that it has a net revenue therefrom of over 1,000*l.* a week, and that the amount of this revenue is increasing, though sales of land from time to time keep that increased rental in check. Coming to the most interesting part of the official statement from which some of these facts are drawn, we have a summary of the gross receipts of the Metropolitan Railway for traffic, and of the numbers of passengers it has carried for over eighteen years. From the financial statement it appears that in the year 1863 the gross traffic receipts of the Metropolitan were 101,707*l.*; whilst in the last complete year they were 506,204*l.*—or, in other words, the receipts are now full five times what they were at the opening of the line. It will be interesting to give fully a statement of the number of passengers over the railway in every one of those years. That statement shows that the numbers were as under for each year:—

Year.	Passengers.
In 1863 there were carried	9,455,175
,, 1864 ,, ,,	11,721,889
,, 1865 ,, ,,	15,763,907
,, 1866 ,, ,,	21,273,104
,, 1867 ,, ,,	23,445,282
,, 1868 ,, ,,	27,778,011
,, 1869 ,, ,,	36,893,791
,, 1870 ,, ,,	39,160,849
,, 1871 ,, ,,	42,765,427
,, 1872 ,, ,,	41,392,449
,, 1873 ,, ,,	43,533,973
,, 1874 ,, ,,	44,118,425
,, 1875 ,, ,,	48,302,324
,, 1876 ,, ,,	52,586,395
,, 1877 ,, ,,	56,175,753
,, 1878 ,, ,,	58,807,038
,, 1879 ,, ,,	60,747,553
,, 1880 (first half) ,,	31,592,429

This growth of passenger traffic on one small line of some dozen miles is wonderful in its rapidity. It will be seen that at the opening the number of passengers was large,—nearly one million per month; but since then there has been such steady progress that at the present time over five millions of passengers are carried monthly over the little Metropolitan line. During the first half of the present year not less than 174,543 persons were carried daily, on the average, over that line, so that every hour of the twenty-four not less than 7,000 persons were carried; or, to put the figures in another way, the stream of traffic was so great that the number carried on the Metropolitan Railway during the first six months of this year was equal to the estimated population of Great Britain and Ireland! And it is evident that the maximum traffic is not yet reached, for at the date to which we have referred there had been expended on lines not opened at the end of June last fully 624,000*l.* One of the lines,—that from Finchley-road to Harrow, has since been opened, and a new source of traffic has consequently been tapped. Other extensions are in progress, and will, in time to come, add to the traffic of the Metropolitan; and though it may be postponed, yet the Inner Circle Railway must some day be completed, and a large volume of traffic now blocked off will flow over the underground line. It has already been stated that the numbers given are those of passengers on the Metropolitan Railway, and that over a series of years the allied line (but not yet connected by that inner circle), the Metropolitan District, has carried half as many. It is clear, then, that the possibilities of passenger traffic in the metropolis are almost illimitable; and it is evident that there is a great future before the railways which practically monopolise that vast traffic. The oldest of these,—the Metropolitan,—has already become a very profitable company to its shareholders; and it is fair to add that its service to the public has been immense. It is clear from the history of the past that its passenger traffic will grow; and it is evident that it can, from the experience of "busy days," almost double the number it carries, without largely adding either to its staff or its working stock, so that it is evident that as branches long in completion are opened out, the volume of passenger traffic on the great Metropolitan Railway will continue to grow.

V.C.—HONOUR FOR SAVING LIFE.

THE decoration of the Iron Cross, the possession of which is indicated by the addition of the letters V.C. to the name, is rightly prized by the English soldier as the highest distinction that he can hope to attain. That decoration, indeed, vouches for the display of the two sister, though sometimes separated, virtues of courage and mercy. It is conferred for the saving of life under the fire of the enemy.

Somewhat allied in its character to the Victoria Cross, though bestowed by less exalted judges, is the medal of the Royal Humane Society. It is a distinction of which it would be desirable to enhance the value, by exalting the dignity of the awarder of the decoration. The idea that underlies the two badges of honour is the same; and it is one that is eminently germane to the English character.

We want a third step in this noble brotherhood. We want an honour for those who save life, or perhaps many lives, at the risk of their own—by promptitude and energy, though neither under the fire of the enemy, nor in the dangers of sea or river. Not a few instances may be recalled of heroic and devoted courage in the mine, or the railway, even in the crowded street. It is possible that the guard who, on the 19th of August, ran along the line of rails in the Bleamoor Tunnel to attach fog-signals to the way, and thus to give the only possible warning of danger to the engineer of the Pullman express rushing to his own destruction and that of a whole trainful of passengers, did not consciously risk his life in so doing. But when we remember the fate, within a few days of the same event, of an experienced railway official killed in crossing the line at a station, we must admit that the action referred to was not unattended with danger. And beyond all doubt it showed promptitude, presence of mind, perception of the best thing to do in a sudden and grave emergency, and its result was the avoidance of a catastrophe more terrible than any that has occurred in the United Kingdom, save the fall of the Tay Bridge. Demands of this nature, in prompt courage and ready thought, are of daily occurrence on our railways. Why should not a due token of commendation be added to our social encouragements for noble conduct? If a man has the virtue to become rich, testimonials are there to greet him. How if he only save the lives of fifty or a hundred people?

HAY AND CORN DRYING MACHINE.

THE weather has varied so much in the different parts of the island that it is difficult to form a reliable estimate of the prospects of the harvest. Abundance is promised by many of the fields that we have seen, while bad accounts come from other districts. The same may be said as to the hay. Everywhere late, in some districts there has been a fair, if not a heavy crop; while in some there has been little but a contribution to the dunghill.

In no respect is man a greater debtor to Science than when she presents him with the means of increasing or preserving the yield of the precious fruits of the earth. Nor has Science been behindhand, of late years, with the demand made on the genius of her votaries. The very misfortune of labour-contests has not been without some countervailing advantage, in the way in which it has turned the attention of mechanists to the production of labour-saving machines. In our actual state it may be said that these implements are characterised by utility rather than by elegance. By that we do not mean artistic elegance, but that true beauty of scientific construction in which the aim sought is attained with the greatest economy of material consistent with durability. As it is, advancing without heat of drum, the hay-cutting and hay-making machines seem to have arrested, at all events in many parts of England, the once usual annual invasion of Irish labourers.

Hay-making, however, proverbially requires sunshine. The same is true to a much more limited extent, of hay-cutting. But in the present year we have very often witnessed the mowing, by machine or by hand, of a fine grass crop, under the encouragement of a bright day or two, succeeded by a steady downpour on the prostrate grass. It is in cases like this that the farmer will listen, with all his ears, to the promises of Mr. W. A. Gibbs, of Gilswell-park, Chingford, Essex. Nor are these simply

promises—or ideas set in cursory order on paper alone. Mr. Gibbs has not only invented, but also constructed, a hay-making apparatus, of which actual experience has been made by Mr. G. P. Fuller, of Neston Park, near Corsham, Wiltshire, quite recently. The apparatus is in two parts. It comprises a frame upon wheels, supporting a sheet-iron reciprocating trough, along which the hay is slowly passed, subjected to a powerful current of heated air, and turned about by rows of revolving forks. A second apparatus, also on wheels, contains a furnace for heating the blast, and a fan for producing it. A portable steam-engine forms a third portion of the contrivance; but this is already to be found on many farms.

The effect of this machine is thoroughly to dry grass that would otherwise have been entirely spoiled. It does this at the rate of four one-horse cart-loads per hour, in other words, it saves the hay of an acre in an hour. At Neston-park 117 acres were cut. The crop was light. By the use of the Gibbs machine the whole 117 acres were cleared in three weeks, two of which were continuously wet. Details are given of the cost of the cutting and clearing of 43 acres in one week. The crop was very light, only 30 tons being made from the 43 acres. The cost amounted to 9s. 6d. per acre, or 13s. 6d. per ton. The machine was actually at work for only twenty-four hours during this time, so that it made about 1½ ton of hay per hour. The hay is said to be as fragrant as that made by the ordinary process.

Our readers will remember the interest with which we have always regarded every fresh appliance which engineering has offered to agriculture, and that we urged the possibility of saving the hay crop by artificial means long before Mr. Gibbs's invention was made. The saving of labour, or value of the cost of labour, by the substitution of mechanical for human or for animal power, is as legitimate an object for the farmer as it is for the cotton-spinner, nor do we see any reason why the economy should not be as great in the one case as in the other. But it is not only cost that is saved. The great advantage of mechanical power, as compared with animal power, is the rapidity with which it can be developed and applied in such cases as cotton-spinning; this rapidity only means saving of time, and thus saving on the interest of money invested in the business. But in agriculture it means much more. It means such a command of time as renders the farmer to some extent independent of the caprices of the season. Now another step is proposed. It is one which, sooner or later, we hold to be certain of accomplishment. It is to make the agriculturist, to a great extent, independent of the weather. The possession of a hay-drying machine, if it be one that actually does all that it is said to do, will be to the farmer equivalent to the earnings of the hay crop. As we have usually one day wet to one fine, and as July is one of the wettest months of the year, this ought to be equal to a saving of at least 25 per cent. of the annual hay crop, or to the reduction, whoever pockets the benefit, of a fourth in the cost of hay.

But this is but little in comparison to what may be effected as to corn. We do not suppose that any corn-drying machine would be of use in those cases where the corn damps in growing and mildews instead of ripening. But we are under the apprehension that the great loss that the farmer experiences in his cereals is not of this nature, but is due to the deterioration or partial germination of the grain after it has ripened in the ear, and while the solstitial rains, perhaps rather later than usual, keep the reaper from the field. We can see no reason why artificial harvesting should not, in these cases, be successfully adopted. And we invite those who have saved their hay by hot blast to have the courage of their experience, and to try a corn-saving machine.

Electric Lighting at Liverpool-street Terminus. — So satisfied are the Great Eastern Railway Company with the electric light at their Liverpool-street Terminus, that they have increased the number of lamps from 16 to 31. Three of the new lamps are outside the station. The system is also extended into the booking-offices, and instead of being confined, as heretofore, to the main platform, has been carried to the suburban platform also. The variety of light in use here is that known as the "Brush" system.

THE MERCERS' COMPANY'S NEW BUILDING IN CHEAPSIDE.

THE new building for the Mercers' Company consists of a lofty pile, 200 ft. long, with returns in Ironmonger-lane and Old Jewry. It is faced with Portland stone and polished granite, with statuary and carving, and has a lofty tower over the entrance to the hall. It was designed by Mr. Barnes Williams, the Company's architect, so as to harmonise with the old entrance to the hall,* which has been literally reproduced.

The parts of the building east and west of the entrance are devoted to commercial purposes, and are principally let to former tenants of the company. The remainder forms the entrance, vestibule, staircase, and suite of rooms for the use of the Company.

This building completes the line of frontage which has been formed by setting back the houses on the north side of the Poultry.

Messrs. Ashby & Horner are the contractors. Mr. Fenning supplied the granite. Messrs. Ronnson & Drew supplied the constructional ironwork; Mr. Shrivell the ornamental ironwork. Messrs. Holden & Co. furnished the ornamental zincwork. Mr. S. Trickett supplied the stone. The carving was executed by Mr. Sansom. Messrs. Benham & Co. are fitting up the kitchens, the hot-water apparatus, and the gas-work. Mr. Julius Sax fits up the electric bells; Mr. Crace has the contract for the decoration. Mr. James Wilkinson has acted as clerk of the works. Mr. Hyatt has supplied all the pavement and stallboard lights.

A KINDLY WORKMAN.

IN one of the antiquated towns of Emilia, only a few miles from Bologna, on the romantic road to Ravenna, so long the capital of Italy, was celebrated not long since a simple yet characteristic ceremony, which roused from the dead slumber of bygone magnificence the quiet, town of Castel San Pietro, sleeping under the now useless protection of its Middle Age castle, and almost in the shadow of the towering Apennines. An honest carrier of the Castel San Pietro has bequeathed to the Working Man's Society of his town the small savings of a life-time, to give a little marriage-portion to a poor girl every two years. The Senator Pepoli, president of the working man's society of Castel San Pietro, has wisely addressed to all the similar societies throughout Italy a circular stating the circumstances of the generous gift of the worthy Francisco Fabbri, whose example and memory merit even wider notice than such a step will assure his philanthropic action. From his boyhood a carrier, Fabbri toiling honestly and laboriously, commenced to set aside his savings that were to assure him in his old age a happy existence in the bosom of his family. But even in his youth—we quote from the Senator Pepoli's circular—in his leisure hours, or when the fogs and wind prevented him exercising his business, he betook himself to the well-peopled slopes of the Apennines, gladdening with the sound of fiddle the joyous meetings of the country-folk, and never ashamed to gather from his work its ill-paid gains. The sums thus amassed and jealously set aside were never expended on himself. He used to tell his friends and relations that he had in view a secret object, which he would in due time make known. The day has at last come, and the honest old fellow has kept his word. During last Easter he came, accompanied by a notary, to the rooms of the working man's society of his town and declared, —so states the Senator Pepoli,—that he presented to the Association seven hundred *lire* (about 30*l.*), scraped together by him little by little, with the intention that two hundred *lire* should go to augment the loan fund, and five hundred *lire* to serve to form a capital which, at five per cent., would enable the sum of fifty *lire* to be given every two years to the daughter —chosen by lots—of one of the members of the Association. Astonished at such a bequest, I asked, continues Senator Pepoli, whether such was in reality his fixed desire. Fabbri's reply, in its curt simplicity, is a model of eloquence:— "This has been the dream of my life. To have the pleasure of being useful to my fellows I have worked incessantly, and now I have attained my object, and I am happier than a Cæsar."

When a wealthy person, either during his lifetime or on his death-bed, presents to the poor of his native town a sum of money to alleviate their suffering there rises throughout the country a cry of gratitude, and the example is in everybody's mouth. It seems to me, remarks Senator Pepoli, that the fact I have related contains the sublimest expression of human charity, and that this honest and aged benefactor deserves the gratitude of the nation and of the Government. It is a noble example which it is to be hoped will find emulative imitators, as it visibly raises the moral level of the workman in the face of the incredulity and selfishness of his eternal detractors, and this example merits to be inserted in the transactions of all the working men's associations throughout the country.

As a further and even more lasting token of Fabbri's generous donation an inscription has been placed on the house in which he was born, "Here Francesco Fabbri, a workman, gave on the 29th of March, 1880, the economies of a long and honest life to the working man's society of Castel San Pietro to afford a marriage-portion to a poor young girl,—the public sentiment hopes that from the marriages thus made may spring citizens, laborious, upright, and provident like their pious benefactor."

* The old entrance to the hall it is asserted was designed by an Italian architect in the seventeenth century. If there be any old pupil left of the Company's late architect, Mr. George Smith, we should like to hear what he has to say on this subject.

BUILDING NOTES FROM SOUTH AFRICA.

As South Africa is a quarter of the empire that was seldom spoken of before the era of the Zulu war, and is even yet a *terra incognita* to the trade, the readers of the *Builder* will doubtless appreciate a few miscellaneous notes from these colonies. During the past eight or ten years times have been generally prosperous throughout the South African colonies, notwithstanding the native wars that have occurred. Comparatively vast strides have naturally followed this prosperity in the nature and character of the building operations throughout the country. The oldest and most venerable buildings to be found in South Africa are of Dutch architecture, and their style has left a certain impress on the buildings of even the present day in most of the larger towns of the Cape colony. Dutch buildings are, however, more exclusively the peculiarity of Cape Town. The tiny-paned, wide-sashed windows, almost flush with the walls, the handsome and curious fanlights, the gracefully-outlined gable, and the high walled-in "stoep," occupying the whole of the space where the side-walk would be in an English street, are features which strike the eye of every stranger on landing from Table Bay. Solid board shutters folding inside the window, and walls a couple of feet thick in solid masonry, give evidence of good judgment as to the requirements of the climate; for the days are warm (seldom above 100°, however, at Cape Town) and the summer dusty in the town. Here and there may be seen a building partaking of the East Indian style, and showing evidence of the settlement here of more than one Indian officer. Nearly all of the public buildings here were built by the Dutch. The new central railway station, a handsome and well-planned structure, finished in 1879, marks the new era of English-designed buildings, and throughout the town the old "stoeps" are giving way gradually to side-walks and English shop-fronts. The new Parliament Houses of Cape Town, designed, no doubt, to hold the members of the confederate Parliament of the future, have again been commenced, a number of workmen being now engaged on the foundations. This building, which in external appearance more resembles the Capitol at Washington than the British Houses of Parliament, will prove to be a great ornament to the town. It is situated just below the present Government House (the private and official residence of the Cape Governors), and just at the entrance to the Avenue and Botanic Gardens, where its prominence may add to its attraction as a "feature" of the town. Its cost is estimated at 120,000*l.*

In Cape Town and the principal towns of the western province of the Cape the bulk of builders' work is carried on by the Malays, who have constituted the mechanical class of the population for the past hundred years in those districts. Although quiet, sober, intelligent, and industrious, compared with the native classes, and even compared with Europeans, the

Malay lacks that faculty of steady application, the spirit of genius, which can be displayed by the Englishman or the American, and consequently the European mechanic steps in as foreman or overseer, and takes the place of preference, particularly in all jobs or work requiring more than the average skill. In the eastern parts of the Cape, in Natal, the Free States, and Diamond Fields, and the Transvaal, the Malay and native (negro) mechanic may be found, but they are not so numerous or so skilful as the low average of the English mechanic.

We may as well here speak of the prospects of mechanics who may desire to emigrate to these parts. They are in great demand in nearly all parts of South Africa, and for the past several years no class has thriven better, all things considered, than they, compared with the same classes in other colonies. But in a population of about a million whites it must be distinctly understood that this demand has somewhat narrow limits, and will not apply to all classes of mechanics. For instance, a carpenter, a mason, or bricklayer, who had only worked in one branch of his trade, might find it most difficult to get a living unless he could in some way "pick up" the other branches and perform general work. The population being sparse in most parts, and the towns and villages small, the mechanic is called upon to do, in small jobs, the variety of work represented by a large shop in England. It is not expected, however, that the general work of such will be equal in quality to that turned out by the English establishment. What is known as the "handy man" will succeed the best in South Africa; a man who can make a box or chest, solder a kettle, or repair an umbrella. In this, as more or less in other colonies, the trade of mason is generally found united to that of bricklayer and plasterer, and a man who can combine a knowledge of these three trades is almost certain to do well. Wages vary from 1*l.* 10*s.* to 3*l.* per week, but as many differing circumstances of climate, land, situation, and price of living, have to be taken into account, that we must refrain from attempting any specific information on that subject. Such information can be best obtained through the Cape Emigration Office in London.

As to the style of building, it is only recently that the era of three and four story buildings has dawned. The Dutch built nearly all their houses of a single story, and it was only in 1878, we believe, that the first four-story structure was erected in Cape Town. Here the houses, both stories and dwellings, are built in brick and stucco, and the roofs are flat and plastered, a depression on one side carrying off the water. In most of the inland towns, such as Grahamstown, King Williamstown, and Maritzburg, Natal, brick buildings prevail. Within a few years past several experiments have been made in the importation of wooden buildings from England and America, ready-made, and only requiring to be fitted up. A church at Kimberley and one at East London have been erected in this way, and it is believed that cottages may be imported very cheaply in the same way. These experiments are, of course, partially a result of the scarcity of mechanical labour. In some districts stone is largely used, though none of the quality of the sandstone of England will be found. A kind of hardy, slaty rock is to be found, but granite abounds in most parts of the country. This is a very hard, light-grey granite, very durable, and capable of taking an excellent polish, but it is difficult of working on account of its extreme hardness In Table Valley (at Cape Town) and at the Paarl, extensive quarries are now in operation. At the latter place there is a large mountain of solid granite, sufficient to supply the world as far as quantity is concerned. The quarries here are chiefly used to supply the dock-works of Table Bay. Although possessed of some remarkably fine forests, South Africa is a treeless country, and, of course, native woods do not enter largely into the builder's materials except for shop purposes, such as cabinet and wagon making. Considerable quantities of pine and deal are, therefore, imported from Norway, Sweden, and latterly from Canada; but the English mechanic will have to get accustomed there to the use of the native woods. Although the larger forests of the Cape, Natal, and the Transvaal have not been thoroughly worked, owing to the difficulties of transport, yet several varieties of South African woods are obtaining celebrity. A common wood there is the yellow wood,—a light-coloured wood, heavier than deal, and of finer, closer grain, and considerably harder to work. This wood comes in for much of the cabinet and furniture work of the colony, and is very durable. The "sneezewood" is another beautiful and fine-grained wood, very hard, and likewise used much in furniture and wagon making. For this purpose it is invaluable, as it will withstand the heat of the driest inland districts, where an article made from imported wood will warp and shrink up, and often literally fall to pieces. This excellent quality pertains to most of the other woods of the Cape. But perhaps the most valuable of all the native woods here is the "stinkwood," so called from a peculiar but not disagreeable odour emitted by it when freshly cut. This wood is generally as dark as mahogany (it is, in fact, called the Cape mahogany), but is more variegated in shade; it is of the most compact texture and finest grain. One of its eminent qualities,—which has never yet been properly taken into account by woodworkers,—is its susceptibility of polish. When properly polished, it can be made to assume more the appearance of some kind of metal than wood, and figures to excellent advantage in carving. Specimens of carving in this wood may be seen in the Dutch Reformed Church, Adderley-street, and in the Lutheran Church, Strand-street, Cape Town, and are well worth a visit by the traveller in South Africa. They not only show the excellence of the wood, but the taste of the Dutch sculptors, which is not to be despised. A wood which is no doubt destined to figure prominently in marine architecture in the future is the mangrove. This wood, as is known, possesses the rare property of resisting the effects of seawater, but though found on the American coasts and in some other parts, has never been got in pieces of sufficient length and straightness to be utilised as piles and dock timbers. The discoveries recently made by Mr. St. Vincent Erskine along the Zanzibar coast and at the mouth of the Congo have revealed forests of magnificent timber fitted in all respects for dock works. These trees, especially at the mouth of the Congo, grow 2 ft. in thickness, and many of them 100 ft. high. Standing in the water, where they grow naturally, their appearance is very striking to the traveller. The mangrove from these places has been tested with the most satisfactory results, and, once they are brought to the attention of marine engineers and harbour builders, will, without doubt, play an important part in future harbour construction.

THE BRITISH ASSOCIATION AT SWANSEA.

THIS year's meeting of the British Association for the Advancement of Science commenced in Swansea on the 25th ult. Thirty-two years ago the Association met in Swansea. The present year's meeting has not been very largely attended, but has been signalised by the very able and interesting address by the president, Professor Ramsay, F.R.S., Director-general of the Geological Survey, which dealt with the subject of the recurrence of certain phenomena in geological time.

On Thursday, the 26th inst., in Section B, Chemical Science, Mr. H. B. Dixon, M.A., read the paper by Dr. J. Pattinson, containing the report of the committee on the heat means for the development of light from coal-gas of different qualities. The paper gave information regarding the burning of what is known as common gas, or gas made from the common bituminous coal of the Newcastle and other coalfields, or from this class of coal mixed with a small quantity of cannel coal, and having an illuminating power equal to sixteen standard sperm candles when consumed at the rate of 5 cubic feet per hour in Sugg's No. 1 London argand burner, —the standard burner adopted in London by the London gas referees, and prescribed in nearly all Acts of Parliament of gas companies. After observing that the principal condition to be observed in order to develop the maximum amount of light from coal-gas was to supply the flame in a suitable manner with just a sufficient amount of air to effect the complete combustion of gas, Mr. Pattinson gave the results of experiment with union jet burners. In the case of each burner there was a certain consumption and a certain pressure, and at all other consumptions or pressures above or below this the results were worse. There was, therefore, a limit to the reduction of pressure causing an increase of the illuminating power of the gas consumed, and this limit was reached when the flame ceased to have a somewhat definite form, and burned in a languid waving manner, showing very low intensity of combustion, and having a tendency to smoke.

In Section D, Biology, Dr. Gunther, in his address as President of the Section, spoke on the subject of museums and their management. With regard to the British or National Museum, he said he believed that some of the members of the British Association would feel somewhat disappointed that the zoological and botanical collections on the one hand, and the palæontological on the other, continue to be kept distinct.

In the Anthropological Department of Section D, Professor Rudler read a paper on "The Ethnical Relations of the Typical Man of South Wales." In the same department, several papers of interest were afterwards read, including one by Mr. B. Jones, of Llanelly, on "The Antiquities of Lancarum, or Loughor Castle." Mr. Jones pointed out that Loughor was originally a Roman station called Lancarum, and was situate on the "Via Julia," which ran from Gloucestershire into Pembrokeshire. The Romans had a castle on the east bank of this river, and a Hospicium on the west bank. The "Via Julia" passed from Neath through Penller-gaer, which was at one time a Roman camp. To the north of the Penller-gaer was a place called Tre-di-ar-y-gaer, or Tredegar. A Roman bridge crossed the river at Llanidlo Talybont, and there was a watercourse extending from the castle to Lliw Bridge, which could still be traced. The castle was supposed to be of British origin, and to have been utilised by the Romans.

In Section F, Economic Science and Statistics, Mr. James Heywood, F.R.S., presided, and Dr. J. H. Gladstone introduced a report of a committee on the "Importance of her Majesty's Inspectors of Schools being appointed with reference to their scientific attainments." In the discussion which followed, Mr. Wilkinson said a system prevailed in France which we as a nation would do well to adopt. There a boy got technical instruction and a knowledge of ordinary literature, and a general education, in fact, which was all that was required to make him when he left school competent to earn his own livelihood. Dr. Silvanus Thompson suggested that workshops should be attached to schools—that in all schools boys should be trained to acquire a knowledge of the principles that underlie the work they would probably have to do—that they should learn something of the laws of general science, chemistry, and physics, and physiology. Mr. Botly read a paper on "Agricultural Statistics and Land Tenure," in which he gave in a tabular form the acreage under various crops, with the annual increase or decrease on the year, the quantities and value of imports of cereals, cattle, sheep, and swine, and the number of horses used in agriculture. He showed the importance and necessity of some alteration in the land laws, so as to develop a greater outcome from the land by giving larger security to the occupier for increased investment of capital in the cultivation of the soil. The paper was supplemented by a table showing the number of agricultural holdings in the United Kingdom, with the number of cattle, sheep, and swine to the acre, and the rental in England, Scotland, and Ireland.

In the evening a *soirée* was given by the Mayor in a large building erected for the Eisteddfod, when about 3,000 persons were present.

Of the excursions, that on Thursday, to Dowlais Works, on the invitation of Mr. G. T. Clark, was one of the most important and interesting. Mr. and Mrs. Clark, and Mr. Menelaus, received the visitors, who, under the guidance of Mr. W. Menelaus, were conducted over the various departments of these famous iron and steel-making works. Subsequently the visitors were entertained by Mr. Clark at luncheon in the Guest Memorial Building.

On Friday, in Section A, Mathematics, Professor Everett read the report of a committee upon "Underground Temperature." Observations, it was stated, had been taken in the Tolergoch Lead Mine, Flintshire, between Rhyl and Presteign. The top of the shaft was 190 ft. above the level of the sea, and was at the foot of a hill 500 ft. above the sea. The lowest workings were 900 ft. below sea level. The veins ran across an angle of carboniferous lime-

stone, bounded on both sides by faults which threw down coal-measure shale for a considerable distance. The limestone dipped at angles varying from 45 deg. to 55 deg., and was of two kinds, one white and massive, the other thin, bedded, black, with thin shale partings. There were levels at intervals of about twenty yards vertically in the vein, most of which had been driven for some years. The observations had been taken by boring a hole 24 in. deep, at a distance of from 1½ to five yards from the fore-breast, and, either on the same day or on the next day, inserting one of the committee's slow action thermometers, with a foot of plugging, consisting of dry rag and clay behind it. After an interval, generally of four days, the thermometer was taken out and read, then re-inserted and read again about a week later, the difference between the two readings never amounting to so much as half a degree.

In the Chemical Science Section, Dr. Gilbert, the President of the Section, delivered his opening address, which took for its subject "The Application of Chemistry to Agriculture."

In Section C, Geology, Mr. Edward Wethered read a paper "On the Sandstones and Grits of the Lower and Middle Series of the Bristol Coalfield." In the course of his remarks he said:—The Bristol coalfield is noted for its series of grits and sandstones, and these probably have their equivalents in the South Wales and Forest of Dean coalfields, as well as in that of Somersetshire. The first point raised was the application of the term grit and sandstone. The author confirmed the statement of Mr. Sorby in his presidential address to the Geological Society in 1880, to the effect that the carboniferous sandstones were composed of angular grains. Of those examined by the author, the grains of the millstone grit were the least angular. It was also pointed out that, as rocks show such variation of coarseness in the same deposit, this could not be taken into consideration as a test for grit. It was therefore suggested that the term grit should be confined to those rocks which show regularity of grains, irrespective of coarseness; and the term sandstone to those which are composed of rounded grains (*i.e.*, from which the angularity has been removed). In any case, the term grit must be more generally applied to carboniferous rocks than has been the case hitherto. After a careful examination of the rocks of the coalfield, the author had come to the conclusion that, owing to the great similarity of carboniferous arenaceous rocks, occurring at different horizons, it was at the risk of serious error to rely upon them for correlation or stratigraphical landmarks. The proportion of silica could be sometimes used as a guide in determining one from another, but little reliance could be placed on it over a large area, as so many contained nearly about the same amount.

In the Section of Economic Science and Statistics, Mr. Stephen Bourne read a paper on the "Revival of Trade." In the course of his remarks, comparing 1878-9 with 1879-80, he said:—The increased export trade has been principally in iron and cotton goods, the one being 8 44*l.*, one-third of the whole increase of 27·00*l.*, and the other 7 30*l.*, or one-fourth. Iron has greatly risen in price, but cottons have slightly, woollens considerably, fallen. An analysis of the figures shows, in the first place, that great as has been the increase in our exportations, that of our import trade has been far greater, the excesses of one over the other being 27,000,000*l.* Secondly, that the revival has been much more to the advantage of those who have sold to us than to those who have sold our produce and manufactures. Thirdly, that the whole excess in the value of the exports is scarcely equivalent to the entire cost of the food we have imported or consumed. Bad harvests have forced us to buy from others, especially the United States of America, who thus, having profits to expend, and looking to permanent extension, have purchased our manufactures at depressed prices. Good harvests at home, especially, abroad as well, may reverse this.

Mr. James Abernethy, V.P. Inst. C.E., delivered his address as President of the Mechanical Science Section, his theme being the past and present condition of the Port of Swansea as typical of the rise and progress of the various ports in the Bristol Channel within the last half century, and the vast improvements which have been effected in the nature and extent of the accommodation provided to meet the requirements of the shipping of the present day as regards dock facilities and appliances for the rapid and economical loading and discharging of their cargoes. Having described the existing dock works, he said that in consequence of the great increase in the size and number of the steam-shipping frequenting the port, particularly steam-vessels, it has been found indispensable to provide an entrance-lock of greater size and depth of water over the cill, with an additional extensive dock and spacious quays so as to furnish ample siding accommodation for the shipment of coal, and increased facilities generally for the loading and discharging of cargoes. In consequence, the trustees have entered into a contract for the construction of a dock in Fabian's Bay of 23¾ acres area of water space, together with an entrance-lock 450 ft. in length, and 60 ft. in width, with 32 ft. of water over the outer cill at H. W. O. S. T.; the dock to be kept (as in the case of the South Dock) above the tide of the day by the surplus water from Port Tennant Canal and other sources discharging into it. As regards the shipment of coal, it is proposed to be conducted on the same system as that at the Alexandra Dock at Newport, viz., by gravitation from the sidings to the hoists both for the loaded and empty wagons, the whole machinery of the dock appliances to be worked by hydraulic power, it having been found possible by this system at a very moderate cost to ship from 150 to 200 tons of coal per hour at each hoist. In addition to providing this extensive dock accommodation, the embanking of the indent termed "Fabian's Bay," within the eastern pier, will it is anticipated, as in other well-known cases, tend to accelerate the tidal flow into the upper reaches of the river, and give a better direction and greater force to the ebbing tidal current for the future maintenance of the entrance channel at present in progress of being further deepened by dredging. These various works are now in course of construction, under Mr. Abernethy's superintendence.

A paper by Mr. J. M'Connochie, on the Bute Docks, Cardiff, was next read.

Saturday was chiefly devoted to excursions, St. David's Cathedral, Dynevor Castle and Park, Gower, and other places being visited. A great many of the members visited the new docks at Swansea, under the guidance of Mr. Abernethy.

On Monday, in the Mechanical Science Section, Mr. Baldwin Latham, C.E., read a paper on "The Temperature of Town Water Supplies," to which we shall return.

M. Ernest Benedict made a new suggestion as to a Channel tunnel to France. He gave an elaborate account of the engineering operations requisite for its construction, which would require an outlay of 6,000,000*l.*, probably increased to 8,000,000*l.* by the cost of apparatus, &c. That capital would require 500,000*l.* a year to pay 5 per cent., or 27 trains in each direction, at an average profit of 1*l.* per train mile; and that would be less than a third of the total number of trains that could be worked through the tube daily. The increased traffic on the connected railways on each side of the Channel would be great, and it would pay those railways to subscribe the capital required. That being the commercial aspect of the enterprise, it was desirable to remember that the undertaking would be of great national importance. There was not a country in the world except England which could turn out the materials within any reasonable period. It would stimulate trade during construction, and after its completion would result in a permanently increased development of traffic in many articles of commerce. The peculiarity of this scheme was that, instead of tunnelling through doubtful geological strata, which might have faults like those met with at the tunnel under the Severn near Bristol, it was proposed to carry across the Channel a tube 16 ft. in diameter, at 35 ft. below the lowest water level.—M. Bergeran, C.E., of France, said the plan was not worthy of serious examination. The plan now being carried out was simple in idea and easy of execution. It was simply a tunnel through a bed of chalk 160 ft. thick.

In the Section of Economic Science and Statistics, the report of the Anthropometric Committee was read by Mr. F. P. Fellowes. It stated that since their first appointment at the Bristol meeting in 1875, they had had the advantage of being presided over by Dr. Farr, who had always taken deep interest in their labours, and had placed at their service his unrivalled experience in the collection and arrangement of statistics. Dr. Farr, they regretted to say, had intimated his desire to retire on the ground of ill-health, and Mr. Francis Galton, F.R.S., had been nominated chairman in his place. The committee considered that they were carrying on a work of no mean value to social statistics, supplementary to the national census. The classification of the returns is based on the principle of collecting into a standard class as large a number of cases as possible, which imply the most favourable conditions of existence in respect to fresh air, exercise, and wholesome and sufficient food, and specialising into classes, which may be compared with this standard, those which depart more or less from the standard class. This system was recommended for adoption by Mr. C. Roberts. The influence of mental and manual work, the influence of food and clothing on development, and of climate and sanitary conditions, and the influence of town and country life, may, as materials accumulate, be determined. The statistics already received have been formed into twenty-eight tables.

The President of the Section (Mr. G. W. Hastings, M.P.), in the course of his address, subsequently delivered, said that what Dr. Farr had done for the Registration Office, to which he had been so long attached, it was needless to say. To him it was mainly due that the carefully compiled tables, the admirable reports, the impulse given to the sanitary and social improvement, had been carried out as they had been. Many had earnestly desired that Dr. Farr should become the head of the department which he had done so much to create and amplify. That was not to be, but none the less—rather more—was a great debt owing by the people to a man who had laboured for them so continuously. A committee had been formed to raise a testimonial adequate, in some degree, to Dr. Farr's eminent services.

In the evening an address was delivered in the Music Hall by Mr. Francis Galton, F.R.S., on "Mental Imagery."

We may mention other papers next week.

GLASGOW MUNICIPAL BUILDINGS COMPETITION.

The architect called in to advise in this competition (Mr. C. Barry) sent in his report on Tuesday last, and it will probably be dealt with by the Corporation this week. On Monday next the whole of the drawings will be open for two or three days to the view of the Corporation and the competitors; and then for two or three days more for the general public, in the Corporation galleries, Sauchiehall-street.

We have already received a letter from an architect complaining as to the result, but as nothing certain can yet be known, this is, at any rate, premature.

SEMINARY AT CLAPHAM, FOR THE ROMAN CATHOLIC DIOCESE OF SOUTHWARK.

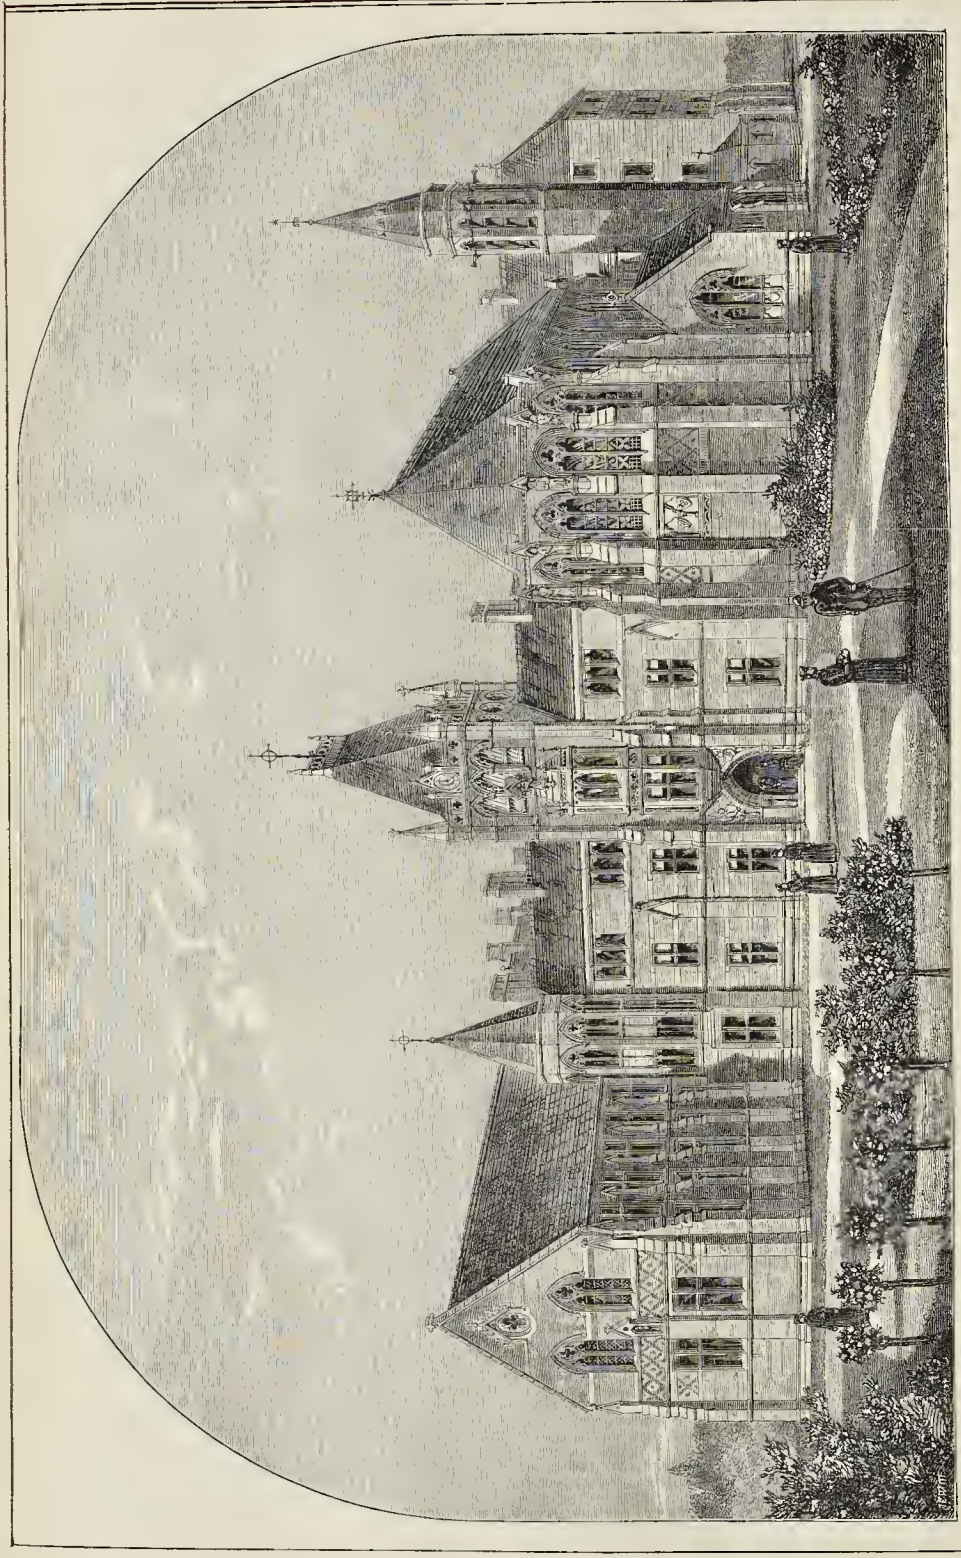
The design is planned to suit the somewhat restricted site in the Clapham-road; care, however, has been taken to secure ventilation, and at the same time to obtain a certain portion of the sun's rays to every part of the building at some part of the day. The style is a free adaptation of the Decorated. The walls will be faced with red brick and freestone dressings; the roofs will be covered with green slates.

The building will afford accommodation for sixty-nine students (each having a separate bedroom), and with suitable lecture-hall, museum, and recreation-rooms. There will be apartments for the bishop, the president, the vice-president, and three professors; large refectory, library, chapel, and the usual kitchen offices.

It is proposed to carry out the work in sections, the first of which will provide accommodation for sixteen students, the professors being lodged for the present in the existing house.

The total cost of the buildings will be about 37,000*l.* The architect is Mr. John Crawley, of Bloomsbury-square.

A Testimonial.—On Monday, the 30th of August, the *employés* of Mr. George Jennings, sanitary engineer, Palace Wharf, Seamgate, met at the Mitre Hotel, Palace-road, to make a presentation of a handsome timepiece to Mr. John Gordon, foreman of plumbers, on his retiring from the firm, after nine years' service. The chair was taken by Mr. R. Lucas, cashier of the firm, and a pleasant evening was spent.



SEMINARY AT CLAPHAM FOR THE R.C. DIOCESE OF SOUTHWARK.

MILTON-NEXT-SITTINGBOURNE COFFEE-TAVERN.

At the beginning of this year a public meeting was held to discuss the desirability of establishing a coffee-tavern in Milton, and there being a strong feeling that such an institution would prove a means of doing good, it was decided to form a Coffee-Tavern Company, and invite applications for shares; a considerable number of which were at once taken. The offers of several sites were obtained, and eventually one in close proximity to the quay was secured at a cost of 360*l*. Mr. W. Leonard Grant, of Sittingbourne, was appointed architect to the Company, and instructed to prepare a design for a house to cost about 900*l*. Tenders were invited for the work, and that of Mr. J. Sosger, of Borden (823*l*. 10s., exclusive of fittings), was accepted. The accommodation provided is as follows: On ground-floor, a bar 26 ft. by 13 ft. 6 in. (approached by angle-entrance), coffee, smoking, and store-rooms, kitchen, scullery, and usual offices; a separate entrance and staircase leading to a hall 39 ft. by 26 ft. on first-floor; on second-floor is provided a manager's bedroom, four cubicles for lodgers, linen-stores, and w.c. The building is faced with warm-coloured stocks, with red brick dressings, chimneys, piers, &c., and is covered with red plain tiles. The ceilings of hall and bar are to be panelled with V-jointed boarding, varnished, the panels being formed by the iron-girders (which are exposed, and painted a light blue colour), with moulded wood cross-girders. The memorial-stone was laid by Miss Hinde (one of the oldest inhabitants of the town) in the presence of the secretaries of the Church of England Temperance Society (the Rev. J. H. Potter, and Mr. A. Sargant), the chairman and directors of the company, and a large concourse of spectators.

EASTBURY MANOR HOUSE, ESSEX.

The manor of Eastbury was part of the possessions of the Abbey of Barking, which latter was dissolved in 1539. In 1545 the manor was granted to Sir W. Denham, kt., sheriff of London, who, dying three years after, bequeathed it to his heir, William Abbott, who, after holding it eight years, conveyed it to John Keele, the latter selling it in the same year (1557) to Clement Sisby.

Tradition relates that the date 1572 was at no remote period conspicuous on several parts of the existing edifice, notably in the hall and on the water-spouts, and there is reason for assuming that the present structure was erected by Clement Sisby. The manor continued in the possession of this family for fifty years. In or before 1608 it was sold by Thomas Sisby to Augustine Steward. The property again changed hands in 1646, 1714, 1740, 1773, and 1802. After which date it was occupied by a Mr. Scott, who made considerable alterations—tearing up the floors and taking down the chimney-pieces, some of which were sold to the Rev. T. Fanshaw, by whom they were placed in his house at Parsloes, where, we believe, they still exist. The manor was sold by Mr. Bushfield in 1845 to Mr. Sterry, in whose possession it still remains. At the time these drawings were made the occupier (Mr. F. Whitbread) had expended a considerable sum in restorations. The house, which was built in the reign of Queen Elizabeth, is entirely of brick. At this period a marked change is observable in the general arrangement of country houses. Prior to this time houses were built round a central courtyard, with all the windows looking upon it,—a few loops and such openings as were required for defensive purposes only being made in the outer walls. Owing to the less turbulent state of the country, and the greater security against outrage, buildings were now erected more in accordance with the requirements of a domestic dwelling than with those of a feudal stronghold. One of the most radical changes being connected with the windows, which were made of larger size and boldly placed in the outer walls, instead of looking upon an inner court.

The present plan of the house consists of a south front and two wings, the fourth side of the court being closed by a blank wall (see plan and perspective sketch).

The principal entrance is on the north front, being an arched opening with traceried spandrels in cut brickwork. The ground-plan is self-explanatory; the portions shown with cross lines are restorations. On the first-floor there was a room over the hall of similar size, having the walls decorated with paintings. On one side a number of men and women, in the costume of the period, under niches; and on the other side a painting representing the "Miraculous Draught of Fishes." The western wing appears to have been devoted to sleeping apartments, whilst the eastern wing comprised one large chamber. On the second floor were three galleries extending the entire length of each block. The roofs which are now open to the tiles, were ceiled, so that each gallery formed a long low chamber, with a cradle roof and a large window at each end; the side windows formed small recesses or pseudo bays. There are to be found such galleries in most old houses of this period, *e.g.*, Knole, Hever, and Haddon Hall. In the eastern gallery the remains of decorative embellishments in distemper are clearly discernible.

The house at present is, in many parts, in a ruined and dilapidated condition. That portion which is inhabited has been considerably altered and modernised.

Our perspective view shows the courtyard in its original condition, not as it at present exists.

The tower staircase in the south-east angle had a well-cut handrail in brick (a detail of it is given), which denotes this as the principal staircase, there being no such handrail in the tower now standing.

The general character of the building and details are well worthy of study, and notwithstanding the ravages of time and the destructive proclivities of some modern restorers, there still remains sufficient of the original work whereby we can form some idea as to the beauty and stateliness of the edifice originally.

Our illustrations are prepared from measured drawings by Mr. Edward Clarke, architect, 6, Adam-street, Adelphi, made some years ago.

THE LATE MR. CHAS. LEE.

We regret to have to announce the death of Charles Lee (formerly of Golden-square, and more recently of Adelphi Terrace), whose name has long been familiar as one of the leading London surveyors. The event occurred at his residence, Ravenswood, West-hill, Putney-heath, on Saturday last, at the age of seventy-six, after an illness of four years' duration, brought on by overwork in his profession. Losing his parents in early life, Mr. Lee was brought up with his relative, Mr. Williams, a surveyor of the old school, practising at Islington, and he was placed to learn the practical part of the profession with Mr. Thomas Cubitt, the well-known builder of Belgravia. After thus spending two or three years he entered as articled pupil the office of Mr. John Nash, the Government architect of the day, and while there took an active part in carrying out the great improvements at the West End, in the construction of Regent-street, the demolition of the King's-mews at Charing-cross, and the formation of Trafalgar-square, as also the Regent's Park and the buildings adjacent, having for his fellow clerks the late Mr. James Pennethorne, Mr. Mathieson (afterwards the Government architect for Scotland), and other well-known members of the profession who have now passed away. On Mr. Nash's retirement Mr. Lee became associated with Mr. Jas. Morgan, who succeeded to a part of Mr. Nash's practice, and was by profession chiefly an engineer, having constructed the Regent's Canal, in which Mr. Lee was largely engaged. While with Mr. Morgan, Mr. Lee prepared the designs and superintended the erection of the Haymarket Theatre as it stood prior to the recent alterations. He afterwards entered into partnership with the late Mr. Henry Duesbury, and with him carried out, among other works, the Town-hall, Derby; the Derby Lunatic Asylum; two or three churches and schools, in the first days of the Gothic revival; as also several houses in Westbourne-terrace and the neighbourhood. On Mr. Duesbury's retirement, Mr. Lee took into partnership in architectural matters the late Mr. Thomas Talbot Bury, who, as a pupil of the elder Pugin, had formerly been brought much in contact with Mr. Nash. Messrs. Lee & Bury carried out churches at Bovingdon, Aldenham, Battersea, and Weymouth, and some other architectural works. After the dissolution of this partnership, Mr. Lee practised alone for some time; but for the last sixteen years the names of Mr. Lee's sons with that of Mr. William Pain (for many years in the office) were associated with his own, the firm being Messrs. Lee, Sons, & Pain. Industrial Schools at Anerley, Sutton, and Wandsworth-common; alteration of St. James's Church, Piccadilly; St. Luke's Church, Holloway; St. John's Church, Putney; many private residences, and notably, of late years, the rebuilding of Her Majesty's Theatre after the fire, may be mentioned as further illustrations of Mr. Lee's practice.*

It is, however, in connexion with his lengthened experience and extensive practice as a surveyor and valuer that Mr. Lee's name is best known. Commencing in the early days of the Tithe Commutation and Poor-rate Assessment Acts and of the valuations for the Metropolitan Improvements, he was contemporary with the late Mr. Higgins, Messrs. G. Allen & Porter, Mr. John Shaw, Mr. Wiltshire, and others, then the leading surveyors, but many of whose names are scarcely recognised by the present generation. From that time till within the last four or five years Mr. Lee may be said to have been concerned in most of the important rating or compensation cases which have occurred in the metropolis and neighbourhood. He valued for rating and for other purposes, on several occasions, the parishes of St. James, Westminster; St. George, Hanover-square; Lambeth, Wandsworth, Battersea, Putney, Wimbledon, and Fulham, and was employed for or against nearly all the water and gas companies. In the year 1853 he valued for re-assessment the whole of the property supplied by the New River Company. He was engaged in the compensation cases for Battersea Park, the South-Western Extension to Waterloo, the Blackwall Railway, and later in the London, Chatham and Dover, and Charing-cross Railways, and other railway Extensions and Improvements; the Hull, the Sunderland, and the Birkenhead Docks, the Cambridge Gas and Water Companies, Carlisle Water Company, and the Dundee Gas Company. He also acted on the part of the Government in the important cases arising out of the Defence Works at Portsmouth, Plymouth, Sheerness, &c. He had also considerable practice in the management and development of building estates; he arranged the sale and letting of the Old Grand Junction Waterworks' Reservoir (now the site of the Great Western Railway Terminus and Norfolk-square), the Copenhagen Estate at Islington (in connection with which he sold to the City the land for the New Cattle Market), and those of many private owners.

Mr. Lee was a man of good general ability and wonderful power of memory, possessed of great tenacity of purpose and of a genial and kindly disposition to those with whom he was intimate. His death will be the most regretted by those who knew him best.

Upon the frame of an engraving which hung over the fireplace in Mr. Lee's room in Golden-square he had pasted a cutting from some book, containing the following lines:—

"RULES FOR SUCCESS.

Be firm; one constant element in luck,
Is genuine, solid, old Teutonic pluck;
Stick to your aim; the mongrel's hold may slip,
But only crowbars loose the bull-dog's grip;
Small as he looks, the jaw that never yields,
Drags down the bellowing monarch of the fields."

The power of sticking to his aim, combined with excellent natural ability, was the secret of Mr. Lee's success in his profession; and in these days of divided aims in life the lines are possibly worthy of reproduction.

Cost of Cologne Cathedral.—The *Wochenblatt für Architekten und Ingenieure*, discussing the question of the cost of Cologne Cathedral, says:—"The sums which between 1821 and the present time have been contributed to the cathedral building fund, both from public and private sources, amount to 18,000,000 marks (900,000*l*.). This amount has been pretty evenly expended on the erection of the towers and the additions to the church. If to this we add the moneys contributed during past centuries, and notably what has been sunk in the colossal foundations and spent in purchasing various necessary parcels of ground, it will appear that the cathedral as it now stands represents about 40,000,000 marks (2,000,000*l*.)."

* Illustrations will be found in our pages of St. Luke's, Holloway (1859, p. 499), Her Majesty's Theatre (1869 p. 507), &c.

WIND-PRESSURE.

Among the many points which were brought into notice during the Tay Bridge inquiry there was no one of greater interest than the question of wind-pressure. To builders the effect of atmospheric disturbances had long been familiar, and the records of destruction, both among finished structures, but more especially in the case of gables during the course of erection, are neither few nor far between. It is somewhat astounding, therefore, to find that a danger to which every structure that is acted upon by the force of the wind is more or less exposed should not only have almost entirely escaped the notice of engineers, but should also have failed to elicit that amount of attention on the part of scientific investigators which in other branches of the profession generally afforded some reliable data as a foundation for the every-day use of practical men. Nevertheless, there is some apology to be found for the indifference with which it has been hitherto regarded by engineers in practice. Until lately the allowances that have been made for resisting what may be spoken of as the ordinary statical strains to which such structures as high bridges are more especially subjected, have been considered more than sufficient to withstand the force of the wind when added to the lateral strains thus provided for. In this way wind-pressure in the every-day practice of civil engineers in this country came to be very much overlooked, and although a large allowance has always been made for atmospheric disturbances, both in France and in America, the subject has never attracted much attention in England. The failure on the part of science to supply reliable information seems to have confirmed the indifference which arose from the matter having been considered of little practical importance.

The exceptional circumstances under which it was proposed to throw a bridge over the estuary of the Forth brought the question into notice, and in the light of the terrible disaster of the night of the 28th of December last it would have been well if the inquiry had been made earlier, with special reference to the Tay Bridge as well.

In looking into the history of the subject it appears that the source of information to which engineers generally applied was a table presented by Smeaton to the Royal Society in 1759. Omitting atmospheric phenomena, which experience had shown to be confined to the tropics, he estimated the pressure of the wind in this country at six pounds per square foot of surface for high winds, eight or nine pounds for very high winds, and twelve pounds for a storm or tempest. These figures no doubt obtained considerable sanction on account of the distinguished character of the authority with which they were associated, and from the fact that the structures, more especially lighthouses, which had been presumably constructed on the basis of these estimates, had been constantly exposed to the utmost fury of the winds, and remained as monuments of their ability to resist them. But even in the face of such assurances there was at least one good reason why engineers in this country should have reconsidered the subject, from the fact, that in France and America the practice has been to allow 55 lb. and 50 lb. for wind-pressures respectively. Besides the very much greater margin which prevailed abroad, there were isolated instances in this country which proved conclusively that the wind reached a maximum intensity far beyond that which had been laid down by Smeaton. There are several authentic cases of railway carriages having been upset by the wind, both in France and America, and India as well, but of still greater importance as affecting the rules for providing against wind-pressure in the British Isles, is the record of a carriage having been thrown over by a hurricane, on the Chester and Holyhead line, in 1868. Quoting from the report of the Commissioners appointed to inquire into the circumstances attending the fall of the Tay Bridge, it appears that "the pressure required to overturn railway carriages may be taken to vary between 28 lb. and 40 lb. per square foot," so that it became necessary in the light of this exceptional instance to inquire how far such a pressure was likely to act upon the more extended surface of a wide and lofty bridge. It is here that we find a great discrepancy of opinion among practical men and an absence of reliable information to assist us in forming a judgment. It appears that there is no record of any pressure approaching to that which upset the railway carriage on the Chester line ever having acted upon an extended area, but on the other hand, there is no record of how great the extent of surface may be over which such an exceptional pressure may exert its force. It appears that a hurricane at Walmer, of an intensity that perhaps exceeded the pressure which upset the railway carriage, acted over a width varying from 450 ft. to 700 ft., and that a somewhat similar cyclone passed over the Isle of Wight during the winter of 1877. In the face of such facts it is difficult to escape from the conclusion that the wind may in a similar manner act upon a lofty structure of similar width, and that, therefore, it is imperative to provide against the possibility of its doing so.

Nevertheless, when the proposal to build a bridge across the Forth, with spans of 1,600 ft., came to be discussed, a very different conclusion was arrived at. It appears, as our readers have heard more than once, that Mr. Barlow and Dr. Pole, to whom the subject was remitted for detailed investigation, not being satisfied with their own judgment, consulted the Astronomer-Royal, and afterwards spoke of his opinion as "highly authoritative and valuable." The conclusion at which he arrived was "that the greatest wind-pressure to which a plain surface like that of the bridge will be subjected in its whole extent is 10 lb. per square foot." Although the plans for the Tay Bridge had been completed a long time before this opinion was made known, Sir Thomas Bouch seemed to have considered that it was applicable to that undertaking, and no doubt felt his mind much relieved in consequence. When the Astronomer-Royal, however, was examined before the Commissioners he drew a distinction between the two bridges, which, in the light of the opinion already referred to, is somewhat difficult to understand. In his letter to Dr. Pole and Mr. Barlow he said that although "upon very limited surfaces, and for very limited times, the pressure of the wind does amount sometimes to 40 lb. per square foot, or in Scotland probably to more," yet that, looking at the character of that bridge, which was a suspension-bridge with two spans of 1,600 ft. each, the greatest amount of pressure to which it would probably be subjected on its whole extent, would, in his opinion, not be more than 10 lb. per square foot. If an engineer, without further explanation, had drawn the conclusion that this opinion meant that the wind-pressure would not be more than 10 lb. upon a span of 1,600 ft., but that it might be 40 lb. or 50 lb. over an area of 450 ft., he would have found it consistent with what the Astronomer Royal afterwards stated; but, at the same time, we do not think that one engineer in a hundred would have made such an interpretation of the original opinion.

As matters stand at present, we have first the authority of Smeaton, and afterwards the opinion of the present Astronomer-Royal confirming it, for undefined areas between 450 ft. and 1,600 ft. On the other hand, the conclusion arrived at by one of the Commissioners on the Tay Bridge is that the estimate of French and American engineers is much nearer the mark, and "that there can be no reason to doubt that there may be wind-pressure of 45 lb. and even 50 lb. in this country." In saying this, however, they do not commit themselves to any opinion as to the width of the structure, which would be sufficiently great to admit of a lower estimate being taken. To make matters still more complicated, Mr. Baker, who "is a civil engineer of eminence," and "who seems to have devoted much time and attention to the subject of wind-pressures," said that for the last fifteen years he had looked very carefully for evidence of any structure capable of standing a uniform pressure of 20 lb. which had been blown down, and that he had never found a single instance,—that there were hundreds of buildings in this country that would be blown down with a pressure of 20 lb. on the square foot, and miles of wall on the edges of cliffs and on open downs which would be blown down with a pressure of even 13 lb. In the face of all this apparently conflicting evidence, there will be a natural anxiety on the part both of the travelling public and the engineering profession to have the subject thoroughly investigated, and meanwhile there is every prospect that the promoters of such undertakings as the Tay Bridge will find it a very difficult task to raise money unless they are able to convince subscribers that the question of wind-pressure has not only been successfully investigated, but that measures have been taken to render such lofty structures thoroughly secure.

LEAD-MINING AND SMELTING IN DERBYSHIRE.

The annual excursion of the Chesterfield and Derbyshire Institute of Mining, Mechanical, and Civil Engineers took place a few days since under the presidency of Lord Edward Cavendish, M.P. The principal visits made were to several of the best-known lead-mines in the county, especially to the Millclose Stoop, from which (says the *Mining Journal*) is drawn as much lead as from all the other mines now being worked in Derbyshire. To the extraordinary customs or rights as regards lead-mining which prevail in the Peak and other districts must be attributed the small quantity of ore raised for the number of mines opened out, for men without capital are able to sink and carry on operations in the most primitive manner, without any machinery whatever.

On the last day of the gathering Mr. Stokes, of Derby, Assistant Government Inspector of Mines for the district, read an interesting paper on "Lead and Lead-Mining in Derbyshire." The lead-mines, it appears, became the property of the Crown at a very early period; and in the old Roman town of Wirksworth there was lead ore raised in 714, the dues going to support a nunnery at Repton, the abbess of which, it is said, sent a sarcophagus of lead to Croyland, in Lincolnshire, for the interment of St. Cuthlac, a monk, the lead having been obtained from the Wirksworth Mines. Mr. Stokes showed from well-founded data that lead was raised in Derbyshire during the reigns of Tiberius Cæsar, Domitian Cæsar, and Hadrian in the early part of the Christian era. In 1469 the mineral duties north of the Trent were leased to Richard Earl of Warwick, and others, for a term of forty years. At the death of Charles II. the Dowager Queen Catherine had the mines of Derbyshire. About seventy years ago Mr. Richard Arkwright purchased the lease of mines from the Rolls family, and it is still held by the descendant of the former. In the High Peak district since 1690 they have been held by the Dukes of Devonshire, having been leased from the Duchy of Lancaster. Some of the customs prevailing 200 or 300 years ago in connexion with the mines were most peculiar, and we are told that whisky was not allowed to be taken into a mine lest it should frighten away the ore. In relation to the Acts on mining passed in the reigns of Edward I. and VI., Philip and Mary, there is an old poem or rhyme, by Manlove, a local writer, who in allusion to them says:—

> "For stealing ore twice from the minery
> The thief that 's taken fined twice shall be.
> But the third time that he commits such theft
> Shall have a knife stuck through his hand to the heft
> Into the stone, and there till death shall stand,
> Or loose himself by cutting loose his hand";
> And shall forswear the franchise of the mine,
> And always lose his freedom from that time."

As to the mode of smelting lead there are still standing records in what are known as the Bole Hills, the ancient smelting hearths being termed "boles," and consisting of loose stones built upon the brows of hills. Upon these rudely-constructed hearths wood was laid, and over that again the ore was placed. Fire was then applied to the wood, and then the air at first was the only means of kindling the fire to the necessary heat to smelt the ore. After a time bellows were introduced, in some cases being so large they had to be worked by horses. For smelting, it was a custom at one time to cut down timber anywhere within reach for the purpose, and one of the articles made at Great Barmote Court, held in 1665, was,—"We say that for the payment of the said lot miners within the wapentake of Wirksworth ought to have liberty to work the ground within the wapentake, and to have timber also in the king's wastes to work their ground withal, and egress and regress from the highway to their grooves and mines." The timber was not only used for smelting the ore, but it was also burnt for breaking down the sides of veins and getting the mineral before blasting by gunpowder was employed in Derbyshire, as shown by another Court article,—"We say that any miner in an open rake may kindle and light his fire after four o'clock in the afternoon, giving his neighbour lawful warning thereof." This free use of timber in all probability was abandoned when the value and use of coal and gunpowder became known. Bole hills, however, are the most clearly defined geographical position of the ancient smelting hearth; but the word "tor," of which there are many in Derbyshire, may also indicate a smelting-place. The

mining customs first received the Royal sanction from Edward I., after a petition from the miners had been presented to him and an inquiry held at Ashbourne, in 1287, by the king's direction, by the Sheriff of Derbyshire. Those customs have been modified, and reduced to legal rights by Acts passed in 1851 and 1852. The right of all persons to search for, dig, and sink mines on any person's land seems anything but right to the owner, who sees his land cut up, roads made across his fields, and water ingress and egress allowed to the miner. But, at the same time, it should be remembered that the miner had the same rights when the whole of the Peak was a "vast howling wilderness" without cultivation, and belonged to the Crown; also that the present owners bought the land subject to those privileges. There is little doubt that the mining rights at one time, as well as the income from the lead, were of more importance than the surface value,—so that it was of advantage to the Crown that every encouragement should be given to the miners to pursue their calling. These customs once established, have been clung to by the miners with the greatest tenacity, and have been fought for in the law courts, and, as they have been confirmed by the Acts of 1851 and 1852, both miners and landowners know the limit of their privileges as well as their inconveniences.

As to lead itself, Mr. Stokes remarks that some writers consider the veins to be a sedimentary deposit, slowly accumulating or growing similar to stalagmites; whilst others consider that the mineral has been thrown up from below, similar to all igneous rocks, filling fissures or cracks in the strata. Engineering skill and science have done little to improve the mode of working in the lead mines of Derbyshire, which in most instances is somewhat similar to what it was 100 years ago or more, or, indeed, little better than it was in the old Saxon period. In the whole of the lead-mining districts there are only two shafts where the ascent and descent are performed by mechanical means. In all the others ladders are used, or else a still more antiquated system, called "stemples" and "footholds." Stemples are hand and foot rests of wood, driven in horizontally in the shaft, up which the miner climbs by alternately stepping from one to the other, with the risk of being killed by failing to the bottom of the shaft should he miss his hold. In the large mines there are three classes of men employed underground,—tutmen, tributers, and daymen. Tutmen work the levels, tributers work the ore after it has been proved by the levels; and where work is let by the fathom it is called tutwork. As showing the value formerly of some of the mines, it is stated that in 1769 the viewers' tithes for the Wirksworth mines alone were 1,000*l.* per annum.

THE CONDITION OF CISTERNS.

THE official water examiner, Lieut.-Col. Frank Bolton, makes some observations on this subject in his last report, to which attention should be paid. We willingly give them the additional circulation of our columns:—"In the absence of a duly authorised and official 'standard of filtration' regulating the quantity of water to be passed through a given area in a given time, it has been found during the past eight years that when the rate of filtration does not exceed 540 gallons per square yard of filter bed each twenty-four hours, the filtration is effectual, and this has been generally recognised as a tentative standard rate of filtration. The water companies now nearly all keep within this limit, but it is disheartening to reflect that, notwithstanding the efforts that have been made and the large expenditure that has been incurred in works for properly treating and improving the quality of the water, these efforts are rendered nearly abortive and but of little value by the apathy and carelessness of a great number of the householders. The water delivered for domestic purposes is frequently deteriorated after leaving the companies' mains by the dirty state of the cisterns on the premises of the consumers. Many of the cisterns, tanks, and butts for containing water in small tenement houses in the metropolis are in a disgusting and filthy state. An opportunity for inspecting these presents itself when travelling on some of the metropolitan and suburban lines. Cisterns may be seen without lids and with portions of rotten lids floating in the water, full of rank and decaying vegetation, and other most objectionable substances, such as old rags and paper; and on closer examination the contents would show more or less organic deposit, and under the microscope would be found to abound in infusorial life. All cisterns should, therefore, be properly covered and be frequently cleaned out, and every care should be taken to prevent the contamination of the domestic supply after delivery. Now, as heretofore, it appears to be the rule in building a certain class of houses to place the cistern over the water-closet with an untrapped waste-pipe communicating with the drains. These cisterns are often open and regularly receive the drippings from the roofs and gutters; they are, moreover, in close proximity to the dust-bins and other deposits of filth and garbage, while children amuse themselves by throwing all sorts of dirty rubbish into the water, including dead puppies and kittens, with an occasional cat. These are facts known by personal observation. The purest and best filtered water in England would be poisoned by such a system of storage.

The Public Health Act of 1875, section 70, gives power to any local authority, in case of complaint, to inspect and remedy such evils, but, probably, the only remedy for this state of affairs will be found in the establishment of the constant supply system and the consequent total abolition of these unfit receptacles; meanwhile, and until the system of constant supply is completed, the owners and occupiers of houses are surely very wrong in permitting such a condition of things to exist."

NATIONAL INSURANCE.

AT the annual conference of local government administrators of the four northern counties of England, held recently, at Gilsland, under the presidency of Earl Percy, Mr. Cropper read a paper on "National Insurance." At last year's conference Mr. Cropper read a paper on the same subject, but too late for discussion, so he read another this year amended so as to include knowledge acquired during the year. Lord Carnarvon said, that as we compelled the solvent to provide for the destitute, it could not be wrong to make a man provide for himself. It would be well if such provision could be made voluntarily, but it had better be enforced by law than be left wanting. In Germany payment to sick societies was compulsory, masters of artisans being bound to deduct the fortnightly payment due to the clubs, and no difficulty ever arose in the practice of this rule. In the third place his lordship said the majority of existing British Benefit Societies were insolvent. British working men earned higher wages than the same class in any other country, yet they expected to be supported in their old age. The sick-club or friendly society was a man's natural resource. Lord Carnarvon said that, in 1879, 150 registered friendly societies became insolvent. A million and a half of people now belonged to societies which professed to provide for sickness and infirmities, and probably most of them would find their payments thrown away, and of no use when the time of their need came. Lord Carnarvon proposed to reduce the cost of insurance by making every man join in payment. Many contributors would not seek the benefit. Yet it was not unfair as a national scheme, because it would not be asserted beforehand that anybody would not claim, and the ease to the poor-rate would overcome any objection to it. The London and North-Western Railway Company insisted upon a deposit of 2½ per cent. of the salary, and added a similar amount. A servant on leaving with a good character could claim half, and if rendered incapable he received an income of one-third his pay. He did not believe a compulsory system of insurance would ever take the place of the Poor-Law. There would still be women and children of stray workmen who had been missed. It would not do the work of all the existing sick societies, because it would lack the aid of the self-interest of the members of those societies which at present helped to check pretence. Employers also might object to make the deduction, and might think that in the end they would have to pay the insurance, and add it to their workmen's wages. But the employers would soon learn their own interest, and they rarely objected to rules, however arbitrary, if only applied alike to all their competitors in trade.

In the discussion which followed, Sir Charles Trevelyan said he gave an unqualified opposition to the principle advocated in the paper. He admitted the excellence of Mr. Blackley's notion amid all his failures. Compulsory providence was a pure fallacy. Providence was a moral quality. Man must be able to stand, yet free to fall. Action such as that proposed might turn a man into a machine. Out-door relief was provided for a man if he saved nothing at all, and all the powers in the world would not promote thrift and providence while those diverse influences prevailed. Some friendly societies were now extremely well-managed associations.

GLAZED TERRA COTTA FOR ARCHITECTURAL PURPOSES.

OUR recent articles on terra cotta have brought us communications from two or three manufacturers, amongst others, which seem to show a praiseworthy desire to take any steps that may promise to improve their wares and promote the application of them. We may have occasion hereafter to refer to these.

From Messrs. Wilcock & Co., of Burmantofts, we have received a number of specimens of their glazed faïence, which they, no doubt correctly, consider the most recent development of terra cotta for architectural purposes. The material of which this faïence is made is a very fine fire-clay; it being essential that the clay should be almost chemically pure, otherwise it will not stand the great heat to which the articles are subjected, in order to secure hardness and durability. The clay is prepared in the usual way, and in a thoroughly plastic condition is pressed into plaster moulds, and, indeed, up to the point of being ready for the kiln, is treated precisely as if it were terra cotta, only it is handled with additional care.

When carefully placed in the kiln it is subjected to an intense fire for from forty to fifty hours; after being allowed to cool it is ready for going through some preparatory processes prior to being glazed. These processes have been arrived at after repeated trials and failures, but these have resulted in it being now possible to produce a very great variety of effects and colours. If, as they claim, the glaze is imperishable and unaffected by either atmosphere or temperature, the ware is certainly eminently suitable for either interior or exterior decoration.

We are not bound to admire the taste displayed in all the specimens sent, but the plastic quality of the material obviously fits it for fine work, and it admits of a great variety of colouring.

THE RUSSIAN YACHT *LIVADIA*.

THE construction, interior decoration, and furnishing of the Imperial state saloon of this yacht have been entrusted to Mr. Robert Christie, and some of the most important pieces of furniture made for the purpose have been on view for a few days in the rooms of the Royal School of Art Needlework, Exhibition-road, South Kensington. The principal pieces are in what is called white and gold, including sideboard, settee, chairs, &c., and are solid and handsome; the metal-work seems good, and the same may be said of the gilding, but we are bound to say that they please us less than some of the simpler and cheaper furniture to be found near them in the rooms. The forms are clumsy, and the embroidered satin with which the chairs and settee are covered is hard and staring. Some red plush curtains, with an almost metallic lustre, are very rich in appearance.

This School of Art Needlework, by the way, is scarcely so well known as it ought to be.

Bricks.—A correspondent writes:—"What is the average annual consumption of bricks for building purposes in London? I think I saw in a paper that at a meeting of brickmakers, held last autumn at the Cannon-street Hotel, the chairman stated the average metropolitan consumption to be 750,000,000." A precise answer to this could not be given without special inquiries. Mr. W. T. Wiseman, who is agent for many of the manufacturers, supposes in reply to our question, "that probably 800 millions of bricks annually (taking the average of the past five years) are sent to London within a radius of four or five miles from London Bridge."

OBITUARY.

Mr. W. Penstone.—The death of this young architect, from consumption, took place last week. He was a member of the Committee of the Architectural Association last session, but would not allow himself to be nominated again in consequence of his failing health. The noteworthy paper on "Late Wrought Ironwork," read during the session 1878-79, and which we printed, gave a few of the results of considerable study of the work of the seventeenth and eighteenth centuries in various arts. No. 1096 in this year's Exhibition of the Royal Academy showed in clever drawing two buildings erected from his designs. A good draughtsman and hard-worker will be missed in the Association, and another right-minded and pleasant companion remembered with regret.

Mr. Hakewill. — We mention with great personal regret that Mr. John Henry Hakewill, Fellow of the Institute of Architects, died at his residence, 77, Inverness-terrace, on the 30th ult., in his seventieth year. We will take another opportunity to speak of his works. Death has been sadly busy in the ranks of the architectural profession of late.

ROYAL HOTEL, BLACKFRIARS.

We mentioned briefly in our last that the second section, which completes the building of the "Royal Hotel," at Blackfriars, is now commenced. The work is in the hands of Messrs. Lucas Brothers, who are pushing on rapidly with the contract, in order at as early a date as possible to meet the demand for accommodation at the present hotel, which, large as it is, is not able now to do so. In the new building there will be many arrangements for the comfort of the visitors and the easy working of the business of the hotel. Two high class hydraulic lifts will be erected for conveying visitors and their luggage to the different floors of the hotel. Special arrangements have been made for the safety of the visitors using the apparatus. Mr. E. A. Gruning is the architect, and Mr. F. Colyer is the engineer, who has designed the lifts and other engineering appliances, and will superintend the same in conjunction with the architect. Messrs. Simpson & Co. have the contract for the lifts; Messrs. Siebe, Gorman, & Co., for the heating apparatus; and Messrs. S. J. Baker & Sons, for the wells.

SOCIAL NOTES.

An Extraordinary Delusion.—At the last meeting of the Orrell (near Wigan) Local Board, the medical officer of health in his monthly report stated that one case of scarlatina had occurred at Gathurst, which seemed to have been due to infection imported into the district. The clerk mentioned that there was an extraordinary superstition in the minds of some of the parents in the Board's district. Believing that it was better children should have the whooping-cough while they were young, parents were in the habit of taking their children where whooping-cough was prevalent, in order that they might catch the infection. In one case he knew a woman—the mother of eight children—take her children to a house where there were persons residing suffering from scarlet-fever, so that they might have the fever while they were young. The medical officer said that was a recognised notion amongst the poorer classes. There is evidently wide scope for the use of health primers in our Board schools, and for the missionary zeal of ladies' sanitary associations.

The Coffee-Tavern Movement.—At Kidderminster, a new coffee-tavern, erected for the County and City of Worcester Coffee-Tavern Company in Vicar-street, Kidderminster, was opened on the 14th ult., by Lord Lyttelton, the chairman of the company. The tavern has been built specially for its intended purpose by Mr. Julian, and taken on a twenty-one years' lease by the company.——A coffee-tavern has been opened at Kingston, which, by permission of Prince Leopold, is called the Leopold Tavern. The Prince is a shareholder.

Working Men's Clubs.—On the 17th ult., the building which is to be the head-quarters in future of the Twerton-on-Avon Club Institute and Reading-room (formerly known as the Working Men's Club), together with a new hall in the rear, was opened. Messrs. Carr a short time since purchased the building known as the George Inn, and a plot of ground adjoining, on which the new hall has been erected. The old building has been thoroughly renovated, and fitted for the use of the club. The Club-house has on the ground-floor a library of 700 volumes, a reading-room, and a smoking-room. The first-floor has also three rooms, which will be used for committee, writing, and billiard-rooms, respectively. The new hall, which is built of stone, is capable of holding 400 persons. The builder was Mr. Thomas Harrison, of Twerton, and Mr. J. L. Asher supplied the gas-fittings.

YE ANTIENT HOUSE.*

Hollow home oft will come
Rattling to the ground;
Birds will flee, o'er the sea
Other homes will found;
When returned, old one's spurned,
New's more cheap and sound.

Men of old, as we're told,
Their own time could take;
Strikes unknown, each one shown
What he was to make;
Now-a-days—railway age—
Man must keep awake!

Holy men, living then,
Built both well and strong.
Why? Because each "had pause";
Labour for a song.
Money, too, then, they knew,
Need not "hum along."

Sages say, in his day,
No one gains his crown,—
Be it praise, glory, bays,—
Envy hunts him down;
When he dies *then* fame cries,
"Great is his renown"!

So we praise other days—
Ever sing the past;
Giants, then, were the men
Ne'er to be surpass'd!
Passing by, mockingly,
Pearls before us cast.

Let me stay 'ero I stray
Farther from my theme;
Long and low,—plan so, so,—
Built without a scheme;
Here a stair, leading—where?
Ancient houses seem.

Ceilings low, as you go,—
Mind, you'll hump your head!
Dusty, too,—gracious!—phew!
Roofs, part stripp'd of lead;
Draughts as well—who can tell
Where rats are *not* bred!

Walls so bulged, bricks divulged;
Filled with ghostly sounds;
Rooms so large—turn a barge;
Lumbago abounds.
It is but a draughty hut,
Grown beyond its bounds.

Herbert.

The Employers' Liability Bill was read a third time in the House of Lords on Tuesday last, having previously passed through Committee, in the course of which passage sub-section 3 of Clause 1 was omitted, on the motion of Lord Brabourne. On the motion, after the third reading, "That this Bill do pass," the Lord Chancellor moved the insertion of the word "any" in the second sub-section of Clause 1, making the clause read as follows:—"By reason of the negligence of any person in the service of the employer who has 'any' superintendence entrusted to him." This amendment was agreed to. Lord Stanley of Alderley then moved the re-insertion of the sub-section in question, which ran as follows:—"Where, after the commencement of this Act, personal injury is caused to a workman. . . . . by reason of the negligence of any person in the service of the employer to whose orders or directions the workman at the time of the injury was bound to conform, and did conform, where such injury resulted from his having so conformed." Lord Shaftesbury expressed his regret at the course taken by their lordships in omitting this sub-section in committee, but the amendment was negatived and the Bill passed.

* Thinking the other side of the question in the matter of "the modern mansion" might as well be set forth, I submit the following.—H. L. S.

ENGINEERING ITEMS.

Concrete.—The Royal Engineers have almost completed the 100-ton gun *emplacement* in the Government Marshes adjacent to the Royal Arsenal, Woolwich, the construction of which has been required for experiment prior to mounting the heavy guns of the same type in the fortifications at Gibraltar and Malta. The work, which covers an area of about 80 square feet, is composed principally of concrete in imitation of masonry.

Society of Engineers.—The members and associates of this society have visited the works of the London and South-Western Railway Company at Nine Elms. Mr. W. Adams, locomotive superintendent, received the visitors and conducted them over the works, and with him were Mr. W. Beattie, chief assistant to the locomotive superintendent; Mr. Mather, works manager; Mr. Brown, principal foreman of the carriage department; Mr. Sullivan, chief draughtsman; and Mr. Garrett, who has charge of the works alterations. The company visited the drawing-offices, the carriage-trimming department, the carriage-painting, boiler, machine, fitting, tyre, wood, and moulding shops. In the wood shop is a large circular saw, made without hammering, the speciality of the Lane Manufacturing Company, of America. This implement sawed through a log 15 ft. long and 15 in. thick in ten seconds. In the same department several machines by Ransome & Co., of Chelsea, for planing, sawing, slotting, &c., were exhibited. In the moulding shop the process of making moulds for axle-boxes with the machine of Butterfield & Co., of Keighley, was observed with much interest. About 1,500 workmen are employed at these works.

LIVERPOOL NEWS.

A New Roman Catholic Home for the Aged Poor.—The new home for aged poor people, near to the Church of St. Margaret, Belmont-road, was opened by Dr. O'Reilly, R.C. Bishop of Liverpool, on the 19th ult. The new building is from designs by Messrs. Goldie and Child, architects, London, and has been erected by Messrs. Holme & Nicol, the builders, Liverpool. The land, which is of considerable extent, has been paid for, but the building, erected at a cost of upwards of 9,000*l*., has a debt upon it of about 5,000*l*. The new building (which is under the management of "The Little Sisters of the Poor") has at present sixty-four inmates, but there is sleeping accommodation for 100.

New Dock Works at the North End.—At a recent meeting of the Mersey Docks and Harbour Board, the minutes of the Works Committee contained a recommendation to proceed with the construction of the northernmost section of the new works at the north end, and to accept a tender for the excavation in connection therewith; but the consideration of the subject was adjourned.

The Junior Reform Club.—A temporary habitation for the members of this club has been provided in Eberle-street. The building is at present undergoing structural alteration at the hands of Messrs. Roberts & Robinson, of Liverpool, and will be ready for formal opening by Lord Northbrook on the 16th ult. Messrs. White & Son, of Duke-street, are doing the decorating, painting, and paperhanging work; Messrs. N. & T. Dutton, Great George-street, are supplying the furniture; Messrs. Ray & Miles, the carpets, &c.; and Messrs. Walker, Pendleton, & Co., Dale-street, the kitchen-ranges and stoves.

FROM SCOTLAND.

New Farm-steading at Troves, Elgin.—New farm-buildings have been erected on the farm of Troves, on the Fife estates, and about a mile to the south of Linkwood. Entering at the south gable, and passing through a large turnip store, the visitor finds himself in the feeding and cow byres, which are fitted up with all modern improvements. There is an entrance from the turnip-shed into the folds, and thus turnips can be conveyed to byres and folds without going outside. Next comes the men's sleeping apartment, which has good ventilation. The stable, which adjoins, contains six stalls. It is airy and well-lighted. After this comes the straw barn and threshing-mill, from which a stair leads up to a very commodious and well-ventilated grain loft. There is also an entrance to this loft from the north gable. The cart-

shed follows, but an intervening passage, leading from the stackyard into the square, divides it from the barn. We now come to the principal fold for the rearing of fat stock. Immediately in front of the fold is an open cattle court. Here the main entrance to the square intervenes, to the left of which are another fold and open cattle court. The folds are covered with corrugated iron, but the rest of the steading is roofed with blue slate. The poultry yard lies to the east of the steading. There are also piggeries and a shed for bolding farm implements. The architects were Messrs. A. & W. Reid, Elgin.

Aberdeen Hydropathic Establishment.—New buildings at the junction of Bridge-place, Bath-street, and Windmill Brae, intended for use as a *café* and hydropathic and Turkish bath establishment, have been erected. The building has a frontage of about 90 ft., and has five stories, the height from basement to roof being 72 ft., and to summit of tower, 80 ft. The baths department includes "cooling rooms," smoking-room, tepidarium, large plunge-bath (lined with Portland cement, and finished on the lower part with Torbay white naval enamelled paint, the upper part being lined with glazed tiles), and five smaller plunge baths. The walls of the various rooms in the two departments of the baths are of cement concrete, plastered with Portland cement, and finished with Parian cement, no lime-plaster being used in the work at all. The woodwork is of pitch-pine, stop-chamfered and finished. The hydropathic portion of the building contains a number of large apartments. In the southern wing, immediately above the *café* dining-room, is the principal drawing-room, a lofty hall, lighted by three single and three double windows. Adjoining it is a ladies' drawing-room. The rest of the flat consists of bedrooms, a store-room, the resident physician's consulting-room, and the housekeeper's parlour, communication being established between this floor and the baths. The dining-room is the principal apartment on the second floor, occupying the southern wing, and designed to seat fifty persons. The arrangements for ventilating the rooms in this department of the building comprise circular gratings in the ceilings of all the apartments, communicating with shafts which unite and have their point of egress in the summit of the tower, where a Boyle's patent air-pump ventilator is fixed. Mr. D. Macandrew has been the architect of the building, and Mr. Winchester clerk of works; and the tradesmen were:—Masons, Messrs. P. Murray & Co.; carpenters, M'Robbie & Milne; slaters, M'Grigor & Shand; plumbers and gasfitters, Smith & M'Kenzie; plasterers, R. Henderson's Trustees; painters and glaziers, Gordon & Watt; heating engineer, John Taylor; bellhanging, &c., James Laing & Co.; lamps, W. Shirras & Son; encaustic flooring, &c., James Bannochie. Mr. Winchester was inspector of works; Mr. Murray, mason; and Mr. King, foreman carpenter.

Grangemouth Park.—At a special meeting of the Police Commissioners of Grangemouth, on the 17th ult., an offer from the Earl of Zetland of eight acres of ground for recreation purposes was laid before the meeting, and unanimously accepted by the Commissioners in behalf of the town. It was suggested that the park bear the name of either the Earl or the Countess, and be called the Lumley, Dundas, or Zetland Park.

BUILDINGS FOR POOR LAW ADMINISTRATION.

Fulham.—At a recent meeting of the Fulham Board of Guardians a long discussion took place respecting the instructions to be given to architects for preparations of plans, &c., and it was resolved that 100 guineas be awarded to the architect whose plan should be accepted by the Guardians, and 50 guineas to the architect who should stand second in the estimation of the Board, such plans to become the sole property of the Board.—On the motion of Mr. Pickersgill, seconded by Mr. Turner, it was decided to allow the architect of the new building 5 per cent. up to 20,000*l.* and 2½ per cent. on any outlay beyond that sum. Mr. Hunt, in reply to Mr. Thompson, who contended that 5 per cent. up to 10,000*l.* would meet the case, said that it was not always the lowest figure that turned out the cheapest, and he believed the higher figure would be more favourable to the Board in the end. The Clerk having remarked that it was usual in similar cases to appoint some one to supply the levels, Mr. Green moved and Mr. Cockerell seconded that Mr. Sanders, of King-street, supply the levels at a fee not exceeding 10 guineas. A discussion followed, some members contending that five guineas would be an ample fee, and others thinking that such matters should be left entirely in the hands of the architect; but ultimately Mr. Sanders was appointed at the fee originally proposed. The Clerk then, at the instance of the Board, went *seriatim* through a list of requirements to be submitted to the architects on behalf of the Board. The new building must afford accommodation for upwards of 360 cases, exclusive of separate arrangements for lock and other special cases. After considerable discussion it was resolved, "That an eminent architect (such architect to be a member of the Institute of British Architects) be called in to assist the Board in deciding how far the plans submitted conform to their requirements, and also as to their relative value."

Clerkenwell.—The Guardians of the Poor of the Holborn Union propose to erect a new infirmary on the site of the old Clerkenwell workhouse, King's-cross-road (formerly Coppice-row). The cost of the proposed buildings is estimated at 60,000*l.*

Mitcham.—At the meeting of the Holborn Guardians on the 18th ult., the tender of Messrs. May Brothers, of High Holborn, for the laundry works at the Mitcham Schools, for the sum of 1,260*l.*, was accepted. It was referred to a committee of the whole Board to meet Mr. Snell, the architect, and confer with him as to the erection of a new infirmary at the schools.

PROVINCIAL NEWS.

Reading.—At a special meeting of the Court of Governors of the Royal Berkshire Hospital, Reading, on the 3rd ult., the following proposals for providing additional accommodation were submitted by the Board of management and the medical staff:—(1.) That the Nurses' Home be raised another story, to provide additional accommodation for nine private nurses and probationers, at an estimated cost of 1,700*l.* (2.) That an additional block be built on the south end of the Nurses' Home, for the accommodation of the housekeeper and twelve servants, at an estimated cost of 1,500*l.* (3.) That the laundry be erected at the south end of the proposed new dormitories, at an estimated cost of 1,500*l.* (4.) That the Nurses' Home, new dormitories, and laundry be connected with the main building by an inclosed way, to be carried along the south wall of the female convalescent ward, at an estimated cost of 500*l.* (5.) That the chapel be removed from its present position, and the side walls reduced in length to open out the quadrangle. The centre block of the hospital to be remodelled and extended. The present museum and library to be converted into a chapel, with operating-theatre and small ward over, at an estimated cost of 3,500*l.* (6.) That the out-patients' department be raised another story, to provide rooms for museum, library, and such other purposes as may be considered necessary, at an estimated cost of about 2,000*l.* (7.) That the kitchen be altered by having a lobby made at the entrance, and fitted with a ventilation-shaft, to prevent the smells of cooking, &c., from entering the wards, and the present laundry to be converted into a dining-hall for servants, at an estimated cost of 350*l.* Plans of the proposed new buildings and alterations were exhibited by Mr. Joseph Morris, the architect, and it was resolved to carry them into execution. The total estimated outlay is 11,000*l.*

Coggeshall.—A lych-gate has recently been erected at the principal entrance to the parish churchyard, as a memorial to the late Mrs. Bonton, the mother of the donors. It is executed in the style of the fifteenth century, and has been constructed in English oak, by Mr. C. H. Oldridge, of Colchester, from the designs and under the direction of Mr. E. J. Dannpier, architect.

Bath.—On the 19th ult. Mr. S. J. Smith, C.E., one of the inspectors from the Local Government Board, held an inquiry in the Council Chamber, at the Guildhall, relative to the application of the town council (acting as the Urban Sanitary Authority) for the sanction of the Board to borrow 7,700*l.* for works of wood-paving. The surveyor (Mr. Parfitt), in answer to the question by the inspector, "What wood do you propose to lay down?" replied, "Archangel; that is the best material we can find, in my opinion." The inspector: You have selected good resinous, tough wood? The surveyor replied in the affirmative, and added, that it was intended to lay the blocks with open joints, filled with concrete and bituminous compound. The inspector, before closing the inquiry, pointed out the necessity there was for care in selecting the wood; that would be the greatest boon to themselves. The good or bad selection of material would make a difference of four or five, or even six or seven years, to the life of it. If they got soft pine-wood it would only have a short life. Doctors differ!

Stafford.—The corner-stone of the new butchers' market has been laid. The buildings are being erected from the plans of Mr. Joyce, which were selected in competition. Mr. Bridgett is the contractor.

Bilston.—A special meeting of the township commissioners was held on the 10th ult., to receive the sanction for, and to authorise the borrowing of, 1,500*l.* on the security of the General Improvement rate, and of 1,200*l.* on the security of the Free Library rate, and to give instructions as to the proposed Town Hall and Free Library extensions. The Chairman said he was pleased that the Local Government Board had sanctioned the proposed expenditure. At the recent Local Board inquiry an unexpected opposition sprang up, and much was said about the state of the town. Distant papers had also published articles referring to Bilston as a "doomed town," with its collieries worked or drowned out and its manufactories closed, but this was exaggeration. Better times were in store for the town, and as the extensions were greatly needed the sooner they were commenced the better it would be.

Dudley.—On the 23rd ult. the new Corporation baths erected at Dudley were opened by the mayor. Alderman W. North, the ex-mayor, gave a detailed account of the work of the Sanitary Committee, who had had the undertaking in hand. In the course of his remarks he stated that the contract for the building was a little over 4,000*l.*, the machinery would cost about 1,500*l.*, the land was purchased for 600*l.*, and it was expected that the whole would be completed for 7,800*l.* or 8,000*l.* The Mayor having referred at some length to the various Acts of Parliament passed during the last thirty years for the sanitary improvement of the people, amongst which stood the Baths and Wash-houses Act, declared the baths opened. The baths are built of red brick, the front elevation being relieved by mouldings of a corresponding colour. There are three entrances leading directly to the private baths, sixteen in number; four first-class for ladies, and six first and six second-class for gentlemen. The swimming-bath is 10½ ft. long in its total length, but it will be divided to afford accommodation for first and second class bathers. The breadth is 30 ft. and the depth ranges from 3 ft. 6 in. to 5 ft. 6 in., and the bath is capable of holding 88,000 gallons of water. The machinery is fixed in the rear of the baths, and includes a Davey's patent differential engine of nominally 40-horse power. Two Lancashire boilers, 20 ft. by 6 ft. 6 in., generate the steam both for the pumping-engine and for heating the water in the swimming-baths. The exhaust steam is conveyed to a Berryman's water-heater, whence it is forced by Pearn's quadruple-acting pump into the boilers and to supply the private baths. An iron tank has been placed on the top of the engine-house for holding a supply of water in case of any accident to the machinery. The pumps, which are particularly adapted for the work, are fixed in a shaft 120 yards deep, from which the supply of water for the baths is taken. Messrs. Davies & Middleton are the architects, and Messrs. Holland & Son the builders. The machinery was selected and laid down by Mr. Alexander Smith, C.E.

WESTMINSTER OFFICES COMPETITION.

We understand that the referee, Mr. Charles Barry, has made his report upon the designs submitted, and that it is now being printed, in order to be dealt with at a special vestry meeting to be held next week.

Surveyorships.—At a meeting of the Aldershott Local Board of Health, held on the 10th ult., Mr. W. L. Coulson was unanimously elected surveyor out of 108 candidates.

"FOOTINGS ON ANOTHER MAN'S LAND."

THE brief note which we appended to a letter under this heading seems to have surprised a number of persons, and we have received letters from several solicitors, amongst others, calling on us to justify the assertion we made. The following will serve to represent what they say:—

"Sir,—In the *Builder* of August 21st, page 249, appears a letter, headed 'Footings on another Man's Land.' You append a note at foot saying Building Bills have been before Parliament giving right to place footings on an adjoining owner's ground. Will you kindly inform me when these bills or acts were passed and where I can obtain a copy? because there is hardly a week passes that I have not disputes brought to me as to the encroachments of the footings, and in nearly all cases I say that according to common law no man has a right to place a single brick on the adjoining property without the consent of the owner.

HENRY W. MICHELL."

We said nothing about "Acts" or Bills passed. What we said was, "Building Bills which have been brought before Parliament have contained a clause giving right to a building owner to place footings on adjoining owner's ground." The Bill to which we more immediately referred was that prepared by the Metropolitan Board of Works and ordered by the House of Commons to be printed 20th March, 1874.

Part 4, Clause 24, sets forth how, where grounds of different owners adjoin and are unbuilt on at the line of junction, and the owner of one piece of ground is about to build thereon, he is to proceed; and thus concludes:—

"Where in either of the cases aforesaid the building-owner proceeds to build an external wall on his own ground, he shall have a right at his own expense at any time after the expiration of one month from the service of the notice, *to place on the ground of the adjoining owner the projecting footings of the external wall with concrete or other solid substructure thereunder*, making compensation to the adjoining owner or occupier for any damage occasioned thereby."

This Bill never became an Act.

We might have gone farther than we did in our note, and said that at one time it was the law of the land that a building owner might place his footings on the adjoining owner's property without his consent. For the benefit of our legal friends, some of whom seem a little behindhand in this matter, we will make this clear.

The Metropolitan Buildings Act, 7th and 8th Vic., cap. lxxxiv., sec. xxxviii. says,—

"And be it enacted, with regard to walls, so far as relates to the building thereof on vacant ground at the line of junction of premises belonging to different owners or in different occupations. That one month before the owner of any piece of vacant ground, or ground not hitherto built upon, shall build any building adjoining to another piece of vacant ground, or ground not hitherto built upon, or build a fence-wall for such piece of ground, it shall be his duty, and he is hereby required to give to the owner or occupier of such adjoining vacant ground a notice, which must be in writing, and must set forth his desire to build a party-wall or party-fence-wall, and describe the thicknesses and dimensions of such desired party-wall or party-fence-wall, according to the form (No. 16) in the schedule of notices, or to the like effect; and that if within such period of one month such adjoining owner shall signify his consent in writing, then the same must be built partly on the ground of one of the said owners or occupiers, and partly on the ground of the other owner, and such last-mentioned part is to be paid for as is hereinafter directed by such other owner or occupier; but if he do not signify such consent, then it shall be the duty of the building owner to build an external wall for such building, and fence-wall for such ground, entirely upon his own ground, *except as to the footings of any such wall.*"

We may therefore repeat what we originally said, and with an addition,—Building Bills which have been brought before Parliament have contained a clause giving right to a building owner to place footings on adjoining owner's ground; and at one time, viz., till the abrogation of the 7th and 8th of Victoria, cap. lxxxiv., this was the law in London.

English Cholera in Sandbach, Cheshire. Whether the cause be the impure condition of the water in the town and the district, or whether, as alleged by Dr. Davies, it is the result of neglect in the removal of nightsoil, the fact remains that in and around Sandbach, the *Warrington Guardian* says, the epidemic, which was reported in its columns a few weeks ago, has not abated in any degree. The Local Board, it is stated, seem fully alive to the urgency of providing an adequate and purer water supply, and have in view a scheme that will furnish Sandbach with all the blessings of a full and pure supply of water.

SEWAGE IRRIGATION.

Kidderminster.—At the last quarterly meeting of the Kidderminster Town Council a discussion took place with reference to a plan prepared by Mr. Pritchard, C.E., for draining the Sewage Farm.—Mr. H. Dixon, the Chairman of the Drainage and Waterworks Committee, read his report, which stated that subsequent to the visit of the members of the Town Council to the Sewage Farm, Mr. Pritchard, at their suggestion, prepared and sent in a modified scheme and plan for the drainage and distribution of the sewage, which could be carried out for a sum varying from 2,500*l.* to 2,800*l.* It was resolved to carry out the work.

Warwick.—On the 19th ult. Mr. Thornhill Harrison, C.E., one of the inspectors of the Local Government Board, held a public inquiry respecting an application by the Warwick Town Council for the Board's official sanction to a loan of 2,500*l.* The Town Clerk explained that the money was required for the sewage farm, the management of which had recently reverted to the council. There was no opposition.

AMERICAN NOTES.

A Town Burned Down.—Eureka, a mining town of Nevada, was almost entirely burnt down on the 17th ult. The loss is estimated at $1,000,000. This fire, following closely upon the severe fire which occurred last year, has considerably discouraged the inhabitants, who had scarcely finished their rebuilding.

A Big Blast.—A big blast at the Blue Tent diggings was fired off on July 2. The charge consisted of 1,542 kegs of powder, at 25 lb. to the keg, making in all 38,550 lb. The firing was done by electricity. The result was very successful. The bank, which is 238 ft. perpendicular, was torn away for about 150 ft. back, and 200 ft. wide. It is believed that this is the largest piece of ground torn from its foundation in one blast that has ever taken place in California.

Elevated Railway for Chicago.—The Metropolitan Elevated Railway Company of Chicago, with a capital stock of $5,000,000, has been licensed by the Secretary of State.

American Locomotives.—Advices from New York state that a large new locomotive, constructed by the Baldwin Locomotive Works, to be run on the Bound Brook branch of the Philadelphia and Reading railroad, and which has since the suspension of that company remained in the possession of its builders, has been purchased by Mr. F. W. Eames, of Watertown, New York, for brake trials and tests in England. It was to be fitted with the Eames duplex automatic vacuum brake and shipped to London. Mr. Eames proposes, while showing the action of the Eames brake on railway trains at the highest speed which it is possible to attain, at the same time to settle the vexed question of the relative superiority of American and English locomotives.

Proposed Colony of English Workmen.—It is stated that Mr. Thomas Hughes, Q.C., will, during his visit to the United States, lay the foundation of a new town in East Tennessee, where a colony for English workmen is to be established. The land is fertile, and the soil rich in minerals. An American paper suggests that it be called "Tomhrown."

A Wonderful Gas-Well.—An occasional correspondent of the *Globe*, writing from Sheffield, Warren County, Penn., U.S., says:—The most wonderful part of Sheffield is a natural gas-well. The gas from this well is used in the furnace of the tannery of Horton, Crary, & Co., and runs the machinery; it also lights all the houses in the town, being brought in iron pipes two miles from the well. It was discovered in boring for petroleum. Escape pipes have been run up to a height of some 20 ft., and the huge flames from these pipes flare away day and night, and have done so for the last five years. The daily amount given off is estimated at 2,000,000 ft. The gas was found at a depth of 1,350 ft., and blew all the boring machinery out of the well. The pressure is so great when turned full on that the gas blows itself out. The smell is not the same as coal-gas, but more like petroleum. There is little doubt this gas-vein is on the edge of a petroleum field, or more probably all the land near is underlaid with it. The amount has not been found to lessen nor the pressure diminish in the whole five years.

New Colleges and Schools.—The executors of the late Alexander T. Stewart have appropriated sums, which will probably amount in the aggregate to $3,000,000, to the establishment at Garden City, Long Island, of a college for the education of young persons of both sexes at a charge of less than $100 a year, including travelling expenses from New York or Brooklyn. The first building, nearly complete, will accommodate 500 students. Two other buildings of equal dimensions will be erected beside it. A building, to accommodate 300 young women, occupying 25 acres, with annexes and surrounding grounds, will also be completed very soon. A divinity-school, to educate young men for the ministry of the Episcopal Church will also be established in Garden City.

CONTINENTAL ITEMS.

Observatory on Mount Etna.—Professor Silvestri, of Catania, says that in a short time the Observatory on Etna will be an accomplished fact. The Italian Government contributes half of the expenses, the Province of Catania a fourth, and the Commune of Catania the remaining fourth. The object of the Observatory is the study of vulcanology, and therefore it has been built at the base of the central cone, exactly on the former site of the well-known refuge called the "Casa degli Inglesi."

The Vieille Montagne Zinc Mines.—The general production of the Vieille Montagne Company's zinc mines last year was 65,839 tons, as compared with 75,955 tons in 1878. The production of galena effected by the company also declined to 5,907 tons last year, as compared with 6,499 tons in 1878. The reduction in the production indicated by these figures was effected voluntarily by the Sardinian and Algerian agencies, as in consequence of the low strength of the minerals obtained in those countries, and the difficulties attending their working, they do not yield any profit when prices fall below a certain point.

Communication with Belgium.—Sir Edward Watkin, Sir Henry Tufton, Mr. Myles Fenton, and Mr. Abernethy, C.E., of the South-Eastern Railway, have had an audience with the King of the Belgians, in reference to the construction of additional ports and harbours on the Medway and the Belgian coast, and the establishment of a fast and commodious line of steamers between the two countries.

Fire in St. Petersburg.—What is described as the most extensive fire that has occurred in St. Petersburg for the last seventeen years took place on the 16th ult., in the Ligofka quarter. More than twenty buildings were destroyed.

A large Lathe.—What is stated to be the largest lathe, not only in France, but in the world, has just been erected at the St. Chamond Steel Works, in the Department of the Loire. It is destined for the turning of 100-ton guns, and was supplied by Sir Joseph Whitworth & Co., of Manchester.

WATER SUPPLY.

Liverpool.—The Bill to enable the authorities of Liverpool to take a supply of water from the Severn has received the Royal Assent, and on the 9th ult. the Town Council resolved to proceed at once with the first section of the works. It is expected that the whole scheme will be carried out in five years, and will secure an additional supply of 13,000,000 gallons of water per day for Liverpool. Mr. Wilson, chairman of the Water Committee, remarked that the Bill provided for Liverpool a *minimum* quantity of forty gallons daily per head, and it enabled the corporation to sell water to their neighbours at a fair price. What, however, was of great importance was that the corporation had power ultimately to retain the whole water supply, the condition being that five years' notice to discontinue can be given when only thirty gallons per head are available for increased population. The only payments to which the corporation were committed were to the various interests on the Severn, 30,500*l.*, and to other petitioners for legal expenses some 1,400*l.* The engineers had confidence that the estimates submitted to the council would be ample to carry out the work. They would be increased to the extent of 25,000*l.*, owing to the additional height of the embankment at the Vyrnwy necessary to meet the increased compensation water to be given to the Severn. No amount had been included in the engineer's estimate for the purchase of

the watershed, but about 8,000 acres had been acquired for 61,000*l.*: and if the remainder of the shed round the lake could be bought it would insure the absolute purity of the water for all time. Manchester had wisely acquired the watershed at Thirlmere, and it was to be hoped the same thing would be done by Liverpool at Vyrnwy.

Llandudno.—The new Llandudno Waterworks, opened by the Prince of Wales a short time since, draw their supply from two lakes, Dulyn and Melynllyn, having an acreage of 32 and 18 acres respectively, in the Snowdonian range, and distant from Llandudno about fifteen miles. The report of Professor Frankland respecting the Dulyn water says, "For the supply of a town it is fully equal to the celebrated Loch Katrine water." The lake being 1,700 ft. above the average level of the town of Llandudno, there is no apprehension as to the flow by gravitation. The second lake (Melynllyn) is secured mainly for supplying the compensation-water stipulated in the Act of 1876. The first four miles of pipes from Dulyn to the service-reservoir are 15 in. in diameter, and, with the exception of valley crossings, are of earthenware pipes. These are laid at easy gradients, and are not under pressure. The valley crossings are provided with wash-out branches and valves. Manholes and ventilators are provided at suitable points for examination and ventilation. The 15-in. conduit-pipes are capable of delivering a sufficient quantity of water to supply the maximum summer population of Llandudno when it is double the present number of 12,000. The pipe-line from the service-reservoir to the town of Llandudno is twelve miles in length, and the pipes are 9 in. in diameter. These are laid in duplicate under the bed of the river Conway, with valve arrangements to use either of the two lines at will. The whole system is provided with sluice, air, and wash-out valves at appropriate places. The scheme authorised by the Act of 1876 included two service-reservoirs, one at Llwyngwaew, four miles from the lakes, and the other at Bryn Gosol, about two miles from Llandudno; but for the present it is considered that the existing service-reservoirs in the town are sufficient, and therefore the cost of constructing the proposed reservoir at Bryn Gosol is saved. The service-reservoir at Llwyngwaew is 535 ft. above the level of the sea. It is constructed of brickwork, backed with concrete. The earthenware conduit terminates, and the pipe-line commences there. There is a by-pass arrangement, so that water can flow direct from Dulyn to the town, while the reservoir is empty for cleaning, repairs, or otherwise. The total cost of the works when completed, including the purchase of lands and easements, is estimated at 40,000*l.* Mr. T. T. Marks, C.E., engineer to the Llandudno Improvement Commissioners, is the author of the scheme.

South Staffordshire.—New works belonging to the South Staffordshire Waterworks Company have been inaugurated. In consequence of applications for the supply of water for domestic and manufacturing purposes, the attention of the directors was in 1873 directed to the water which was being liberated in such abundance by the trial sinking for coal by the Cannock and Huntington Colliery Company at Huntington, and the water was reported upon so favourably by Dr. Hill that in the summer of 1874 the directors decided to make Huntington the site of a new pumping-station. Dr. Hill subsequently reported still more favourably of the Hednesford or Rugeley water, and his analyses were at a later period confirmed by Professor Voelcker; whilst the difficulty experienced by the colliery companies in keeping down the water in their sinkings, and the opinion of Professor Ramsey, justified this company in anticipating an abundant supply. A Bill was therefore obtained in 1875, and arrangements were made for erecting two pumping-stations, one at Huntington, and the other about three miles and a half away, on the side of the main road leading from Hednesford to Rugeley, with a capacious reservoir on the summit of one of the highest hills above Hednesford. The contracts for the engine-houses and buildings were taken by Messrs. Trow, of Wednesbury; that for the engines by Messrs. James Watt & Co., of Soho; and that for the reservoir, which is known as the Scout House Reservoir; and for the laying of the pipes and mains, by Mr. Joseph Walker, of Crewe. These stations were completed about twelve months ago, but owing to the bad weather which prevailed last year the formal inauguration of the extension works was deferred from time to time, and at last postponed until this year. The Huntington pumping-station consists of a Gothic building, of red brick with stone dressings, erected from the designs of Mr. Naden, architect, Birmingham, and it contains two powerful single-action Cornish engines of 165-horse power nominal, working up to perhaps 300-horse power, with a well-pump of 21¾ in. diameter, and a 10 ft. stroke, the quantity of water raised at each lift being something like 340 gallons. Each engine is capable of raising 2½ million gallons in twenty-four hours, or a total of five millions from this station, and a like quantity can be raised from the one at Hednesford. Leaving out of account the older engines at Lichfield, which can raise six or seven million gallons a day, this yield is nearly double the present daily demand upon the company's resources. The water is pumped direct from underground springs in the conglomerate or pebble-bed formation, a subdivision of the new red sandstone rocks, and is carried by mains to Cannock, where, at about the centre of the Market-place, it joins the supply sent down from the Hednesford station, and if there should be a demand for the water, the united streams flow on by mains altogether independent of the old system along the high road through Bloxwich to Walsall and the Black Country, being kept distinct from the Lichfield water until Wednesbury is reached. The surplus water flows back from the point of junction at Cannock to the Scout Hill Reservoir. The Hednesford Station is in arrangement and construction almost a counterpart of the other, the engines being duplicates of those at Huntington; and here, as there, cottages of picturesque design, harmonising with the pumping-houses, have been provided as residences for the engineers and their families, which, paved throughout, covers sixteen acres, and contains when full about 42,000,000 gallons of water. The company has now spent 720,000*l.* on the works, the extensions under notice, with some minor ones elsewhere, having absorbed 313,000*l.* The late Mr. J. R. McClean, M.P., was the engineer.

Littlehampton.—On the 14th ult. the Duke and Duchess of Norfolk visited Littlehampton, and laid the foundation-stone of the new water-tower, in connexion with the extensive new water-works, which are in process of completion. The Local Board, acting under the advice of Mr. R. B. Grantham, their engineer, have bored and excavated till they have obtained a supply estimated to yield 168,000 gallons per day; and, Littlehampton being built on a dead level, a tower was found necessary to distribute the water over the district. The storage capacity of the proposed tower will be 80,000 gallons; and the estimated cost of the entire works is 11,000*l.*

Dundalk.—A public meeting of the ratepayers of Dundalk was held on the 19th ult. for the purpose of obtaining their sanction to the proposed scheme of having waterworks constructed to furnish the town with a supply of pure water, the sanitary authorities having condemned the present supply as inadequate and impure. It was understood that a committee of six, composed of the largest ratepayers in the town, would be asked to assist the Town Commissioners in carrying the matter into execution.

Evesham.—At the quarterly meeting of the Evesham Town Council, a few days ago, the Sanitary Committee reported that the scheme of a supply from the property of Colonel Davies, of Elmley Castle, could not possibly be entertained, the engineer to that gentleman having sent in conditions which rendered it impracticable,—requiring, among other things, that the villages of Elmley Castle, Netherton, &c., should be supplied at cost price, the Corporation laying down pipes, and also that Colonel Davies should have a right of supply for ornamental purposes; and further, if the supply should fail, or other necessity for the abandonment of the work should arise, the whole of the plant should remain upon the estate. These conditions, Councillor New said, rendered it necessary for them to look out for another scheme. The Sanitary Committee were deputed to consider and report upon a scheme for taking a supply from the Avon. The cost of such a scheme was estimated at 16,000*l.*

Telephony.—The authorities at Newcastle have agreed to allow the United Telephone Companies to lay underground wires for telephonic purposes.

LONDON WATER-SUPPLY.

SIR,—Perhaps you will pardon my addressing a letter attempting to introduce a suggestion on so important a matter as that of the London water-supply. Taking it that there will be no dissentients to the holding of the Select Committee that "the supply of water to the Metropolis should be placed under the control of some public body which shall represent the interest and command the confidence of the water consumers," I think this might be attained without the introduction of an entirely new supply from one gigantic source, and without the removal of the existing companies, by a method of subsidising these companies from a new source or new sources of supply. According to this method, the body of control would bring in fresh supplies of water and deliver them to the companies to be distributed by them, and would also introduce water where they could not readily do so. The companies have the means of distributing to a large extent, and could increase their distributing facilities to suit the public demand. Were they supplied abundantly, and a copious filling in where there was a deficiency in any square of the area made, the Metropolis would be well provided with water. How many million gallons above their present run each company would require, what additional mains would be necessary to make the whole circle of supply complete and ample, and how much each company would have to pay for this assistance, would have to be regulated from the statistics and the plans of the city. A word might also have to be spoken by Parliament with regard to the maximum rate at which the commonalty should be supplied with a certain minimum of water, regulated by the size of the bore of the tap through which it flowed. Where a large supply of water is required it must be paid for always accordingly. W. Y. B.

P.S.—In Glasgow, when the Loch Katrine water was introduced, all the machinery for bringing water from the river Clyde was removed. The corporation now find it requisite to restore the machinery for pumping from the Clyde. It is not always advisable to make a clean sweep.

PITCH-PINE: WOOD FOR WINDOW-CILLS.

SIR,—Your correspondent "Pinus" desires further information about pitch-pine than has already been given by "A Civil Engineer." The following is at your service.

When I first used pitch-pine I formed a similar opinion as to its capabilities to that of "Pinus," but after a few years I found, on taking out some sash-frames which were but lately inserted in the building, that the oills were quite decayed, and also that the paint had not adhered to them as it had to the other portions of the frames. I have since had to use it for cills, when specified, but am so dissatisfied with its behaviour that I have not done so of my own accord for many years, considering Memel, or what we call Petersburg red deal, to be much more durable. Some kinds of imported oak (American red, for instance) I have found to be less durable than the red deal, though from the scarcity of English oak imported timber has frequently to be used for cills. An experience of forty years has caused me to form a similar opinion to that of "A Civil Engineer" as to pitch-pine,—its liability to decay quickly when exposed to damp, its tendency to twist in framing, and to shrink in all, or nearly all, situations when used in any but narrow widths. It is also inferior to Memel when exposed to transverse strains, as it snaps short with but little warning when overweighted; whilst Memel deflects considerably before breaking, and its fracture is not so short as pitch-pine.

AN OLD CARPENTER.

SIR,—I have been requested to give my experience of the different woods available and suitable for the cills of window-frames.

I prefer to class them as I consider they stand, viz., oak, chestnut, pitch-pine, Dantzic, and Memel fir. Oak is, doubtless, the most durable, but as it would be too expensive a matter to construct frames entirely of this material generally, and fir being the class of wood well-adapted to the upper portion of frames, and, beside being the cheapest article, is not so subject to warp, some suitable wood should be chosen for the cill. From my experience of the effects of oak on fir, when both are framed together, and the

oak has the slightest chance of imbibing moisture, and of thus imparting its tannin to the fir, I should by no means use it for window-cills; but for door-cills, it is quite another matter, for the wear of the cill will bring about an equal necessity for a new cill, and, partially from decay, new posts. Chestnut, well seasoned, would be decidedly preferable to oak for window-cills, being less likely to warp, less detrimental to fir, and if kept fairly free from wet, a most durable wood. But when we find that with our hard wood (I mean of English growth) fir is somewhat out of place, and fir being the material most used, both for its cheapness, abundance, and ease of working, we should try and find a wood which will by its nature agree with fir, and yet by its inherent strength and quality resist unnecessary wet, and these, it seems to me unite in pitch-pine. This wood seems to me to have been given to us by a wise Providence, not to be wasted, but to be wisely and judiciously used. I have used it for fifteen years, when I could persuade architects to allow me, and can bear witness to its quality; for what is most destructive to many other woods is simply a necessity to this,—I mean dampness, or, rather, wetness,—and that which Baltic fir most needs pitch-pine is most ready to part with, viz., resin, and thus a balance of supply and demand is kept up, and the work is preserved; but I think we ought by no means to despise either Dantzic or Memel fir for window-cills. Both classes of wood contain strong resinous qualities, and this fits them admirably for window-cills, or cills of heavy wood structures; but if I were called upon to decide in this matter, I should choose pitch-pine, both for its cheapness and durability, and also for its natural agreement with the poorer qualities of fir. But I hope that I shall not be understood to be an advocate for pitch-pine for all constructive purposes. Let it be plainly understood that this wood requires a certain amount of feeding either with oil or water; and if neither of these is supplied, and especially if fresh air is withheld from it, it will live upon itself, and, I should think, rapidly decay; and here I may remark that if architects would so arrange the ends of heavy timbers that free ventilation is allowed all round, they would save the annoyance of finding heavy floors subsiding, and main timbers rapidly decaying.

W. B. F.

Sir,—As a result of eight years' experience in the building trade in America, I have found that pitch-pine, when used in external work, will last but few years. Yellow pine, or, as it is called there, white pine, is almost universally used for window-cills and all work exposed to the weather,—of course, being kept well painted. Pitch-pine in the Southern States, where it is cheaper than other varieties, is used for flooring and bearing timber, as joists, rafters, &c.

Saml. Bland.

Sir,—Twenty years ago I bought my first dry pitch-pine plank, and it had gone rotten at the end while standing to dry. Since then I have bought many thousands, but if ever I buy them dry, there are pretty sure to be some rotten on the face, where they have been piled without slips between. I believe any timber-merchant who deals in it will verify this; and the fact that it is nearly always stored *under cover* is another proof of its being unfitted for outdoor work.

One of your correspondents speaks of the large amount of resin, &c., it contains, as being proof of its enduring qualities; but if this is so, how comes it that the best methods of preserving timber proceed on the basis of forcing out the natural juices, and filling the pores with tar, creosote, &c.?

G. M. H.

RAILWAY CATASTROPHES AND WORKMEN'S EDUCATION.

Sir,—In your issue of Aug. 21 (p. 225), under this heading, you again call attention to the necessity there is for extension in the technical or practical education of working men by means of text-books *for each trade*.

I was about to address the engineering papers in connexion with the two recent railway accidents, and to specially mention what I may be allowed to say here.

While in charge of an Eastern Colonial line of railway, I caused to be placed in the hands of every responsible working man, *i.e.*, those in charge of a gang of repairers, a tabulated form, showing position, radius, super-elevation for outer rail, gauge of different curves, inclination of road, &c., with special instructions as to lifting, packing, strengthening, &c., during traffic. I also gave them instructions on the ground on my regular visits to each gang,—visits being by walking, and not by flying past on a trolley, or upon an engine, or in a van. Each bridge was specially cared for much after the same way.

With regard to the drivers, the only information they have about the road is that of the inclination which is painted by the road-side, and seldom noticed after the first few runs.

Engine-drivers as well as repairers ought to have every information possible in their possession regarding the construction of the road, and the latter ought to be visited oftener, and in very different manner from the present, by their immediate superiors. In my opinion more knowledge of the way of keeping the road in repair would have prevented both accidents alluded to.

Jas. Douglass.

SERPENTINE.

Sir,—Referring to the notice of business premises in your paper of the 31st of July last, we shall be glad if you will permit us to state that the information you received on the premises, that the columns and pilasters referred to were of Devonshire marble, is not precisely correct. They were supplied from the Serpentine Quarries at Poltesco, near the Lizard.

Clark & Co.,
Contractors for the Shop Front.

DRAINAGE IN TOTTENHAM AND NEIGHBOURHOOD.

Sir,—I am not a constant reader of the *Builder*, but I was very glad when a friend drew my attention to the correspondence which has appeared in your paper on the above subject. The grievance of the influx of sewage and storm-water in times of heavy rainfall extends as far as Enfield, and I regret to add that my tenants have been greatly inconvenienced thereby. I can fully bear out the testimony of Mr. A. R. Brede (whose letter you published June 26), who states that every storm renders the lower part of the houses uninhabitable, and the water and filth spoil everything. It is really a very heavy loss to the owners of the property thus inundated.

I shall be very glad to be in communication with Messrs. Smith, Webber, and Brede, who have, like myself, had correspondence with the Local Board of Health, and I shall be very glad for any advice and suggestion on the subject. I hope you will be good enough to insert this letter, and that soon we may have the names of other sufferers.

H. B. P.

CHURCH-BUILDING NEWS.

Whittle-le-Woods (near Chorley).—The foundation-stone of St. John's Church was laid by Colonel Crosse, of Shaw Hill, on the 31st of July. The church is in the Early English style, and comprises: nave, 82 ft. long by 32 ft. 6 in. wide, and 45 ft. high; south aisle, 82 ft. long by 13 ft. 6 in. wide, and 30 ft. high; north transept, 19 ft. 9 in. long by 30 ft. 9 in. wide, the roof intercepting with the nave. The chancel will have an octagonal apse, 37 ft. 9 in. by 25 ft. by 32 ft., and will accommodate a choir of forty. The organ-chamber will be 15 ft. by 15 ft, and 30 ft. high, and the vestry under the tower 15 ft. by 15 ft., and 19 ft. 6 in. high. In the area of the church accommodation will be provided for 572 persons. Adjoining the north transept a lofty tower will be erected, to contain a peal of eight bells. The internal dimensions of the tower will be 15 ft. by 15 ft., and 90 ft. high. The belfry and portions of the tower above the ringer's room are not included in the present contract. The nave will be divided from the south aisle by an arcade of five bays, having pillars with enriched carved and moulded caps and bases and moulded arches. All the roofs are open, with curved and moulded principals. The whole of the work has been designed by Messrs. Myres, Veevers, & Myres, architects, Preston, who are carrying out the work. The contractors for the work are the Victoria Timber Company, Chorley, the amount of their contract being 5,428*l*. Mr. John Bowen is acting as clerk of works.

Beverley.—On the 3rd ult., the new church erected in Holmechurch-lane, Beverley, on the site of the old parish church, was consecrated by the Archbishop of York. The building has been erected under the will of the late Lord Wolverton in memory of his son, the Hon. Richard Riversdale Glyn, who was born in 1831, and died in 1859 while returning from India, where he had been engaged with the forces all through the Mutiny, and was buried at Aden. The style is Geometrical, or Early Decorated, and the tower when finished will have a peal of bells. The church comprises a nave 70 ft. long by 23 ft. wide and 47 ft. high to the ridge, a chancel 25 ft. by 23 ft. wide, a porch, organ-chamber, and choir-vestry on the south side. The tower is 19 ft. square, 94 ft. high, and rises at the south-west angle. The building is erected of Bradford stone, with Whitby Crag Moor stone dressings to the window tracery, cills, copings, &c. The interior of the walls is lined with red stock bricks. Messrs. Simpson & Malone, of Hull, and Mr. Elwell, of Beverley, are the contractors. The design of the building is by Messrs. Smith & Brodrick, architects, Hull, who have superintended the erection of the church. Accommodation is provided for a total of 360 persons.

Erlestoke.—A new church has been built at Erlestoke. It is Gothic in style, and has been erected from plans by Mr. Street, R.A. On plan the building consists of a nave, north aisle, chancel, south transept, vestry, tower, and porch. The nave measures 48 ft. by a little over 21 ft. wide, and the chancel is 26 ft. by 17 ft. 6 in.,—making a total length of 74 ft. The height of the tower is 45 ft. to the line of its parapet, and it is surmounted by a sharp-pitched roof. The whole of the roofs generally are covered in with plain red tiles, made by Mr. Box, of Market Lavington, surmounted by crestings, by Cooper, of Maidenhead. The building is built of Box Ground stone throughout,—not only in the dressings but the walling as well,—all the Box stone, after being faced up, is left "batted" from the tool; and in no instance is it "dragged" or rasped up to an affected smooth surface, as is the usual treatment in "soft" stone masonry. The interior walls, like those outside, are all of solid Box Ground stone, tooled over. The roofs throughout,—with the exception of that of the organ-chamber and north aisle, which is flat panelled, divided by longitudinal and transverse moulded ribs,—are open, and of Memel fir. The nave roof is divided into four bays, with moulded and carved and embattled bracketted hammer beams, supporting principals with curved braces and purlins. The principals rest upon stone corbels. The chancel roof is divided into four smaller bays; the principals with their curved ribs abutting on to the wall plates. There is a rise of five steps from the chancel to the altar. The chancel floors are laid with Godwin's encaustic tiles of ornamental design. The steps are of polished Pennant stone, with tiled risers, and the floors of the church generally are laid with Mr. William White, F.S.A.'s, patent Block-wood flooring. This has been put down by Mr. Gregory, of Clapham Junction. The font is of Corsham stone; it is octagonal in plan, richly moulded on all the cants. It stands upon a polished sub-base and step of Pennant stone. The old oak Jacobean pulpit has been utilised again, placed upon a Pennant base. The chancel fittings are of oak, and the body of the church is seated with pitch-pine. It is heated by Messrs. Jones & Son's (of Bankside, London) system of hot-air. The carved work has been executed by Mr. Harry Hems, of Exeter. The builders are Messrs. Hale & Son, of Salisbury, and their managing foreman on the spot was Mr. William Cowley. Mr. Street has been represented by Mr. Thomas Chapelow, his clerk of works. The cost of the church is rather over 6,000*l*., and it is anticipated that it will be opened in September. A new parsonage has been built also from Mr. Street's designs, and by the same contractors.

Marston.—Marston parish church, near Grantham, was re-opened on the 3rd ult. by the Bishop of Lincoln, after restoration. When the rector, the Rev. H. B. Thorold, first undertook to restore the chancel, nearly three years ago, the roof was flat, the east window of the south aisle was partly blocked by a brick-vault, and light was introduced into the nave by a dormer window. The rector's example was followed by, so far as the vertical line is concerned, Sir J. H. Thorold, Bart., who undertook the restoration of the chancel arch and gable over it, together with the Thorold Chapel. The Bishop of Rochester (Dr. Anthony Thorold) contributed the stained glass in the east window, as well as a sum for providing a pulpit and reading-desk and the Dowager Lady Thorold; and other members of the family, by the insertion of painted windows and in other ways, have done their part. The new chancel, built on the foundation of the old, is an example of the fullest development of the Early English style. The stained glass is by Messrs. Ward & Hughes, of London, and the pavement by Messrs. Minton & Hollins. The tower and spire are of Early Decorated work. The south aisle, also of the Decorated period, has been rebuilt and re-roofed, and in connection with it may be remarked the perforated spandrils of the arches on that side of the nave, believed to be unique. The works have been carried out by Messrs. Rudd & Son, of Grantham, from the designs

and under the direction of Messrs. Kirk & Sons, of Sleaford, at a total cost of about 2,000*l.*

Swansea.—On the 5th ult. was laid the foundation-stone of St. John's Church, Cower-road, near Swansea, Mr. John T. D. Llewelyn, of Penllergare, on behalf of himself and father, gave the site for the church (about one acre in extent), and 1,000*l.* towards its construction. The church is to contain 300 sittings. Its estimated cost, with schools, is 2,900*l.* of which sum 1,550*l.* is still required. The architect is Mr. J. B. Fowler, of Brecon, and the contractore are Messrs. Thomas, Watkins & Jenkins, of Swansea.

Culworth.—The parish church of Culworth has been re-opened, after restoration. The church is dedicated to the Blessed Virgin, and consists of a chancel, with vestry attached, nave, and side aisles, and tower containing five bells and a clock. The church was partially restored at considerable expense by the late rector, the Rev. John Spence, and about four years ago it was determined to complete the work then begun, including the restoration of the tower, the reseating of the interior, the building of a new organ-chamber, the removal of the galleries, the opening up of the tower, the insertion of three new windows, the warming and lighting of the church, and the rehanging of the bells. The estimated cost for this was 1,145*l.* A piece of ground, given by the rector, has just been added to the churchyard, and enclosed with a stone wall by the parishioners, at a cost of 105*l.* Sufficient funds having been raised to warrant a commencement of the work, the services of Mr. E. F. Law, architect, Northampton, were retained, and under his directions Mr. Cotterell, builder, of Culworth, proceeded with the work of restoration, which has now been completed. The north aisle has been lengthened, and an organ-chamber constructed at the east end; the galleries beneath the tower have been removed, and the tower opened up; the old high-back pewe have been converted into open seats; new choir-stalls have been placed in the chancel; and the whole of the stonework, which was formerly painted and bedaubed with whitewash, has been scraped and cleaned, and restored to its natural colour. Mr. Cotterell, the builder, has, at his own cost, inserted a small stained-glass window at the west end, representing the Virgin and Child, in memory of his father and mother. The window was painted by Moore & Co., of London. Under the organ-chamber a new heating-apparatus has been put in by Haden & Son, of Trowbridge. The whole of the carving has been executed by Mr. Phillips, of Northampton.

DISSENTING CHURCH-BUILDING NEWS.

St. Austell.—The Congregational Church at St. Anstell has been re-opened, after restoration from plans by Mr. S. Trevail, architect, the contractor being Mr. Thomas J. Smith, of St. Austell. The organ has been re-erected by Mr. George Tucker, of the Octagon Works, Plymouth. The whole of the plumbing work has been carried out by Mr. W. Hawke, of St. Austell. The cost of the entire work amounts to 350*l.*

Newcastle-on-Tyne.—Trinity Presbyterian Church has been re-opened, after alterations and re-decoration. The various works in the church, and in the hall beneath it, and the painting and decorating, have been carried out in a satisfactory manner by Messrs. Copland & Rollo, Northumberland-street, and Mr. James Smart, Stamfordham-place, under the direction and superintendence of Mr. J. J. Lish, architect.

Poole.—On the 18th ult., a new Wesleyan church, built at a cost of 4,000*l.*, was opened at Poole. The architect is Mr. Charles Bell, of London, and the builder was Mr. Clarke, of Parkstone. The building, which will seat 950 persons, is in the Geometric style of Gothic architecture, and is built of Swanage stone, with Bath stone dressings. The main gable faces the High-street. A tower, about 100 ft. in height, is built at the angle of Chapel-lane and High-street, surmounted by a spire. The chapel is divided into a wide nave, with side-aisles, by arcades, supported by polished Shap granite columns, with carved capitals and bases. The pulpit was carved by Mr. Hems, of Exeter. It is of Bath stone, and consists of a projecting half-octagon centre, with side-wings, the stairs being behind. The front is arcaded, with polished Devonshire marble shafts, and enriched with a carved cornice. In the centre panel is a carving of the Transfiguration, and on the two sidee emblems of St. Mark and St. John; whilst in the panels of the returns are an open Bible and emblem of the Trinity, and the head of the Rev. John Wesley, grandfather of the founder of Wesleyanism, who, ejected from the Established Church by the Act of Uniformity in 1662, became a Nonconformist minister in the town. The gas coronæ and the hot-water heating-apparatus have been executed by Messrs. Joyner, of Poole. The end window is the work of Mr. T. Cox, of Southampton-row, and the general glazing by Messrs. Brown & Boreham, of London. The general carving has been executed by Mr. Grasehy, of Dorchester.

Peckham.—A new chapel and schools for the Unitarian body is about to be erected in Avondale-road, Peckham, from designs by Mr. Bruce, architect, Dulwich.

Rushden.—The Succoth Baptist Chapel has been re-opened, after renovated and re-seating. Mr. J. Bayes, of Higham Ferrers, did the mason work and plastering; Mr. S. Knight, jun., Rushden, the carpenter's work; and Mr. J. Margetts, also of Rushden, the painting and decoration.

Statistics of Wesleyan Chapel Building.—At the recent Wesleyan Conference, the Revs. Edwin H. Tindall and Henry J. Pope (Manchester), the general secretaries, presented the report of the Chapel Committee. Under the building department there are two classes of cases, erections and enlargements sanctioned during the year, and erections completed which had been sanctioned in previous years. The following erections and enlargements have been sanctioned:—

101 Chapels, at an estimated cost of	£139,604
15 Ministers' houses	11,989
19 School-rooms	7,194
88 Alterations and enlargements	52,233
97 Modification of cases (additional)	3,720
23 Organs	6,635
341 cases. Outlay.....	£253,655

Of the proposed new chapels, 68, to accommodate 15,253 hearers, are to be erected in places where there were previously no Wesleyan Methodist chapels; and 39, estimated to provide accommodation for 13,978 hearers, are to supersede former erections reported as having provided 7,775 sittings. Three chapels are intended to provide 123 sittinge less than the former buildings. The total accommodation to be provided in the proposed new chapels is, therefore, 21,456 sittings. Under the head erections completed during the year, the following cases have been reported:—

126 Chapels, at a total cost of	£215,415
13 Ministers' houses	11,988
20 School-rooms	17,658
96 Alterations and enlargements	63,256
43 Organs	13,858
297 cases. Total outlay	£318,175

Towards this outlay there has been actually raised by voluntary contributions 215,871*l.*, to which must be added grants, from connexional funds and other sources, of 21,594*l.*, being a total of 237,455*l.* actually raised. The average cost per sitting in the 126 new chapels is 5*l.* 17s. 9½d.

SCHOOL-BOARD SCHOOLS.

Plymouth.—New buildings, erected by the Plymouth School Board, were lately opened. The schools are comprised in a block of buildings measuring about 180 ft. long by 60 ft. deep, and divided into two separate departments for girls and infants. Entering the block by the higher door, the infant department is reached, and to the right there is a suite of four class-rooms, measuring respectively—one 23 ft. by 13 ft., two 18 ft. by 13 ft. 6 in., and another 26 ft. by 13 ft. 6 in.,—fitted up with galleries or desks for the varying ages of the children. To the left of the main passage-way there is cloak-room and lavatory accommodation, the former being arranged with separate doors for ingress and egress, and fitted with wrought-iron hat and cloak hooks, and the latter with Messrs. W. Macfarlane & Co.'s patent lavatory basins, with water laid on from the town mains. To the left is the main infant school, which measures 42 ft. by 22 ft., exclusive of the main gallery recess, 18 ft. 6 in. by 8 ft., and is 20 ft. high to the under-side of the ceiling. The doorway at the end of this room leads to the two teachers' rooms, each 14 ft. by 10 ft. 3 in., fitted with lavatories, cupboards, and other conveniences. This, the infants' portion of the buildings, is of a single story,—the other portions are of two stories. Passing from the teachers' rooms by a short staircase, which forms the line of internal communication from end to end of the entire building, the junior girls' school-room is entered on the ground-floor; it measures 42 ft. by 20 ft., by 15 ft. high. Above this is a senior girls' school-room, of the same dimensions, and 16 ft. high to the under-side of the ceiling. The junior girls' class-rooms measure each 21 ft. by 18 ft., and they are of the same height as the main school-room. Opening out of the main entrance to the girls' school are cloak-rooms, and a doorway leading to the yards. Opposite the main entrance door a staircase communicates with the upper floor, which comprises the senior girls' department, and is similar in area and arrangement to that of the juniors below, excepting that a mezzanine floor occurs over the cloak-rooms, in which there is lavatory and cupboard accommodation. The heating is by open fire-places, and "Tobin's" system has been adopted for ventilation. Internally the walls are dadoed in pitch-pine to the height of the window-sills, and the main timbers of the roof are left open and varnished. Externally the treatment has been that of the Early Domestic Gothic in style. The walls are of blue limestone, with dressings of the same material of a pinkish tint for the sake of contrast. The roofing is of Delabole slate, relieved by fancy cut bands, and is surmounted by a wooden bell-cote rising about 30 ft. above the ridge-line. The playgrounds at the back and end cover an area of about 6,500 superficial feet, and have covered ways and play-sheds. A total school and class-room accommodation is provided for 673 children. The architect is Mr. S. Trevail (whose plans were selected in competition), and the contractors were Messrs. Lethbridge & Foot.

Brightside (Sheffield).—The new schools at Brightside have been opened. They were erected from the designs of Mr. E. R. Robson, F.S.A. The building has not yet an infants' department, though one will be added almost immediately. The building as it now stands, therefore, has only two stories, and it is so planned that one floor can be used for boys and the other for girls, or both floors can be used as a mixed school. The top floor has a duplicated staircase for the sexes. Each floor consists of five rooms, capable of accommodating sixty children in each room, or 600 children in the schools as they now stand. The schools are arranged on the German system of class subdivision so far as is consistent with the system approved of in English elementary schools. The block of buildings in the rear is so contrived that the space is utilised by a mezzanine story, in which cloak-rooms and teachers' rooms are provided. The style of the building may be considered as an adaptation of that prevalent in England during the latter half of the seventeenth century. Messrs. Chambers & Sons are the builders, and Mr. J. Laidler is the clerk of the works. Mr. S. Cole, chairman of the School Board, who presided over the opening ceremony, said the school in which they were assembled was built upon the largest site yet obtained by the Board. It had cost 2,000*l.*, and the total cost of the building and furniture, &c., had been 6,000*l.* additional. For the information of those who had not already seen them he would quote a few statistics about education. It was estimated in 1870 that provision would be required for the education of 300,000 children, but Lord George Hamilton has estimated it at a million and a half. That statement even was found to be below the truth. In 1870 the children in England and Wales upon the school register numbered 2,017,000, whilst in 1879 they numbered 3,710,000, or an increase in nine years of 1,693,000 or 119 per cent. The average attendance in 1870 was 1,152,000; in 1874 it was 1,679,000; and in 1879 it had risen to 2,595,000, being an increase in nine years of 1,443,000, or 125 per cent. In 1870 the accommodation was equal to 1,878,000; in 1874 to 2,872,000; and in 1879 to 4,142,000, being an increase in the nine years of 2,264,000, or 121 per cent. Notwithstanding that very large increase, and notwithstanding the influence of compulsion, there were still outside the schools between 400,000 and 500,000 children who had not yet been brought under the benefit of instruction. The cost of school buildings had been about 20,000,000*l.*, of which school boards had expended about 13,000,000*l.*

Royal Manchester Institution.—The sixtieth annual exhibition of modern works of art opens to the public this Friday, the 3rd.

Miscellanea.

Colour-Blindness.—Dr. Joy Jeffries has lately reported to the School Board of Boston, U.S., on the result of his examination of 27,927 school children for colour-blindness, with the following general results:—Of 14,469 male students, 608 were colour-blind, or 4·202 per cent.; of 13,458 female students, 9 only were colour-blind, or 0·066 per cent." He adds, "These results are so near what is found by the best observers in Europe that we may take it as the expression of a general law. Colour-blindness is not curable by any known methods, and the colour-sense does not alter through life; hence the statistics gathered from the schools apply to the whole community. We may conclude that one male in twenty-five is more or less colour-blind, and that the defect very rarely occurs among females. I would here again respectfully call the attention of the Board to the fact that whilst something is done in the primary schools in reference to teaching the name of colours, the question of colour-blindness on the part of the boys is entirely overlooked. . . . . In my previous report I spoke of the extraordinary lack of knowledge and use of colour-names by boys. My work in testing since then has still further convinced me that this does not show itself in school life, in examinations or exhibitions. Such want does, however, show itself very quickly when the boy comes out into every-day life and occupations. Thus it is that the necessity of teaching colours and colour-names to boys has been overlooked. . . . . The cultivation of the sense of colour is at present almost wholly neglected, as was once the sense of hearing and the voice. Colour-blindness, of conrse, has been as nnrecognised as nnknown. For this no blame can be attached to teachers, or those who direct their efforts. It is only since the colour-sense and its defects have been talked about and tested within the last three years, that here, as elsewhere in the world, it has been discovered that men were quite without the nse and knowledge of colonr-names compared with women, very much as it was wholly unknown, hut equally true, that the latter were so extraordinarily exempt from colour-blindness." The subject of colour-blindness was treated of in the *Builder* many years ago, at a time when the prevalence of the defect was little known.

Encouragement for Workmen.—Messrs. William Denny & Brothers, of the Leven Shipyard, Dumbarton, have issued an intimation to their workmen, in which they state that they have noticed during the last two years many improvements in the methods of the work and appliances introduced by their workmen into their yard. They state that they very readily recognise the advantage accruing to their business from these efforts of skill, and they are desirous that they should not pass unrewarded. They have therefore decided that the authors of such improvements introduced after this date shall have a claim upon the firm for reward; and to enable these claims to be readily and easily adjusted, they have appointed a committee of awards. The rewards are to be given as follows:—To anyone who has either invented or introduced a new machine or hand-tool into the yard; to anyone who applies existing machinery or hand-tools to a new class of work; to anyone who has discovered or introduced any new method of carrying on or arranging work; or, generally to anyone who has made any change by which the work of the yard is rendered either superior in quality or more economical in cost. The awards are not to be less than 2*l.* and not more than 10*l.*; but the firm may give more if satisfied that the invention deserves it.

Dock Extension in the River Thames.—The works for enlarging Messrs. Hy. Fletcher, Son, & Fearnall's upper dock at the Union Dockyard, Limehouse, are now nearly completed, and last week the works for widening, deepening, and lengthening the middle dock were commenced. The walls will be built of brickwork, backed up with concrete, and the flooring of timber and concrete. The entrance will have an iron caisson. When completed, the dock will measure nearly 360 ft. The whole of the works are being carried out nnder the superintendence of Mr. E. C. Homer, C.E.

Child's New Banking House.—The massive strong-room doors here, gates, and shutters were, with one exception, designed and supplied by Messrs. Chubb & Sons, and are fitted with their patent locks.

Proposed Art Museum, Mancheater.—On the 20th ult., a deputation from the Art Museum Committee waited hy appointment on the Parks Committee of the Manchester City Council at the Town-hall, with respect to the scheme for erecting a gallery in Alexandra Park for the reception of certain works of art of the present value of 5,000*l.* Mr. Horsfall gave a general outline of the scheme in question, and stated that a building of the simplest possible construction would, in the first instance, meet the wishes of the Art Museum Committee. Nor were they particular as to its being erected in Alexandra Park; any other of the parks would answer their purpose. He proposed that the Parks Committee should accept the gentlemen at present constituting the Art Museum Committee as tenants for the contemplated building for a period of four years, the City Council to have during that time two representatives on the Museum Committee. It was suggested that at the end of the four years the Corporation should pay the salaries of the curators, and that the management should then be vested in a committee. The Museum Committee agreed that all works of art placed by them in the gallery, except such as were only lent hy their owners, should he the property of the Corporation acting as trnstees for the citizens, and they undertook to place in the gallery immediately after its completion works of art of the before-mentioned value, and to add thereto, prior to the close of their tenancy, other works worth 5,000*l.* They believed that a gallery suited for the object which they had in view might be built at a cost of 6,000*l.* It was intimated to the deputation that a snb-committee would be appointed to meet the Art Museum Committee for the purpose of discussing the details of the project.

The Cambrian Archæological Society held its annual gathering last week at Pembroke, under the presidency of Mr. C. E. G. Phillips. The principal excursion made during the meeting was to Pembroke Castle and Monkton Priory Hall, the latter building being described by Professor Babington. Some of the excursionists visited St. Mary's Church, Pembroke, which was described in a paper hy the Rev. W. Coddington. Professor Babington, in speaking at a meeting in the Town-hall, said that Pembroke Castle originally consisted of two wards, or large inclosures within the walls. The position of the dividing wall was shown hy a ridge, under which, doubtless, were the foundations of the wall. In the inner wall there was a magnificent Norman tower, such a one as he did not believe existed anywhere else in the United Kingdom. This tower was surrounded hy openings in the outer shell, which were intended as sockets for beams to support platforms, from which stones, hot lead, and such missiles might be cast upon a besieging party by those within. With regard to that portion of the castle which was generally called the chapel, he gave his decided opinion that that room was not the chapel, but the hall, where the head persons of the castle took their food, and probably slept upon the floor. The castle appeared to have consisted of three courts, in addition to the keep itself, so giving a very great power of resistance. Monkton Hall was being altered, and not for the better as far as antiquaries were concerned. The Rev. Dr. D. R. Thomas, late general association secretary, referred briefly to the explorations in Caldy Island. He said that antiquaries would view with sorrow the brewing operations which were being carried on in what had been the chancel of the old Priory Church. Mr. Edward Laws, of Tenby, read a paper dealing with the history and probable uses of the numerous camps and earthworks found in various parts of the county of Pembroke. He said there were eighty-three of them in all.

The Great New Gasholder at Kennington.—At the recent meeting of the South Metropolitan Gas Company, with which the Phœnix Company is now amalgamated, the chairman adverted to the immense gasholder just erected at the Kennington station. He atated that its capacity was greater than that of any similar structure yet erected, being the largest known gasholder at the present time. He added that its total cost, with tank and everything complete, would he ahont 47,000*l.*, or something nnder 9*l.* per 1,000 ft. of capacity; the usual price of smaller holders being 18*l.* or 20*l.* for this amount of capacity, showing that its cost is scarcely one-half of the average of those which have hitherto been built.

The Burning of Whitechapel Church.—We briefly mentioned last week that Whitechapel parish church (St. Mary Matfelon) was destroyed by fire on the 26th ult. We gave views of the interior, and of the reredos, in our volume for 1878, pp. 268-269. The church which has been destroyed was entirely new, and was consecrated and opened for service in February, 1877. The building was erected at a total cost of more than 30,000*l.*, out of which a sum of abont 10,000*l.* was raised by public subscription, and the remainder was supplied by the munificence of Mr. O. E. Coope, M.P. Prominent among other objects of interest in the church was the organ, constructed by Messrs. Hill & Son. This, as our interior view of the church shows, was carried upwards from the organ-chamber past the clearstory windows, so as to reach nearly to the roof of the nave. When the fire bad gained a hold on the body of the organ this front formed a ready means of communicating with the roof, and this will account for the astonishingly rapid progress of the devastating fire. On the day of the firo, according to the rector (the Rev. J. F. Kitto), Messrs. Hill's tuner, with two lads as assistants, were at work in the organ. It is admitted that a henzoline lamp was used by the tnner in order to gain access to the organ, and that a candle was lighted hy the lad who blew the bellows. But it is asserted that the lamp was put out at least two hours, and the candle half-an-hour, before the staff left the church at one o'clock for dinner. However this may be, at half-past one the fire was discovered, and upon entry being made the whole of the organ was seen to be in flames. Surely this onght to be a warning, not only to organ-builders, but also to the clergy and to the public. The church was only insured to the amount of 16,800*l.* As we stated last week, Mr. Ernest C. Lee was the architect of the church.

Westerdale Parish Church (near Yarm), has just received a three-light stained-glass east window, the gift of the Rev. J. Rathbone Ellis, the rector, in memory of his late wife and danghter. The subject, occupying all the lights, is the Crucifixion, after the narrative of St. John. At the foot of Jesus on the Cross is the prostrate form of the weeping Magdalene. On either side are respectively the Virgin Mother and the other Mary; St. John and the Centurion, above whom two adoring witness-angels complete the group. The window is from the studio of Powell, Brothers, of Leeds.

City and Guilds of London Institute.—Programmes of the lectures to he delivered at the Cowper-street Schools, Finsbury, are being extensively circulated, from which workmen and others may learn the opportnnities there are for acquiring practical scientific knowledge that will be nsefnl to them in their trades. Advertisements, too, are appearing, and we desire to aid in directing attention to this movement on the part of the City and Guilds of London Institute to impart by laboratory and tutorial courses technical education at merely nominal fees. During the last spring term 192 students attended, taking out 353 tickets for the different courses of technical instruction.

Palæolithic Flint Implements. — Dr. Joseph Stevens writes to say that the brief *résumé* we gave of his paper on the discovery of flint implements in the Reading Drift, read before the Archæological Congress at Devizes, does not represent what he said. He has never found implements or animal remains in green-sand, and he did not use Sir John Lubbock's name in connexion with skulls of any kind, but Professor Rolleston's.

Trade School for Society of Merchant Venturers, Briatol.—The treasurer has informed some inquiring would-be competitors that the guinea to be paid for particulars, according to advertisement, will *not* be returned to those who send in designs, and that the Society will not bind themselves to call in a professional referee, or to employ the author of the successful design. This ought to limit the number of competitors.

Liverpool.—Memorial-stones of new Sunday schools in connexion with the Methodist Free Church, Hamilton-road, were laid on the 6th ult. The site of the proposed schools is at the back of the chapel, and when erected the building will accommodate about 400 children. The cost of the schools is estimated at 2,500*l.* This amount, however, includes the expense incurred in placing galleries inside the chapel. The contractor is Mr. William Litt, of Bootle.

Eighteen feet and a-half in Budge-row, City.—A freehold plot of ground, in Budge-row, Cannon-street, with a frontage to the street of 18 ft. 6 in., and containing about 870 square feet (with an old house on it, shortly coming down), was sold by auction on Saturday, at the Mart, by Messrs. Foster, of Pall-mall, for 6,500*l.*—equal to 7*l.* 10*s.* a square foot, or at the rate of 326,000*l.* per acre.

Berlin Academy of Arts.—The fifty-fourth autumn exhibition of this Academy has been opened. It contains about 1,000 objects of painting and sculpture, the former greatly predominating, and including the handiwork of all the chief living German masters, as well as contributions from several well-known English and American artists.

Wood Paving.—The Kensington Vestry have decided to pave the whole of High-street, Kensington, with wood, and have accepted the tender of Messrs. Nowell & Robson, 10,055*l.*

The Simla Art Exhibition is to be opened on September 18th. Lord Ripon presents a prize for the best original picture by an amateur artist.

TENDERS

For new ironing rooms at Milton House, Brompton, for the London Female Preventive and Reformatory Institution. Mr. W. P. Griffith, architect:—

Fricker	£252 0 0
Swan	210 0 0
Nixon (accepted)	166 0 0

For erecting chimney-shaft and retaining walls, at Angel-alley, Bishopsgate-street Without, for Messrs. Allen & Sons. Mr. Geo. Barnes Williams, architect:—

Parrish (accepted)	£265 0 0

For the erection of four cottages in Cardinal-street, Ipswich, for Captain Morton. Mr. Henry G. Bishop, architect:—

Bennett	£900 0 0
Cunnold	737 0 0
Felgate	675 0 0
Moss	637 0 0
Gibbons (accepted)	600 0 0

For the erection of a pair of semi-detached villas in Hampton-road, Ipswich, for Mr. W. Revens. Mr. Henry G. Bishop, architect:—

Pollard (accepted)	620 0 0

For works to Hertford House, Connaught-place, Hyde Park. Messrs. Davis & Emanuel, architects:—

For General Repairs.		
Phillips & Son	£1,300	0 0
Burdett & Sons	1,288	17 0
Colls & Sons	982	0 0
Ashwell & Stevenson	898	0 0
For Decorative Works.		
Hackforth	693	12 0
Phillips & Son	686	0 0
Burdett & Sons	640	10 0
Mellier & Co.	487	3 0
Ashwell & Stevenson	432	0 0
For Sanitary Works.		
Ashwell & Stevenson	440	0 0
C. & F. Mansfield	442	15 2

For repairs and alterations to Woodlands, Streatham, for Mr. R. H. Measures. Mr. F. Carter, architect:—

Smith	£1,600	11 weeks
Newstead (accepted)	1,470	10 ,,
Markwell	1,316	15 ,,
Cantell (part only)	922	8 ,,

For farm buildings, &c., proposed to be erected at North Forty Farm, Sudbury, Middlesex, for trustees of Mr. Young. Mr. A. R. Stenning, architect. Quantities by Messrs. Linsdell & Giffard:—

	If timbered and boarded.	If brick built.
Farm Buildings.		
Batchelor, Sudbury	£1,820	£1,916
Hussey, Harrow	1,730	1,860
Veare & Co., London	1,675	1,832
Nye, Ealing	1,543	1,678
Adamson & Son, Turnham Green	1,525	1,596
Haynes, Alperton	1,380	1,410
House.		
Veare & Co.	£1,218	0 0
Batchelor	1,107	0 0
Adamson & Sons	1,100	0 0
Nye	1,077	0 0
Hussey	1,068	0 0
Haynes	950	0 0

For the erection of six houses, Coleman-street, Southampton, exclusive of smith's work and ironmongery. Mr. W. H. Mitchell, architect:—

Dyer	£1,206 0 0
Rowland	1,272 0 0
Chapman	1,194 0 0
Crook	1,147 10 0
Stevens & Son (accepted)	1,133 0 0

For alterations and additions to the carpet manufactory of Messrs. B. Woodward & Co., Mill-street, Kidderminster. Mr. J. Mossop, architect. Quantities by the architect:—

Building.	
Thompson	£1,999 10 0
Bimnan & Son	1,684 0 0
Smith	1,515 0 0
Guest	1,310 0 0
Vale, Kidderminster and Birmingham (accepted)	1,300 0 0
Ironwork.	
Bradley (accepted)	207 10 0
J. & S. Roberts (items per ton)	—

For repairs and redecoration to West Ham Parish Church. Mr. J. T. Newman, architect:—

Gentry	£620 0 0
Cheffins	536 0 0
Reed	483 0 0
Morter	460 0 0
Norton & Son (accepted)	444 0 0

For completing six shops and premises at Willesden, for Mr. David Tildesley. Mr. W. Graves, architect. No quantities:—

Kellond (accepted)	£975 0 0

For erecting new premises, Queen's-road, Bayswater, for Mr. W. Whiteley. Mr. J. E. Saunders, architect. Quantities supplied by Messrs. Gsborn & Russell:—

Ashby & Horner	£33,979 0 0
Adamson & Son	31,196 0 0
Sabey & Son	31,150 0 0
Holland & Hannen	30,560 0 0
Lawrence	30,472 0 0
Brass	29,183 0 0

For additions, alterations, and repairs, to Griffin Public House, for Messrs. Reid & Co. Mr. W. Ansell, architect:—

Godden	£2,312 0 0
Shurmur	2,258 0 0
Oxford	2,237 0 0
Richards	2,215 0 0
Patman & Fotheringham	2,150 0 0
Macey	2,088 0 0
Langmead & Way	2,076 0 0
Anley	1,990 0 0
Cocks	1,936 0 0

For the erection of stables and fittings at Honor Oak Park, for Mr. Marshall. Mr. E. Gregg, architect. No quantities supplied:—

Lidstone & Son	£380 0 0
Pritchard	480 0 0
Amer	430 0 0
Watson & Dennett, Dulwich (accepted)	428 17 6

For alterations and additions to No. —, Orchard-street, Oxford-street. Mr. W. D. Church, architect:—

Dove, Bros.	£910 0 0
Shurmur	605 0 0
Godden	571 0 0

For erecting three houses, Astley's-row, River-street, Islington. Mr. W. Smith, architect:—

Mattock, Bros.	£2,172 0 0
Steel, Bros.	2,140 0 0
Harper	1,953 0 0
Shurmur	1,845 0 0

For foundations, &c, Monument-yard. Mr. W. Smith, architect:—

Durnford and Langhsm	£1,688 0 0
Mattock, Bros.	1,443 0 0
Larke	1,370 0 0
Harper	1,287 0 0
Shurmur	1,260 0 0
Steel, Bros.	1,223 0 0
Crabb	960 0 0

For decorative repairs and alterations to No. 12, Cornwall-terrace, Regent's Park, and to stabling in Cornwall Mews, for Mr. Charles Burge. Messrs. Ebbetts & Cobb, architects:—

Sanders (accepted)	£400 0 0

For fourteen private houses in Friern and Goodrich roads, for Mr. W. Cocking. Mr. C. W. Lovett, architect:—

Eldridge & Gee (accepted)	£5,300 0 0

For five private houses in Lordship-lane, East Dulwich, for Mr. C. Smith. Mr. C. W. Lovett, architect:—

Goad	£4,893 0 0
Fisher, Bros.	4,869 0 0
Croaker	4,390 0 0
Eldridge & Gee	3,893 0 0
Hearsum (accepted)	3,890 0 0

For a pair of semi-detached villas in Friern-road, East Dulwich, for Mr. C. Smith. Mr. C. W. Lovett, architect:—

Fisher, Bros.	£1,625 0 0
Watson & Dennett	1,527 0 0
Eldridge & Gee	1,498 0 0
Goad	1,291 0 0
Hearsum (accepted)	1,221 0 0

For rebuilding premises in High-street, Peckham. Mr. C. W. Lovett, architect:—

Thompson & Son	1,532 0 0
Eldridge & Gee	1,375 0 0
Goad	1,372 0 0
Croaker, Brothers (accepted)	1,283 0 0

For building two shops, High-street, Sutton, Surrey, for Mr. F. Monks. Mr. C. W. Lovett, architect:—

Parkin	£950 0 0
Fisher, Bros.	777 0 0
Eldridge & Gee	770 0 0
Humphreys	740 0 0
Hurbert (accepted)	541 12 0

For building stable, loft, and alteration to shop, for Mr. Ilsley. Mr. C. W. Lovett, architect:—

Colls & Sons	£670 0 0
Thompson & Son	578 0 0
Eldridge & Gee	494 0 0
Croaker, Bros.	491 0 0
Goad	477 0 0
Fisher, Bros.	469 0 0

For altering shop for Mr. Lomas, Chouinert-road. Mr. C. W. Lovett, architect:—

Peto	£249 0 0
Goad	195 0 0
Eldridge & Gee (accepted)	187 0 0

For alterations and additions to the Town-hall at Newbury, Berks. Mr. J. H. Money, architect. Quantities by Messrs. Curtis & Sons:—

Crook	£883 0 0
Nightingale	842 0 0
James	749 17 4
Harrison	739 14 0
Elliot	734 2 0
Simonds	672 0 0
Morter (accepted)	654 0 0

For completing four shops and dwellings, being Nos. 403, 405, 407, and 409, Portobello-road, Notting-hill, and four stables in the Mews in the rear thereof, for Mr. E. P. Landon and Mr. G. H. Tatham. Messrs. Ebbetts & Cobb, architects. No quantities supplied:—

King & Walker	£2,890 0 0
Holt	2,648 0 0
Burman	2,260 0 0
Shapley	2,260 0 0
Carmody	2,183 0 0
Sanders	2,092 0 0

For alterations and additions to No. 60, Hickman's Folly, Dockhead, for Mr. J. Watts. Mr. E. Crosse, architect:—

Tyler, Jamaica-road (accepted)	£405 0 0

For building ten houses for Messrs. Bliss & Sons. Mr. Charles Dunch, architect:—

Taylor & Parfitt	£2,889 0 0
Shurmur	2,880 0 0
Johnson	2,694 0 0
Wood	2,542 0 0
Wire	2,500 0 0
Higgs	2,345 0 0

For alterations to the Rose and Crown Tavern, Cullum-street, for Mr. H. Watson. Mr. W. J. Miller, architect:—

Higgs	£373 0 0
Adams (accepted)	347 0 0

For a new Infirmary, for the Guardians of the Barnsley Union. Messrs. Dixon & Moxon, architects:—

	Local Stone.	Brighouse Stone.
Powell & Sons, Sheffield	£22,224	£23,374
Howell & Son, Bristol	—	22,900
Whiteley, Leeds	20,700	21,000
Nicholson & Son, Leeds	19,413	20,197
Raynor, Barnsley	—	18,929
Longden & Son, Sheffield	18,497	18,811
Robinson & Son, Barnsley	18,000	18 750
Chadwick & Co., Rotherham	17,879	18,629
Brier, Sons, & Wilson, Dewsbury	17,023	17,393
Fidler, Eckington	16,950	17,380
Taylor & Sons, Barnsley	16,450	17,350
Armitage & Hodgon, Leeds	17,130	17,330
Humphreys & Moulson, Bradford	16,653	17,103
Bustard, Barnsley	—	16,885
Hinchliffe & Moore,* Barnsley	15,187	15,687

* Accepted, Brighouse Stone.

For rebuilding the county bridge over the Ravensbourne, at Deptford. Mr. F. W. Ruck, county surveyor. Quantities by Messrs. Ruck, Son, & Smith:—

	Con. No. 1. Ironfounder's Work.	Con. No. 2. Builder's Work.
Finch & Co., Chepstow	£3,020 0 0	—
Hanea, Donald, & Wilson, Paisley	2,760 0 0	—
Stockton Forge Company, Stockton	2,374 3 6	—
Webster, London	2,155 0 0	£4,331
Butler, Stanniogley	2,039 7 0	—
Butterley Iron Company	2,022 17 0	—
Dixon, London	2,000 0 0	2,000
Weeks & Son, Maidstone	1,963 19 8	—
Cochrane & Co., near Dudley	1,941 0 0	—
Maxwell, London	1,921 0 0	2,390
Cooke & Co., London	1,892 0 0	2,175
Tees Side Ironworks, Middlesboro'	1,736 3 7	—
Wilson, Brothers, & Co., London	1,685 0 0	—
Ball & Gammon,* Gillingham	1,663 0 0	2,080
Shaw & Co., London	1,549 15 0	2,220
Jukes, Coulson, Stokes, & Co., London	1,406 0 0	—

* Accepted.

For constructing road and retaining walls at Rochester, for the Trustees of St. Bartholomew's Hospital. The late Mr. G. Ruck, surveyor. Quantities by Messrs. Ruck, Son, & Smith:—

Calluud & Son, Rochester (accepted)	£990 0 0

For the erection of two shops and dwelling houses in Week-street, Maidstone, for Messrs. Gegan. Messrs. Ruck, Son, & Smith, architects. Quantities supplied:—

Bishop, Birling	£1,770 0 0
Naylar, Rochester	1,747 0 0
Cox, Brothers, Maidstone	1,730 0 0
Bridge, sen., Maidstone	1,720 0 0
Avard, Maidstone	1,695 0 0
Elmore, Maidstone	1,676 0 0
Vaughan, Brothers, Maidstone	1,637 0 0
Wallis & Clements,* Maidstone	1,594 0 0

* Accepted.

For the erection of a shop and dwelling-house, West Borough, Maidstone, for Messrs. Hammerton. Messrs. Ruck, Son, & Smith, architects. Quantities by Mr. T. Ladds:—

Cox, Brothers, Maidstone	£1,409 0 0
Avard, Maidstone	1,390 0 0
Naylar, Rochester	1,359 0 0
Vaughan, Bros., Maidstone	1,342 0 0
Wallis & Clements,* Maidstone	1,332 0 0

* Accepted

For the construction of a brick and concrete reservoir, filtering-chamber, &c., and the providing and laying of 9,500 yards run of cast-iron pipes, at Budleigh, Salterton, Devon. Mr. C. W. Whitaker, engineer. Quantities supplied:—

Willey	£5,867 0 0
Kerslake	5,550 0 0
Facey	5,509 0 0
Painter	5,193 0 0
Gould	4,916 0 0
Stephens & Bastow	4,795 0 0
Bell	4,795 0 0
Hawkins & Best	4,582 0 0
Shaddock	4,567 0 0
Coldridge	4,477 0 0
Phillips	4,394 0 0
Crockam	4,110 0 0
Small	4,000 0 0
Gibson (accepted)	3,620 0 0

For road making at Upper Holloway. Mr. Charles Higgins, surveyor:—

Girdlestone-road.

Waddingham, Upper Holloway	£422	0	0
Rutty, Bromley-by-Bow	394	0	0
Taylor, Upper Holloway	389	0	0
Williamson, Islington	373	10	0
Pizzey, Hornsey	350	12	0
Wilson, Chiswick	330	0	0
Irons, Dalston	324	12	0
Walker, Upper Holloway (accepted)	320	0	0

Langdon-Road.

Waddingham	414	0	0

Southern	5,272 19 0	5,133 3 0
Wilson, Bros.	5,213 15 6	5,013 15 6
Musgrave	5,990 0 0	4,790 0 0
Jackson & Son*	6,050 0 0	4,750 0 0

* Accepted. All of Hull.

For sundry works at the Spread Eagle, Stangate-street, Lambeth. Mr. W. C. Banks, architect:—

For New Girder and Alterations.

Tarrant & Son	£259	0	0
Sharp & Everard	198	0	0
Elliot (accepted)	185	0	0

For Bar Fittings.

Warne	243	0	0
Watts & Co.	241	7	0
Elliott (accepted)	237	10	0

For repairs and additions to house and new shop on the Forecourt, 124, Southwark Park-road, for Mr. John Morgan. Mr. E. Crosse, architect:—

Almond, Jamaica-road	£575	0	0
Eldridge & Gee, Fendall-street	468	0	0
White, Peckham-rye (accepted)	432	0	0

For repairs and redecoration to St. John's Church, Broadway, Stratford. Mr. J. T. Newman, architect:—

Repairs and Redecoration.

North, Bros.	£550	0	0
Hoskings	529	0	0
Morter	461	0	0
Norton & Son (accepted)	452	0	0

Gas Engineering.

Carter	85	0	0
Land & Co.	80	0	0
Wentworth	73	0	0

For alterations and repairs to 15 and 17, Old Montague-street, Whitechapel, for Mr. G. Burnell. Mr. J. T. Newman, architect:—

Knightly (accepted)	£589	0	0

For the completion of Arundel-road, Harold Wood Estate, Essex, for Mr. J. Compton. Mr. J. T. Newman, architect:—

Jackson	£348	0	0
Harris	351	0	0
Pound (accepted)	306	0	0

For stable, coach-house, &c. at Wanstead, for Mr. H. Compton. Mr. J. T. Newman, architect:—

Clevares	£220	0	0
Reed	180	0	0

NOTE.—The responsibility of signed articles, and papers read at public meetings, rests, of course with the authors.

NOTICE TO SUBSCRIBERS.

THE INDEX and TITLE PAGE for Volume xxxviii. (January to June, 1880) was given as a Supplement with our Number for July 10.

A COLOURED TITLE-PAGE may be had, gratis, on personal application at the Office.

CLOTH CASES for binding the Numbers are now ready, price 2s. 6d. each; also

READING-CASES (Cloth), with Strings, to hold a Month's Numbers, price 2s. each.

THE THIRTY-EIGHTH VOLUME of "The Builder" (bound) is now ready, price Twelve Shillings and Sixpence.

SUBSCRIBERS' VOLUMES, on being sent to the Office, will be bound at a cost of 3s. 6d. each.

The Builder.

VOL. XXXIX. No. 1962. SATURDAY, SEPTEMBER 11, 1880.

CONTENTS.

The Kandahar Railway.

IF man has been justly defined by one of the greatest of English writers as the "minister and interpreter of nature," it is none the less true that he is on his way to become the conqueror of difficulties, and the master of nature, both organic and inorganic. Thus every tale of daring and perseverance, of struggle with the elements, of victory over time and distance, has not only the charm of a romance, but the value of a fresh title-deed of the dominion of man. Another story of successful conflict,—this time with the heat of climate, and the barren inhospitality of the desert, has been that of the completion of the first section of the Kandahar railway, extending from the river Indus for 133½ miles towards the mouth of the Bolan Pass, in four months from the time of the receipt of telegraphic order from the supreme Government of India to commence the undertaking.

In the autumn of 1876, as Colonel Sir Andrew Clarke, R.E., has recently told the Institution of Civil Engineers, that officer suggested to the Government of India the importance of taking measures for keeping open, at all times and seasons, at least one available route from British India into Afghanistan. It was not, however, until September, 1879, that authority was given for the execution of a railway from Ruk, on the Sind, Punjaub, and Delhi Railway, to Quetta, in Beloochistan.

The original project of the Indian Government was for one party to make this line as far as Dadur, at the foot of the Bolan Pass, under the direction of the Engineer-in-Chief of the Indus Valley Railway, while a second party should at the same time survey the pass, with a view to the laying of a temporary narrow-gauge railway, or tramway, on the military road from Dadur to Quetta. It was found advisable for this second party to set out the line across the desert from Jacobabad to Dadur, so as to relieve the railway staff from all anxiety except as to the actual construction. It was finally arranged that the survey party, under Colonel James G. Lindsay, R.E., should not only set out the line, but should erect huts for the expected platelayers, and do all the work that was possible in advance of the platelaying party.

Thus two distinct parties were simultaneously at work, each of which attacked the problem of housing, feeding, and watering the workers in the desert from a separate point of view. The platelayers, relying on Sukkur, Shikarpur, and Jacobabad as bases, supplied everything by railway, carrying on their materials over the line as they laid it. The surveyors proposed to rely on the natural resources of the country traversed, and to hring in supplies, partly from Jacobabad, but mainly from the scattered villages and wells along the course of the Narf; and Lehri rivers, by carts, camels, and manual labour. The resources of the country, however, proved inadequate to the demand thus made upon them, and the platelaying staff was left to carry out the greater portion of the work.

Great assistance, however, was rendered to the undertaking by the construction, by the survey party, of a reservoir of the capacity of two millions of gallons, at the forty-fourth mile, being the point farthest from the Indus at which the existing channels from the Begarri and its effluent canals could deliver water. This reservoir was filled soon after the rails were laid up to it, and was frequently refilled.

The first project for housing the labourers consisted of a train of twenty covered goods wagons, to each side of which a stout sail-cloth awning 30 ft. wide was attached, which, when stretched and lashed to rails laid temporarily on either side, formed a continuous tent 400 ft. long and 70 ft. wide, the wagons serving as the ridge. The men do not seem to have taken kindly to this common shelter, and temporary huts of reed mats were constructed, and rebuilt at every three miles of the advance of the head of the work. About 100 men were constantly employed in the erection of these flying cities, and a wagon-load of fresh mats and hamboos accompanied every train. The mats were about 4 ft. 6 in. square. A single row of mats on edge formed the back wall of the shed, and another row laid flat formed the roof. The sheds were built with their backs to the north, and gave enough shelter to allow the men to sleep under them when provided with blankets. The nights are cold enough to produce ice, while the days are as hot as in an English summer. But as, contrary to expectation, no rain fell during the progress of the works, the mat-huts turned out to be a success.

The wagons before mentioned formed a travelling shop, store, hospital, and treasury. They stood at the head of the line, and were pushed forward on the arrival of each train. They also contained a reserve supply of water, for any case of emergency, under lock and key. This was chiefly kept in 400-gallon ships' tanks.

Two trains a day appear to have been run, each carrying materials for from 1 to 1½ mile of way. The afternoon train brought out 100 tons of water; the morning train brought out the miscellaneous stores, such as 3½ tons of daily food, 5 tons of daily fuel, 5 or 6 tons of building materials for sheds, and occasionally 20 tons of forage for the cattle. The officers lived in tents, and moved camp every six miles.

In the first 45 miles no difficulties were experienced in hutting the men, or in supplying food and water. But the labour of cutting the jungle, and preparing the seat of the line over the rough ground, was considerable. For the remaining 88½ miles, the line crossed the desert, and, with few exceptions, no physical difficulties were encountered. The arrangements for supply answered perfectly. The water train never once failed. The health of the men was perfect, and the weather delightful. The first 38 miles of the line were constructed in 32 days. Then a general strike of the labourers took place; but on the 12th of November most of the men returned to their work, the ringleaders having been carefully removed, and the arrangements made for crossing the desert having been fully explained to the remainder of the men. By the 5th of December they seem to have got into the full spirit of the undertaking. During that month, 49¾ miles were laid, though two days were lost. On the 1st of January (of the present year), 2½ miles were laid for the first time,—a length that was repeated on six different days; while in one day 2¾ miles were laid. The total time occupied in the work was 101 days; of which 17 were lost, leaving 84 days for the completion of 133½ miles of railway, and, including sidings and stations, of 165 miles of single track. The actual cost of this labour amounted to 515*l.* per mile, which was thus made up:—

	Per Mile.
(1.) General charges, for collecting labour, hutting and clothing men, water and fuel	£91
(2.) Store charges for unloading, sorting, straightening and reloading materials	60
(3.) Carriage of materials and stores, and maintenance of way and rolling stock	112
(4.) Carriage of material by carts	73
(5.) Platelaying	171

The work was commenced at Ruk with 600 men, and the number was increased as fresh hands could be obtained. A mixed system of day-labour and piece-work was adopted, every man receiving a fixed daily allowance, and a fixed addition to the same for every half mile of way laid in the day over the first mile. The system was highly popular with the men, and tended greatly to ensure the rapid progress of the work.

On the arrival of each train, the materials for the way were taken from the wagons, and loaded into carts, from which they were laid out along the line ready for the platelayers to use. The laying gangs picked up the material and laid it in line. They were followed by keymen, gangers, horers, spikers, straighteners, and lifters. A third party packed and finally straightened the line. When the work was in full swing five thousand men were engaged, of whom 1,600 were platelayers.

The main difference between this series of operations and those which were carried out through the *Grandes Landes*, in 1855, by Mr. Conder, C.E., for the *Chemin de Fer du Midi* (see Proceedings of the Institution of Civil Engineers, vol. xvi.), seems to consist in the use of carts for the forwarding of the materials from the front of the completed line over the way a-head. Six hundred carts were employed, and this part of the work appears

to have cost altogether, as we have shown, nearly 138*l.* per mile. It is probable that extra speed was thus gained, but at the risk of depending on hired cattle, and to some extent on the Sindee carters. On the *Landes* the rails were sent to the head of the work, and laid at once, wagon-load by wagon-load, provisionally, as a road over which each succeeding wagon-load of materials was carried. Economy and regularity were thus secured. The rate of progress in the *Landes* only attained a mean speed of 2·06 kilomètres, or 1·26 miles per diem (which was all that was required), while that on the Kandahar line was nearly 1·6 mile per day. But the 5,000 Indian workmen were about ten times as many as the Englishmen and Frenchmen employed on the *Landes*, and some dozen horses only were at work there, instead of the 2,000 beasts which were required in India. Occasions may occur when everything must be sacrificed to speed. But when a progress of a mile or a mile and a quarter a day is enough to meet the requirements of the case, it is worth the serious attention of the engineer to endeavour to dispense with cartage, especially with hired cartage, and to make the rails themselves answer as a temporary, as well as a permanent, road for the feeding of the platelayers with materials.

The details, for which we cannot find space, will be accessible to those of our readers whom they may interest in the forthcoming quarterly volume of the Proceedings of the Institution of Civil Engineers, in the form of communications from Colonel Sir Andrew Clarke, R.E., Mr. James Richard Bell, C.E., and Mr. George Moyle, C.E.

BRIDGES AND ROOFS.

With the introduction of the railway system it became necessary to cover much larger spaces than had before been required, at the same time that the constant demand made on metallurgic industry was transposing the manufacture of iron. The earliest railway roof in the south of England, that of the station of the London and Birmingham Railway at Euston, was one of unpretending simplicity. That built by Mr. Brunel, at Paddington, remains one of the most architecturally-proportioned and graceful of our large roofs. But the desire for large unbroken spans led to further innovations, of which the science is more unquestionable than the taste. An unbroken span of 166 ft. has been provided at Charing-cross Station; one of 190 ft. at Cannon-street; and one of the enormous width of 240 ft. at St. Pancras. The height of the centre line of the soffit of this last roof, above the level of the rails, is 96 ft. We may add that the cost per square (of 100 ft.) of the three last-named roofs, exclusive of gables, was respectively 34*l.*, 43*l.* 10s., and 31*l.* 11s. There is, then, no reason to suppose that we have reached the structural limit of roof spans, nor, as the above prices indicate, the financial or economical limit. On the other hand, it may be held that the limit of architectural beauty has been wholly disregarded,—and that a very serious question may some day arise as to the prudence of erecting roofs of this magnitude, if they are not in some extraordinary way secured against the fury of an unusual, but not unprecedented, storm. If a violent wind once got under one of these roofs we should not like to answer for the consequences.

A general view of the whole subject of the arch, vault, or roof, laying down the first principles of structure; showing how these principles apply to the various materials, as affording resistance to crushing weight or to tensile strain, and citing the most famous and instructive examples of the mode in which the different cases of the problem have been solved by the great builders of the past, or of the present day, has yet to be written. It would be a work of singular value if ably executed. Our present task is less ambitious. While not closing our eyes to the certain results which science has already attained, we rather wish to take a practical view of some of the most successful examples of dealing with the problem of covering large spaces, which are,—or ought to be,—familiar to the English student. And though such a study cannot fail to result in the indication of rough general rules, we do not propose, at all events at present, to offer to our readers anything of the exhaustive and precise character of a treatise on the arch or the truss. Naturally we have to inquire into the best examples of the single arch,—as bridge, or vault, or arcade,—before we discuss the dome or roof.

Architects and engineers meet on common ground when it is a question of the design of a noble bridge. Architecturally considered, it is the elevation of the structure which first attracts the attention. When the case is one of the erection of a national monument, or the adornment of a capital, it is not easy to insist too strongly on those graceful proportions, well-defined shadows, and appropriate treatment of fit structural material, which must ever be the features that first catch, and last charm, the eye.

But when it is a question of sinking the bases of the monumental structures beneath rapid currents or stormy tides, of dealing with the treacherous basis of mud or of quicksand, of providing against the erosion of the bed of the river beneath the footings of the piers, the duty is usually handed over to the engineer. We do not wish now to raise any question as to which branch of the great structural profession is most deeply concerned in the matter. But we ask a moment's attention while we pursue the inquiry which must have suggested itself to many of our readers. How far are we in possession of materials for drawing up an approximate rule as to the determination of the best span to be used in any given case, such, for instance, as that of carrying a road or railway over a wide river valley?

A bridge is essentially a contrivance for utilising the same topographical area at two different levels, or in two different stages. Whether it be to convey traffic over water, water over traffic, water over water, or traffic over traffic, and whether we call the contrivance a bridge, an aqueduct, a tunnel, or a viaduct, the principle is the same. The most familiar and most simple example of the principle of the bridge is that afforded by the permanent way of a railway. Each line of rail is, in point of fact, a continuous bridge; of which the piers are represented by the chairs, and the arches by the rails; the object of the structure being the support of the rolling-wheels of the vehicles at a determined level.

The illustration is obvious; but it is introduced for the reason that it will enable us at once to grasp the law which regulates the strength of piers. Leaving aside for the moment the functions of the abutment, whether as a retaining wall (with which it is often combined), or as a point of resistance to the lateral thrust of an arch, the piers of a bridge have to do the duty which would have come upon the ground covered by the structure, supposing a weight to have been brought upon it equal to that which the bridge supports. Thus, if there be an arch or a girder of 100 ft. long, supported on two piers, the weight that will come on these piers will be that which would have come upon the 100 ft. of road way, plus the weight of the arch or platform itself, and the first element of proportion in calculation comes in here. If we were to omit all practical considerations, such as the fact that it may be cheaper to build one pier of 10 ft. square than two piers of 10 ft. by 5 ft., and to suppose that weight and resistance are exactly balanced, so that there is no structural waste, it would be a matter of indifference as to cost how many piers were used within a given distance. The weight of the 100 ft. of roadway demands a certain area of support, whatever that be, divided between two or more points of support.

But we have to remember that, as far as regards the weight of the structure itself, that will be, for a certain portion of it, proportionate, not to the length covered, but to the square of the spans into which it is divided. In cases of very wide spans, we shall afterwards have occasion to test the application of this rule; but we now rather look for practical examples of the difference of cost incurred by doubling the span.

The simplest method of estimating the cubic quantity of masonry that would be necessary for crossing a given valley would be to suppose the erection of a brick or stone wall across the whole interval to be spanned, under each line of rail. Since as much as 18 tons pressure is known to come on a pair of driving-wheels in some of the locomotives now in use, and since the width of a railway sleeper may be as low as 9 in., a wall of 1 ft. 6 in. thick would be subject to a moving pressure of almost exactly eight tons on the square foot. If we take 2 ft. as the thickness of the wall, we obtain a pressure of 6 tons on the square foot. The rule proposed by the Board of Trade for the breaking weight of a cast-iron bridge is not less than three times the permanent load due to the weight of the superstructure, added to six times the greatest moving load that can be brought upon it. Ordinary brickwork is tabulated to crush at 232 tons per square inch, or 33·4 tons per square foot; so that a weight of eight tons per square foot allows a fair margin, according to the usual rules for the strength of materials.

To this allowance has to be added that of the weight of the wall itself, which may be taken as about one hundredweight per cubic foot. If we allow 6 tons per square foot as the normal pressure, this pressure would be doubled at the base of a wall of 120 ft. high, so that one-sixtieth part should be added to the strength of the wall for each foot in height, in order to maintain an equal pressure. If a higher resisting power be allowed for, the proportion of addition for height will be calculated in the same manner.

On these bases, the mean width of the supposed walls for crossing a valley of 120 ft. in depth would be, for a double track of rails, $8+\frac{8}{2}=12$ ft., and the cubic contents per foot run would be 1,440 cubic feet, or 72 tons.

In the case, however, of a bridge where the resistance is not continuous, but concentrated on piers, the weight to be dealt with is not the maximum which can come in a moment on a certain point, as on a chair or a sleeper, but the aggregate of that which can come on the platform supported between two piers of the bridge. The heaviest weight that can thus come is that of the locomotive; and if we allow for this at 60 tons per 30 ft. run, or 2 tons per foot of bridge, we shall be within the mark, for a single line of track; taking, of course, the double for a double track. This gives so small a pressure compared to the other, that we should have to regard the resistance of materials to buckling or twisting, rather than that to crushing power, were it all for which we had to provide; and the pressure of a pier of 120 ft. high on its own base would be more than that of the load the bridge had to sustain. Without any allowance for the weight of the platform, the wall requisite to support the distributed load of four tons per foot run would be one-ninth of the former allowance, or six tons per foot run.

We have, however, to take into account the weight of the platform, or arch, itself. We may take as an example the Lockwood Viaduct, built by Mr. Hawkshaw on the Huddersfield and Sheffield Railway, which consists of thirty-two arches of 30 ft. span, with an extreme height of 122 ft. to the rails. The arches are of brick, and are shown on the section as 1 ft. 6 in. thick, or one-twentieth of the span. The width of the arch is 28 ft. The weight of the arch, spandrils, and backing is 312 tons, exclusive of parapets, or rather less than ten tons per foot linear of bridge, from centre to centre of pier. The load, as before estimated, is 138 tons, making a total pressure of 450 tons for the spans, of 34·5 ft. The resulting weight to be borne by the piers is thus equal to about 13 tons per foot run of centre line. This weight, compared with that before given of 6 tons per foot run, shows an addition of 7 tons per foot run for the weight of the arch, taking a 30 ft. span.

The piers on this viaduct measure, on plan, 4 ft. 6 in. by 28 ft. at springing, or 126 square feet, sustaining a pressure of 3·57 tons per square foot. At 116 ft. lower, the area is enlarged to 7 ft. 6 in. by 28 ft., or 216 square feet. The resulting pressure on the base of the piers, comprising the weight of the arch, that of the pier itself, and that of the maximum load, is 6·7 tons per square foot, showing that the engineer accurately calculated the taper to be given to his piers.

Proceeding to inquire, in the first instance, as a matter of practice, into the increase of the thickness of arch that accompanies the increase of span, we take the example of the Royal Border Bridge, over the river Tweed, which was completed in March, 1850. This fine viaduct consists of twenty-eight semicircular arches, each of 61 ft. 6 in. span. The total length is 2,160 ft., and the extreme height 129 ft. The bridge is divided into two portions by a central abutment. The width between the parapets is 24 ft. The piers are 8 ft. 6 in. wide under the springing, increasing almost immediately to 10 ft. The area above the footings of the highest pier is 11 ft. 6 in. by 26 ft. 3 in. The arch, where it rises free of the hacking, is 2 ft., and 7½ in. thick. Thus measured, to-

gether with the backing and spandrels, contains about 754 tons of masonry. To these has to be added 280 tons for the moving load, making a total pressure of 1,034 tons per pier, or about 5 tons per square foot of area. On the base, exclusive of the relief afforded by the projection of the footings, the pressure is about 7.2 tons per square foot; the total cubic contents of the arch, backing, and pier, being about 31 tons of masonry per foot run of the centre line of the viaduct, almost evenly divided between arch and pier.

We thus find, not as a matter of theory, but as a deduction from practice, taking two very admirable examples of the work of the bridge-builder, that the quantity of masonry per foot run for the 60 ft. arched viaduct is, as compared to that for the 30 ft. arched viaduct, as 31 to 13; or, abstracting the weight required for supporting the moving load alone, before taken at 6 tons per foot, we have a platform or arch weight of 7 tons per foot run, for a 30 ft. span, compared with one of 25 tons per foot run for a 60 ft. span, which is not very far from 4 to 1, the relation of the squares of the spans. And it will be remembered that in each of the arches cited the thickness of the ring is in a like proportion to the span, being almost exactly one-twentieth part of the same. The observance of this proportion might have led to the anticipation that a greater economy would be effected by the use of larger arches. It is thus the more instructive to take out all the quantities of a span of masonry, including piers, as well as arch and hacking, as by this means we arrive at the certitude that, in the additional cost attending other things being alike, on the wider arch practice accords fairly with theory.

This thickness given to the arch, in proportion to the span, is much greater in the brick arches of which we have been speaking, than is the case in some of the most celebrated stone-bridges of recent times. Of these we cite the cases of five famous bridges,—two English, two Welsh, and one Italian.

Name of Bridge.	River.	Span.	Key.	Proportion.
Pont y Cysyllte	Taaf	140	2·5	1 to 56
Waterloo	Thames ...	120	4·5	1 to 26·6
New London...	Thames ...	152	4·75	1 to 32
Chester	Dee	200	4·0	1 to 50
Turin	Dora Grossa	147	4·92	1 to 30

Of these five bridges, those over the Taaf and the Dee are of limestone, and the other three are of granite. The boldness of the two former structures is as noteworthy as the architectural beauty of the others. The first-named bridge, the work, as we have before mentioned, of William Edwards, a self-trained country mason, approaches wonderfully close to the limits of scientific precision. The thickness of the key-stone is only one fifty-sixth part of the span. The voussoirs are ashlar, but the rest of the arch is only coursed rubble. The pressure at the crown, according to an analysis to be found in vol. v. of the "Proceedings of the Institution of Civil Engineers" (p. 472) is equal to the weight of 938 cubic feet of masonry per square foot, and that at the second point of rupture (or rather where rupture would, if anywhere, occur) is 936 cubic feet per square foot. Allowing 1¼ cwt. per cube foot for the weight of the limestone masonry, we have thus a weight of 70 tons per square foot of section. This is less than half the crushing limit of magnesian limestone, which, according to Fairbairn, is 1·36 tons per square inch. But it is pretty certain that the bridge would not have stood if built in brick. In that case the weight would have been 46·6 tons per square foot (supposing the dimensions to be the same), but the resistance, according to Mr. Clark, is only ·232 tons per square inch, or 33·1 tons per foot. The rise of the arch is 35 ft., and the radius of the arc which it forms is 87 ft. 6 in. Neither the cost of the bridge nor the cubic contents of the masonry is stated in either of the three accounts of the structure to which we have referred. It is hard to form an opinion how far Edwards was guided by the instinct of genius and how far by geometry and knowledge of the strength of material, but it is highly instructive to observe the light and graceful form of an arch constructed of rough limestone masonry, of dimensions which would have caused a collapse as soon as the centre was struck had they been executed in brickwork.

We may take the 200 ft. span of the Dee Bridge as the practical limit to the width of the stone arch. As to brick, if firebricks set in cement be employed, the material may be equal in its resistance to stone. But as far as ordinary brick set in mortar is concerned, we apprehend that 120 ft. may be taken as the practical limit of span. This has been reached in India, in an arch of 4 ft. wide. But the mortar there is exceptionally good. Indian builders adopt the Italian method of wetting the lime for their mortar at the very commencement of the work, and keeping it constantly wet. Some lime which had been thus prepared by Tippoo Sahib was long after used by the English engineers at Seringapatam, with fully satisfactory results.

With regard to cost, that mode of comparing the excellence of one method of structure with another depends on so many conditions that the simple statement of cost per foot run is not in itself fully instructive. In the case of the bridges that we have cited, the cost was as under:—

Work.	Feet run.	Cost.	Per foot run.
		£.	£.
Lockwood Viaduct ...	1,428	33,000	23·1
Royal Border Bridge	2,160	120,000	55·5
Dee Bridge	426	40,900	126
Dora Grossa Bridge...	320	56,000	180
London Bridge.....	782	1,028,000	1,383
Waterloo Bridge	1,280	1,050,000	821
Thames Tunnel	1,200	454,810	379

With regard to the above prices, the first two apply to viaduct alone, without approaches. In the other case the cost of approaches is included. In the Dee Bridge the approaches cost 7,500*l.* In the Dora Bridge the cost is not distinguished. In Waterloo Bridge the land cost 373,000*l.*, and the approaches cost 112,000*l.* As to London Bridge, full particulars of the work and designs are to be found in the autobiography of Sir John Rennie, but he is remarkably reticent on the subject of cost.

THE LATE MR. J. H. HAKEWILL, ARCHITECT.

WE mentioned briefly in our last the death of Mr. John Henry Hakewill, at his residence in Inverness-terrace, in the seventieth year of his age, surviving his most intimate friend, Mr. Benjamin Ferrey, who lived in the same terrace, only eight days. Mr. Hakewill belonged to an artistic family. His father was the architect of Rugby School, and of many other public and private buildings, and one of his uncles was the author of Hakewill's "Italy." His brother, Edward Chas. Hakewill, who died a few years ago, was also an architect, and erected some good churches.

John Henry Hakewill, whom we now lament, was articled to his father, who died when John was only nineteen. His friend, the Hon. and Rev. Wm. Spenser, early employed him to rebuild his church at Erchfont, in Wiltshire, and this led to many works in that county, both in churches and parsonage-houses. He built Howbury, near Wallingford; Boulney Court, near Henley; the County Hospital at Bury St. Edmunds; and more recently Stowlangtoffe Hall, near Bury St. Edmunds; and he was also engaged on many churches, schools, and parsonages in many counties, especially in Suffolk, Essex, and Wilts. He had not many works in London, the Rectory, St. James's, Westminster; the Boys' School, Marylebone; and the *original* of St. Matthias's Church, South Kensington, being the principal.

Mr. Hakewill was elected a Fellow of the Royal Institute of British Architects in 1854. He was one of the consulting architects of the Church Building Society, and with a few intimate friends assisted in originating the Architects' Benevolent Fund. Not longer ago than March last Mr. Hakewill communicated to us some curious memoranda, left by his father, concerning the visit paid by the Prince Regent and other illustrious persons to Oxford, in 1814, which will be found in our volume xxxviii, p. 339.

Camberwell.—St. George's Church, Wells-street, Camberwell, has been re-opened, after having undergone extensive internal repairs, which have been carried out by Mr. L. C. Shipton, of Camberwell. The pulpit has been carved and decorated by Mr. R. C. Baker, its donor.

THE NEW MUNICIPAL BUILDINGS FOR GLASGOW.

THE award of Mr. C. Barry on the competitive designs for the new municipal buildings for Glasgow was unsealed on the 2nd, and it was read by Dr. Marwick, the town clerk, at the usual monthly meeting of the Town Council, over which Lord Provost Collins presided.

Mr. Marwick read the report, which stated that Mr. Barry had made two lengthened visits to Glasgow, and had devoted a great deal of time to the consideration of the ninety-six sets of designs sent for competition, comprising in all 724 drawings. He had taken twenty-one of the best designs, and had himself priced them out. Of these he had selected three of the best that he could put before the Corporation, apparently coming under or about the 150,000*l.* Of these three designs he had shown in tabular form the cost, taking as the basis the cubical contents deduced from the plans and the information therein as to height of stories, &c. He also took into consideration the least cost that, in his judgment, each of the three designs could be well executed for in a solid, durable, plain manner, without marble or expensive sculpture externally or internally, for which purpose a large extra sum could be appropriated in any design carried out. He placed these three designs before the Corporation, and thought that the premiums must be awarded to them, inasmuch as they most clearly were in accordance with the embarrassing letter of the instructions. The mottos of three designs were:—First (1), "Carton," estimated by the author to cost 150,432*l.*, his plans being 89, 90, and 91. The cost at the same rate of Mr. Carrick's plan, which was 150,000*l.*, would be 158,800*l.*, and the cost as estimated by Mr. Barry, without expensive sculpture, would be 220,000*l.* The second place is awarded to the plans marked "Fidelity." No estimate is given of the cost; but, according to Mr. Carrick, the cost would be 151,000*l.*, and according to Mr. Barry, about 200,000*l.* The third is given to the motto, "Let Glasgow flourish for ever," which the author estimates at 143,728*l.*, but according to Mr. Carrick it would be 141,500*l.*, and to Mr. Barry, 188,000*l.* Mr. Barry stated that there had been sent in designs of much superior merit to any of the three which he had selected, but also more costly, though not in his opinion too costly for so important a city as Glasgow. The cost of these ranged from 180,000*l.* to 250,000*l.* He regretted that, as he was bound by his instructions, he did not feel at liberty to mention these.

The Lord Provost stated that, on opening the envelopes which accompanied the designs mentioned, it was found that they had been contributed as follows:—That with the motto "Carton," by Mr. G. Corson, architect, 25, Cooperage-street, Leeds (750*l.*); "Fidelity," by Messrs. Coe & Robinson, architects, 4, Furnival's Inn, London (500*l.*); and "Let Glasgow flourish for ever," by Mr. E. Clarke, architect, 6, Adam-street, Adelphi, London (250*l.*).

It was stated that Mr. Barry had also sent a private letter to the Corporation, and it was agreed not to publish the contents of it without his consent.

GLASGOW MUNICIPAL BUILDINGS COMPETITION.*

IN response to an invitation issued some time ago for architects to compete for the elevations of the Municipal Offices at Glasgow, the plans of which were prepared by the City Surveyor, ninety-six sets of designs have been sent in, as mentioned above. The building is to occupy a rectangular and almost level site in George-square. The square having some of the most handsome Classical buildings of all the handsome buildings of this Classical city facing on to it, the designs were to be strictly Classic. The design to which the first premium is awarded is by Mr. Corson, of Leeds, and we will endeavour to describe to our readers the frontages, beginning with the principal one to George-square, which has double pilasters between the windows on the first floor, with colonnade between the windows. These columns support a moulded enriched cornice. The blocking course is circular, and on this rises the attic story, which is treated similarly to the first floor, with columns between

* From a Correspondent.

the windows, and above, again, a cornice similar to the lower one, with haluetrade. The angles of the huildinge project, ae Mr. Brodrick makee all his huildings, particnlarly the Leeds Town-hall, and the central portion next to the entrance ie brought forward and eupported by double columne at the ends, and filled in between with a three-light window over the principal entrance. Above the window ie a pediment with moulded cornice and coping, under which ie a group of carved figuree. Above this central pediment rises a tower which is, however, not etrong enongh, heing as elender ae that of the Bradford Town-hall, and having the appearance of being top-heavy. The lower portion of the tower is well finished, and the npper part arranged for a hell-tower. At each side of the main entrance are projecting piere, with niches for statnes, finished at the level of the roof with pediments. All the cills project so as to form a balcony around, and are eupported on corbels. The basement windowe have square heads, and all the others are cironlar, with moulded archivolts to them, and the epace hetween the windows on the ground-floor ie panelled. The windows to the ground-floor are of similar character to those of tbe first floor, hut ehorter, with carved panele nnder. The angles of the huildinge are finished with mansard roofe, breaking the outline in a picturesque manner. The George-street and Cochrane-etreet frontages partake of the character of the George-square frontage in the position and eize and ehape of the windows, with pilastere or panele between, bnt the central part is broken hy the entrance to the quadrangle, and Mr. Corson has treated thie well. The arch is enriched, and the spandrels filled in with oarving; at each side of thie entrance are projecting piere similar to the entrance to George-square, with nichee for statues. There are, again, three lights over this entrance. On the cornice of the roof and over all the double piere are placed turrets. A dome ie shown over the entrance to the qnadrangle on George-street, with gahle in the same and three-light attic window, which is far better proportioned, and looke better altogether, than the tower to the front. A elight alteration is made hetween these two frontages, that to Cochrane-street having plain square tower. A great fanlt in the John-etreet frontage of this design conoists in having no definite mode of distingniehing which part of the huilding is intended to he used ae the town-hall, otherwise the John-etreet frontage is ae expeneive as any of the othere. An area wall aronnd the building is ntilised to form a place for statnes. The drawings are well got up.

"Fidelity," by Messrs. Coe & Robinson, to which the second premium is awarded, is ae different as poseible from the deeign previously described. The ground-floor and hasement are rusticated. The ends and centre project. At the level of the first floor runs a moulded cornice of a decided Doric character, and above thie the central projection forms itself into a pediment, snppoited hy eix Corinthian pilasters, two on each side, and one between each window, while the pediment is further finished with a carved group of figures. The end projections receive dignity from the four pilasters to each, which are flated three-fourths of the distance down. The space hetween the central and end projections is perfectly plain, leaving the other portions conspicuons. The whole of the window-heads of the haement and ground floor are square. The first-floor windowe have also sqnare heads, and have moulded jambs and corhels to snpport the moulded canopy over, while the window-heads hetween the pilastere have relieving arches thrown over, the under side of which is carved; hut the key-stones of theee arches are disproportionately large, and wreathed aronnd. There is only one tower to thie design, fronting George-sqnare. The hase is vermiculated, and over thie are three windows, with columne between, and donhle colnmne at the end snpport the cornice, which, examined in detail, is the niceet part of the strnctare. The whole tower is placed on a sqnare platform, and groupe of figures occnpy the corners. But one drawing is nsed to show the Cochrane-street and George-street frontages. The entrance to the court in the centre projects, and has a eemicircular arch over two pilastere; and two columne over enpport plain pediments with dentils in coping, and cornice ends project and have double columns at the ends and single columns hetween the four windows. Gronps of figures are placed over the entrance in the pediment. An infinity of time has been epent in making drawinge of the ceilings, which are elahorately drawn and do great credit to the draughteman.

"Let Glasgow Flourish, A," by Mr. E. Clarke, the recipient of the third premium, is a design in some respects better than the others, and any exhibitor in the room might learn eomething from it. The frontage to George-square shows an ashlar basement and a rusticated ground-floor, above which is a cornice with good bold ancones nnder. The first floor, rising from this cornice, deeerves to be described in full. At each end a single-light window is arranged, with three columne on each eide and a canopy over, with enriched cornice and coping; hetween all the other windows two colnmns are placed, and all the windows have square heads with small canopy over, without any carving; hnt all the windowe have moulded architraves. Tbe central portion projecte with three pilasters at each end, which snpport a large pediment with carved group of figuree. Tbere are three semi-circular-headed windowe in this central projection, and pillare between. Square heads would have heen more effective. Over all this etory runs the main cornice of the building, backed up hy a perfectly plain attic etory, with plain square-headed windows. Probably it would be better if statues were placed hetween each window on the attic-story. A small cornice, not at all obtrusive, snrmonnts the whole building, and above, at anglee over the canopies before specified, are angle-turrete. But the thing that marks thie for a prize design is the carefully-proportioned central domed tower, with turrete at angles on a square platform. The tower is circular on plan, and pilastere and windows alternate around. Above are cornice, colonnade, and cupolas. The dome which riese above ie very gracefully proportioned. The ground-floor of tbie elevation is not good. The entrance is by three doors, fairly good hut for the pilastere between, which are out of place. This design ie one of the few that are not coloured, and exhibits more real merit than many of them. The elevatione to Cochrane-street and George-street are similar to each other. The ends are exactly similar to the ends of the George-square frontage. The entrance to the court is badly treated in most of the deeigne, and in this one it is not an exception. From the drawing, the quadrangle appeare to he expensive, but it is one of the best quadranglee in the collection. In the John-street elevation the windows over the cornice are eimilar to those to George-equare, with canopies over, while the main cornice is interrupted hy a pediment over the entrance to the hall offices. A very neat dome is placed above this, which is not thrust conepicuonsly forward, and adds a great charm to the elevation.

Several rooms are filled with deeigne, and it is ohviously impossihle to go over them all carefully, so we shall select a few of the best; foremost among which we recognise the carefully-etndied drawings of Mr. William Hill, the author of the Bolton Town-hall, signed "Adelensis." This shows three-quarter pilasters from the level of the ground-floor, two etoriee high, over the rusticated hasement, while the architrave finishes around the pilasters to the first-floor windows. The parapet above, following the lines of the cornice, forms cills for the windowe, and pedestals for figuree of all the kings and queens of Scotland, to which a dignified Classical attic etory forms a fitting hackground. The attic windowe have pilastere and cornices; and above the whole, rnnning aronnd the building, is another cornice snrmounted with an open parapet, with vases above, each end finished with emall angle-turrete. The entrance ie through three doore, with pilasters. Above is a tower, rather slender, hut suitable in every way for the style of building, placed nearly in the centre of the building, with rusticated basement, and colonnade over, and vaes above columns. On each side of the central tower are bell-turrets in harmony with the central tower. The elevations to Cochrane and George streets are spoiled completely by the entrancee to the qnadrangle; if they were away this design wonld be enhanced in valne considerably. It has pilasters on each side similar to the front on a eimilar rusticated basement. Tbe moulded frieze is taken hack the depth of the reveals of the windowe and forms moulded impoets to the same. A small room ie obtained in the turret, and forme a central object in these frontagee. The windows over the arches are richly carved. The elevation to John-street is spoiled by the anthor trying to keep within the coet epecified; and it ie easily eeen he has reduced the expense on this frontage by having no pilastere between the central projection and the projectione at the ends, and otherwise cutting down the coet where practicahle. The entrance to the town-hall ie the best in the exhihition, and the design could be carried out for the money intended to be spent.

"Classio" may come next. The walling ie boeted, with sunk joints. Square heads are shown to all the windows. The three entrances have circular heads. The ende and centre project as in other designs. There are two pilasters at the ends of the central projection, and six columns between the windowe, snpporting a moulded frieze, with wreaths carved on, and cornice and colonnade over. The windows on the firet floor have circular heads, square canopies over, supported by large corhels; ends have similar windows, but with pediments ovor, carved. Tbe second-floor windowe are circnlar, and between every window circular-headed niches for figures are formed. Each story is treated separately. There is a good tower, and well-proportioned dome over. The author shows an alternative plan, with a elender tower, with olock in eame, and no columns in the design throughout, the centre being sufficiently marked by the position of the tower.

"Clyde" sends a good design, ehowing a rnsticated gronnd-story, with frieze and monlded cornice, on which rise pillars hetween each window. The angles and the entrance project forward, and have very good turrets, raised one story, admitting of figures in the niches. The pediments are filled with carved figuree over the entrance. The gronnd and first-floor windows have circular heads, and the attic has square heads, finiehed juet under the cornice. The area-wall ie hold, showing a deoided line. "Clyde" also sends another design, showing rusticated hasement and gronnd storiee, and Ionic columns to the firet floor, supporting cornice and colonnade, above which is the attic story, with dormer lights. Tbe whole is too enriched and folinted, but it has a good cornice and colonnade.

"Civis snm," hy Messrs. Campbell Douglas & Sellars, shows a ground-story formed with one window in each angle, which is projected forward, and has bold monlded archivolts aronnd. The three entrances are also treated in a similar manner, while the portion between the ends and centre is recesed, and has threo windows with moulds aronnd. The windowe to the first floor have Ionic colnmns eupporting monlded frieze, used ae a head witb canopy, and the epace above filled in with moulded arch, with small figures under on tbe cornice. The pilastere are two storiee in height, with Corinthian caps and moulded frieze; in a line with them there is a deep cornice, blocking, and colonnade. The angles in the attic story have horseehoe-shaped windows, which are anything but in keeping, and turreted roofe over. There are two bell-tnrrets next the tower, which is octagonal, and after the etyle of Wren's tower at St. Stephen's, Walhrook.

"Lippen to me, bnt look to yonreelf," has a good elevation, with rnstic hasement and panelled gronnd-etory. There are sqnare heads to all the windowe throughont, a plain frieze, and plain projecting hlocking conse with bed-mould, above which rise Corinthian columns two storiee bigh, the windows hetween having carved panele under the firet-floor windows, and nnder the second-floor wiudow cills a key pattern string-conree. There is a deep frieze, splayed hlocking, and richly carved pediment over the entrance, and a nicely-proportioned dome is over the clock-tower, square seats at the ends heing reserved for groups of figures. This is the design of Mr. Salmon, of Glasgow.

"Spes Dulce Malum" is a very well-drawn deeign, hy Mr. Burnett, sen., finished in a pale ink, eomewhat Florentine in style, with rnstic ground-story and projecting piers for etatues hetween centre and angles, making each appear receeeed. There is only one entrance, which hae a semicircular arched head. There is also one window in each end with similar semicirenlar head, and three othere, forming an arcade between the ende and the entrance. The windows are not satisfactory.

Mr. James Barlow Fraser sent a shaded drawing, nnder the motto "Rnyal," which shows a vermiculated baement, with sqnare heads to the windows, and similar windows to the gronnd-floor, with entrances in the centre with arched

heads. The columns rise from the first floor to the roof, with Ionic caps in the central and end part of the building. The plans are very well drawn, but there is a desperately ugly dome, with the clock-tower under. There are three pediments, and the centre one is carved, and all the windows above the ground-floor have canopies over them. The design that comes next was, we may say, universally admitted to be one of the best drawings in the exhibition. It is, however, impossible to mistake it for a Classical building. The motto is given as "S. P. Q. G."

"Roman" occupies his first and ground floor with a range of pilasters. The angles and the centre project. Central columns support a cornice projecting 5 ft. 6 in., and the attic story comes on as a blocking course. This is a decided mistake. The first-floor windows have pediments over them, and the angles are raised a story, and finished each in four turrets. The tower is considerably too large for the building. There is a small cornice over the attic story.

"Suum Cuique," another shaded drawing, is by Mr. William Teit, of Glasgow. Each story is treated separately. The ground-floor has square-headed windows, and the first floor has also windows with square heads, but they have canopies circular and pointed alternately over them. The turret is peculiarly ugly, and is supported by four columns.

"Old Tee Square" has a vermiculated ground-story. In the centre are the principal doors, and over these are well-drawn fluted columns in the centre, and square columns elsewhere between each window. These columns are all two stories high, and there is a pediment in the centre with group carved therein.

"Why not?" has pediments at the ends, and central tower, large circular head to door, with projecting piers at each side, and large circular heads to windows on the first and second floors, while there are nicely-moulded window-heads of a reasonable size to the ground-story.

"Let Glasgow Flourish" (red ink) has a vermiculated ground-story with columns above two stories high, central pediment with frieze and wreaths over, and carved figures in the pediment. All the window-heads are square.

"Mottoes only" has ground and basement story rusticated and plain; small projecting pediments in centre; the ends also project. There are shown three doors, with pillars above between windows. Connected with colonnade is a deep perfectly-plain frieze and cornice, with colonnade over. Angle-turrets are placed at the ends and square tower, but the attic over the centre pediment is dwarfed.

"In Honour true," by Mr. Eaglesham,—a fanciful design. All the windows have circular heads. The ends are raised a story, and a horrible clock-tower is attached.

"Clutha," a design of Mr. Bell, is elegant; all square heads to windows, and each story is treated separately. The ground-floor shows panels between windows, and on the first and second stories columns are arranged instead between the windows. The windows have architraves, and the angles are raised one story. The clock-tower is passable.

The ground-floor in the design marked "B" has square windows. The design is of astylar composition. There are gables at ends, and a gorgeous turret. The town-hall is well marked.

"G" is very dignified. The columns commence at the ground-level, and are two stories high. There is a centre pediment, and the ends project. There is a colonnade and cornice over, and panelled attic story. The ends are surmounted by domes, and a large dome is shown in the centre.

In "Aiblins," Mr. Maclaren shows a basement battered, which gives an appearance of stability. There is a string on the level of the ground-floor, and the windows have square heads; the walling on the ground-floor is panelled. On the first floor great arched openings are evidently intended to represent Classical windows, but we fail to see the correspondence; there are three windows in each bay, and one at each end. There is a small pediment in the centre, and square windows to the second floor in the frieze. Pilasters are shown to the ends and centre dwarf domes, with buttresses around.

"1880" is a well-drawn and fair design. Entrance is very tame,—too much sameness.

We believe Mr. Thompson sent "Cavia," a good design, and it would have been better without pilasters taken up three stories; panelled ground and first floors, and fluted pilasters above at the ends, over which are well-shaped domes.

"Nitor" is a good design lost among so many others. The columns, of the Corinthian order, are two stories high from the first-floor level, and there is a panelled frieze above the angle-turrets and pediments: ugly stone transomes are shown to the first-floor windows, below arches. The centre projects, and there are figures in the pediments.

"Finis coronat Opus:" effective front, columns between each window, and two at angles. A pediment is shown in the centre, and the colonnade at the level of the attic story, above the windows and statues, looks well, but the pediment is much too large. There are mansard roofs over the angles, and large tower, and circular dormer window.

Mr. Stark sends "Palladian," which has Corinthian columns to front, fluted from ground-floor two stories high; the ground-floor windows have square heads, and the first floor circular; the cornice frieze, and colonnade over these windows are 15 ft. high. The attic windows are placed in panels with statues between.

"City Chambers," by Mr. J. Bierd, has the ground-story panelled with vermiculated quoins and archstones to heads, angle-turrets too lofty. The central projection is supported on wide, heavy pilasters, resting on slender ones, with domed roof and good dormer windows.

The walling on the ground-story to "Palladio" shows the joints sunk. There are some good corbels to support the cornice, and a central pediment is placed on the George-square front, supported by eight columns, while the end projections have four similar columns each. Over the pediment is a central domed tower, and turrets are also placed over the ends. The colonnade and cupolas are too lofty. All the windows have square heads, with canopies over, those to the first floor being circular, and those to the second floor pointed.

The following are the mottoes of various other designs that have been sent in:—"Experience," a building four stories high; "Progress" is spoilt with having no lights on the second floor; "Peace, Progress, and Plenty," an Egyptian study, very good, but out of place in Glasgow; "Fiat lux," too lofty, and perfectly plain; "Speedwell" vermiculated and plain courses, alternately, to ground-story, and very neat upper-story, supported on corbels; "Bourgeois" (by Messrs. Turnbull & Thomson), no columns, central part with angles raised a story, the centre part projecting, and the basement battered; "Ad rem" has three pediments, the centre one with six Ionic columns, and the outer ones with five columns each; "Finis coronat Opus" very similar, but the centre pediment is larger than the outer ones, and it has a better tower; "Salonica" is a well-drawn design, the centre and ends are three stories high, and between these the building is two stories high; "Apropos," a highly-shaded and coloured drawing; "Art with Economy," very plain; "Light and Shade," "Centre of Commerce," "Motto," "Town Hall," a sketchy, Gothic drawing; "Civis," "Grecian Doric," "Tree, Bird, Bell, and Fish," "Rebaiothis," "Conor," "Immutatus," "Per non Dormire:" the centre and angles project with panelled quoins at the ends and columns between, and very good dome; "Non quo sed quo modo," a poor design, covered with the Broomhall tiles; "Our will became the servant to defect, which else should free have wrought;" "Con amore" motto, St. Mungo, is a good design, and deserves a better place in our report. It has a rustic basement, and the columns are two stories high, with attic over and centre pediments, each with dome over. It was said to be by Mr. Anderson. Mr. Landless also sends a drawing, signed "St. Kentigern Primus." It is plain, with a good central dome. We should advise this young Glasgow man to persevere, as he will obtain prizes in time. "Child," by Mr. J. Thomson, Glasgow. "Let Glasgow flourish." "Justice," sketchy, and very poor. "Let Glasgow Flourish," with fish and mitre. "Glasgow floreto," columns too heavy, and too near together. "Experto crede," very gaudy. "Ex propriis St. Mungo," two lofty turrets at the ends. "Bruce," "Bannockburn," "Mendelssohn," "Quivi Trovammo," "Two Circles," "Nisi Dominus Frustra," "Simplex," "Let Glasgow Flourish," "Concilio et Labore," "Georgiana-square" by Mr. Love; "Revirescam" by Mr. Dalglish; "Curia Municipalis," windows coloured. Mr. Baird, jun., was not successful in making his mark with a design signed "My Mark," and we are not astonished. "Red Star," "Ca' Cannie," "Festina lente"; "Major Domo," enormous dormer and central pediment; "Detur Digniori," a decided Queen Anne. "Desideratum" is well sketched; "Valentine Clyclone" is by a disciple of Queen Anne; and "Athens," a Grecian drawing, is reported to be designed by a German.

THE PROTECTION OF WOOD AND IRON BY PARAFFINE.

DR. EUGEN SCHAL gives some interesting information on this subject in the *Würtembergische Gewerbeblatt*.

In chemical technology great difficulties sometimes arise when it is desired to manufacture on a large scale preparations which may be obtained with ease in the laboratory. In most cases the reason of this failure is the fact that in the manufacture the use of glass, porcelain, platinum, &c., which successfully resist the effects of the various chemical agents must be dispensed with, and cheaper and less easily breakable materials, such as iron, copper, lead, and wood, substituted. Wood especially cannot be replaced by any other material in the wholesale preparation of muriatic lyes, although the same, according to the strength and temperature of the liquid, undergoes sometimes very rapid destruction.

Dr. Schal says he acquired this experience more particularly in 1874-77, in alizarine manufactories, and that he found in paraffine a means which efficiently protects the wood against damp, acids, and alkalis, and by which a great saving is effected. The wooden vessels used, especially tanks of pine wood, for boiling acid and alkaline lyes, as well as casks of oak of the heaviest weights, for separating acid alizarine lyes at a pressure of a half to two atmospheres, were generally totally rotten after a few months, but they lasted for two years when impregnated with paraffine.

Before treating with paraffine, however, the vessels must be thoroughly dried for about three weeks by leaving them in warm and dry air, in order to prepare the wood for the absorption of the paraffine solution in its pores. The latter solution is prepared in the following manner. A part of the paraffine is melted in a spacious metal vessel over a moderate fire, the mass being stirred, the boiler taken from the fire, best moved into the open air, stirred until the mass begins to congeal at the edge, and then about six parts of petroleum, ether, or sulphuret of carbon are poured in, and stirred until solution. The preparation is then put into vessels that may be hermetically closed, or it may be used at once. In preparing the paraffine solution great care must be exercised, as paraffine as well as petroleum ether or sulphuret of carbon especially are very inflammable, and as even the vapour of the two last-mentioned substances, if mixed with air, may give rise to dangerous explosions. Those substances must, therefore, be kept in a cool space, far from light or fire, and well stoppered.

The wood is best saturated in dry and warm weather, as then it dries more quickly, and a smaller quantity of the solving agent is necessary. In winter six parts of the solvent generally do not suffice. This proportion changes with the quality of the paraffine and the temperature; paraffine solving with difficulty is better than the more readily soluble article. Vessels easy of access, such as tanks, tubs, &c., are coated in the open air with the solution as long as the wood will absorb it. The solvents evaporate very quickly, leaving the paraffine behind, so that two or three coatings may be laid on in succession. If the vessel is to be exceptionally well prepared, it is left for a day to dry, and then another layer of the paraffine given.

For vessels in which steam is used for boiling the liquids they contain, be applies after a few days a coating of oil varnish, because the melting-point of paraffine is below the boiling-point of water, and it is thus in time driven out of the pores by the water.

Instead of oil varnish, the vessels, after being well rubbed down, may also be coated with a thin solution of soluble glass, then dried, and washed with diluted hydrochloric acid. The silicic acid thus formed clogs up the pores from the outside, and provides a protection to the paraffine against the hot water. For vessels which are used only with a moderate heat or cold, the coating of paraffine suffices perfectly. The paraffine is hardly dissolved by diluted cold

alcohol, is not poisonous, and may also probably be used with advantage for vessels for keeping liquid. In the case of barrels, the solution was poured in simply after drying them; for an oak barrel holding 9 to 10 hectolitres, 1 kilo of paraffine dissolved in petroleum ether was required. All openings were then well closed and the barrel rolled about and over for about an hour, so as to bring all parts in contact with the solution. The barrels were finally left standing on their ends for half a day, after which time the remainder not absorbed was emptied, and used for the outside coating. Before applying the solution outside, however, the barrels must be well cleaned, for dirt naturally closes the pores of the wood. As these barrels were very expensive, and had to sustain a pressure of two atmospheres, besides being exposed to a high temperature, they received on both sides an additional coating of oil-varnish. It is, however, necessary to let such a barrel stand in the open air at least a fortnight for drying, and as a precaution fire must be kept away from the barrel while being prepared. As a further precaution, in applying the solution inside, the workman must not be left alone, as it frequently happens that stupefying vapours from the solvent of the paraffine arise, which stupefaction, however, soon disappears in the open air. The oil-varnish may also be diluted with petroleum ether, poured into the barrel, and then the latter rolled about, as above described; but many places escape saturation in this operation. After coating with varnish, the barrel is once more dried, and then filled with water, in order to force out the combustible gases. This is much to be advised, as an explosion once took place in consequence of a workman trying to enlarge a hole with a red-hot iron, contrary to orders. After the last operation, the inner sides of the various vessels are rubbed down with a dry duster, so as to take off all loose particles.

If impregnation of wood is intended on a large scale, the wood is best stacked in iron boxes, the paraffine solution poured over it, the solution not absorbed drawn off after some time, the solvent forced out of the wood by means of warm air, and recovered by condensation in a cooling apparatus.

If the various manipulations are carefully carried out, the duration of vessels thus prepared is increased from four to six fold, while the outlay is comparatively small, leaving out of consideration that the contents of such vessels are frequently lost by the bottom being forced out.

Paraffine, melted with equal parts of linseed oil or rapeseed oil, is also useful for coating iron vessels, which without a substantial preservative are very liable to rust in manufactories of chemicals.

Paraffine likewise protects skin efficiently against wet, alkalis (especially lime), acids, &c.

Dr. Sohal says he often found that workmen in alizarine factories suffered much from sore, ulcerating, and swollen hands, especially during winter. After the workmen began to use (twice daily) a solution of paraffine with rapeseed oil and petroleum, chapped hands (not to mention swollen or ulcerated hands) became a scarcity.

The solution is produced by melting three parts each of paraffine and rapeseed oil, removing it from the fire, and adding eight parts of petroleum while stirring the mixture. Before using, the solution is stirred a little, and the hands rubbed with it while they are clean and dry. In larger factories, earthenware and tin vessels, filled with this ointment, are placed at convenient spots, and it is believed that the manufacturer as well as the workman will find this pay.

New Congregational Chapel, Northampton.—The foundation-stone of a new Congregational Chapel, in King-street, Northampton, was recently laid by Mr. John Hensman. The new building will be faced with local stone and white brick, with terra-cotta and Bath stone dressings, moulded white bricks for strings, window cills, and cornices, from the Whitwick Colliery Company, Coalville, Messrs. Gibbs & Canning supplying the terra cotta. Mr. S. J. Newman, of Northampton, is the architect, and the work has been entrusted to Mr. Daniel Ireson, builder, of Derngate, Northampton. The cost of the new chapel, in the erection of which most of the old material has been utilised, and the expenditure, thus curtailed, will, it is estimated, amount to about 1,600*l*.

FROM BRUSSELS.

Brussels, on the occasion of the fiftieth anniversary of its freedom from the Dutch rule, is in gala costume, and the national flag flutters from every window and across every street, recalling in all but the difference of the tricolor the *fête* at Paris a few weeks since. Unconsciously the comparison with Paris slips from under the pen. Brussels, every one carelessly agrees, is "Paris in little." There exists, however, as great a difference as it is perhaps possible to imagine, when the few hours' distance that separates the capitals of France and Belgium is taken into account. The stranger who hurries from the railway station to his hotel in the higher part of the town, and in the evening saunters down the Rue de la Madeleine and through the Galeries St. Hubert, attracted moth-like by the glitter of the shops and *cafés*, and heedless that but a few yards from him lies the picturesque old Grande Place, may, of course, think Brussels a little Paris.

Thank Heaven, however, in spite of successive burgomasters and energetic magistrates, there still remains, and long will remain, a large portion of the dear old Brabançon capital untouched, to delight future generations of seekers of the picturesque. After the imperial grandeur of Paris, the homely character of Brussels is delightful. Perhaps it appeals more to the domestic Englishman than to the boulevard-frequenting Parisian. The incidents that strike the eye are so different; the open small-paned window where the industrious housewife sits knitting, for the long winter, the comfortable stockings and vests so prized by the Low-Country folk; the narrow streets shut in and shaded by their picturesque gables; the homely costumes that surround one,—for machinery has not yet entirely triumphed over tradition; the honest-hearted greetings in the market-place, alive with its vendors of vegetables under their patched and weather-beaten umbrellas,—ever suggestive of sketches for the pocket-book,—these and a thousand other incidents, from the welcome given to the stranger to the wag of the tail of the brindled dog who trundles along so happily his burden of mirror-bright milk-pots, all breathe an air of Flemish comfort and domestic ease that finds no possible comparison on the banks of the Seine, where "the blessings of civilisation" are written on every feature to be met in the streets. Brussels is a capital, and yet delightfully provincial. The Parisian, therefore, will never love Brussels; but the Englishman who knows his Paris well, from a brotherhood of sentiment, if not perhaps of blood and of language, unfailingly be led to prefer the gay little capital of Brabant.

Brussels, now *en fête*, remains still the Brussels of always, less always the difficulty of finding accommodation. The strangers fill the streets of the capital; the provincials fill the innumerable *estaminets*, where gallons upon gallons of excellent *faro*, and, perhaps better, *brune* beer, are consumed amidst revelry whose chief charm lies more in its resemblance to the life of Teniers's contemporaries than in its approach to what modern "culture" and the studies of the Social Science Congress have led us to appreciate.

After the terribly modern aspect of Paris, where the toil of its business of pleasure is stamped deep on every face, it is delightful to find oneself almost transported back in these quiet streets to the realisation of the period which tradition has pictured to us as "the good old times," where all is not scraped by municipal authority every ten years, or built five and six stories high in lines laid down by the T-rule and square. It is the Continent proper, the ideal of foreign travel satisfied, while Paris remains eternally Paris, which, as Charles Blanc remarked but a few days since, is only loved by Parisians because there still exists enough of old Paris to rouse the joyous recollections of the past. Have a care, destructive mayors and magistrates, that in your love of modernising your old towns you do not destroy that warm affection we all feel for the homes in which we have been brought up. The Bruxellois loves his Brabant town, where he sees in after-life the scenes of his youth revived, as his father and grandfather did before him,—the old houses which unconsciously affect his imagination with their quaint picturesqueness, the *estaminet* with its high ceiling, its clean-sanded floor and shady coolness, the well-filled glass of honest beer,—impossible, by the way, to find in Paris,—the satisfying meal,—another difficulty on the banks of the Seine,—and homely comforts enjoyed by his ancestors, and which to him form the great features of his existence.

Purists may shudder at the boorish life, the *bourgeois* existence, the aspect of decadence that stamps each nook and corner of the quiet old Flemish and Brabant towns; but let us remember that this seventeenth century that strikes the eye at every turn was the great period of Belgian history, when after the gigantic effort that shook off the Spanish rule, Belgium, or rather the Low Countries, began that epoch of prosperity it has ever since enjoyed, when the cannon of her great three-deckers,—to the designing of which the decorative skill of Van der Velde was not ashamed to devote itself,—thundered within sound of London Bridge, when still the commerce of the East and West poured through the gates of the Flemish towns, and along the broad flat roads from Ghent, from Bruges, from Antwerp, and from Brussels, to Northern Europe; when foreign influence was stoutly combated, and new-fangled fashions took a century and more to wedge their way into a position, and then, even, never succeeded in taking a good hold, —a fact which nothing shows more plainly than the development in Belgium of the varied architectural styles that have swept over Europe since the Middle Ages. The Low Countries have accepted each of these, like poor Ophelia's rue, "with a difference," and Belgium, for this reason, will retain to the artistic eye, for many a century yet, a peculiar charm of originality due to the peculiar character of the nation.

Respect, then, lover of a purer art and purer periods, the strength of a people whose force was sufficient to resist the foreign influences that neighbouring countries allowed so easily to acclimatise themselves. When one travels abroad, one's tastes must be allowed to become eclectic, in the too-little understood foreign acceptation of that word. They must be riveted temporarily to no one period, to no one fixed idea, or many a pleasurable illusion will be destroyed, and many a disappointment met. Brussels is essentially calculated to try the strength of the prejudices that a home course of artistic study may have engendered. It completely satisfies the ideal of romance, the ideal of the existence of the past, while calm reflection leads one to remember the period to which the greater part of all this effect belongs.

At the present moment, however, it requires a power of abstraction more than usual, not to be affected by the general bustle which attends the *fêtes* and ceremonies, placarded programmes of which enliven with their bright colours the walls of many a gloomy old burgher's warehouse, with flags flying overhead and unusual gaiety in the streets. Brussels in this excitement is the capital of Belgium, but scarcely Brussels itself, except to those who know the town of old; true, the Grande Place, with its familiar features, is little affected by this gaiety, though high up in the air, under the gilt St. Michael and the Dragon, on the spire of the Hôtel de Ville, flutter a bundle of national tricolor flags. In the town, the talk is all of the great historic cavalcade, the success of the first "sortie" of which has led to two further representations. Certainly the cavalcade is all that in the present day we can expect in a thing of this nature.

Needless now to describe the procession in which the whole history of Belgium was represented in costume, the long struggle between the patricians and the burgesses, the communes, the brilliant reign of Philippe le Bon and his artistic and literary court, and the later rule of Maria Theresa, followed by a long series of allegorical representations of the great industries of the time, and the deputations from the various provinces, cantons, and communes of the country. By this feature alone, long will the fiftieth anniversary of the independence of Belgium be remembered.

The exhibition, of course, forms to the stranger the chief object of temporary interest in the city. Being a strictly national show, Belgium is thoroughly well represented in its art, its manufactures, and its science. There remains, therefore, much to be seen,—and said.

Builders' Benevolent Institution Dinner.—The annual dinner in aid of the funds of the above-named Institution is fixed to take place at the Freemasons' Tavern, Lincoln's-Inn, on Thursday, 11th November, Mr. T. F. Rider, president, in the chair. The committee will be glad to hear from volunteer stewards.

AMERICAN PROGRESS.

It is hut natural that a country, whatever may he its size or importance, should look with interest to the period when the time for numhering its inhahitants should arrive, for then is the opportunity afforded for noticing whether its condition is progressive or retrograde; and in proportion to the vitality and energy of that country, so is the interest greater and keener, and the efforts to insure a true and accurate accounit more complete and exhanstive. The period of a census, indeed, is a kind of birthday of a nation, when stock is taken and its values ascertained; and as it is seldom an occnrrence of anything like an annual repetition, it really hecomes an inqniry of the greatest importance. In this matter England, which shonld be first and foremost, is almost hohind every other nation, and seems to care, less than all, to know what way she has made in the last ten years, or to gain that knowledge of herself which is so emphatically useful for futnre guidance.

Our own census is looming hig, and preparations are heing made even now for taking it. Of all the European, American, or other censuses, it will be probably the haldest and the least instrnctive, going very little further than a mere numhering of the people, and wilfully ignoring the openings naturally offered of getting information as to the real condition of the people, social, religions, or indnstrial. It is very much to he regretted that onr Government, either from a misplaced grudging of a few thousands extra (whichare sure to he wasted in some other quarter) or from a fear of injuring its popularity with its political supporters, should have refnsed to allow the census to be made useful for anything hut the hare figures of the population. Perhaps in ten years hence we may learn a little wisdom, and do thon what America is doing now, viz., seeking to find out in what direction her giant powers are extending themselves most, so as to gnide her energies more profitably during tho next decade.

The industrial history of New England is not only a romance of itself, hnt is a romance almost of our own day; and although we in the old country are fond of pointing to the rapid development of some of our manufactnring towns, the rate of progress is thrown into the shade hy most of the American towns; nor have we any reason to donht that, in most cases, the progress is as sound commercially as it has been rapid. It will he instructive to note from time to time some of the principal American cities; for, it must not he forgotten that England and America are becoming so interwoven in commercial matters, and so closely connected hy ocean steamers, telegraphs, and (very soon, probahly) hy telephones, that we all have a directly personal interest in her trade and manufactures, and cannot afford to talk of them as far-off things whioh do not affect us. Looking at America from an American point of view, there are many branches of the snbject of her development which are deeply interesting, and which, perhaps, the *Builder* will tonch upon at another time, snch as the migration of industry from the Eastern States to the Western, and the consequent variations in the halance of the trade and commerce of the country. At present, however, we propose to briefly consider the population of some of the chief centres of the States, in connexion with their past and present progress. It is too soon, as yet, to obtain the statistics generally of the American censns of 1880, hut sufficient is known as to the numerical condition of the great cities to enahle us to draw some conclusions that may be of interest.

The New England States of Connecticut, Maine, Massachusetts, Rhode Island, New Hampshire, and Vermont are all remarkable, from an industrial point; for not only were they amongst the earliest pioneers of trade, hut they stand out from amongst their own people by their peculiar force of character, and hy the perseverance and energy with which they have drawn into their own focus such a large proportion of American trade and manufactures. Let us take, for instance, the small State of Massachusetts and its capital, Boston, which, on the principle that Paris is France, may he spoken of in the same way with regard to the state. Boston, according to the present census, contains 352,000 inhahitants, an increase of 40 per cent. dnring the last decade. Whether this amount includes the neighbouring towns of Roxbury, Charlestown, Dorchester, and Brighton, which have spread ont their wings so greatly as to have become snhnrhs of Boston, seems donhtful; hnt there is no donht that the increase since 1870, when the census reports gave Boston 250,526 inhahitants, has been at a remarkahly-rapid rate. Eighty years ago, the popnlation was returned at 40,000, and the port was then spoken of as "doing a nice little trade" with the East Indies. The nice little trade had risen in 1849 to the value of 1,222,800*l.*, and hy 1878 to 6,130,000*l.*

The six New England states of Massachnsetts, Connecticut, Maine, New Hampshire, Rhode Island, and Vermont, are estimated to possess a capital in the shape of their manufactories of 108,173,840*l.*, and to employ 556,000 workpeople ont of the total population of 3,362,000. The manufacturing capital of Massachnsetts alone amounts to 56,576,720*l.*, while it has 317,000 artisans ont of a popnlation of 1,653,000. The greater part of these artisans are highly skilled, and contribute, together with the perfect machinery in use, to a very large production. Textiles are the main hranch of manufacture, while second only to these is the hoot and shoe trade, which keeps more than 1,400 factories in constant employment, tnrning ont, one year with another, some 60,000,000 pairs of the value of 16,000,000*l.* Several of tbe Massachusetts towns are almost exclnsively devoted to St. Crispin, and it is not too much to say that at least half the hoots and shoes worn in the United States issue from this one little state. A single factory at North Brookfield makes from 5,000 to 8,000 pairs a day, giving work to 1,000 people, at wages from 5s. 6d. to 10s. The watch trade, again, is another marvel of rapid development, dating back for a very few years only since its commencement. It was but in 1850 when two Boston artisans, Allan Denison and Edward Howard hy name, first opened a small workshop for watchmaking at Roxbury; hut, finding the place not sufficiently quiet for their wishes, they changed their locality to Waltham, a little town about 11 miles from Boston, and here they established themselves on the banks of the Charles River. Although they demonstrated the feasihility of making watches hy machinery, they failed in a pecnniary sense, not having started with sufficient capital, and the concern then passed into the hands of Mr. Robbins, who founded in 1858 the now celebrated American Watch Company. Considerably more than a million of watches bave issued from this factory from then till now, and although they were originally intended and expected to supply the home trade only, their cheapness and excellence have canscd a demand for them in foreign countries, England not excepted. Over 800 operatives are employed hy this company, working eleven hours per day (except Saturdays, when tbe limit is nine hours), the men earning daily from 7s. 6d. to 11s., and the women from 3s. to 6s.

The little state of Rhode Island competes hriskly with Massachusetts in industrial honours. Although she is only about 40 miles in length and 82 in hreadth, possessing not more than 250,000 inhabitants, she counts 46,000 of these as working people, with an industrial capital of 13,320,000*l.*, while, according to the last census, the valuo of the manufacturing production was estimated at 22,280,000*l.* What the revenne may he according to the exhaustive inquiries of the present census (now heing made) it is impossible to say; hnt it must clearly show a very great increase. The production of the state of Maine is estimated at 14,000,000*l.*, and that of Vermont at 6,400,000*l.*, the latter state having three specialities, viz.,—tanning, carriage huilding, and the making of scales and weights. Connecticnt, in addition to her textiles, of which we shall have more to say further on, is noted for her hardwares, sewing-machines, axes, and agricultural tools, besides running Massachnsetts closely in the matter of clocks. New Hampshire prides herself on her steam-engines and locomotives. Maine, that happy state where the people will neither drink themselves nor allow anyhody else to do so, except an unlimited supply of water, was formerly nothing but a saw-mill or lumher state. This trade (a very important one, hy the hye) still flonrishes there, and is a valuable source of income; hnt lumher is rather an industry of the more primitive regions, where forests still flourish in their primæval glory and where "clearings" are the first thought of man. Maine still possesses a considerable area of nninhabited country, hut she also has several active business towns, such as Portland and Augusta, which can show a fair proportion of mills and factories, with their hattalions of skilled workmen. Massachusetts is *par excellence* the cotton-spinning state, to which succeed in order Rhode Island and Connecticnt. But although New England may be counted as the Lancashire of America, it is hy no means exclusively so; for, of late years particularly, the cotton trade has increased in a very remarkable degree in the Southern States of Georgia, Tennessee, and North Carolina. A great change is coming over the United States in this respect, as in many other industrial respects. It was possibly a mere chance that first influenced the establishment of mills in the New England states, hnt what fixed them there was the character of the country, and the ample supply of water-power, which commended itself at once to the notice of the early indnstrial settlers. The cotton in those days was, therefore, all brought from the Sonth to the North, just as it is brought to Manchester, and it was not antioipated that a cotton-manufacturing element would grow up in the South. But it has done so, and to a hy no means inconsiderable extent, that is increasing every year. The following hrief table will show how the thin end of the wedge bas been introdnced, giving the figures of the Northern and Southern cotton-spinning States respectively:—

	No. Mills.	No. Spindles.	Pounds of Cotton used.
Northern States.			
Massachusetts	296	3,775,634	2 8,894,352

WORK AND WAGES IN ANCIENT GLASGOW.

THE records from which the following notes are gatherod date from the year 1573 to 1627, at which period the majority of the citizens resided in the neighbourhood of the cathedral and around the preoincts of the bishop's palace, now covered hy the Royal Infirmary. The Drygate was the chief-street, and the Rotten-row of ancient Glasgow, like that of present-day London, was the promenade of nobility. In the middle of the sixteenth century the population of the city did not exceed 2,000, the male portion heing principally made up of ecclesiastics, salmon merchants (Sir Walter Raleigh was as yet unknown on the banks of the Clyde), fishermen, and a ew tradesmen and mechanics. Except in a few instances it is impossible to get at the exact amonnts paid for wages aud work done. The accounts are sometimes terribly mixed. For example: "To Matthew Ker,"—Matthew was the keeper of the Tolbooth, *i.e.*, the court-house, council-chamher, and jail, rolled into one,—"for winter candill and for the mennis suppers that war execnt, 25 shillings and eight pence." In this instance the calculation of the price of candles is rendered impossible by the grim "sundries" in the shape of a last meal to the condemned. When the town hegan to spread to the low lands on the river side, causeway-laying hecame a necessity. The town possessed quarries in its immediate neighhonrhood. The qnarriers were paid by the "ontpnt." "To the quarriers for quarrying of fonr hundred cartloads of whinstone to the calsay, 9 pounds, 6s. 8d. Scots." Causeway-maker Glasgow had not, hut it horrowed one, a Walter Brown, lent by tbe provost and magistrates of Dundee. Walter comes, makes a snrvey of the joh, and departs. October 28, 1577, "To Valtir Brown, calsay maker, for his expensais in cuming fra Dundey and ganging thereto again when he was feit [paid] 40 shillings." Among the items of the

causeway-laying accounts are, "Given at the Maister of Works command to Mathow Millar and John Brokes for leading of threescoir cartis [cartfuls] of stanes to the calsay from the twelt of November to the sixteenth thairof, 30 shillings." "To John Houston for 1 week's labour at the calsaye, 20 shillings." In the following month this same John Houston receives "for the making of ane [oue] rnde and ane half of calsaye above the Grayefriers, 3 pounds Scots." "Item, for Danskyn iron to he ane calsay bammer, 27 shillings." Two kinds of iron are frequently referred to, Spanish and Danisb iron, the latter being used for fine work. Bars and stanchells are wanted by the master of work, wbo, whoever he might be for the time, seems to have been vested with the anthority of a whole Board of Works. At bis order 41 stone 14 lh. of "Spanye irne," price of tbe stone, 12s., and 3 stone of "Danskyn" iron, price of the stone 15s., are "furneist" to the windows of the Tolhooth. The name of the civic blacksmith appears in the following entry:—"To Robert Muir for ane pair of fetters of irne [iron] 3 pounds Scots." The smithcraft was jealously looked after by the anthorities. Feb. 16, 1600: "The provest, bailleis, and counsale, dischargeis" [commands] tbe dcacon and quartermasters of the smithcraft not to visit the smithies in Bannockburn until they produce their warrant and letter of deaconhood. In Scotland in those days the wages of a smith were included in the price of the iron supplied by bim.

Tolerably satisfactory information is given in connexion with the building trades. In 1597 the magistrates covenant with John Liddell, the lime-man, "that he shall deliver to all the inhahitants bis lime, every boll good and sufficient without stones, for eighteen pennies the boll." The price of sand was about one penny Scots a cart-load. A mason's wage was five shillings, and that of his labourer three shillings Scots daily. Until the year 1600 the masons and wrights (carpenters) formed a united craft. On an appeal from the carpenters to the magistrates a separation took place. In the case of two individuals a strange exception is made; "The provost, &c., notwithstanding the letter of deaconhood granted to the wrights this day [May 3, 1600], has ruled that the same shall not prejudge or hurt John Frelands and John Maxwell, that presently works both mason craft and wright craft." As to carpenters' wages. A door is to he made for the Tolhootb. For a plank of oak to be one breadth to the door, three shillings Scots is dishursed. Robert Pettigrew, carpenter, receives for work upon the said door five shillings and eightpence Scots daily, the regnlar wage, as shown in other entries. Glass, in 1627, cost eight shillings Scots, that is eightpence of the present time, per foot. A curious contract exists hetween the Earl of Eglinton and George Elphinstoun, "glasin-wricht," burgess of Glasgow, dated July 12, 1577, by which the latter is bonnd to mend, make new, and repair all the "glassin" work in five towns named, Glasgow being one, during "all the days, years, and terms of his lifetime"; tbe earl furnishing glass hands "soilhnrdis" (frames and sills), lime, and sand, and for remuneration the glass-wright was to receive yearly two holls meal and one stone cheese, besides his "meit" (food) on certain occasions, the use of a horse to carry his panniers of glass and lead, and,—perhaps an important item,—all the blown-down glass and lead.

Three hundred years ago Glasgow had only two town clocks, but no clockmaker: so David Kay, clockmaker in "Carrail," is sent for by the magistrates "to set np and repair" or mend the "twa knokkis," the one made by bimself, and the other old "knok" mended hy bim as often as he is required thereto, for which he is to he paid "rationable" expenses. David Kaye received large sums of money, hut no items of time or labour are given. He receives 100l., Scots for the new clock, and 3l. 6s. 8d. for setting it up. "Carrail" lent a clockmaker to the town that has become the commercial capital of Scotland. Carrail modernised into Crail is now a small village on tbe Fifeshire shore, where gray cairns and green mounds tell of a palace and a priory and noble mansions which stood in their pride when Glasgow was as yet unknown.

The citizens were bound, when called upon by the magistrates, to do their "day works" in carrying out civic improvements, or, failing to do so, forfeit for each day 6s. 8d. Scots. The Dean of Guild appears to have been also city architect. Five "lynaris,"—liners, or land surveyors,—were chosen yearly, and plenty of work they seem to have had in settling disputes as to boundaries, and assisting the Dean of Guild in keeping the streets and houses in proper repair.

In Novemher, 1577, the town purchased "tbe *old* bell that went through the town of *old* at the burial of the dead" for ten ponnds money, and also granted the seller to he made a burgess "gratis," and made special enactments for the safe-keeping of the relic, which was called St. Mungo's Bell. Saint Mungo's Tree is frequently mentioned as a boundary mark. Can it be tbat that bell and that tree were tbe originals of tbose incorporated into the city arms?

TEMPERATURE OF WATER AND THE GENERAL HEALTH.*

In a paper read last year before tbis Association, the author gave the results of a series of experiments, extending over a considerable period, of the temperature of town water-supplies, and referred to the influence of the temperature of town water upon public health.

In tbe communication referred to it was sbown that the temperature of water, as delivered through the water mains to the house of the consumer, was totally independent of the temperature of tbe water at its source, and that the temperature of the water supply was governed, to a great extent, at all periods of the year, by the temperature of the ground at the depth at which the water mains were laid.

It was further pointed out that the influence of temperature upon water supplies had a very marked effect upon certain classes of disease, especially diarrhœa and cholera, and tbat it was not until the temperature of the water reacbed about 62 deg. that these diseases became epidemic in a district.

In order that it may be shown that it is not the effect of increase in atmospheric temperature that is instrumental in the propagation of diarrhœa and cholera, but that these diseases are governed hy the changes which take place in water when its temperature is increased, it may be pointed out that in districts in whicb the source of water supply is not liable to increase of temperature by reason of the arrangements adopted for its distribution, summer diarrhœa does not become epidemic. For example, we will take tbe three years 1877, 1878, and 1879. Both the years 1877 and 1879 (especially the latter year) were years in which the temperature of town water did not reach its most dangerous temperature, hut in 1878 the temperature of town water-supplies arrived at a high and dangerous degree of temperature.

The water distrihnted under the system of constant supply at the author's house in Croydon, when drawn direct from the mains, had, in 1878, a maximum temperature of 64·8°, and in Westminster the water supplied hy the Chelsea Water Company reached a temperature of 68·4°, while water taken from a cistern in Croydon had a maximum temperature, in the same year, of 71·5. In 1879 the highest temperature of the water in the cistern at Croydon already referred to was 67°; the highest temperature of the water as delivered from the mains in Croydon in 1877 was 61·7°, and in 1879, 60·7°; whilst in Westminster the highest temperature of the water in 1879 was 64°.

The deaths from diarrhœa in Croydon in the three years 1877–9 were as follows:—

1877 = 0·48	per thousand	living in the district.
1878 = 1·00	ditto	ditto.
1879 = 0·34	ditto	ditto.

In London the deaths from diarrhœa were:—

1877 = 0·70	per thousand	living in the district.
1878 = 1·02	ditto	ditto.
1879 = 0.52	ditto	ditto.

If these death-rates are compared witb the death-rates of districts in which the water is principally taken direct from wells, it will be seen that in these latter districts tbe death-rates are very much lower; as, for example, in the districts of Mitcham and Merton, which are partly supplied with water from artesian wells (of a uniform temperature of abont 54·6°), partly by surface wells, and partly by the Lambeth Water Company. These two districts have a population at the present time of abont 11,000 persons. In 1877 the death-rate from diarrhœa was ·39 per thonsand; in 1878, ·47 per thonsand; and in 1879, ·46 per thonsand. In Beddington, whicb is also principally snpplied from local wells, in 1877 the death-rate from diarrhœa was ·20 per thousand; in 1878, ·49 per thousand; and in 1879 there were no deaths whatever from diarrhœa.

For the three years 1877–9, in the districts of Mitcham and Merton, there were fourteen deaths from diarrhœa recorded, of which ten occurred in roads supplied with water by the Lambeth Water Company, and four in roads snpplied with water from sballow and artesian wells.

In order to further sbow tbat tbe temperature of water has an influence on bealth, the author placed upon a map the wbole of tbe deaths from diarrbœa whicb have occurred in Croydon during the eleven years, 1869 to 1879 inclusive. Tbe water-supply of Croydon proper is taken from wells, the range in the temperature of tbe water of wbich bas not exceeded 1·15°, its highest recently-observed temperature being 51·9° on the 19th of Jnne, 1880, and the lowest temperature 50·75° on the 15th of Decemher, 1878. The water, after leaving the wells at Croydon Waterworks, is pumped to a summit reservoir, from which it is distributed to tbe town. In order to raise the temperature of the water it is necessary for it to flow a certain distance through the distribnting mains before its temperature becomes affected. It is a significant fact that in the district within a mile of the reservoir in which tbe water is always at its coldest temperature in summer, during the whole period of eleven years not a single death from diarrhœa has taken place in the neighbourhood of the leading mains; but the distribution of the deaths occnrs in the most remote and lowest portions of the district, or those which are naturally subject to the greatest changes in the range of temperature of the water-supply.

The incidence of tbe deaths from diarrhœa in London and neighbonrhood also shows that this disease is due to the increase in the temperature of water-supply, and not to atmospheric temperature, as in all those districts supplied from the river Thames, the water naturally gets to its highest temperature at an earlier period than it does in those districts supplied from wells, as in the Kent Water Company's district, where the temperature of the water at its source is pretty nniform throughout the year, and in wbich the water is naturally colder in snmmer at starting through the mains than is the case with the river water. An examination of the mortality tables of London shows that, while the general mortality from diarrhœa in districts supplied hy the Kent Water Company and the river water companies is practically identical, the disease always first manifests itself in the district taking water from tbe Thames. For example, in 1878, diarrhœa may he said to bave been epidemic in Lambeth, supplied hy river water, in the week ending Jnne 29th, and got to its highest pitch in the week ending July 27th, whereas in Greenwich, supplied by the Kent water, this disease did not become epidemic until the week ending July 27th, and got to its highest pitch in the week ending August 3rd, showing the incidence of this disease to he later in the Kent Water Company's district than in the district supplied from tbe river Thames, the reason being that, as the water of the Kent Company is colder tban the Thames water, naturally it requires the ground to be raised to a bigher temperature before it reaches a dangerous point, and therefore tbe incidence of the disease falls later in the Kent district than in the districts supplied from the river Thames. The development of the disease in these districts is also conformable to water being the cause, and not general atmospberic increase in temperature; for if the cause were due to atmospheric influences, which are general, the incidence of the disease should have fallen at the same period in each district; hut as the incidence is stricty conformable to increase in temperature of the respective water-supplies, and does not conform with atmospheric causes, the inference to be drawn is that summer diarrhœa is governed by the influence of the temperature of our water-supplies, and invariably the disease becomes epidemic when the water, whatever he its source of supply, reaches a temperature of about 62°.

Having now shown that water may be affected for good or evil hy reason of its temperature, and baving shown that the earth has enormous powers of influencing the temperature of water-supplies, the author desires to point out a mode hy which tbe temperature of

* By Mr. Baldwin Latham, C.E., read at the British Association Meeting, Swansea.

the earth may he made nss of in order to give watar a nearly uniform temperature throughout the year, which, if brought into general operation, the author believes will remove these dangerous conditions of town water-supplies arising from an increase of temperature in the summer time, and also, possibly, from the extreme coldness of the water in winter periods, which affect public health.

The great changes of temperature in the earth occur within a few feet of the surface. The greatest range of temperature occurs at the surface, and as we pass downwards from the surface to a depth of from 30 ft. to 35 ft., the temperature becomes nearly uniform throughout the year, and at the point of uniform temperature the temperature is equal to the average yearly temperature of the place where the observations are made.

From a number of observations made by the author at depths varying from 6 in. to 50 ft., it is shown that at a depth of 20 ft. the coldest temperature is experienced in the middle of May, and the warmest temperature at this depth at the end of October. The range in temperature observed at this depth is 5° in Croydon. At 25 ft. in depth the coldest period occurs at the beginning of July, and the warmest period in the winter, the range in temperature being a little over 1°. At a depth of 30 ft. the coldest temperature occurs in July. If an apparatus similar to that which has been invented and patented by Professor J. T. Way and the author is used for tempering the water, and which consists simply of a vertical tube driven or screwed into the ground to a depth of about 25 ft. and the water or other liquid to be tempered is admitted at the top and withdrawn at the bottom of the tube, special arrangements being adopted for the protection of the ascending pipe, the range of temperature in the water required for dietic purposes need not exceed 3° throughout the year when drawn from a 3 in. tube at a rate not exceeding one gallon every half-hour. The range of temperature observed in cistern water at Croydon has been 38·7°, or on the 22nd of July, 1878, it was 71·5°, and on the 20th of January, 1880, it was 32·8°. The town water-supply of Croydon (drawn direct from the mains), the temperature of which has been shown to be nearly uniform at its source in the wells when distributed by a system of constant service, was shown to be 64·8° on the 22nd of July, 1878, and 37·2° on the 28th of January, 1880, giving a range of 27·6°.

In the tempering tube, when the conditions of the water-supply are at the worst, the underground temperature is favourable for modifying these dangerous conditions. The cold of winter only descends to the greater depths in the heat of summer, and the warmth of summer only descends to the greater depths in the winter-time, so that the temperature of the cold water of winter is raised by the previous summer's heat, whilst the warm water of summer is cooled by the previous winter's cold temperature.

Experiments made at the author's house in July, 1880, show that if ten gallons of water are drawn at any time within half an hour, the following results are obtained :—

1st gallon. Temperature of water going into tube, 68° 4′; and the temperature of the water coming out was 50° 4′.
2nd gall. Temperature was reduced from 68° 2′ to 50° 8′.
3rd gall. Temperature was reduced from 68° 2′ to 51° 7′.
4th gall. Temperature was reduced from 68° 0′ to 52° 4′.
5th gall. Temperature was reduced from 68° 0′ to 53° 3′.
6th gall. Temperature was reduced from 68° 0′ to 54° 2′.
7th gall. Temperature was reduced from 68° 0′ to 55° 0′.
8th gall. Temperature was reduced from 68° 0′ to 55° 8′.
9th gall. Temperature was reduced from 68° 0′ to 58° 4′.
10th gall. Temperature was reduced from 67° 9′ to 57° 2′.

These experiments have been repeated several times, and give precisely identical results. In the winter the water is raised in temperature; as, for example, on the 3rd of February, 1880, water going into the tube had a temperature of 34° 8′, and coming out a temperature of 49° 2′.

The advantage of the use of this apparatus consists in the fact that it is entirely self-acting, and the whole of the water supply necessary for dietetic purposes may be filtered, purified, and tempered without any greater cost than now incurred, after the first cost of the apparatus, and without adding anything of a deleterious character to the water, as may be the case when ice is used, which has been shown, especially in America, to be a prolific cause of disease when collected from impure sources. Moreover, the results secured by the tube are more than equal to those attained by the most bountiful use of ice, and further, it is delightful if, by the use of ice in water already subject to influences that are deleterious to health, the time allowed before the water is consumed is sufficient to destroy the noxious properties. In the case of the patent tube, however, a mass of water is gradually undergoing the process of tempering in a perfectly natural way until it arrives at a temperature which is shown by experience to be most healthful.

THE ANTIQUITIES OF THE PYRENEES.

AMONG the papers read at Swansea before the British Association was one by Dr. Phené, "On the Retention of ancient and prehistoric Customs in the Pyrenees." We print a portion of it bearing on statements already made by the writer in our pages :—

It would be too long an occupation of the time of the section to enumerate all the objects, evidently of ancient Celtic arrangement or construction, the quaint churches of the Templars, and the various customs found in these valleys, but on the crests and sides of the mountains, on both sides of the Pyrenees, *i.e.*, in Spain and France, are found sepulchral arrangements of stones, somewhat different to any distinctly recorded amongst our antiquities. These consist of a number of circles adjoining each other, in the centre of each is a cist with an urn, having burned bones, and the form of the circles is that of a wavy or serpentine cross.

Mons. Gourdon gives a drawing of one on the Spanish side, and I have found several on the French side of the Pyrenees.

The quaint old customs of early Celtic life are kept up all along the Pyrenees, but not in the towns in the plains or champagne country,—one of those which I described last year as still existing in Brittany, that of a wooden tally, in lieu of a bill or account, on which the baker marks by notches the number of loaves he supplies, and which attracted the attention of the President of the section last year, is also existent in the Pyrenees. I purchased the baker's bill, now exhibited, at Perpignan a few months ago, and though not so rustic as that of Brittany, it approaches more to our old Exchequer tally, and to the Welsh stick of writing, described in "Bardas," as well as to some elaborate and really wonderful calendars, still to be seen in the Chesthan Museum at Manchester, than to the rustic tally of Brittany. On crossing into Spain and proseconting inquiries, I found the serpent or dragon emblem every where prominent, and even learned that the Tarasque, the ceremony of which is performed at Tarascon, in Provence, of which I gave a detailed account last year in the *Builder*, was a well-known dragon with the Spanish people, and on my explaining that I was making a study of the subject, I was told that though used as a popular diversion at fêtes, it had always a religious meaning, and that an old and well-known Spanish proverb ran thus :—

"*No hay funcion sin Tarasque.*"
"No religious solemnity without the dragon."

The prevalence of this custom in Spain, and the crowded and multitudinous emblems, of this nature, indicate some strong pre-existing national feeling or worship, and perhaps explain a very extraordinary ceremony that takes place annually on the French side of the Pyrenees when on the eve of St. John, the whole Pyrenees being alive with the fires handed down from time immemorial as a custom, a vast pine split into many vertical clefts, is raised at Luchon, and along the route I have described in the most secluded valleys, quite up to the Spanish frontier, as at the Valley du Lys, the pine has a cross of flowers on its summit, and being filled with combustible matter, burns in a brilliant column of fire. The torch is applied by the principal ecclesiastic, after a procession from the church-door, amid the chanting of a litany.

But at Luchon, in particular, living serpents are consumed in the flames. The priest, while he applies the torch, turns his face towards Spain and the Maladetta, or mountain of bad omen. The youths of the village have miniature cloven pines which they burn. I procured one with some little difficulty, which I produce; these they brandish while flaming, in serpentine curves, and cry loudly, "hilla-hilla" (dead),—pronounced "*ella*." Here we have apparently a corruption of the old classic cry of the Bacchanals, who, when lamenting the death of Bacchus, holding serpents in their hands, rushed about wildly crying "Eva, eva." These ceremonies are often prolonged into the night, and the wild cries are heard echoed from mountain to mountain. M. Sacaze states that this cry is an invocation of the Sun God; he that as it may, it is the cry of the ancient Bacchanals, and is here accompanied, sometimes with real serpents, sometimes with simulated serpents of fire.

The split pine was this year raised in my presence, on the back of the principal serpent mound in the valley I have mentioned, amidst the clanging of bells during a service on Sunday. If there had been no other satisfaction to me in this, the evidence that this mound was artificially constructed, and not a natural formation, as shown by the cutting made into it, would have been great. The place where these cries are mostly practised has most remarkable sculptures of serpents, which I had photographed, and now produce.

After the burning of the pine a rush is made by the more powerful, and the burning embers are carried off in their hands regardless of pain. Pieces are then distributed to every household, and kept religiously during the year, as was the custom with the ancient Britons.

SIR JOSIAH MASON'S SCIENCE COLLEGE AT BIRMINGHAM.

THE Gothic buildings erected by Sir Josiah Mason's trustees as a science college for Birmingham and the district, are now very nearly complete in all their internal arrangements, and the institution is to be opened on the 1st of October, with an introductory address by Professor Huxley, the winter term commencing on Monday, the 4th of October. The buildings have a frontage of nearly 150 ft. to Edmund-street, just in the rear of the Town-hall and the site upon which the Free Library is being rebuilt. The front is built of red brick, with Portland stone details. The elevation, which is divided into four parts, rises in the centre to a considerable height, the walls of the upper floor receding sufficiently to allow of a passage guarded by a pierced parapet. On the ground floor in the centre is the large entrance gateway, and on each side, a pair of windows lighting the janitors' rooms and clerks' offices. There is a projecting stone balcony over this gateway, and on the next floor are the six large and lofty pointed windows, which will light the chemical lecture-room. From this floor rises a large bay window, resting on a series of corbels, and above it, dividing the attic story, a small gable, terminating with a turreted niche, the point of which is 122 ft. above the level of the street. Portions recede from the predominant central block, at the extremities of each of which are projecting wings terminating in lofty turreted gables. These projecting wings reach a height of 90 ft., and have three windows grouped together on each floor. The intermediate portions between the gables and central block are lower, being about 55 ft. in height. About 2,400 square yards are occupied by the present building, but when the original plans are fully executed, the edifice will occupy nearly double that area, the extension being made in the rear. At right angles to the block fronting Edmund-street three parallel blocks recede upon the sides of two open courts, and are joined at the south-west by a wing parallel to the front block. The buildings are therefore arranged almost in the shape of a double parallelogram, the central block, which extends from Edmund-street towards Great Charles-street, forming one of the sides for each. The ground floor is entered from Edmund-street by a large and lofty gateway with deeply-recessed shafted jambs and moulded arch, and the main corridor, in which the visitor finds himself, will be eventually continued into Great Charles-street in the rear. The groined arches and moulded ribs rest on dwarf columns, carved capitals and spandrels, and geometrical tracery. The landing on the ground floor, which is reached from this point by ascending a broad flight of steps, is 6 ft. above the level of the street, and from it runs the wide central corridor, another corridor extending in a transverse direction along the Edmund-street frontage, having at each end a staircase leading from the basement to the top of the building. Further down the central corridor, the main staircase is situated, opening to the right, with an arcade of four arches on granite columns, and communicating with every story. Beyond this, the corridor passes into the back range of buildings,

the doors on one side opening to a library and reading-room, and on the other to the physical laboratory. The first floor contains the chemical lecture-room, three other large lecture-rooms, chemical preparation-rooms, professor's apartments, class-room for magnetism, rooms for chemical collections, models, and apparatus, the lecture-rooms being exceedingly handsome and commodious. In the south-west block at the back are several large rooms for drawing. The floors above are entirely devoted to chemistry. In the front block a spacious apartment is set aside as the professor's laboratory, and there are also rooms for the study of organic chemistry, and for gas, water, and spectrum analysis. A large room, formed principally in the roof of the central front block, will be used as a museum for collections of specimens in connexion with the chemical department. There are, in addition to those already mentioned, about twenty-four smaller rooms for professors' assistants, classes, &c., and on each floor opposite the principal staircase are the necessary class-rooms and lavatories. The college contains in all nearly a hundred rooms. The several laboratories will be plentifully fitted with small and large evaporation niches for the removal of injurious vapours and gases, and with the fittings necessary for the various studies.

PROTECTION OF BUILDINGS FROM LIGHTNING.

Mr. Richard Anderson read a paper at Swansea "On the necessity for a Regular Inspection of Lightning Conductors," which demands attention. The closing passages of it will sufficiently explain and emphasise his object:—It is evident that it is not sufficient merely that rods of copper should be attached to a building, but it is necessary that once put up they should be regularly inspected to see if they are in good order, so as to be really efficacious. That this is rarely done is one of the main reasons why accidents by lightning occur in places nominally protected by conductors. It is, perhaps, not too much to assert that at present not one in a thousand of our public buildings in England is regularly tested.

There can be no manner of doubt that in the matter of lightning conductors they manage things better on the other side of the Channel than with us. The French Government are in the constant habit of consulting the most eminent scientific men on the subject of protecting public buildings against the destructive influence of lightning. There is scarcely an instance in which a British Government ever did such a thing. It is true the Houses of Parliament had lightning conductors erected upon them at a very great cost and under scientific advice. But all who understand the subject practically agree in saying that it is very doubtful whether the magnificent pile of buildings in which our legislators assemble is really, that is efficiently, protected. At all events, I understand the earths have never been tested since the conductors were erected in 1852. That the Victoria Tower should have been struck in June, 1868, and slightly damaged, tends to show that the conductors at that time were not in an efficient state.

From the examination I have made, I am pretty correct in stating that one-half of our cathedrals and three-fourths of our churches have not even nominal protection. For all that science has done, the Queen might any day be killed in her apartments in Windsor Castle, the Prince of Wales in Marlborough House, and the Prime Minister in Downing-street. To see the difference between England and France in this respect, one has but to cross the Channel between Dover and Calais. At Dover, there are huge barracks of great length, on the top of high hills, exposed to the full fury of storms sweeping across the Channel, and the few conductors to be found upon them at long intervals are certainly not numerous enough for efficient protection against lightning, and their efficiency has never, so far as I can learn, been tested. The contrast in this respect on crossing the Channel is of the most striking. At Calais, the Hôtel de Ville, in the Grand Place, literally bristles with lightning-conductors, and so all the churches and chief buildings in the town. The same all over France, Germany, and Belgium. Without slavishly imitating our scientific neighbours, we might yet bestow some of the care they do upon the protection of our property as well as our lives against the terrible effects of the electric force.

NEW WESLEYAN SCHOOLS, TOTTENHAM.

These schools are built on a fine open site in the rear of the chapel, having frontages on each side for light, and therefore the architect had ample scope for planning them. They are on the American system, and faced with Kentish rag stone and Bath dressings, with all the class-rooms opening into a large central room. This room has an open-timbered roof and is lighted by windows at each end high up in the gables, and by dormers at the side. On each side of the platform are rooms for select classes, with separate entrances to them. The four class-rooms in front of the platform are for single classes, and each has a window and a fireplace. An infants' room, with separate entrance, is provided, and divided by the library from the school proper. A secretary's room, kitchen, with serving-hatch to the school, and heating chamber are also provided. Offices for the children are carefully arranged with distinct entrances. The school will accommodate 500 children, and seems to be very complete. The warming is by Grundy's hot-air system. The architect is Mr. Charles Bell, of Dashwood House, New Broad-street; and the builder, Mr. Humphrey, of Tottenham. The total cost, including furnishing, will be nearly 3,000*l.*

NEW (R.C.) PRESBYTERY, ORMSKIRK.

This presbytery, now in course of erection for the Rev. J. A. Hickey, O.S.B., is being built with the local red bricks. The cills of windows and weatherings to chimney and cap are the only portions of the building which are of stone. The roofs will be covered with green slates, as also the roof of the corridor which leads from the house to the sacristy. Most of the internal fittings will be of pitch-pine. It is being erected from the design, and under the superintendence, of Messrs. Pugin, architects, Westminster. The total cost will be about 1,522*l.* Messrs. Thomas Riding & Son, of Ormskirk, are the contractors.

RE-ARRANGEMENT OF EXETER HALL.

The two plans we publish will serve to show the chief alterations proposed to be made for the Young Men's Christian Association, under the scheme proposed by Mr. Alfred R. Pite, and which has been determined on. The prominent features of the scheme are,—1. The utilisation of the entire basement. 2. Ground-floor alterations, appropriating the whole area for the Association work: this would comprise spacious reading-room and reference library, with arched recesses for readers, and glazed screens to corridor, convenient coffee-rooms with domestic offices, and arrangements for the enlargement of the lower hall. 3. The mezzanine floor still reserved in its entirety for offices, calculated to secure a valuable rental, or available at any time for class-rooms. 4. The re-arrangement of the large hall, to secure increased accommodation and facility of egress and access, for which latter two spacious staircases are provided, with lavatories accessible for festival occasions. In the *basement* there will be a double gymnasium on the north-side, 28 ft. in height, with access direct to new staircase to Exeter-street and ground-floor; a lecture-room on the south side, capable of accommodating 200 persons, and suitable for tea-meetings, being adjacent to class-rooms, and accessible immediately by new staircase from the front lobby of the Strand entrance, and spacious night-schools, capable of accommodating 300, having also accessory class-rooms.

The *ground-floor*, of which plan is given, presents the largest aspect of alterations to the building, as the whole of the existing offices would be utilised for Association work. On entering the main corridor, by grand staircase, will be found an improved entrance vestibule. A margin of new Portland stone paving will be laid throughout, with a central footway of bright coloured tiles and borders up to the main stairs, which will be cased with Hawksley's patent, the landings being lined with ornamental tiles. Turning from corridor eastward, access will be gained by a staircase to the basement lavatories, and immediately opposite will be the secretary's office, from which point supervision will be exercised over all persons entering the building. On the south-east side a handsome reading-room is obtained, with arched recesses for readers, and glazed screens to corridor, communicating direct with reference-library. For special meetings, the reading-room will be capable of accommodating 250 persons. On the north side the offices are obliterated, and a spacious coffee-room obtained with arcaded recesses for tables, and glass partitions to corridor, all in direct communication with a buffet, having counter and still-room, and the doors opening at foot of main staircase for convenience of large hall. The coffee-room would provide space for a special meeting, to hold 250 persons. The kitchen is made external and placed at the north-east angle of the hall. On the south side, adjoining the secretary's office, and approached by a new corridor, "The Young Men's Parlour" is placed, having central communication direct with the lower hall.

With regard to the Lower Hall the present plan shows the whole area of the present main corridor, above and below, thrown into the hall: this allows a spacious gallery, and taking the present accommodation of the hall to be 450, the enlargement would provide for 770 persons. A second method of enlarging the hall is based on the fact that it is only on exceptional occasions that the large hall and lower hall have meetings proceeding simultaneously, in which case the carriage corridor would be, if not an essential, a great convenience, and to meet this a dado division is placed on dotted line, being the area of the present hall. By this arrangement the corridor egress would still be maintained, and the hall with enlargement provided by galleries over the corridor would accommodate 650 persons. The approach to the lower hall will be improved by an entrance of more dignified character than the present. The gallery to the lower hall will be approached by a new staircase, provided at the south-west corner, and a new lobby-entrance to the corridor.

The saloon off the grand staircase remains untouched; when appropriated for meetings it will accommodate 250 persons. It is proposed to lower the present staging seats to the large hall, and place the floor on an inclined plane from its present central level, but reducing the height. Easy access and egress will be obtained by the two additional staircases. The present platform is to be re-arranged to accommodate 200 persons for public meetings and conferences, having movable seats as fitted fixtures to be placed when required on staged floors for orchestra, so that the conductor of the festival would have the platform placed in position to secure entire control of both the area and seats. Access to ladies' galleries, level with platform, with stairs to the latter are provided, from the north and south retiring-lobbies, while the existing staircases to the organ will remain. By this arrangement of platform, orchestra, and galleries, large gatherings of schools or public institutions can be held without interfering with the body of the hall, and immediate exit will be obtained by the staircases provided.

The expenditure will probably amount to 15,000*l.*

WELSH CALVINISTIC CHAPEL AND SCHOOLS, PENDLETON, MANCHESTER.

These buildings, which have been lately completed, were designed and carried out under the superintendence of Mr. W. Dawes, architect, Manchester. The chapel accommodates 305 on the ground-floor, and 258 in the galleries. Including the schools and chapel-keeper's house, the cost has been about 5,500*l.*

Artisans' Dwellings in Liverpool.—It has been decided by the Liverpool Health Committee to recommend the council to communicate with the Local Government Board, requesting them to approve of the erection by the council, upon the Nash Grove site, of dwellings suitable for the labouring and other classes. The site was cleared, some time ago, of low class and unhealthy property, and the engineer is of opinion that shops fronting the main streets, and improved industrial dwellings, would be the best class of buildings. The estimated cost of carrying out the scheme is 115,000*l.*, the annual expenditure on the property, including interest on the original outlay, repairs, &c., is estimated at 5,377*l.*, and the receipts from rents at 4,259*l.*, showing an annual loss of 1,118*l.* On the other hand, the Markets Committee have recommended (as stated in the *Builder* some time ago), that the site be utilised for the erection of wholesale vegetable, fish, and poultry markets.

WELSH CALVINISTIC CHAPEL, PENDLETON, MANCHESTER.——MR. WILLIAM DAWES, ARCHITECT.

THE HÔTEL DE VILLE, PARIS.

As early as the eleventh century,—at the epoch when in certain provinces the enfranchisement of the communes commenced,—as soon as a city obtained by gold the concession of a charter from his majesty the king, the inhabitants erected a municipal building surmounted by a belfry,—symbol of independence. When the town was menaced, the tocsin was sonnded from the belfry, and the citizens flew to arms, and united together for the general defence.

The Hôtel de Ville of Paris, however, dates no further back than the fourteenth century. It was in 1357 that Étienne Marcel bought, at the cost of the municipality, a house styled the *Hôtel du Dauphin*, later on the "House with the Pillars," and there was held the *Parloir aux Bourgeois*. It was quite near to the Châtelet, and on the site where, later on, in the sixteenth century, the great Hôtel de Ville was destined to be built.

At the commencement, this meeting-house of the citizens consisted, says Sauval, one of the historians of Paris, of a little dwelling surmounted by two gables, and which abutted on to several other domiciles. This building, in which a number of pillars supported the first story, was bought by the Provost of the Trade Guilds for the sum of 2,800 *livres* (of Paris). It contained a state reception-room, an audience-chamber, called the *plaidoyer*, a wainscoted chapel, and a large loft for the arms.

Towards the end of the fifteenth century, notwithstanding reparations, the "House with the Pillars" threatened to fall into ruins, but they managed to preserve it until the reign of Francis I. At length, however, on the 15th of July, 1533, the first stone of a new edifice, the Hôtel de Ville, was laid with great ceremony by Pierre Viole, Provost of the Trade Guilds, assisted hy four sheriffs. While the first stone was being laid, "the fifes, trumpets, tambourines, and clarions were heard; guns too,—fifty arquebuses, carried hy the arquebusiers of the city, who are numerous; and the chimes rang out from the bells of St. Jean en Grève, Saint Esprit, and Saint Jacques de la Boucherie. In the middle of the Place de la Grève casks were tapped, tables laid out, bread and wine given to all comers, while the lesser folk cried with a loud voice, 'Long live the King, and Messieurs of the City.'"

The Italian Dominique Boccador, called of Cortone, had drawn out a plan of the edifice, of which the works, interrupted or suspended hy the religious wars, were resumed in 1606, by an architect named Marin de la Vallée.

In the reign of Louis XIII., in 1628, this monument was completed. It consisted of a central block of buildings surrounding a quadrangular court. The central building was composed of a ground-floor and a first story. The two angle pavilions had one story more. The frontage was pierced with square or arched windows, with columns and ornaments of every description. A stone staircase placed beneath the clock led to the inner court.

It was for a long time a question as to yet further enlarging this fine building, but the project propounded during the First Empire was not put into execution until the reign of Louis Philippe.

The buildings erected from 1837 to 1844 retained the physiognomy of this historical monument, but they doubled the extent of the ancient façade, and formed an enclosure of immense extent. Mr. Godde, architect to the city, assisted by Mr. Lesueur, superintended the building. It contained rooms for the municipal assemblies, offices for the communal and departmental administrations, saloons and galleries for *fêtes*, reception-rooms, and an apartment for the Prefect of the Seine. The edifice formed a rectangle, of which the great sides presented a development of 120 mètres in length hy 80 mètres in hreadth. Niches with pediments between the columns, contained statues of those men who had done something illustrious for the town of Paris. On the ground-floor was the immense Salle St. Jean, where the city lotteries were drawn. All the rooms were richly decorated, and presented a magnificent *ensemble*. We well remember the admiration that was expressed by a large number of our countrymen who were entertained here hy the City of Paris, after the Great Exhibition of 1851.

The important part the Hôtel de Ville has played in the history of Paris is well known to readers. And we have not space here to retrace incidents, though they are full of interest. We will only recall to mind that on the 18th of March, 1871, the Central Committee installed itself here, and in turn gave place to the Commune on the 26th of March. During the month of May the members of this Government maintained their position at the Hôtel de Ville up to the last moment; but when they were no longer protected by barricades they fled, after setting fire to this monument—essentially the "people's"—and scene of so many great deeds. All had been so well prepared for the conflagration, that there only remained of the Hôtel de Ville a few blackened ruins.

It was the palace of the citizens and of the traders of the city, and this building, which had so often opened its doors to receive a victorious people, was destroyed by the people. But the idea of raising it from its ashes could not be abandoned. In 1873 the Government invited designs in competition for the reconstruction of the Hôtel de Ville. Sixty-six projects were presented, and from these a special jury selected that of Messrs. Ballu & Deperthes. We give a view of the new building, which will now soon be completed.

The edifice is erected on the site of the old one, and is essentially the same, with a few slight modifications. A greater development is given to the façade and to the wings, which have a different disposition. But the general aspect is the same, and now Parisians will once more he able to see their Hôtel de Ville,—"The belfry-house" of the old city.

THE WORKING GILDERS OF LONDON.

A MEETING of working gilders and "preparers" in the looking-glass and picture-frame trade was held in the Lectnre Theatre of the schools of St. Thomas, Charterhouse, Goswell-road, on Monday evening last, "to consider the causes of the great depression in the trade at the present time." The chair was occupied by the Rev. Stewart D. Headlam, B.A. About 150 men and youths were present.

Mr. George Ryan, at whose instance the meeting was convened, made a short statement as to the object of the gathering, saying that for the past three years the trade had been in a most depressed condition, partly caused hy the very large importation of German mouldings and the extensive use in this country of "Dutch metal" instead of gold leaf. He read a letter from a tradesman at the West End showing how the public were being deceived by the employment of "Dutch metal," instead of gold, in decorative work, with the inevitable result that in a very short time the so-called "gilding" would turn quite black, and suggested that both in picture and looking-glass frames and decorative work the public might protect themselves by testing the work with aquafortis.

The Chairman having invited others present to speak as to the causes of the depression in the trade, and to offer suggestions for improving the condition of its members,

Mr. Shaw pointed out that although the use of "Dutch metal" and German mouldings had a great deal to do with the low condition of the trade, other causes had been at work, notably the use of oak, walnut, and ebonised frames, and the large demand for what were called "Oxford" frames, which were seldom gilded. He hoped and believed that when the public knew the worthlessness and want of durability of work coated with Dutch metal they would insist upon having genuine gilding.

Mr. Hamer thought that the evil was more deeply seated than some present seemed to think. The use of "Dutch metal" would, he believed, eventually do the gilders a great deal of good, for the failure of the baser material would lead the public to demand honest gilding. Unfortunately, there was foreign competition in the trade in other ways, many young Germans being at work in gilders' shops in London. In his opinion, the low condition of the trade was entirely due to its want of unity and organisation. There was no limitation in the trade as to the number of boys employed. He had been in gilders' shops in London where there were ten boys to every man employed. It had been suggested that a good strong society should be formed for the gilders of the East End of London, but that, though perhaps desirable in itself, would not increase the demand for gilders' work.

Mr. Rayment contended that the use of German metal was doing a great deal of good, inasmuch as it afforded employment for many gilders who would otherwise be doing nothing. There was a demand for very cheap picture and looking-glass frames, and so long as "Dutch metal" was sold as such, and not palmed off upon the public as gilding, there was little to complain of. As to German mouldings and "Dutch metal," it had been suggested that a protective import duty should be put upon them, but surely such a departure from Free Trade would only make matters worse by keeping out of England materials which, though very cheap, yet afforded employment to many people in the gilding trade.

Mr. Hamer said that the only good which the use of "Dutch metal" did for the gilding trade was that it turned black within a very short time. With the use of "Dutch metal," forty men could turn out as much work in a week as could be done by 100 gilders in the same time.

Mr. Williams said a lot of people in the trade grumbled about metal-gilding because they could not do it (cries of "Why, boys do it!"). It took a good mechanic to do a "metal" frame, but a "duffer" could do a gilt one. (Loud expressions of dissent.)

Mr. Mills said any child could do a "metal" frame, but it took a gilder to gild with gold. In his opinion, the great cause of the depression in the trade was the competition amongst the small master-men, known in the trade as "garret-masters," who so underbid each other in the price at which they would take work that they could not afford to pay fair wages to journeymen.

Mr. Thacker, as a small master for sixteen years, admitted that the condition of the trade was very bad. He found it impossible to earn 4s. a day for himself, even though he employed ten men. He should be better off as a journeyman.

Mr. Hamer said that one great object which the establishment of a trade society for the gilders of the East End of London might advance was the reduction of the number of hours worked hy members in the trade, which were sixty per week. That should be reduced to fifty-four per week. The work would he then more evenly distributed amongst the men in the trade.

Upon this several speakers pointed out that if the men in the gilding trade worked only fifty-four hours per week they must not expect, under the present conditions, to earn as much money as when they worked for sixty hours.

A great deal of animated discussion ensued, in the course of which it was stated that the gilders of the East End of London, though forming the majority of the trade in London, were without a trade society; that the gilders of the West End had one or more societies, and would doubtless he willing to help their brethren of the East End if the latter showed a desire to unite and sink minor differences; that a former attempt to maintain a society at the East End had failed from lack of support, although the contributions were only 1d. per week; that this failure was entirely due to lack of unity caused hy "jangles" between members working in different shops. One speaker attributed the depression in the trade to the use of velvet coverings for furniture in lieu of gilt surfaces,—a fashion which, amidst much laughter, he reproached High Church clergymen for introducing. Eventually, resolutions were passed appointing Messrs. Mills, Colloppy, Wyndham, Shaw, Brown, Thorpe, Williams, Wilson, Carpenter, and Richard Thacker a provisional committee (with power to add to their number) to confer together and take steps for the formation of a trade society for the gilders of the East End of London, and it was arranged that a trade meeting be held in the same place on Monday, September 20th, to consider the proposals of the committee, and, if such proposals were approved, for the enrolment of members.

The meeting terminated with brief addresses by the Chairman and Miss Edith Simcox, who referred to the influence of "fashion" on the trade, and exhorted the men to exercise forbearance and to he united for their common good.

In the course of the proceedings it was stated that whereas a book of gold-leaf, costing 1s. 3d., contained only twenty-five leaves $3\frac{3}{8}$ in. square, a book of "Dutch metal," costing only $4\frac{1}{2}$d., contained no fewer than ninety-nine leaves, each $\text{fi}\frac{1}{4}$ in. square. It was, therefore, urged that the public were grossly swindled when they paid for gold and only got "Dutch metal." A show of hands called for during the meeting revealed the fact that nearly one-third of those present were out of work.

SWANSEA WATERWORKS RESERVOIR.

ONE of the excursions made by the members of the British Association during the recent meeting of that body in South Wales was to the Swansea waterworks, where Mr. Edward Cousins, M. Inst. C.E., read a paper embodying some notes on the construction and repairs of the Lliw reservoir, Swansea. He said,—

The Act of Parliament giving powers to the Swansea Town Council, as the Urban Sanitary Authority, to construct reservoirs, on the Llan Lliw and Blaenant Ddu streams, and for laying conduit and mains for conveying water to Swansea, was obtained in 1860. The Town Council thereupon determined to proceed, in the first instance, with the construction of the Lliw reservoir only, and contracts were entered into, and the works commenced in the month of March, 1862. The reservoirs are constructed in valleys of denudation in the coal measures, the strata consisting of alternating beds of rock and shale. The workable seams of coal beneath the reservoir site being at a depth of about 500 ft., the surface of the valley being covered with alluvium, but only to a moderate depth. Through the whole length of these valleys there are springs of water, some permanent, but others which only flow after long-continued rain, the surface-water entering fissures in the exposed joints of rock, and finding an outlet at lower points. The Lliw embankment has a base line in the direction of the valley of 425 feet, with a puddle trench in or about the centre, carried at the deepest part 99 ft., the lower portion being in rock. In this rock there were thin open joints and small springs of water, and on the outer half of the embankment seat other small springs exist, all of which were drained to a common outlet into a permanent drain cut in the rocks and covered with lime concrete. The bottom of the trench was also directed to be formed with concrete so as to prevent injurious action of the small springs on the bottom of the central puddle wall. The drain from the outer part of the embankment delivered a steady flow of clean water, increased after heavy rain, but unaffected by any head of water in the reservoir. The volume of water varied from 27,360 gallons per day to 54,720 gallons, after much rain. This water went to provide compensation. The contingency of springs of water in puddle trenches and beneath the outer portions of embankments is common to most reservoir embankments of considerable size, and these are usually provided for in some such way by drains as here indicated. There are, of course, springs of water within the puddle wall, that is, over the area covered by the inner half of the embankment as also that area covered by the impounded water. The Lliw Embankment was completed and the reservoir filled to overflowing in October, 1867, impounding about 300,000,000 gallons of water, the depth from the full water-line to the surface of the ground being 66 ft., and to the bottom of the puddle-trench 94 ft. The reservoir continued in work, and apparently water-tight up to February, 1873. In the spring of 1873, violent and heavy storms of rain occurred, and apparently water found its way by seams and fissures to the bottom of the puddle-trench, and ultimately to set up a small flow of water from the reservoir through the leak thus formed. That some action must have caused such leak was shown by the outflow of water from the embankment drain becoming turbid. When, by examination and continued observation, it was made evident that a leak had been sprung, the head of water within the reservoir was reduced, the action of the drain carefully watched, and the results duly recorded. It was noted that the action was intermittent; that is, the leak varied in turbidity from time to time, and the volume escaping increased as the head of water in the reservoir increased. About January, 1874, it was noted that visible subsidence in the embankment had commenced, when extra care was taken to reduce the head of water in the reservoir, and to watch the flow from the drain. It became evident that the leak was not likely to stop, and as water was necessary for Swansea, the Blaenant Ddu reservoir was commenced, and when completed, tested, and found to be sound; means were then at once ordered to be adopted to restore the Lliw to its original state. This work was commenced in June, 1879, and will be completed about the end of October next. The method adopted in repairing the embankment was as follows:—An open cutting was made transversely through the embankment 160 ft. wide at the top, and 50 ft. wide at the bottom, to a depth of 36 ft. below the top of the embankment. A trench 30 ft. long and 20 ft. wide was then sunk from the bottom of this cutting through the puddle wall to the rock, a depth of 70 ft., or a total depth of 106 ft. from the top of the embankment. In sinking this trench, indications were soon observed that the puddle wall was fractured. The fractures as at first discovered were small and branching, and were filled with sand formed by the washing of the selected material from the inside slope of the embankment. At a depth of 24 ft. in the trench, the puddle wall was found completely punched through, and this fissure (which was about 2 ft. wide) was filled up with the coarser parts of the selected material of the embankment. This fissure extended down to the face of the rock where a spring was discovered that had evidently, during the extraordinary rainfall in 1873, burst through the layer of concrete on the rock at the bottom of the puddle trench. The spring must then have acted directly upon the base of the clay puddle wall until it formed a passage across the bottom of the puddle-trench, thus allowing the water in the reservoir to find its way through the puddle-wall into the drains underneath the outer slope of the embankment, the outlet of which is at the base of the bank. This continual wearing and washing-away process of the clay-puddle caused it to settle down from time to time, resulting in the puddle becoming fractured, and the pressure of the water in the reservoir caused the material from the inside slope of the embankment to wash into and fill up these fractures in the clay wall. Having proved that the defect was confined well within the extent of the trench, it afterwards became necessary before commencing to refill the trench to make provision for relieving the pressure of water arising from the spring, and for this purpose the rock at the bottom of the trench was excavated to sufficient depth, and the drains were constructed over the several fissures conveying the water to one point, from which an iron pipe was laid, passing up the shaft to a height of 17 ft., and passing thence through a heading to the drains underneath the outer slope of the embankment. The brick drains and the whole area of the bottom of the shafts were then covered with a layer of Portland cement and afterwards with Portland cement concrete, which was carried up to the level of the old concrete. After this was completed, the drains and pipes were tested, when it was found that the spring water rose to a height of 17 ft. through the iron pipes, and then discharged itself into the old drains underneath the embankment without the slightest indication of any escape of water at the bottom of the shaft. The trench was then filled with fresh pugged clay puddle, and well rammed by means of hand rammers and a monkey, weighing 1¼ cwt., with a fall of about 6 ft. The new clay was put into the shaft with a very little admixture of water, in order to obviate as much as possible any subsequent settlement, and the new clay was well jagged in the face of the old clay at both ends of the trench. In sinking the trench it had to be timbered in a substantial manner, and in such a way that the timbers in refilling could be withdrawn in small sections, so as to prevent any settlement or movement in the remainder of the embankment, as had any settlement taken place in the old clay puddle during the progress of the work, it would have proved fatal to the success of the scheme. In carrying out these repairs, no indication of any settlement has shown itself at either end of the trench, and I have great confidence that the works having been so far carried on satisfactorily, will prove a success, and that the embankment will be made sound and watertight. The embankment of the reservoir is 80 ft. in height, having a water area of 32 acres, and containing, when full, 300,000,000 gallons. Mr. Robert Rawlinson, civil engineer, was engineer to the Corporation of Swansea during the first period of the works, as for the original surveys, the obtaining of the Act, and the partial completion of the embankment, Mr. Hugh Unsworth being resident engineer up to the completion of the Lliw Embankment. Mr. Rawlinson re-entered Government service before the embankment was fully completed, but by special leave of the then Home Secretary continued to act as consulting engineer to the completion of the works. For the repairs and restoration of the Lliw reservoir I have been the acting engineer, and Mr. Rawlinson, with the sanction of the president of the Local Government Board, the consulting engineer, as it was considered desirable by the Water Company of Swansea that the engineer who designed and executed the works which had given way should be responsible for their restoration.

INDUSTRIAL EXHIBITION AT THE ALEXANDRA PALACE.

THE Industrial Exhibition opened here on Saturday, the 4th inst., and to remain open until the 30th inst., by no means deserves the prefix "Great" which has been bestowed upon it by its promoters. The exhibition, which is arranged in the large banqueting-hall in the park, contains some good things, of course,—the best of these being, as is usually the case, the products of men working in their own special crafts,—but, on the whole, it does not strike us as being equal in interest and value to the exhibition (which, as we remarked at the time, had its shortcomings) lately held at Bow; and this notwithstanding the fact that a large number of the articles exhibited in the hall of the Bow and Bromley Institute have been transferred to Muswell-hill. While, however, the present collection falls far short of what we conceive to be the *beau idéal* of an industrial exhibition, we do not desire to convey the inference that nothing is to be learnt or gained by an inspection of its contents. The intelligent mechanic will be able to pick up a little practical information here and there; but those of our industrial classes, male and female, who have profited by the teaching of our schools of art, will be rendered uncomfortable when their eyes light upon such inanities as a drawing-room chair, full-size, made of "pure sugar" in different colours, and the Berlin-wool representations of the Oxford and Cambridge Boat-race and of a train on the Great Northern Railway,—the locomotive especially being "fearfully and wonderfully made." There is a great deal of very good and useful needlework; but even a brief glance at some of the patchwork quilts is very trying to the eyes of any who have the least notion of the right use of colour. The contents of the exhibition are divided into seven sections, viz.,—Mechanical; Artistic; General; Fabrics and Fancy Work; Miscellaneous; Drawings, &c.; and Work done by School Children. Each of these sections is subdivided into separate classes of exhibits, the total number of entries being 942. It is not quite easy to see why carved work in wood should be included in Class 2 of Section I., "Mechanical"; one would have looked for it under the head of "Artistic." However, there is some very good carved work shown, together with fretwork and the productions of the lathe. In Class 8 of this section there are some excellent models of steam-engines, and in Class 9 ("Mechanical Models and Inventions") there are one or two appliances intended to be of service in aiding the work of sanitary improvement. In Class 13, Mr. William Elliott, of Cumberland-street, Caledonian-road, exhibits (No. 186) a model of sash-windows opening inwards for cleaning; we have seen the same thing, if we mistake not, somewhere else. It is questionable whether sash-windows made on this principle would be sufficiently wind and water-tight. In Section II., "Artistic," there are some good specimens (Class 5) of modelling in clay and plaster. Class 7, "Water-Colours," contains specimens of better work than Class 6, "Oil-Painting." In Class 8, "Pen and Pencil Drawings," we note that Mr. Thomas G. Mansfield, described as a "medicine case maker," exhibits three drawings copied by him from illustrations that have lately appeared in the *Builder*. In Class 11,—"Designs, Architectural, Mechanical, &c.,"—we note that one or two working carpenters and joiners exhibit designs for school and other buildings. Class 12, "Decorative Painting on Glass, China, &c.," includes some good work. In connexion with this class of work, we note that Mr. T. Cox, of Southampton-row, Russel-square, exhibits a quantity of excellent stained glass, painted tiles and plaques, terra-cotta vases, and other decorative work, a great deal of which was shown by him at the Bow Exhibition. Class 14, "Graining and Marbling," includes some very good specimens of this imitative art. In Class 16 there are one or two well-executed specimens of wrought-iron work.

The rules and regulations for the manage-

ment of the Exhibition state that persons eligible to compete for prizes "must belong to the working classes, in the usual acceptation of the term, or as defined by the judges,"—whose names do not appear in the catalogue. Medals and other prizes to the value of 200*l.* are offered by the promoters, but if, in the opinion of the adjudicators, there shall not be sufficient merit in any of the exhibits, no prize will be awarded.

ONE HUNDRED AND SIXTY NEW HOUSES IN THE AUCTION MART.

THE UPTON PARK ESTATE.

A LARGE estate at West Ham, known as the Upton Park Estate, a short distance beyond Plaistow, on the London, Tilbury, and Southend Railway, has recently been laid out for building upon, and upwards of 800 small houses have already been erected upon it, whilst others of a like description are at present in progress. Several of the tenements are semi-detached, and to a certain extent built of concrete blocks, having spacious gardens front and back, each side of the several streets or roads being planted with trees in boulevard fashion. The builders or owners of a large number of these dwellings do not appear to have been commercially successful; for, on Friday, the 3rd instant, 160 of the houses were offered for sale at the Auction Mart, Tokenhouse-yard, by order of the mortgagees, the Everton and West Derby Building Society, Liverpool, who, it was stated, have advanced upwards of 20,000*l.* upon the property. The particulars state that the property was estimated to produce 3,072*l.* per annum at present rentals, and that about three-fourths of the entire number of houses were already let, the remaining portion being in hand. They were stated to be held on leases for an unexpired term of eighty-five years, at an aggregate ground-rent of 640*l.* a year, the rates and taxes paid by the landlord, amounting to about 570*l.* per annum, showing a net annual rental of 1,962*l.* It was stated that the property would, in the first instance, be offered in one lot, and this arrangement was carried out; but as no bids were made, it was next offered in twenty-six lots, each lot containing six, seven, and eight houses each, for which the offers ranged from 600*l.* up to 1,400*l.* each, or an aggregate of about 22,000*l.*, but they were all withdrawn, the offers not being considered equal to the value of the various lots. It was stated in the room that the minimum value placed upon the property was 25,000*l.* Mr. Hosking, the Building Society's secretary at Liverpool, was present at the sale, instructing Mr. W. V. May, the auctioneer.

A "NATIONAL" COFFEE PUBLIC-HOUSE IN FLEET-STREET.

UNDER the title of the "Caxton," the National Coffee Public-house Company are about to open one of their establishments in Fleet-street. The Company have purchased the premises at the corner of Fleet-street and Bouverie-street, and are now converting them for their intended future purpose, the internal portion of the building undergoing an entire re-construction. It contains four floors, besides the basement, the whole of which is intended to be appropriated to the business of the Company. Nearly the whole of the interior partition walls forming the apartments on the several floors have been removed, admitting of the construction of spacious coffee and dining rooms on each floor, upwards of 50 ft. in depth from the Fleet-street frontage. A special feature of the establishment consists of a large and handsomely-fitted billiard-room in the rear. This apartment is about 50 ft. square. The new staircases from the ground-floor to the upper part of the building are wide and commodious. The basement, which will be appropriated as the culinary department, is being fitted up with ranges and cooking apparatus, and there are hydraulic lifts to the upper floors. The portion of the second floor at the rear of the building in Bouverie-street contains the manager's apartments. The principal entrance to the establishment is in Fleet-street, but there are also two other entrances in Bouverie-street.

The re-construction of the building has been carried out under the superintendence of Messrs. Parr & Strong, architects, of Finsbury-square; Messrs. Mark Patrick, & Son, of Westminster Bridge-road, being the contractors.

HARVESTING MACHINES.

SIR,—By the turned-down page in the pamphlet I send by this post, you will perceive that you were amongst the first to encourage me in my labours to save the harvests of the country. I have sown my thousands, done my task, but up to this present date reaped nothing but excessive toil,—possibly this will be my only "crop"; but it is a satisfaction to know that one has done something, and that men like yourself approve the "doing."

Chingford, Essex. WM. A. GIBBS.

*** The evidence as to the value of the machines is so strong that it seems extraordinary that the company for constructing and letting them, which it was proposed to establish, has not been formed.—ED.

WHEELING THROUGH LIFE.

PAUSING on the level bit of road by the parish church, just at the foot of the bridge, sat two young men in a vehicle, on the like of which my eyes had not before rested. In the first bloom of youth, they might have been prize-men from some public school. But their courteous replies to a man senior to themselves rather gave the impression that they were Oxford freshmen. They asked some question as to an hotel, and readily replied to my inquiries as to their carriage. The morning was intensely hot, the time just about ten a.m. They had come, they said, from Sunbury (which was a distance of about sixteen miles), and had got over the ground at the rate of eight miles an hour. They did not look in any way distressed or fatigued. They were warm, but not warmer than any one might have been at the end of a mile's walk. After a little chat the vehicle noiselessly began to move. It ran backwards up the ascent of the bridge, turned round in half the width of the road, and then briskly ran up the steep pitch to the White Lion, at, I should say, nearer ten than eight miles per hour.

The vehicle was without a horse, and happily without a boiler. Was it propelled by electricity? Yes, by the electric force of the two young occupants. It was what, I suppose, would be called a quadricycle, made to carry two passengers. The pair sat side by side, between two large skeleton wheels; and one small central wheel in front, and a corresponding one behind, so arranged that the two would not touch the ground at the same moment, gave safety to the little spider-like car, and I conclude were of use in steering. The movement was given by treadles, and I observed that the two inner and the two outer legs of the drivers acted together. The facility and grace of the motion of the vehicle were admirable; nor was there any appearance of the strained and anxious look on the faces of the travellers which is characteristic of the rider on a bicycle.

It occurred to me that a more delightful vehicle for a summer excursion had been never designed. Conversation would be uninterrupted by the noise of wheels. A brisk movement through the air would be kept up with less expenditure, I should judge, of energy than that of the pedestrian, if measured by time, and of very far less if measured by distance. Of course, there may be drawbacks which do not appear at the first glance. But it seemed to me that the new vehicle was much more enjoyable than any single-horse carriage for such a purpose as a tour, and much more economical, and, indeed, manageable, than a pair-horse phaëton, or that pride of the ancient road, a curricle.

It struck me that some thankful notice should be taken of this visible embodiment of one of the ideas of an engineer to whom the world has, perhaps, not yet rendered his due,—General Sir Arthur Cotton. It is now five or six years since Sir Arthur proposed what I think he called a compound bicycle. His idea was to have a machine something like three or four bicycles combined in one, in which two footmen should propel their master, or their master and mistress. It appeared to me that the case was one in which it was not clear that twice two made four. The wonderful freedom of the bicycle seemed to me to depend very much on the singleness of the propelling wheel. Friction between the different parts of the carriage, and twist between the wheels, which together absorb no small portion of motive power, are avoided in the bicycle. It seemed to me probable that the base of the vehicle could not be extended, and the working parts complicated, without bringing back so much of the torsion and working friction as to render propulsion very hard work. The *rencontre* of this morning served to show me that I was wrong, and that Sir Arthur Cotton was right. At all events, I feel that I may be doing good service to many a tourist by calling attention to so sociable a conveyance. "Did you see that carriage go up the hill?" I asked of one of the town-councillors whom I met by the way. "Never saw anything like it before," was the reply. "How pleasant it would be to take out one's young lady in such a carriage!" C. E.

THE ARCHITECTURAL FITNESS OF PICTURES IN ITALIAN BUILDINGS.

My attention was first attracted to the above characteristic of Italian art when contemplating Leonardo's "Last Supper," in the refectory of the Monastery of Sta. Maria delle Grazie, at Milan.

No notion can be formed of the meaning of the architecture in this picture from the copies and engravings. To understand it one must visit the original; then it will be seen that the architecture of the painting is a continuation of the architecture of the room in which it is painted. The end wall is, as it were, painted away. The room is extended with windows, &c., of the same height and pattern, and at the end, on a dais, the table is set, and our Lord and the Twelve are partaking of the Last Supper.

How truly could the old monks understand as they sat at meat the idea the painter has brought out so finely, that they were disciples of the Lord, and eating with him.

No copy hanging in a frame can give the least notion of the feelings experienced in gazing on a scene going on in the same room with oneself: the very framing of the copy is fatal to it.

At Florence, too, in the Monastery of St. Marco, is a splendid painting of the Last Supper, to which the same remarks will apply. This is in the small refectory, and by Chirlandajo, and is in beautiful preservation (in this respect very different from Leonardo's). In this painting one feels that the light actually falls from the windows on to the forms in the painting, and the glasses on the table acquire a wonderful lustre, without detracting from the noble forms around the table.

In Giulio Romano's work, at the Palazzo del Te, the same treatment can be seen in almost every room. Each painting is treated as though it were a fact actually going on in the room, or seen through architectural spaces, the architecture being sometimes real and sometimes painted, but always forming part of the building. This is in contrast with our ideas of pictures hanging on the wall.

The Sala dei Giganti is a bold, but in many respects a vulgar performance. Here the giants are overthrown by Zeus, and a thunderbolt has struck the room itself, the walls come down in tottering masses on the spectators' heads; the giants are all around, some crushed by the fall, others still grasping pieces of rock: the whole place is a ruin, a few bricks still remaining to prop up the doorway. Rocks have fallen through in places, under which legs and arms of giants protrude, and heads half crushed, their eyes still gazing into the sky in terror, for there is seen the almighty hand of Zeus grasping a thunderbolt which will complete the destruction. The whole room is painted into this scene, walls, ceiling, and all, so that the spectator feels that he is in the centre of the general ruin, and that the next thunderbolt will be launched at him.

All through Italy frescoes by the best masters can be seen treated in this manner. Correggio's work at Parma, Raffaelle's at the Vatican, &c. The architecture is so beautifully shaded from the real lights in the room that it is with the greatest difficulty one discovers whether it is painted or real, and it is this that helps forward the reality of the paintings, for the painted architecture is so wonderfully blended with the real that one fails to look on these scenes as paintings, but feels that he is in the presence of realities.

My observations lead me to think that the old masters designed the architecture of their pictures to fit the architecture of the building they were painting, and the light and shade were made to fall naturally from the openings in the architecture.

I think there is much of the architecture one meets with in old paintings, and which often strikes one as being out of place and inconguous, cut, as it often is, from walls or ceilings, which, if seen in the light and in the place for which it was painted, would be not only understandable, but really beautiful.

OWEN GIBBONS.

MASTER AND SCHOLAR.

SIR,—In my paper on "Mural Decoration," read at the Liverpool meeting of the Social Science Association, I laid great stress on the importance of scholarship, as scholarship existed in the best days of Italian art,—for men practically acquainted with historical painting very well know that the teaching in the public building and the studio, such as Raffaelle's scholars had, is the very best of art-teaching. In the paper referred to, however, I took care not to confound cause and effect. Italian art was not primarily developed by the institution of scholarships, but by the great and continuous demand of the Church and the wealthy for painting, sculpture, and architecture, necessitating the employment of assistants or scholars by the master. I was myself against the question being entered on the list of questions of the Art Section of the Social Science Association in its present form, for I think that form is misleading. Art questions should, in my opinion, be put in an instructive form. The system of scholarships could not be forced into existence without a prospect of employment, for young men are not likely to go in for historical painting when historical painting does not pay. Moreover, the *atelier* of a master in which there should be no opportunities for practising the higher forms of art would be destitute of those advantages which made the system, as it existed of old time, so valuable. It is the necessity of adapting art in mural decoration to the conditions imposed by its architectural setting that develops mastery in design from the figure painter to the ornamentist.

The system of master and pupil, in a sort of jog-trot fashion, has always existed in England, without its leading to a school of historical painting. Portrait and *genre* painters have frequently had scholars who have been brought up to follow the same kinds of art as themselves. But even here the extent of scholarship is in a great measure regulated by the demand for these kinds of painting. The parent and the artist student calculate the chances of employment, of earning a living, by following in the footsteps of the artists to whom the pupils are about to be articled. But the taking of pupils is by no means a general practice in this country. Some of our most popular artists have unfortunately refused to have scholars.

In direct contravention of the procedure in the great art epochs, we have adopted a system of art-schools without any reference, without any co-ordination, to a demand; and Artists' Benevolent Societies will in a few years be utterly unable to respond to a tithe of the applications which will be made upon them for pecuniary assistance. In no country has there been such a repetition of lectures upon the history of art as in this. What the *dilettanti* heads expect from these lectures, goodness alone knows,—but we do know that they are advocates for every kind of measure for promoting art which is diametrically opposed to the teaching of such history.

The people must be told again and again that the art of this country firstly depends upon their own state of culture; that English art will always be up to, if not in advance, of their understanding. That its status depends upon the quality and the quantity of their demand for it, and upon the public money being directly spent upon the employment of the artist, and not on throwing it away upon all the paraphernalia of art-schools, museums, &c. These may be all very well in their way and to a certain extent. But the modern craze for the multiplication of such establishments is absolutely pernicious.

W. CAVE THOMAS.

Four Masons Drowned.—On Monday evening, while seven masons were at work in the pit of the Great Western Company's Colliery, near Maesteg, Glamorganshire, the guide siderope of the north shaft stage broke, and four of the seven men were thrown into the water below and drowned.

LIGHT AND AIR.

SIR,—The article in the *Builder* of August 28th "On some Points in the Law of Light and Air," reminds me that, some years ago, in reading the Bill then proposed and not yet passed for amending the "Metropolitan Buildings Act," it struck me that, taken together, the regulations seemed to imply that the law stands thus:—That, in the absence of prescriptive rights, an owner in building must depend for light and air entirely upon the area over his own ground, and over any adjoining public way; having no claim whatever in these respects to the area over the ground of an adjoining owner. The Bill contained sundry regulations as to heights of buildings, which secure to the building owner a certain amount of light and air, and prevent him from obstructing those on the opposite side.

It seemed rather a pity that the Bill did not distinctly state that an owner cannot, by infringing the implied law, establish in the course of time a right over the ground of an adjoining owner, which might inflict great hardship. A clause something like the following might perhaps answer the purpose:—"Within the limits of the metropolis, no claim for ancient light shall accrue on account of any light which was not an ancient light at the date of the passing of this Act."

The subject is worth discussing in your columns.

J. M.

MODEL ESTIMATING.

THE following is a list of tenders delivered for building a new wing and executing alterations, including all ironwork and verandah, to Thidy Villa, Underhill-road, Lordship-lane, for Mr. W. Howell. Mr. George Howell, architect. Quantities were not supplied:—

J. & S. Bowyer	£1,000	0	0
Watson & Dennett	665	0	0
Gammon	620	0	0
Edwards & Hayes	550	0	0
Cais & Beldom	530	0	0
Rice	483	0	0
Taylor	410	0	0
Hogan (accepted)	400	0	0
Buchan	380	0	0
Ayers	250	0	0

GRAINING AND MARBLING.

SIR,—Will you kindly use your powerful organ in assisting me to find out the cause of the decline in public favour of a now almost obsolete profession, viz., Graining and Marbling. It is well known to the trade that architects and the fashionable decorators have tried to stamp out graining whenever and wherever they can, so that they can introduce the system of colour-painting now so very fashionable, but a very poor substitute for art. I fear that without some assistance from you and your readers as to the actual cause of the decline of a once much-appreciated profession, there will be but little prospect of improvement. To be a good grainer requires the study of a lifetime, and in some cases great energy. I trust you will assist me in ventilating this argument.

A POOR GRAINER.

TO EVERY ONE HIS OWN.

SIR,—Some papers on quantity surveying written by me were published in one of your contemporaries in the years 1878 and 1879. Much of the matter and phraseology of the additional chapters of the third edition of Mr. Banister Fletcher's book, "Quantities," published by Mr. Batsford since my articles appeared, is identical with portions of those articles.

My papers (with additions) are shortly to be published by Messrs. Spon, and as I am anxious to guard myself against the suspicion of plagiarism, I shall be glad if you will allow me to make this statement through your paper.

JOHN LEANING.

Rowland Hill Memorial.—At the last meeting of the City Commission of Sewers, the Streets Committee brought up a report in regard to a communication from the Lord Mayor, as the chairman of the Rowland Hill Memorial Committee, asking the sanction of the Commission to the erection of a bronze statue of the late Sir Rowland Hill in the open space at the south-east corner of the Royal Exchange, facing Cornhill; the statue was about to be entrusted to a competent sculptor, and, as a work of art, would be worthy of the City of London. The committee had viewed the locality and found that the space available at the spot in question would admit of the erection of the statue without inconvenience to the public, and they recommended that, subject to their approval of the plan and models of the statue, the Court's permission to its erection at that site should be given. On Mr. Innes's motion, the committee's report was adopted.

GOOD NEWS.

THE BRISTOL VENTURERS.

SIR,—Two hundred guineas and upwards per week may be easily and safely earned by persons of either sex, without detriment to present employment, or previous knowledge of the business.

This assertion reads very like an advertisement which has haunted the daily papers for some years past, and which, from its longevity, one may suppose has worked wonders among Mr. Carlyle's "thirty millions, mostly fools." The only drawback attending this speculation (and it seems to be considered no inconsiderable one) is that it has been known, upon some rare occasions, to bring its enterprising projectors within reach of the proverbially strong arm of the law.

Perfectly free from any such vexatious amenity, and infinitely more lucrative, is the scheme devised by the Society of Merchant Venturers of Bristol for making capital out of the simple faith of their fellow-men,—a scheme which fully warrants the cheering announcement with which I commence my letter. The El Dorado discovered by these ingenious gentlemen is none other than the promotion of architectural competitions; and from what I can learn of the success of their first venture, they must be flattering themselves that, this time, they have indeed "struck ile."

A reference to the advertisement inserted by them in your paper, some weeks ago, will throw some light upon their exact method of procedure. It is headed "New Trades School, Bristol," and is somewhat discreetly worded; we are told that plans are required for this building, and that a premium of 100 guineas will be awarded to the author of the best design. There is no mention of the approximate cost of the work, nor are we told whether a professional referee is to be employed; the only further information we are vouchsafed is that all applications for particulars must be accompanied by one guinea. Prominent among the particulars so obtained will be found the fact that your guinea is gone from you for ever, the Society gently but firmly declining to return it under any circumstances whatever. You may further learn that they do not pledge themselves to build any Trades School at all, or if they do, to employ the architect whose design has been placed first,—the fact being that they do not bind themselves to anything beyond disgorging one hundred out of the three hundred guineas which they are likely to obtain from confiding members of our profession.

Let me pay my tribute of heartfelt admiration to the master-mind that put up this dowmost of downy dodges. Artemus Ward stored one when he "hogged the public" with a waterproof tent and a pea-green cow. A certain prominent member of the Stock Exchange, not long ago, exhibited some shiny tricks, which were very admirable in their simplicity. The confidence trick and the painted sparrow are plants which reflect much credit on their respective authors. But all these must pale their ineffectual fires before this last great light, who may fairly rank beside the intellectual Colossus who first conceived the idea of deriving an income from three thimbles and a little pea.

It is pitiful to think how many signers "this merry bond" is likely to find among the younger and poorer members of our profession.

LOUIS KNAPP.

NOTES FROM EDINBURGH.

The New Medical School Buildings.—The Anatomical Department of these buildings will be ready for occupation by the students of the School of Medicine at the beginning of the winter session, early next month. The buildings are ranged round two large quadrangular courts, which serve the double purpose of promoting ventilation and increasing the facilities for lighting. The north court, measuring 127 ft. by 85 ft., lies parallel to Teviot-row. The range of buildings on the north side of this court is intended chiefly for the departments of Materia Medica and Medical Jurisprudence; and in the comparatively short period since that contract was let, Messrs. Beattie & Sons have made good progress with the work. The east end of the south court (which measures 97 ft. by 53 ft.) is occupied by the anatomy class-room, measuring 58 ft. by 42 ft. Of the range forming the south side of the south court the whole upper floor, measuring 108 feet in length by 39 ft. in width, and 27 ft. in height, is set apart as the dissecting-room, the roof being formed in ridges glazed towards the north, so as to afford as much as possible of steady light. In some of the rooms ventilating-grates have been introduced, while in nearly all extraction-shafts have been erected for the purpose of carrying away the vitiated air to the tall brick column which recently formed the subject of some discussion in Edinburgh on the score of its alleged unsightliness. The stalk in question rests on a square base 18 ft. wide, and rises to a height of about 180 ft. Near the bottom the shaft is 50 ft. 6in. in circumference, while at the top it is contracted to 17 ft. 6 in. About 150 ft. from the base there are eight ornamental openings for the outlet of the vitiated air led into the shaft. Up the centre runs a chimney, made of malleable iron boiler-plate, 2 ft. 6in. in diameter, which will have its escape at the cone-shaped summit of the shaft, and which, by heating the air encircling it, is expected to produce an efficient draught for ventilating purposes. The contract for the southern division of the building, which is in the hands of the Brothers Meikle, of Ayr, does not expire till the 31st of August, 1881, so

that the anatomical department, with the exception of the museum, which is 112 ft. long and 40 ft. wide, and the principal entrance-hall from Park-place, has virtually been completed a year before the specified time.

The Calton Gaol.—A representation has been made to the Secretary of State by the County of Edinburgh Prison Board with reference to the claim of the Government against the county and burghs in respect of the alleged inadequacy of the Calton Jail. The Board represent that the sanitary state of the prison and the uniform health of the prisoners,—which is the best test of adequacy and fitness,—are pre-eminently good. Having pointed out that Sir Richard Cross had no hesitation in certifying that the east division was "unexceptionable," the memorial goes on to say that the west division, which was built in 1816, has been objected to on the alleged ground that "the cells are almost all of small cubic capacity, defective in ventilation and also in heating." It is stated that when rule 21 of the Rules for Prisons in Scotland was made in 1874, providing that for each prisoner there shall be not less than 800 cubic feet, the Board protested against its being applied to existing prisons, and especially to the prison of Edinburgh. The Board, therefore, express the opinion that to take down the west division would be a most unjustifiable waste of money. The number of cells in that division is 127, while in the east division and the civil prison there are 111, the total number being 238. The Board admit that the part of the prison called Bridewell, and which is used for female prisoners, is objectionable as a place of confinement,—not at all in a sanitary point of view, for they hold it is as healthy as the rest of the prison, nor because the accommodation is inadequate, but on account of its being, from its construction, unsuitable for proper discipline. The condition of the building itself is very good, the materials are valuable, and, perhaps, the Board suggest, it could be altered or even rebuilt at comparatively small expense. To this representation a reply has been received from the present Home Secretary, setting forth that, after consulting with the Lord Advocate on the subject, he finds that he cannot depart from the conditions laid down by his predecessor in office.

NEW WAREHOUSES IN SUNDERLAND.

AMONG the improvements indicated in a recent article in these columns, entitled "Progress in Sunderland," were certain new buildings in Union-street, on the west side of the Central Railway Station. These three blocks of premises are all to be applied to business purposes, and include the new warehouse of Messrs. Blacket & Son, drapers, that of Messrs. Pearman & Corder, wholesale grocers, and a new public market, which is being erected by private enterprise. The buildings are ornate in style, and of considerable dimensions. Messrs. Pearman & Corder's premises, which are now all but completed,—indeed, partially occupied by the firm,—are built mostly on the site of the old premises destroyed by fire over eighteen months ago. In commemoration of this fact, the firm has named its new warehouse "The Phœnix Buildings," and has adopted a representation of the fabled bird as a trade-mark. The new structure is erected after an Italian design. Its frontage includes a substantial tower, rising from the central pavilion roof. The tower is adorned with arches and pilasters with Corinthian capitals, and bears a dome of glass, glazed on Mr. Rendle's patent principle. In front, the building is divided into five spaces by a slight projection in the middle and at each end. The ground story is rusticated. The windows of the first floor are separated by pilasters of polished red granite, with Corinthian columns. Surmounting this is an enriched stone cornice, and extending the whole length of the façade. Above is a stone parapet supporting a French pavilion roof at either end and in the middle, the plain line of parapet opposite the principal roof-features being relieved by pedimented dormer windows executed in stone. Resting on the central pediment is a carved stone Phœnix. The stone front is continued round the corners of two side streets, about 22 ft. at each end, the counting-house being thus distinguished from the warehouse proper, which is a brick building of five stories, situated in the rear. The white freestone used in the construction of this, and for facing the adjoining building of Messrs. Blacket's, is from Denwick Quarry, near Alnwick, the property of the Duke of Northumberland. By the front entrance the counting-house is reached,—an apartment 60 ft. by 20 ft., exclusive of a retail shop, which will be let off, at either end. The interior of the counting-house is fitted up with mahogany, the floors laid with marble mosaic. But the main staircase, reached from the front entrance, is the most striking feature of the interior. It is constructed entirely of iron and glass, and rises in the tower to a height of five or six stories underneath the glass dome above mentioned. The different floors throughout the structure are composed of Portland cement concrete. In the large brick-built warehouse at the rear of Union-street, every facility has been provided for carrying on an extensive trade, the southern section being devoted to the grocery, and the northern to the provision department. Spiral staircases afford communication between the lower and upper portions of the building. In the bacon department there are complex appliances for washing and preparing the article after its arrival in huge boxes from America. With a view to maintain the required current of air, two long fans are fixed on the shaft from which the lifts are worked, which shaft runs the entire length of the building, and by the rapid revolution of the shaft the desired object will be effected. On the western side of the upper floor is a large tea-mill by R. Waygood & Co., engineers, London, workable by either steam or hand power, and capable of mixing 500 lb. of tea at a time. In a central chamber to the west, on the top floor, is an eight-horse power Otto gas-engine for working the central despatch-hoists, and two reception-hoists or lifts, as well as the tea-mixer, coffee-mill, &c. The coffee-roaster, also by Waygood & Co., is heated by a row of gas-jets, the gas being mixed with the air by means of a force-pump. When the coffee has been "done" it is dropped from the roaster into a shallow box-like apparatus, with double bottom, the one being perforated. A fan is then connected with the box, and at the rate of 4,000 revolutions per minute, the cool air is drawn through the coffee, the heat being conveyed through the wall into the street. The appliances for the delivery and despatch of goods are very complete. Telephonic communication will be established all over the building, while electric-bells will be hung in the private office of members of the firm. Mr. Frank Caws, of Sunderland, is the architect of the new building. The excavating, brickwork, and concrete flooring have been carried out by Mr. Robert Hudson, jun.; stone front and joiners' work by Messrs. John Hirst & Sons; and slating by Mr. J. E. Nelson, all of Sunderland.

GILCHRIST ENGINEERING SCHOLARSHIPS, UNIVERSITY COLLEGE.

THE regulations for prizes and scholarships at this college, just now issued, show how numerous are the opportunities there which offer themselves to young men of ability and energy. We wish, however, to call attention specially to the Gilchrist Engineering Scholarships, the gift of the Gilchrist trustees, and which are offered this year for the first time in connexion with the Engineering Department of the college. Two entrance scholarships, each of the value of 35*l.* per annum for two years, are offered for public competition, which is limited to those who have not previously been students of the college. Candidates must, on or before the 23rd of September in each year, send to the secretary written notice of their intention to compete.

Copies of these regulations, and of the prospectus of the college classes, can be had on application to the secretary of the college.

The Lincrusta - Walton Company, Limited.—Under this title a company is being formed for the purpose of acquiring and developing the English patents of Mr. Frederick Walton, of London, the inventor and patentee of linoleum, for the application of compounds of solidified oils to the manufacture of wall decorations in solid relief, and other articles specified, together with the machinery and apparatus employed in the various processes substantially as described in the said patents; also the goodwill and business connexions and the buildings and plant. The new fabric possesses qualities which for decorative and other purposes are unique. It seems to us a mistake giving up the original name.

WESTMINSTER OFFICES COMPETITION.

WE are informed that the report of the referee, Mr. Charles Barry, has this week been discussed by the committee to whom the matter was delegated, and that they have agreed upon their report, which will probably be taken into consideration at a meeting of the Vestry to be held on Tuesday, the 21st inst. In the meantime, the recommendations of the Committee will, it is understood, be kept secret.

PARLIAMENTARY JOTTINGS.

Compulsory Purchase of Land for Public Purposes.—In the House of Commons, Mr. Watkin Williams asked whether the Government would, in the recess, consider the propriety of amending the law so as to give facilities to the people to obtain land by compulsory purchase for public purposes, such as chapels, markets, and the like, by some speedier and less expensive process than by Act of Parliament. Mr. Dodson, in reply, said:—Great facilities are now given for the compulsory purchase of land for sanitary purposes, such as sewage-farms, water supply, the clearing of over-crowded areas in large towns, sites for hospitals and mortuaries, street improvements, cemeteries, &c., by means of provisional orders. Lands for markets may also be purchased by the same process, which, except where the confirming Bill is opposed in Parliament, is, as a rule, a very inexpensive process. Parliament has always reserved to itself the right of vetoing the compulsory purchase of private property, and at present there is no authority to which this power can properly be delegated. At the same time, there are cases to which the provisional order system may advantageously be extended, and I will not fail to consider the matter during the recess.

Leases Bill.—On the order of the day for going into Committee on this Bill, Mr. O. Morgan said that this was a question connected with land reform with which the Government would have to deal next year, and he hoped, therefore, the hon. member opposite would not persist in moving to go into committee.—Mr. Warton said he would not press the Bill against the wish of the Government, though he did not believe in their dealing with the question next year. The Bill was withdrawn.

City Lands (Thames Embankment) Bill.—On the motion for the second reading of this Bill (which was promoted by the Corporation of London to sanction certain arrangements with the Government as to the acquisition of a site for the proposed new Mint), an hon. member moved that the House be counted, and the House was counted out.

The Employers' Liability Bill.—The House of Commons, on the 2nd inst., considered the Lords' amendments to the Employers' Liability Bill. Most of them were agreed to, but the House disagreed with Lord Brabourne's amendment, omitting Sub-section 3 of Clause 1. On Lord Beaconsfield's new clause, limiting the Bill to the end of 1882, Mr. Dodson proposed to amend it further by substituting 1887 for 1882,—thus giving, as he explained, seven years' experience of the Bill, and throwing the onus of renewing or amending it on the next Parliament. This proposal was concurred in after a short debate, but a division was taken on Lord Beaconsfield's clause as thus amended, with the result that the House resolved to agree to it by 72 to 33.——The Bill again came before the House of Lords on the following evening, when the Lord Chancellor moved that their lordships would not insist upon their amendment omitting Sub-section 3, Clause 1.—Lord Brabourne said that after what had occurred in another place he had nothing to do but to retreat from the position he had taken up with what grace he might. It had been stated in the course of the discussion on the Bill that he had acted solely in the interest of the employers. It was true that he had moved the amendment in consequence of a resolution passed by employers of labour representing an immense amount of capital; but he would not have done so if he did not conscientiously believe that it was for the interest of the employed as well as of the employers. He believed still that it was for the best interest of the workmen to feel a community of interest with their employers. The Bill, he feared, would disturb that feeling, and plunge the workmen into litigation, so that the only persons who in the long run would benefit by it would be the lawyers. He had before stated

that he did not regard the Bill as a compromise, and that it would lead to fresh agitation, and he had only to call attention to the fact that the gentlemen who represented the Trade Unions, and had seats in the other House, had deliberately stated that when the Act expired the workmen were certain of getting an ulterior measure which would embody all their demands. He had only again to say that in taking the course he had adopted he had acted only for what he firmly believed to be the public interest. The motion was agreed to, as was also one agreeing to the Commons' amendment to the Lords' amendment extending the operation of the Bill from two to seven years. A message was agreed to be sent to the Commons accordingly, and the Royal Assent has since been given.

ART EXHIBITIONS.

Liverpool.—The private view of the Autumn Exhibition of pictures in the Walker Art Gallery took place on Saturday last. Several of the most prominent pictures from this year's Royal Academy Exhibition are on view. The exhibition promises to be one of the most attractive yet held in the city.

Kirkcaldy.—Last week the annual exhibition in connexion with the Fine Arts Association was formally opened to the public. On the present occasion space has been found in the galleries for 874 works in oil painting, water colour, and sculpture, as compared with 683 placed last year.

Birmingham.—An exhibition of paintings on china has been opened in the rooms of Mr. Thrupp, New-street.

CHURCH-BUILDING NEWS.

Aston.—The first section of the enlarged and restored parish church of Aston, Birmingham, has been formally opened. This portion consists of an extension of the nave and aisles in an eastward direction over the site of the old chancel. It was commenced rather more than a year ago, and the memorial-stone was laid by Lord Leigh on the 24th of September last year. The entire contract embraces the almost complete rebuilding of the church, with the exception of the tower, and its enlargement to nearly double its former dimensions, at a cost of about 10,000*l.* Originally the church was only capable of seating 800 persons, but when the works now in progress are completed, accommodation will be provided for an additional 500 persons. The work is being carried out under the direction and from the designs of Mr. J. A. Chatwin, architect, Birmingham. The portion of the work now completed has cost about 4,000*l.* The erection of the chancel, Erdington Chapel, and organ-chamber will next be proceeded with, and when the additional space thus obtained is secured, it is intended to restore the old portion of the nave and aisles, and to raise the clear-story to the height of the new work. The western entrance to the church will consist of a Perpendicular doorway, the arcade being in the Early English style. The inside of the church is faced with Sutton stone from the same quarry as that used in the erection of the tower and spire, and a much harder stone from Penkridge has been used for the external work. In the north aisle the altar tomb, the earliest monument of the Holte family, remains *in situ*. The monument represents William Holte, who died in 1514, and his wife Joanna. The other monuments of the Holte family have been refixed on the walls of the north aisle. In the south aisle, near their former position, have been placed the monuments of the Bagot family. The altar-tombs to the Ardens, Erdingtons, and Devereux, and other monuments formerly in the chancel, have been, we are told, "carefully packed up," and will, it is hoped, shortly be placed in their respective positions in the new chancel and Erdington Chapel. It is proposed to re-erect the pictorial window to Letitia Dearden, by Eggington, in the east end of the chancel aisle.

Frome.—St. Katherine's Church, Frome, has been re-opened. The chancel was restored about eleven years ago, and now the nave has been almost entirely rebuilt, as well as the south porch, leaving the tower to be restored at some future time. The whole of the new windows are of the Early Decorated style, and they are filled with cathedral glass of various tints. The floor of the nave and aisles is of encaustic tiles, and beneath the seats it is of blocks of wood arranged in what is known as herring-bone fashion. A new organ has also been added. The architect was Mr. J. L. Pearson, A.R.A., and the work has been executed by Messrs. F. P. & G. Brown, of Frome.

Walsall.—The memorial-stone of the south aisle of the Church of St. Michael and All Angels, Walsall, has been laid. The church is being built in sections as funds are obtained, the work commencing with the nave and chancel in 1868, and the north aisle following last year, and both being constructed by Mr. Lovatt, of Wolverhampton. The section now commenced is being carried out by Mr. Garlick, of the Saltley Works, and when it is finished there will still remain, to complete the design, the spire at the western and the organ-chamber and vestry at the eastern end. The church is in the Early English style, the materials used being Hammerwich stone for the walls and Bath stone for the dressings, with cathedral glass for the aisle and clearstory windows, and nave columns of Himley stone. Mr. J. Veall is the architect. The cost of the south aisle will be between 500*l.* and 600*l.*

Painswick.—Since the re-opening of Painswick Church, a year ago, many additional improvements have been effected. The stove, with its ugly and obtrusive appendages, has been superseded by Messrs. Haden's warming apparatus; and a stone pulpit has taken the place of the wooden structure; it is the gift of Mr. U. J. Davis, of the Court-house, and has been executed from designs by Messrs. Waller, architects, Gloucester, who superintended the restoration of the church. Before the restoration the pulpit stood on the south side of the chancel-arch; now it is placed on the north side of the same arch, in front of the curious "squint." The old east window has been pulled down, and the altar-piece, as it was termed, has been removed, and a new three-light painted window has been inserted. The subjects are,—North, our Saviour bearing the Cross; centre, the Crucifixion; south, the Entombment. This window is the gift of Mr. H. C. McCrea, father of the vicar, and is the work of Messrs. Dixon, London. A carved oak screen now divides the Chantry Chapel, which is used as the organ-chamber, from the nave. It was made by Mr. T. Guide, of Pitchcombe, who was contractor for the restoration of the church.

SCHOOL-BUILDING NEWS.

Exeter.—The new buildings of the Exeter Grammar School have been opened by the Bishop of Exeter. The new school is situated at Victoria Park. About nineteen acres of land were secured for 8,200*l.*, and the necessary buildings have been erected, except the chapel, which has yet to be built, on about two acres of this, at a cost of nearly 14,000*l.* The schools have been constructed of brick-work, with Box Ground stone dressings, by Messrs. Stephens & Bastow, of Bristol, from the designs of Mr. W. Butterfield. The style is described as "Modern Gothic." On the ground-floor of the main centre building is placed the large class-room, 30 ft. by 20 ft., and 13 ft. 3 in. in height. Adjoining are four smaller class-rooms, each 22 ft. by 20 ft., and 13 ft. high. The entrances to these apartments, which stretch along nearly the whole front of the building, are from a broad lofty corridor, on the opposite side of which are placed retiring and other rooms; on the left of this passage, entering from the front door, is situated the great dining-hall, 66 ft. by 22 ft. It has an open arched roof, is 25 ft. in height at the apex, and 15 ft. at the wall-plate, and is lighted on both sides by traceried windows filled with cathedral glass. The necessary domestic offices are situated at the north end, and the food will be brought up from the kitchen by means of a lift. At the extreme north-east corner of the building, facing the front, is situated the master's common-room, and in the rear are the domestic offices, which are entered by a door on the east side approached by a flight of steps leading from Victoria-road. Over the class-rooms are ranged on the first-floor nineteen studies for boys, 12 ft. by 7 ft. 9 in., and 8 ft. 6 in. high. Each study is ventilated into the long passage, which in turn is ventilated at both ends. On the same floor, at the north-east angle of the building, are situated two masters' sitting-rooms, one master's bedroom, and the matron's sitting-room. The approach to the boys' studies is by a flight of stairs leading from one end of the long passage on the ground-floor. This staircase is carried to the other apartments above, where the large dormitory is situated. The dormitory is 120 ft. by 20 ft. 6 in., and 15 ft. in height. At present it is fitted up with forty-two beds. It is ventilated by Sheringham's ventilator. In the turret portion of the edifice, at the north-east end, are placed the master's bed and sitting rooms, three bath-rooms, and a linen-room. On the third-floor of the higher part of the building are the matron's bedroom and a sick-room. The servants' rooms are in the attics, and over and above are water-tanks containing 1,000 gallons for use in case of fire. The class-room, boys' studies, dormitory, and dining-hall are heated by hot water, and the private rooms have open fireplaces. The heating-apparatus has been furnished by Messrs. Edwards & Son, of Marlborough-street, London, and Mr. Hunter, of Bristol, has done the plumbing. Mr. J. H. Newton has acted throughout as clerk of the works, and Mr. C. Hampton as foreman, and the building has been thus far completed without an accident.

Wolverhampton.—The trustees of the old Wolverhampton Blue-coat School have purchased a piece of land for the erection of new buildings, the Corporation requiring the old school buildings for improvements under the Artisans' Dwellings Act. Designs for the new buildings have been prepared by Mr. T. H. Fleeming, architect, Wolverhampton. The buildings consist of a centre block with two wings, in the form of the letter H. The main entrance to the building is in the centre block, whilst the wings on each side are for the respective accommodation of the children, schoolroom, master and mistress's department, storeroom, &c. The south wing contains on the ground-floor a schoolroom and classroom accommodating eighty children; and on the first floor, boys' dormitory for twelve inmates, lavatory, and storeroom. The north wing contains on the ground-floor the master's private rooms, and beyond these is the general kitchen department, over which is placed the girls' dormitory for ten inmates, with lavatory accommodation similar to that provided for the boys. In the centre block on the ground-floor are the dining-hall and dayrooms for the children, and immediately adjoining these are separate lavatories and cloakroom for the day scholars; also separate staircases to the boys' and girls' dormitories. The buildings, the elevations of which are of a simple character, will be erected in red brick, with moulded brick bands and strings, and the roof covered with brindled tiles. The work is being carried out by Mr. Lovatt, at a cost of about 3,500*l.*

Lewisham.—The memorial stone of the new Sunday Schools in connexion with and adjoining the Lewisham Congregational Church has been laid. There will be accommodation for about 500 children, with numerous class-rooms around the central space, also large room with gallery for infants. The opportunity is being taken to add a new and more commodious vestry for the use of the deacons. Mr. George Sherrin, of Broad-street-buildings, is the architect, and the work is being carried by Messrs. Staines & Son, of Great Eastern-street.

SCHOOL-BOARD SCHOOLS.

Buckingham.—The new buildings erected by the School Board in Well-street will accommodate 300 children, in two departments, arranged in a T form, viz., a schoolroom, 44 ft. long, fitted up with galleries and desks for 120 infants, and another for 140 boys and girls, 67 ft. long, with a class-room for forty children 20 ft. long attached, and both fitted with dual desks. All the rooms are of the same width (22 ft.) and height (14 ft. up to plate, and 28 ft to ridge), the roofs being of open timber description, with arched principals and plastering between the rafters. The walls are formed of hollow brickwork, and a course of gas-tar and slate has been put throughout them at the level of the ground. The red brickwork has been relieved by white bricks of both a plain and ornamental character, as well as other red ones of a deeper tone, and blue Staffordshire ones for the more exposed surfaces, such as water-tables to chimney-stacks and buttresses. The roofs are covered with brown and blue Broseley tiles and the ridges with Cooper's red ornamental crests. Each room is provided with a ventilating spirette, having rough plate-glass louvres finished by one of Macfarlane's iron terminals the one over the class-room being utilised for

the bell, provided by Mr. J. Barwell, of Birmingham. Elsley's patent ventilating-grates are adopted throughout. Separate porches, cloak-rooms, and lavatories, paved with Wehh's (Worcester) encaustic tiles, are provided for each sex. The works have been carried out by Messrs. Marshall & Boyse, of Buckingham (the cost heing 2,240*l.*), from the designs and under the superintendence of the architect, Mr. E. H. Lingen-Barker.

VARIORUM.

"THE Columnar Architecture of the Egyptians" is the general title of two essays by Waldo S. Pratt, of New York City, which have been reprinted from the "Proceedings of the American Academy of Arts and Sciences." The first of these is an examination of the well-known archæological question,—Was the Doric order imported into Greece from Egypt? in so far as that question is illumined by an investigation into the theoretic origin and development of the column and the pier as architectural members. The chronological, geographical, and politico-historical elements of the problem are for the time forgotten, and the attention fixed on the comparative artistic valne and significance of the so-called "proto-Doric" pillars in Egypt and the columns of the Doric style in Greece, as capable of bearing important testimony to the actual connexion between the two. In the present state of our knowledge, this method of attacking the question Mr. Pratt thinks the only one that leads to even measurably certain conclusions. It is an able essay, and the writer says in conclusion, "If I have succeeded in showing by this rather extended piece of argumentation how the Greek and Egyptian forms in question may have arrived at the similarity that they exhibit from entirely different starting-points; how it is probable, both from the general tendencies of architecture in the two countries and from the divergences of the forms themselves, that this difference of origin is real; and how this conclusion renders it altogether probahle that the Greek order is not an imitation or derivative of the Egyptian, I have attained my object." The second paper is "A Classification of Egyptian Columns."

——The current number of the *Nineteenth Century* includes, under the title, "A Real 'Saviour of Society,'" hy Sedley Taylor, an instructive account of the present position of the establishment founded by the Parisian house-decorator Leclaire, to a knowledge of which we were the first to introdnce English readers many years ago. Its present condition appears to he very satisfactory.——The twenty-second edition of "Black's Picturesque Tourist in Scotland" (Black, Edinhnrgh), now before us, calls for the warmest commendation. It is very fully illustrated with well-drawn views, plans, and maps, and shonld be obtained by all who are about to cross the Border. It is so arranged that reference to any part required is very easy.——*House and Home* is now the organ of the Working Men's Club movement. Its design is to elevate, and its editor is making efforts to carry ont this design.——Messrs. Dalziel, Brothers, have for many years been engaged on a series of Bible Illustrations from original drawings hy some of our most eminent British artists. An India paper edition, of limited number, will he issued as "Dalziel's Bible Gallery," and will contain drawings by Sir Frederick Leighton, P.R.A., E. J. Poynter, R.A., G. F. Watts, R.A., E. Burne Jones, F. Madox Brown, Holman Hunt, and others. The volume will be issued early in November, by Messrs. George Routledge & Sons.

Miscellanea.

Chapel of St. Columha's College, Dublin. A few days ago the Archbishop of Dublin opened the new chapel, dedicated to St. Mark, at St. Columba's College, near Dublin, which has been erected at a cost of nearly 7,000*l.*, from designs by Mr. W. Butterfield. The trnstees of the late Marshal Beresford's fund contributed the greater portion of the money. The chapel is 80 ft. in length, 28 ft. in width, and 40 ft. in height, and many of the fittings of the former chapel have been transferred to it. Rich marbles are used in the chancel, and several windows are filled with stained glass. The Earl of Erne, Mr. and Lady Mildred Beresford-Hope, Lady Helena Trench, and others, have given many of the ornaments.

The Electrical Railway.—Siemens's electrical railway is running constantly every day at the Brussels Exhibition, and earning a great deal of money. It runs under bridges, whisks round and over bridges at the speed of a fast trotting horse. The engine is no bigger than a tea-box, and the driver sits astride of it with the brake and contact lever in his hands. There are three carriages, each carrying six persons, seated back to back, after the manner of an Irish jaunting-car. The power being greatest when the current is let on and the coils of the locomotive are stationary, there is a sharp jerk on starting. In going uphill the driving current is also stronger than in going downhill, for the same reason, namely, that there is a greater difference between the velocity of the revolving coil in the stationary dynamo-electric machine, or generator, and that of the revolving coil in the moving machine or locomotive in the former case than in the latter. The electric railway is evidently quite a success, and we observe that an experimental line is being fitted up on the Camden and Amboy Railway in New Jersey, in order to test whether the system is applicable to the New York elevated railways.—*The Electrician.*

A New School of Art.—A building is about to be erected at Chiswick for nse as a school of art, in connexion with the Science and Art Department, and nnder the direction Mr. E. S. Burchett, of the South Kensington Schools, and Mr. F. Hamilton Jackson, late of the Slade School. The president is his Grace the Duke of Devonshire, and the committee consists chiefly of artists and architects resident in the locality. The course of instruction will comprehend the following subjects:—Freehand in all its branches, practical geometry and perspective; architectural and mechanical drawing; painting,—in oil, tempera, and water-colours,—of ornament, flowers, objects of still-life, &c.; the figure from the antique and the life; and the study of anatomy as applicable to art. The new building will be situated in the Bath-road, Bedford Park, and will be in harmony with the adjoining church and stores, the style chosen being "Old English," in red brick and rough-cast plaster work. Mr. Maurice B. Adams is the architect.

Pluckington Bank, Liverpool.—Mr. Hamilton Fulton, engineer, who has had largo experience in river improvements, has been appealed to to express his views respecting the removal of this serious obstruction to the Mersey navigation. His impression is that the proposed operation of sluicing would prove utterly abortive. He thinks the most effectual means of correcting the evil would he the erection of training walls of certain heights and lengths both on the eastern and western sides of the Mersey, and that this is a matter which ought to have been faced years ago, and that delay has been very pernicious.

The Tay Bridge Works.—For some time workmen have been engaged, under the direction of Mr. Barlow, C.E., in sinking an experimental cylinder at the west side of the Tay Bridge, for the purpose of ascertaining the nature of the strata of the bed of the river at a depth of from 20 ft. to 30 ft. Huge piles have been driven into the ground, and the staging was almost erected when, on Monday night, a south-westerly gale of great violence sprang up, and the whole of the staging was swept away, nothing being left save the bare piles. Fortunately, the workmen had ceased their labonrs before the gale began.

Leyland Local Board, Lancashire.—A general meeting of this Board was held on the 6th inst. for the purpose of considering the competitive schemes for the sewerage of the No. 1 District of Leyland. The schemes were four in number, and were submitted by Messrs. Addie & Sons, Preston,—estimated cost, 4,126*l.* 11s. 6d.; Messrs. Brierley & Holt, of Blackburn,—5,616*l.* 2s.; Mr. Charles Tomlison, of Rotherham,—3,750*l.*; and Mr. William Wrennall, of Castle-street, Liverpool,—5,000*l.* It was resolved to adopt the plans of Mr. Wm. Wrennall.

Fall of a Girder.—Last week a fatal accident occurred at the New Public Hall buildings, Perth. A large girder of 56 ft. span, and weighing 2½ tons, was being raised by means of a crane, and when nearly placed in its position on the tops of the walls, the ropes by which it was supported snapped, and it fell to the ground, a distance of 30 ft., taking with it a scaffold on which were several workmen. James Agen, jun., labourer, sustained severe internal injuries, from which he died in the infirmary.

TENDERS

For the erection of buildings at Cricklewood Farm, Edgware-road. Mr. Robert Hutchinson, architect:—

Gummow	£2,202 0 0
Cooke	2,155 0 0
Kearley	2,148 0 0
Rice	2,110 0 0
Angood	2,080 0 0
Van Camp	2,077 0 0
Beale	1,945 0 0
Doune	1,855 0 0
Parker	1,850 0 0
Newton	1,842 0 0

* Accepted for A and B. † Accepted for C.

For erecting three villa residences, River-street, Islington. Mr. Wm. Smith, architect. Amended estimates:—

Mattock Bros.	£2,170 0 0
Steel Bros.	2,140 0 0
Harper	1,953 0 0
Shurmur (accepted)	1,845 0 0

For foundations, &c., of new building at No. 1, Monument-yard. Mr. William Smith, architect:—

Crabb (accepted)	£960 10 0

For erecting stables, &c., Holloway-road, Islington. Mr. William Smith, architect:—

Combes & Son	£836 0 0
Mattock Bros.	666 0 0
Shurmur	666 0 0
Harper	659 0 0
Carke & Son	614 0 0
Dunford & Langham	594 0 0
Steel Bros.	591 19 0

For the erection of additional vagrant wards at the Chesterfield Union Workhouse. Messrs. Robinson & Son, architects:—

Brown & Heath	£1,649 5 0
Shacklock	1,470 0 0
Stevenson	1,430 0 0
Cropper	1,355 0 0
Palfreyman	1,297 0 0
Wright	1,270 0 0
Gough	1,259 0 0
Glossop	1,250 0 0
G. & T. Margerrison, Barlow, near Chesterfield (accepted)	1,216 10 5
Brown	1,149 0 0
Knowles (withdrawn)	972 0 0

For warehouse, Little Queen-street, Holborn. Quantities supplied by Messrs. Williams & Gritten. Mr. Lewis Solomon, architect:—

Carter & Son	£2,599 0 0
Kirk & Randall	2,558 0 0
Mark	2,419 0 0
Larter & Son	2,385 0 0
Conder	2,292 0 0
Palmer	2,223 0 0
Patman & Fotheringham	2,185 0 0
Downs (accepted)	2,035 0 0

For alterations Gloncester-place, Portman-square. Mr. Lewis Solomon, architect:—

Verzall & Griffiths	£1,719 0 0
Years	1,549 10 0
Davey	1,539 0 0
Canning & Mullins	1,509 0 0
Downs (accepted)	1,378 0 0

For shops and offices to be erected upon the site of No. 42, Old Broad-street, for Mr. E. J. Cave. Mr. E. G. Wyatt, architect:—

Wrought and Cast Iron Work, including Fixing, &c.

McLaren & Co.	£1,100 0 0
Measures Bros.	1,076 0 0
Dawnay	1,075 0 0
Gardner & Co. (accepted)	937 15 0
Stanley, Hall, & Co. (too late).	

Portland, Bath, and Dumfries Stoneworks, including Carving.

Tildesley	£2,493 19 0
Lear	2,369 0 8
Outhwaite	2,156 15 0
Seale (accepted)	2,104 12 0

For the erection and completion of the new asylum for the borough of Kingston-upon-Hull. Messrs. Smith & Brodrick, architects:—

Barry, Scarborough	£58,523	14	1
Lovett, Wolverhampton	58,000	0	0
Ives & Son, Shipley	55,878	0	0
Howell & Son, Bristol	55,200	0	0
Brier, Sons, & Wilson, Dewsbury	55,200	0	0
Hughes & Stirling, Bootle	55,0 0	0	0
Musgrave, jun., Hull	54,200	0	0
Simpson & Malone, Hull	53,516	14	5
Horseman, Wolverhampton	53,500	0	0
Dennison & Son, York	52,930	0	0
Sergeant & Son, Hull	52,340	0	0
Garlick, Birmingham	51,899	0	0
Vidler, Chesterfield	50,951	0	0
Wilson & Son, Headingley	50,829	0	0
Riggal & Hewins, Grimsby	49,995	0	0
Hockney & Liggins, Hull	49,904	0	0
Holdsworth, Bradford	49,869	0	0
Wilson Bros., Hull	49 809	0	0
Jackson & Son, Hull (accepted)	43,652	10	0

The tenders of Messrs. Haden & Son, Trowbridge, for general engineering; Porter & Co., Lincoln, for gas-works; Bradford & Co., Manchester, for laundry fittings; and other minor contracts, being the lowest, were also accepted, amounting in all to the sum of 6,664*l.* 4s. 6d., making the total cost 49,716*l.* 14s. 6d.

For new Free Library, Science and Art Schools, and Museum, Cardiff. Messrs. James, Seward, & Thomas, architects:—

Lissaman, Leamington	£10,193	0	0
Stephens & Bastow, Bristol	9,699	0	0
Bowers, Hereford	9,500	0	0
Furnell & Fry, Cardiff	9,380	0	0
Brock & Bruce, Bristol	9,239	0	0
Webb & Co., Cardiff	9,140	0	0
Elliott, Cardiff (too late)	8,969	0	0
Shepton, Cardiff	8,750	0	0
Howell & Son, Bristol	8,695	0	0
Miles, Newport, Monmouthshire	8,595	0	0
Davies Cousins, Cardiff	8,550	0	0
Lock, Cardiff	8,540	0	0
Roberts, Cardiff (accepted)	7,934	0	0

For alterations to the town-hall buildings, Bilston. Messrs. Bidlake & Fleeming, architects:—

Bradney & Co.	£3,735	0	0
Higham Bros.	3,550	0	0
Sansom	3,540	0	0
Lovatt	3,500	0	0
Hunter	3,499	0	0
Jones & Sons	3,295	0	0
Ford	3,275	0	0
Nevett Bros.	3,190	0	0
Bedford	3,125	0	0
Nelson (accepted)	2,996	0	0
Trow	2,960	0	0

For manufactory, Camden-town, for the Anglo-Russian Iron and Tin Plate Company. Mr. Francis Butler, architect. Quantities by Mr. Lesning:—

Lathey Bros.	£16,100	0	0
Stephenson	14,780	0	0
Chappell	14,375	0	0
Patrick & Sons	14,158	0	0
Roberts	13,936	0	0
Shepherd	13,633	0	0
Nightingale	13,081	0	0
Tarrant & Son	12,863	0	0

For the erection of a school chapel, Laytonstone. Mr. J. Randall-Vining, architect:—

Bangs & Co., Stratford	£1,093	0	0
Boyce, Bow	1,093	0	0
Gentry, Stratford	995	0	0
Mansfield, Stratford (accepted)	978	5	0

For cleaning and painting works to interior of Wesleyan Chapel, Quax-road, Kilburn, for the Committee:—

Wright	£226	10	0
Pitman & Son	177	1	0
Hawtin (accepted)	133	0	0

For additions to St. Bartholomew's Parsonage, Sydenham. Mr. Cutts, architect. Quantities supplied:—

Bowyer	£825	0	0
Lathey Bros. (accepted)	820	0	0

For cleaning, painting, and paperhanging works at "Exford," Louis-road, Clapham, for Mr. E. Price. Mr. W. Newton Dunn, architect:—
Pitman & Son, accepted.

For the erection of stables, Farm-street, Berkeley-square, Mr. F. W. Hunt, architect:—
Downs & Co. accepted.

For proposed enlargement of the Clarkson-street Schools, for the West Ham School Board, to accommodate 309 children. Mr. J. T. Newman, architect. Quantities supplied by Messrs. Curtis & Sons:—

Catley	£2,450	0	0
Hosking	2,197	0	0
Boyce	2,165	0	0
Morter	2,073	0	0
Abrahams	2,064	0	0
North Bros.	1,998	0	0
Reed	1,997	0	0
Hearle & Son	1,953	0	0
Nightingale	1,921	0	0
Gentry (accepted)	1,890	0	0

For repairs and re-decoration of the King's Weigh-house Chapel, Fish-street-hill. Mr. J. E. Saunders, architect:—

Sabey & Son	£750	0	0
Dove Bros.	595	0	0
Colls & Sons	495	0	0
Greenwood	499	0	0
Staines & Son	384	0	0

For additions to No. 28, Avenue-road, Regent's Park. Mr. E. Hoole, architect. No quantities:—

Dove Bros.	£3,295	0	0
Williams & Son	3,065	0	0
Bywaters	2,853	0	0
Lathey Bros. (accepted)	2,834	0	0

For building three houses and stable at Tulse-hill, for Mr. Stevenson. Mr. C. W. Lovett, architect:—
Fisher Bros. (accepted) £1,540 0 0

For building a villa residence at Esher, for Messrs. Wells & Lemottee. Mr. C. W. Lovett, architect:—
Fisher Bros. (accepted) £490 0 0

For building a villa residence, Ballenden-road, Peckham. Mr. C. W. Lovett, architect:—
Batstone (accepted) £350 0 0

TO CORRESPONDENTS.

Norwich and the Architectural Association.—We shall let our readers hear something more on this head next week.

M. I. B. A (many thanks for kind expressions; letter would be out of place in the *Builder*).—E. G. W. (first list did not reach us).—W. S.—H. & J.—A. M.—A. J. B.—A. G. & Co.—Mr. G.—W. R. D.—J. R. V.—C. & Sons.—P. & Son.—C. F.—W. B. D.—T. C.—J. L.—W. & D.—S. R. & Son.—A. B.—G. C.—W. H.—R. H.—W. W.—L. S.—D. Bros.—S. & R.—W. C. B.—T. N.—H. S.—S. N.—H. W.—S. & S. rs.—L. Bros.—A. B. (received).—R. M. B. (next week)

All statements of facts, lists of tenders, &c. must be accompanied by the name and address of the sender, not necessarily for publication.

We are compelled to decline pointing out books and giving addresses.

NOTE.—The responsibility of signed articles, and papers read at public meetings, rests, of course with the authors.

The Builder.

The Queen's Messages and the Protection of Human Life.

ENGLAND has heard, and English-speaking men and women throughout the world will hear, with an emotion that it is more easy to share than to describe, of the recent, or, we should rather say, the present efforts of Queen Victoria to protect her subjects against those fearful forms of sudden death,—more fatal than murder, or even than battle,—which have, of late, become so common and so distressing. "The Queen," it was announced in the morning newspapers of the 8th of September (a day which a large portion of her Majesty's subjects have been in the habit of especially associating with acts of protective grace), "the Queen has been much distressed by the accounts of the recent railway accidents, and her Majesty has been in frequent communication with the Government as to the means to be adopted to provide, as far as possible, for the safety of those who travel upon, or are connected with, the working of railways." The very day that informed her Majesty's subjects that, at the Queen's command, the servants of the crown were applying to practical science for a safeguard against preventible calamity, echoed a double cry of suffering. For the first time, as well as we can remember, since railways have been placed at the service of the coal-winner, have the black and ugly headings,—Serious Railway Accident! and Fearful Colliery Explosion!—appeared side by side in the same page of a morning newspaper. Of calamities thus associated in the time of their occurrence as well as in their unexpected and fatal nature, it is difficult for the moment to speak apart. At half-past two a.m. on the 8th of September, a terrible explosion occurred at Seaham Colliery, which killed, according to the accounts of the officers of the Miners' Permanent Relief Fund, 151 persons, although it is believed that as many as from 160 to 170 have perished. Applications to the fund for relief have been received from 121 persons, of whom 84 are widows, with an aggregate of 212 children. Sir Henry Ponsonby, by the Queen's command, at once telegraphed to the Marquis of Londonderry, the proprietor of Seaham Colliery, to ask how many lives had been saved, and what was the probable cause of the terrible explosion. The Queen asked the Marquis "to convey to the relatives of the missing men her sincere sympathy with them in their distress."

On the afternoon of the very same day, as the 4 p.m. Caledonian train from Glasgow was approaching Paisley, it ran, at full speed, into a mineral train which was standing on the line. The engine was broken to atoms, the following guard's van was crushed, and the four succeeding carriages were "telescoped." The guard and two passengers were killed on the spot, and eighteen passengers were injured, some of them very badly, one of whom has since died.

Serious as is the annual list of the number of persons killed and injured on our railways, it bears no proportion to the death-rate of the miners. The general report annually made to the Board of Trade upon the accidents which have occurred upon the railways of the United Kingdom is still liable to the just condemnation that it supplies full information only as to the casualties to passengers, and but scanty and ill-arranged information as to the greater number of casualties from which the servants of the companies have suffered. Taking passengers alone, the fatal injuries, which averaged 38 per annum from 1874 to 1877 inclusive, were reduced to 24 in 1878. In 1879 they had been only 2, up to the time of the Tay Bridge disaster, which added 73 to the list. From 1847 to 1849, one passenger out of 4½ millions of passenger journeys was killed from causes beyond his own control. The proportionate safety has since that time increased nearly five-fold. From 1856 to 1877 the death-rate has been about one in twelve millions of journeys. In 1878 it had sunk to one in twenty-three and a half millions. But for the Tay Bridge (which is not an ordinary working accident) the safety in 1879 would have been represented by the great ratio of one to two hundred and eighty millions. But 1880 has already shown a return to a less satisfactory relation.

In the mines of the United Kingdom, on the other hand, out of 523,870 persons employed in them in 1879, no fewer than 1,037 were killed in 843 different accidents. On the railways in the same year only 110 accidents were made subjects of inquiry, having involved the death of eleven persons, and injury to 589. But we apprehend that this does not include the deaths and injuries to servants of the companies other than those which arose from train accidents reported on by the officers of the Board of Trade. It will be seen that the death-rate in the mines is by very far the most alarming. We have before expressed the opinion that it is within the power of the engineer to prevent explosions by offering to the miner a lamp which he will have no temptation to open. But it must be remembered that the men killed by falls of the roof in mines are on the average twice as many as those killed by explosions. The essential importance of ample light in order to warn the miner against a fall is thus practically at least as great as the need for closing his lamp so as to prevent explosions.

In nine cases out of ten (and probably in many more) explosions are preventible. It is not so sure that they are absolutely preventible. The sudden disengagement of a large volume of gas is a phenomenon that almost mocks human care. We gave, some little time back, an account of one of these escapes of gas, which became lighted outside the pit, but communicated the flame to the workings. In another recent case a safety-lamp was found broken by a blow of a pick; but it did not appear whether this damage occurred before or even at the moment of the explosion. Ventilation is the great safeguard of the miner in fiery pits. This is not only well known to be the fact, but in most cases the ventilation is carefully and completely carried out.

The main point for the saving of human life in mines in which legislation can now be of much use, appears to us to be to insist that no mine should be worked from a single shaft. The Seaham explosion illustrates the value of this rule. It also suggests the question (which we put with due reserve to the mining engineer), whether it is not desirable that there should be a shaft of communication, totally independent of the main shafts, between the different seams or levels of the same mine? Such a shaft could be closed with trap-doors, so as in no way to interfere with the ventilation. It would be, in fact, a sort of back staircase, to be resorted to only in case of danger. We cannot but think that such an expedient would have probably saved a large proportion of the lives in the Seaham pit.

It will not fail to be remarked by those who have given attention to the subject that the collision at Paisley is a return to that class of accident, common some years back, which we had good reason to believe would be almost or altogether prevented by the block and interlocking systems. It is intimated by Messrs. Calcraft and Giffen, in their "General Report to the Board of Trade on the Railways of the United Kingdom" for 1879, that the introduction of the block system has occasioned a permanent increase in the working staff of railways which is represented by the cost of something like 1½d. per train mile. We say intimated, because those gentlemen, like ourselves, are unable to speak with precision as to any single item of railway cost so long as no return is made of the work done by the railway companies, stated in terms of definite weights conveyed for definite distances. Against this cost, however, Messrs. Calcraft and Giffen set the reduction in the item of compensation for personal injuries, and damages to goods. This saving, however, only amounts, on their own showing, to 0·21d. per train mile for the former, and 0·10d. for the latter, in 1879, as compared with 1874. We may add that in 1878,—which we fear we must rather take to be a normal year in this respect than 1879,—the cost of compensation was 0·42d. for passengers, and 0·39d. for goods, per train mile. In 1876 the figures were 0·53d. and 0·54d. respectively, and in 1877 0·47d. and 0·50d. Thus while there is a certain improvement, we find that the average cost of accidents has been only from ½d. to 1d. per train mile, so that if,—which we take leave to doubt,—the block system has really cost the companies 1½d. or thereabouts per train mile, there is no margin for recouping

them. All this, however, shows the urgent need of better accounts.

But the great lesson to be drawn from this late collision (which, even since the above was in the hands of the printer, has been followed by a fatal collision at Nine Elms), is, that we should not allow our attention to be drawn away from the main cause of railway catastrophes, viz., the carriage of passenger and mineral traffic over the same lines. That this is the real cause is shown by the almost absolute safety with which the enormous traffic of the Metropolitan Railway, being almost exclusively passenger or light goods, is carried on. It must be remembered that the short distance from station to station on this line, involving as it does frequent and sudden stoppages, is in itself a great and special element of danger. So is the darkness in which the trains travel. And yet the enormous number of 3¾ millions of passengers per mile of railway are safely carried on the line, being more than one hundred times the average of the railway passenger traffic in the United Kingdom! On the London and North-Western Railway the passengers carried are only 28,319 per mile of line; on the Great Northern, about the same; and on the Midland, 21,370. It is thus clear that an unmixed swift traffic can be carried on to an enormous extent with safety, while a mixed traffic certainly attains its maximum, consistently with safety, when it earns about 5,000*l.* per mile per annum. The Metropolitan earns 38,500*l.* per mile, or more than seven times as much as a mixed-traffic line (except in the case where the up and down traffic balances, which is never the case with coal-carrying lines) can earn, and that with regularity and safety.

Now, in the four serious railway accidents that occurred in the month of August, although not one was a case of direct collision with a mineral train, it must not be left out of sight that all arose from circumstances attendant on the conduct of a mixed traffic. The mode in which the rails are occupied by trains running on the line at very different rates of speed is so perplexing that every effort has to be made to save time. Thus instead of gradually stopping at the stations, a train is made to come up at full speed, being thrown on its haunches, as it were, by the brake. In the frequent, and, therefore, comparatively short, trains of the Metropolitan Railway, the powerful engine has the train in hand. Disproportionate cost, both of engine-power and of permanent-way expenditure, is caused by these rapid stoppages, but great danger is absent. For the long passenger and goods trains of the mixed lines, on the other hand, great brake-power is needed for any sudden stoppage. Our attention has been turned of late to the increase of this brake-power as a means of safety. But there are two sides to that question. First comes the question of the absolute durability, or reliability under any circumstance, of the brake. Second is the fact that the railway managers have now got into the habit of so timing their trains, in dependence on this brake-power, that if the slightest hitch occurs in the brake, accident is inevitable. This was the common cause of the four accidents of August last; so that these, indirectly, as much as the accident of the 8th current directly, are really attributable to the intermingling of the fast and slow traffic.

We earnestly trust that whatever be the steps taken by the Government in obedience to the commands of Her Majesty, such impartial and exhaustive investigation of the whole case will be made as will show first what is the cost in danger of the interference of fast and slow traffic, and, secondly, what is the gain—or, from our point of view, the loss—incurred by the adherence to a system which can only be compared to that of sending coals from Newcastle to London in post-chaises instead of in boats, if we revert in our memory to the state of our communications fifty years ago. This point, essential as it is to the protection of human life, has hitherto been persistently blinked. We trust that, under her Majesty's guidance, it will now be honestly looked in the face. The result of that investigation is one of greater national importance than we can now attempt to show.

Pictures at Brighton.—The seventh annual exhibition of modern pictures in oil at the Pavilion is now open. There was a private view last Wednesday.

IN AND ABOUT NORWICH, WITH THE ARCHITECTURAL ASSOCIATION.*

NORWICH has greatly improved its principal line of communication by the recent widening of London-street, the rather eccentric thoroughfare, as seen on the map, which connects the Market-place with the long sloping road leading to the Foundry Bridge and the Thorpe Railway Station, the station which practically does the work,—for the Victoria Station seems in the main an ornamental appendage. The curved line of the approach is in reality rather convenient for animals and wheeled vehicles,—for the Market-place is well above the level of the bottom of the Castle Meadow, where the new Post-office, formerly the Bank, makes a creditable show as the first public building brought well into view on entering;—the longer distance allows a flatter roadway. There is altogether much less of a feeling, of entering by the back door, than frequently happens in getting to the heart of an old town from the railway station. The Prince of Wales-road, now lined with a set of good-looking private dwellings, is, however, pretty certain to be metamorphosed and lined with shops before many years are over. The Market-place may remain one of the foci, but the figure, which is to include the best business part of the city, will apparently stretch itself more and more to the direct east of that noteworthy square,—which gets a natural picturesqueness from its situation on the hill-side and the varying ground level of the buildings that surround it, and has the chequered front of the Guildhall at its northern, and the bulk of St. Peter Mancroft towering above the houses at its south-western end. London-street might, however, run danger of being left altogether, if general topography came to the front; and that would be a pity,—for the new buildings erected on the south side are decidedly creditable,—tall shop-buildings of red Costessey brick, with part-in red Mansfield stone,—a thought heavy, perhaps, above the shop-fronts, and some details a little too evidently modelled on the fashionable type of what stands for early eighteenth-century architecture;—but noteworthy for bulk, for sobriety, and for purpose-like character. This public improvement is the one which makes the most considerable impression on the mind of a looker-out for recent changes. The transformation of the Chapel Field, now in progress,—adding grace and flower-beds to the grass and well-grown trees, which it has supplied so long to the high west of old Norwich, should serve as training for carrying out a greater scheme, whispered about at intervals,—which would convert Mousehold Heath into a park-like resort, reached by a new road cutting up the rising ground between the barracks and Bishopgate Bridge. Access by a back gate is at present too grandiloquent a way of describing any short cut from the heart of the city to the open Heath, which Crome taught us to delight in, and to use for looking out over the city and the Wensum valley. The back gate is locked, and it is necessary to climb over the top of it. Some more agreeable way, of approaching the Hampstead Heath of the capital of East Anglia, would be welcomed by the world, and, no doubt, by the inhabitants. When the ice has been thus broken, and a plunge into the various extensions of the city,—the modern buildings, businesses, and business aspects of the place might follow,—it would seem judicious to draw back, and be content with mentioning that there are such things in the busy and well-to-do modern city. We may turn towards considerations which are recognised by old custom as more suitable for expansive discourse,—appraising with suavity the performances of the predecessors of the present inhabitants, the good people of Norfolk, who in old times lived and worked in the little district submitted to an inspection in the course of this expedition. They were, to all seeming, not very inactive in any part of the time between remote antiquity to the seventeenth century, being well occupied in making paths and setting up landmarks,—for their own satisfaction, first of all, but not without thought also for the ungrateful posterity, which now dispenses with much impartiality, and not a little indifference, meed or blame,—taking to its inheritance with snorts and sniffs, and disposed to oscillate between weariness of the burdens, much admiration for their weight and costliness, and a desire for "wholesome clearing away of the rubbish accumulated in long periods of time, in consequence of the prevalence of an irrational passion for mere preservation."

Duly looked down upon from the castle and from the tops of towers,—from the site of St. Leonard's Priory, and from pleasant Mousehold,—looked at also from within in persistent wanderings through its winding streets, lanes, and alleys,—Norwich is found to retain a good deal of that happy power of keeping interest alive, which is a fairy gift rarely bestowed on a town, except in addition to a winding river, hills approaching it pretty closely, a longish history, and some considerable size; and sometimes withheld when all these are accorded. Mr. Evelyn wrote down, in cutting words, his views about the Wensum,—but then they were only parts of a larger argument involving advice in favour of a building scheme in London. The old palace of the dukes of Norfolk, which dazzled Macaulay when he imagined it by the aid of Edward Browne's Journal, January, 1663-64, also fared badly in Mr. Evelyn's note-book in September, 1671, as "a wretched old building, and that part of it newly built in brick is very ill understood . . . . and tho' neere a river, yet a very narrow muddy one, and without any extent." Nowadays a little too much fragrancy between St. Andrew's Hall and the Mill Dam does not prevent appreciation of good intentions, shown from the source at Fakenham along the devious course to Heigham, and through the city;—and does not secure favour for the Jacob, called the Yare, which, a little to the eastward of the remains of Carrow Priory, pours a tiny volume into the Wensum, and in doing so washes away its name. The rising ground, on the west and south of the river, albeit nothing to boast about when fully-developed hills are in question, does not fail to make itself felt, nor to do its part honestly enough in furnishing pictures which derive value, in some eyes, and do not lose it in others, from their accidental character. The great square block of castle on its mound fills in to advantage the end of a perspective of steep street, running up from the river side, near St. Andrew's. The row of churches, of which St. Andrew's, St. John's at Maddermarket, and St. Lawrence are three,—built on a line of streets nearly parallel to the river,—are looked up to from the north, and seen on the level on the south, and lanes of becoming steepness run down the slopes on the east and west of them, sometimes under parts of the actual fabrics. The bold tower of St. Giles's at the top of a street,—flanked and closed in by gabled houses,—is as happy a piece of accidental grouping as can be seen anywhere. The cathedral does not churlishly hold aloof from combinations and contrasts. Near upon 300 ft. of height enables the spire, although on the low ground, to do a manful part without fussy self-assertion, among the towers which are dotted about so plentifully on the slopes. Compared with the other English spires of the same rank—those at Salisbury and Chichester—that at Norwich comes poorly out of the contest. Filling out the outline of the octagon with small buttresses running up the angles, puzzling the eye at the same time by varying slopes, and by detached finials, is a workmanlike expedient,—but in carrying it out, as in applying the spire lights, the designer lacked the courage of his convictions, and the weakness is made all too manifest by juxtaposition with the bold work of the Norman tower,—a piece of vigorous and very individual design. The happy relation of tower and spire at Salisbury, and as rebuilt at Chichester, so that no one fancies things could have possibly been much different from what we see, are nice instances to prove, that the right mixture of imagination, knowledge, audacity, and good luck which brings about a great success in architecture, and sometimes in other things, may be found once and again, if properly sought for. People, who can pass by or forget all the archæologies, have maintained, in a spirit of paradox, that Bishop Herbert Lozinga should, in 1096, have recognised the claims of the Norwich of 1880, and placed the first stone of his cathedral near about the Chapel Field, or where St. Giles's Church now stands; and these impugners, of the selection of site over eight hundred years ago, are not to be silenced by talk of City boundaries and the wardship of the castle over the lands between it and the river. Mr. Gunn's contention that Herbert had in mind existing ecclesiastical buildings when he determined to remove the seat of the see from Thetford to Norwich, that the great new church was started just by a still more ancient one, looks so reason-

* See pp. 229, 259, *ante*.

able on the face of it, that the Bishop might be held justified at once by any one anxious to be convinced, and anxious to carry back the history of the dedication of the site to church purposes to pre-Conquestal times. The west wall of the cloisters has a very doubtful look. A simple flint wall, about 180 ft. long, could hardly be beyond the powers of the Saxon builders, and a thickness of under 3 ft. would accord more with their views, than with those of the layers of very heavy loads upon the earth who followed after them. The small circular openings, each about 1 ft. in diameter, with large splays outside and inside, and no freestone anywhere,—as they might be of almost any date, but are probably very early,—leave in agreeable suspense this little controversy, on which accident may some day throw light, when a bit of the facing in the cloister is taken down, or some of the personal belongings—of some one who worked at or watched its erection—are found in the upper wall. St. Peter's Mancroft claims, in all respects, the highest place among the parish churches. The view from the south-east,—from the Cattle Market,—requires to be taken with the south view from the Haymarket; and with the other view of this noble church from the Market-square, which surely recalls Wells Cathedral from the south-west, and various Continental scenes to the memory,—a view which has piqued the attention of many draughtsmen and painters who have felt the charm of tower, roof, windows, and turrets appearing above broken lines of house-roofs.

A longish connexion with human history can be laid claim to by the castle mound, if the British (pre-Roman) origin of the earthworks ought not to be doubted; and considerable size is only expressed in other words when it is mentioned that, in the last decade of the seventeenth century, the population was near upon 30,000. For the purpose of architectural notes it is rarely customary to pay anybody, after 1720, the compliment of acknowledging his existence, or it might be prophesied that the new census will find more than three times that number in the city, and that it would be difficult, except as a matter of mapping, to explain why a larger number still should not be reckoned in making up a gross total. The old civic and domestic work helps to give one an interest in the city which churches alone could not rouse. The outside of the Guildhall has met with evil fate; its southern flank and the eastern turret show a very different touch, from that which disposed so happily the main portion of the eastern front; but when the old chamber inside is reached, it is possible to forget the ills outside, and to view with special satisfaction this almost unaltered work of the sixteenth century,—of good proportion and general expression, and marked by much neatness and completeness of design. The carved panellings, and many of the animals which stand on the little pedestals, are very clever in idea and execution. This interior does not miss the praise which is its due. The less remarked but very interesting work at Charing-cross,—a little later in date, a rare thing in its way,—conserves also the memory of the sixteenth century; as do the buildings in back yards out of Surry-street. The good trees growing in the grounds of the large houses adjoining, and overshadowing these combinations of dormers and bracketed upper stories, tiled roofs, plaster and brick,—combinations prepared for painters by time and nature;—the surroundings of them altogether gently suggest that the day of doom is at hand, and that the west side of Surry-street will resemble Portland-place through all its length, and not tolerate longer these (1570) poor relations. The long lines of King-street and of spacious Ber-street show dormers, and timber and plaster, and show also how the seventeenth century glided into the eighteenth while this district was being moulded into the shape it now wears. Colegate-street, "over the water," affords in well-designed square-windowed houses, with handsome doorways, further evidences of seventeenth and eighteenth century comfortableness, and of the tendency of things now-a-days, when new warehouses are supplanting the old houses, and when the old houses are being altered to suit the needs of the Gresham-street of Norwich.

It is to be feared that Norwich, although she is already the subject of a very considerable mass of literature, might resent such slight notes anent her features and aspects if some touch of apology should not be introduced,—before casting a glance along the centuries from the eleventh to the seventeenth, and picking out notable works, as would become a disciple who had "sat in his corner," and learnt humbly from Mr. John Horner, of Mells, that there is much art in reaching what is best and choicest, and that it is well not to leave virtue without praise.

The prosperity of the later centuries led to the clearing away of a good deal of earlier work,—no doubt very meritorious,—which, if there had not been money enough and to spare, in the country of cloth and worsted, throughout the fourteenth and fifteenth centuries, might have remained for our delectation to-day. Of Norman the cathedral and the castle supply no stint, and there are fragments elsewhere. The naves of the cathedral, of Wymondham, and Binham, are linked together in one's imagination,—the treatment of the triforium and its relation to the ground-story being similar in each case. These naves met with diverse fates,—Wymondham is crowned by Perpendicular clearstories and covered with one of the noblest timber roofs ever designed. The nave at Norwich was covered by Bishop Lehart with stone vaulting in the middle of the fifteenth century, the wall-ribs starting at the level of the lowest caps, thus striking away part of its size from the Norman church. Binham was less fortunate than Wymondham, although that,—so far as the ground-story is concerned,—is sufficiently unhappy at present, the shafts being either cut away or buried in masses of accretion. At Binham, the aisles disappeared altogether from the plan, and clear-stories, triforia, and ground stories were all walled in; some windows in the ground-story affording the main lighting. Of the Transitional period, the antiquary with a hulimy for examples of that most interesting period of our art,—the period which Mr. Sharpe loved with such entire devotion,—must fain be content with mere morsels, such as the south doorway of the south aisle at Dereham, and the remains of the arcade not so long ago running along the Lower Close at Norwich,—now reduced to a column or two, but of much beauty, and brought to a red hue apparently by the action of fire on the stone. In the recent fire at Wells-by-the-Sea, the vestry doorway,—about the best thing in the church,—gained a peculiar red hue without being substantially injured. The beautiful, not-dissimilar colour of the very grand fifteenth-century Morley monument on the north of Hingham chancel suggests a similar origin, and might, indeed, justify an attempt to produce the colour artificially by the use of some moderate flame. To work in the manner of Ho-ti and Bo-ho would be too desperate an expedient,—with the sight of Wells in memory,—where all the woodwork was reduced to ashes, and the nave walls so shattered that complete rebuilding has been resorted to. The uncomely mouldings of badly-designed Perpendicular are being reproduced,—under compulsion,—by the architect, in every detail. The north transept at Bromholm Priory, an elegant design externally and internally, was really the most important work of Transitional date which came under notice,—work which has stood well for 700 years, and is clean and sharp in detail,—notwithstanding that the usage of it has not been too tender. Some protection for the tops of these walls, some reduction of the strong growths about the remains generally, would be well;—and a devotion of them all to mere existence apart from farmers' needs, might be urged upon Lord Kimberley, who owns them. The great gateway has a clever Late arch, with flint flushwork in the spandrels,—of course, a rarity in its way. Nor is Early English work plentiful. A country which holds West Walton, even in a corner of the Marshland, and a couple of miles from the border, must always stand its ground; and the detail at Binham is beyond cavil,—the lower stage of the west front being perfect,—except that there is no wall-space in it,—as indeed there is none anywhere in the façade. The refectory at Walsingham might well be joined with West Walton and Binham; but among the parish churches in this part of the country Early English work is as rare as Transitional.

Great Ellingham would be worth remark anywhere, as an example of pure Decorated work from end to end, and as an example of vigorous whitewashing of stone and wood work,—and Hingham and Old Walsingham would make up a very good series, running well on in the style. The Walsingham windows,—capital examples of flowing tracery,—are not the only parts of that sadly-neglected structure which fix it firmly in the memory; the arcades and tower arch are of fine bold design, also Curvilinear; and the church contains a most handsome array of rotting, mouldy, and dirty Perpendicular oak work, showing fertility and power in design, and a very noteworthy capacity of execution. Worstead, the most perfect of all the towers,—in general mass, in staging, in the proportion and detail of its openings, in the treatment of its buttresses, is Decorated, as the gentle reader knows well from his Brandon; and there are other portions of the church which belong to the time of change when tracery bars were beginning to stiffen into vertical lines. The wonderful modern angle pinnacles which, from near and far, do their best to destroy the outline of the tower, should be hauled off their posts forthwith, and their too liberal bulk reduced to comely proportions. The tower-top should be sought for a look-out over the well-cultivated and well-wooded district through which the Ant creeps, and towards the region of the Broads where the Bure loiters so lazily on his course. The little roadside chapel of Houghton-in-the-Dale would take its place near the Transition. Its blocked-up doorway, covered with auction bills,—a mullion of the three-light window missing, and all the signs of rude patching against wind and weather, hardly prepare one's mind for Murray's careful mention of "a richly-groined roof, lately restored." A rough floor, thrust in half-way up the walls, and a sight of the sky through displaced tiles on the battered timbers of the old roof, suggest satirical purpose in, or revelation from dreamland to, that painstaking writer.

When what Mr. Ruskin called so pleasantly (in the "Seven Lamps,"—but that was over five-and-twenty years ago,—perhaps he has reformed since then) "our detestable Perpendicular" is reached the difficulty is not to find examples, but to pick out a few churches from the crowd. Cawston, Salle, and St. Peter's Mancroft prevent anybody from feeling doubtful about the first three of them; a second three might be harder to pick out. These have fine dimensions, and there is nothing wanting in them,—no missing or uncompleted part externally or internally. This renders it unnecessary to look at once at the details, as so frequently happens where accident or mutilation has put unity, and the appearance of rounded completeness, out of the question. Sustained dignity at St. Peter's, spacious plan and varied outlines at Salle, are the first strong impressions, derived from looking round these churches,—not in a critical, but a purely receptive spirit;—which is, after all, the right way of getting at the result,—however necessary it may be to take thereafter a different course in order to penetrate the mystery, and know the means by which the result has been attained. At Cawston, it must be confessed, that the splendid nave roof is a little beyond its surroundings,—the majestic hammer-beam construction,—notable for its tier of winged angels standing on the ends of the much-projected beams,—would justify a more virile and a richer substructure. As, however, there are things about plans, continuous clear-stories, towers and their terminations, two-story porches and vestries, flint walling and flush work, roofs of all sorts, from tie-beamed to hammer-beamed (most of them in the "detestable" style), which have good right to be noted, the fact of the Cawston roof being "a feature" may pass with a caution. Of the chancel and tower screens, fonts and font-covers, stalls, benches, and desks, brasses, lecterns, and other metal work, and the decorative painting, it would also not be difficult to make recital; for notwithstanding the conscientious exertions of Dowsing in Norfolk, a perfectly clean sweep was not made of all the "scandalous" work out of the churches, and the worthy William Dowsing would have been shocked at the "angels and cherubims," the pictures and the covers of fonts which, if his active mind and hand had wrought reformation thereabouts would have been "taken down." In a well-known book catalogue our old friend "Dowsing (William) of Hull," and of "The Timber Merchant's and Builder's Companion," is thus localised in order that he may be clearly marked off as a different person from the "William Dowsing (of Stratford)," who, by the simple expedient of keeping a diary, has already won the affectionate esteem of four or five generations of his countrymen.

East Barsham, without Renaissance feeling, and Snoring, a very similar work, with the slightest touch of it, might stand for examples of good Tudor; and the remarkable structure on the south side of the nave, near the altar, at Wymondham, should be compared with the

tomb in the north aisle of the chancel of St. George's, Colegate, which may have been worked by the same workmen, who *may* have been Italian workmen employed at Ely (or elsewhere), as Mr. Petit suggested. The cenotaph, now in the south aisle of the nave at Blickling, a work of the later half of the sixteenth century, with much exquisite detail in it, might form a third example in this rare class. The Paston monument at North Walsham, the Suckling (father and mother of the poet) monuments at St. Andrew's, Norwich, the Sidney monument at New Walsingham, are all three fair bits of Stuart work,—the Suckling monument perhaps the most characteristic; but they are trifles when measured with Blickling. The north, east, and entrance sides of the moated, red-brick house look,—barring the clock-tower,—as if they had suffered no important changes since their completion at the end of the first quarter of the seventeenth century. The bold modelling of the façades, especially of the east front,—strong projections, well-marked horizontal lines, many gables, much piercing of wall surface, neutralised by the unpierced walls in the ogee-capped angle towers,—these are some of the features which, with others without and within, supply the examples we are seeking for,—examples of the application of the principles of our art in different times, and by widely different minds, but the principles themselves unchanged amid all changes of detail,—unchanged though the resulting expression may vary from severity, or even sternness, to the air of lettered ease, of smiling content, which makes Blickling so suitable to finish off with,—so pleasant a thing to see and to remember.

THE BRUSSELS EXHIBITION OF 1880.

Now that the fêtes by which Belgium has commemorated the fiftieth anniversary of her independence from Dutch rule are over, the flags being pulled down, the triumphal arches demolished, and the pretty garlands and wreaths ruthlessly torn down, Brussels is returning to its familiar aspect of sober industrious gaiety, and the visitors who still crowd the city at last have time to devote their attention more specially to the Exhibition, and the marvels it contains,—marvels truly, for in this small country have been exercised, as they still are, some of the most characteristic and most refined of the great industries of the past and the present, and there is gathered together in this Exhibition as complete a collection of these industries as it is possible to imagine. A purely national exhibition, it forms thus a marked contrast both in completeness and in unity, with the large and cumbersome world's shows to which we have been accustomed within the last generation.

The Exhibition buildings occupy the site of the old Champ de Mars, a dreary sandy waste some distance from the city, and which those who know Brussels will recollect rarely to have visited except on the occasion of a review or the annual races; here the Exhibition has been skilfully laid out, and surrounded with a belt of greenery and artificial water. Needless to describe the excellent plan of the Exhibition, to which a notice has already been devoted in these pages, together with a view of the section occupied by the Art Industries of the past and one of the central portico.* This pavilion is situated on the left of that erected in honour of the Industrial Arts, on the right of which lies the pavilion of the modern art industries, and behind all this stretches the larger portion of the Exhibition, the machinery in motion and the general agglomeration of industries which always form so important a feature in modern exhibitions.

For the first time, the industrious little kingdom of Belgium, with a population which barely surpasses that of our own gigantic metropolis, shows to the world in a really complete manner the true character of the modern national industries which have succeeded to the busy activity of its past commercial fame. Unlike Italy, whose Middle-age and Renaissance history and commercial development close for it the period of its prosperity, in Belgium the glowing traditions of the past are still alive, and promise a brilliant future. Side by side may be seen here the productions of its artists and its workmen in the days gone by and in the present; and few countries, if any, can stand this comparison so satisfactorily as Belgium. If it has not now the equals of the great artists who have enriched with their names the golden book of the history of art, she has more than one honest workman whose name merits to be placed alongside of that too long list of unknown, unappreciated labourers who toiled so sturdily to build up the edifice of our modern civilisation and its thousand traditions dead and living.

A peculiarly interesting and instructive feature of this exhibition is the essentially national character of the whole show, a feature carried out as far as possible in the exhibits which fill the large section devoted to the Retrospective Industrial Arts. In this pavilion, to which we will first devote our attention, has been gathered together such a collection of national productions as probably no other country, save Italy,—that still unexhausted though so well worked mine of artistic marvels,—could hope to show to the world. Bewildering in the richness, the rarity, and, above all, in the number of the exhibits that fill the nave and the side aisles of this position, it is calculated somewhat to daunt one's descriptive powers to mention even a tithe of what meets the eye in a rapid walk through this section. More lengthy inspection reveals a still larger number of treasures, the enumeration of the more important of which would suffice to fill more space than is at our disposal.

From the opening years of the Christian era down to the close of the last century, the whole history of industrial art may be traced with ease; for Belgium, let it be remembered, entered early into the field of artistic production; and throughout the numerous vicissitudes that this interesting corner of Europe,—so constantly the battle-field of rival nations that it has not unjustly been termed "the cock-pit of Enrope,"—has passed, this early precedence has stamped indelibly with a special character the art productions of Belgium, and this character the excellent means adopted by the Government in their modern system of industrial and art education promises still to favour.

With all these treasures, to be counted literally by thousands, gathered around us, one is lost in amazement at the consciousness of the many thousand others that exist no longer, that are scattered over the world, that are reposing in the various museums throughout the country or in the hands of other private collectors than those who have helped so liberally to form this Exhibition; but it is not alone these that have come forward,—the churches and religious establishments, the various archæological societies of Belgium, and the corporations and educational establishments, have all aided. Those who remember the Manchester Exhibition of 1857, to which the various colleges and corporations contributed so generously their treasures, will have some conception of the nature of the collection which the Pavilion of Retrospective Art shows to the public.

It was a happy idea this, the religious communities and the corporations coming forward to make known the artistic glory of the country; for it remains one of the reasons for the exceptional interest and splendour of the Belgian art industries of the past, the patronage afforded by the Church, and especially by the corporations, to the famous artists, and less known, but no less artistic, workmen who found in the Court, the cloister, and the town-hall that encouragement without which could never have been produced the marvels that time has transmitted so jealously to our care.

The wonderful productions of the Flemish looms that in the past were prized so highly are displayed here in a gorgeous collection of tapestry of every style and period. Nearly two hundred important pieces ornament, in their decorative, sober brilliancy and speaking suggestiveness, the walls and rooms of the Retrospective Art Section, each piece a history in itself, and which might afford matter for columns of instructive inquiry. These products of the Flemish looms stand, of course, foremost among the great art-industries of Belgium.

Among the tapestries, those lent by the King of Spain possess a special interest, not alone for their beauty, but for the historical associations with which they are connected. These royal treasures, five in number, woven in silk and gold from cartoons in the school of Roger van der Weyden, were, tradition states, purchased early in the sixteenth century by the aunt of Charles V., Marguerite of Austria, from Pierre de Pannemacker, the renowned tapestry-weaver, and often must the worthy Princess have visited the old workman's home at Brussels, in the Craenstraat, to watch the slow but certain progress of the work on the loom, as one by one the numberless figures which tell each its Biblical tale, were created under the hand of the skilful weaver. Well may these pieces of tapestry he preserved and regarded at Madrid as the pearl of the Spanish treasury. Time has respected their beauty and toned them with a loving hand which has enhanced their brilliant sobriety. But, in the midst of numerous other marvels of the Brussels and Flemish looms, even these "pearls" lose a portion of their interest, surrounded as they are by so many other works of the fifteenth, sixteenth, and succeeding centuries, not alone contributed by Belgium, but by foreign collections, among which let us not forget to mention the numerous loans on the part of the English ambassador, Sir J. Savile Lumley,* and the South Kensington Museum,—authorities who, in addition to several choice specimens of tapestry, have filled a whole room with well-chosen objects made in, or relating to, the Low Countries.

Here, in lines, hang tapestry after tapestry,—tapestries by Karel van Mander, tapestries by Jan Raes, the younger; tapestries by Jan de Kuipper, by Marc de Vas, by the Leyniers, of Brussels, by De Pannemacker, Van Leefdael, by Van den Hecke, from their now silent looms in the old Rue Haute; by Van der Borght, by Christoffel de Roveere, from designs by Raffaelle, by Rubens, by Teniers, and many other artists; from the busy workshops of Brussels, of Arras, of Tournai, of Ypres, of Antwerp, of Oudenarde, of Ghent, of Bruges, of St. Trond, and Enghien; subjects religious historical, mythological, allegorical, and symbolic, in *haute-lisse* and *basse-lisse*,† suggestive of lengthy description, and worthy the closest attention. Each of the 184 tapestries exhibited is a history in itself,—an open book for all to read,—telling of morality, of patience, of honest work, of past manners, past costume, and past traditions. Belgium is the land of tapestry, and here are shown some of the marvels of her world-famed looms, closed only in the last century, when fashion, with its inexorable laws, ceased to demand, for decorative purposes, the suggestive aid of tapestry. The last of the Van der Borghts died in 1794, and with him is closed the history of the honest artisans who bore so high the reputation of the Low Countries. The art, thanks to the efforts of a few people of taste, as can be seen here, promises to be revived, but never can we hope to see again produced such splendours as those of the busy looms in the days gone by.

But thousands literally of other treasures await a mention, though collective mention alone can be accorded them. Wonders of the patient embroiderer's lovely art, pictures painted with the needle, as the Classics termed embroidery,—works produced in days before the art had become a trade; gorgeous chasubles and religious vestments thick with gold thread and delicate coloured silks, brilliant as the pages of an illuminated missal, but toned down by age; brought forth from the safe-keeping of generations in the silent sacristies of the cathedrals and the churches for which, four and five centuries ago, they were designed and executed so lovingly by patient fingers and the minute point of the needle.

Specimens of the metal-worker's art by thousands, in gold, in silver, in iron, in pewter, in copper, and in brass, executed for the princely corporations which ruled Belgium in the past; vast hanaps and loving-cups, goblets innumerable, and solid candlesticks, which decorated so effectively their monumental "dressers" and sideboards, and their solid banqueting-tables, too stout to groan even under the weight of viands and of plate crowded on their generous expanse; maces, badges of office, "collars" and every species of insignia worn by the officials and servants on state occasions;—all are shown here in profusion, from many a famous city of the Low Countries, whose history stands noted in the great struggles which Motley has described so glowingly.

Such is the wealth and completeness of the show that it is possible with care to examine each branch of industry that was exercised in the industrious provinces of this little country.

Particularly in the metal-worker's art the

* See *Builder*, vol. xxxviii., p. 777.

* Whose "Teniers" tapestries are similar to the splendid series owned by Mr. Beresford Hope, and which adorn his drawing-room at Bedgbury.

† See *Builder*, 1876. Exhibition, Union Centrale, *haute* and *basse lisse* described.

Belgians have shown that they take a very high place. What the treasuriee of the cathedrals and churches of Europe owe to the Flemish goldsmithe is incalculable, and rich and rare are the specimens contributed here by the cathedral churches for which so many centuries ago these works were produced. Shelf after shelf exhibits chalices of the choicest kind, fashioned with a depth of religious faith that betokens strangely the difference of the spirit that animated the workmen of the past and of the present; such work as that of Brother Hugo, exquisite in that delicacy and beauty so peculiar to the early portion of the thirteenth century. More than one work by that perfect artist is here exhibited; particularly two reliquaries, parcel-gilt and enamelled, and a choicer treasure still, the cover of an evangelary, gorgeous in its glow of finely-wrought metal and *niello*, and scarcely less precious stones, among which, as usual, it is easy to distinguish more than one production of pagan art. What other treasures are exhibited in the shape of croziers, pyxes, reliquaries, shrines, crosses, monstrances, diptychs, triptychs, episcopal rings, "baisere de paix," holy-water pots, altar-bells and candlesticks, lanterns, basins, &c., may be more easily collectively mentioned than described as they each and all merit. From the earliest and choicest periods down to the more familiar Renaissance there are to be seen here specimens of the religious metal-worker's art, contributed by numerous collectors, and not a few of the recent gems from the cathedrals and monastic establishments for which they were designed. The chiselers of Flanders merit, indeed, the reputation they long have borne not alone as artists, but as honest workmen.

In a more homely branch of the metal-worker's art, the superiority of the Flemish casters and chiseliers in brass and copper is even more widely known; and to what varied uses this effective art was carried may be judged by the very large number of specimens of this work that may be seen here. Baptismal fonts, altar-railings, lecterns,—a number of these latter belonging to the fifteenth century, forming a conspicuous feature in the chief aisle of the Exhibition,—lamps, chandeliers, chafing-dishes, *couvres feu*, or curfews, mortars, for domestic and chemical uses, and of which there are here several hundred choice specimens of all sizes, and *raffraichissoirs*, those very characteristic wine-coolers that in the Flemish feasting-pictures of the seventeenth century form so conspicuous a feature in the foreground, and which we see used, if we are not mistaken, in Hogarth's drinking scene at the Rose tavern. This work has received, from the industrious town the head-quarters of the industry, Dinant, on the Meuse,—one of Turner's sketches shows us a charming view of the old place with Vauban's fortifications on the heights above,—the name, familiar to all collectors of "Dinanderies," signifying objects in brass or copper, cast or punched with the hammer (*repoussé*). How old this interesting branch of trade is may be judged from the fact that mention is made of it in the eleventh century, but there now remain few objects of an earlier date than the fifteenth century, when the destruction of the industrial rival of Dinant, the town of Bouvignes, gave a fresh impetus to an essentially useful branch of trade; work produced before this period is known to exist, and the names of more than one skilful artisan are now placed beyond the possibility of that oblivion that has overtaken too many of the art-workers of the past.

Nor is Belgium behind other countries in the production of objects in pewter, a base metal which the work of the Renaissance artists has made almost worth its weight in gold; and numerous are the delicate ewers and plates, corporation cups, and cast and chiselled plaques that are exhibited here, and which completes a beauty the exquisite work produced contemporaneously in France by François Briot, with whom Gaspar Enderlein may be fairly compared.

What noble metal-workers the Flemings of the past were is admirably shown in this Exhibition, and almost countless are the specimens of the productions of the united aid of the anvil and the file,—a useful, but dangerous tool that in the hands of the unskilful workman does so much injury,—confined not to the coarse objects familiar in other countries, but to the most delicate usages of refined existence; exquisite little boxes, locks, keys, hinges, knockers, fire-dogs, fire-plates, weather-cocks, railings, and what not, in which last somewhat vague category may be mentioned a frame for a Venetian mirror; here it is not alone the wonderful foliage and flowers and scrolls which the seventeenth and eighteenth centuries have left to surprise us, but thirteenth, fourteenth, fifteenth, and sixteenth century work, far bolder, freer, and nobler in design, and more deserving the imitative or rather emulative admiration of the modern workman than what the French and English at present too often take as models. As we shall see, in considering the modern industrial art section, the Belgians have not yet lost the secrets of the metal-workers' art.

As wood-carvers the Flemings have long borne a high reputation, which is well enforced by the collection of works exhibited here. It is always interesting to see the wonderful minuteness of the altar-screens, with their numerous figures so carefully costumed, which the carvers of the fifteenth and sixteenth centuries produced; the statues, the crucifixes, the credence-tables, the rood-screens, the "dressers," cabinets, coffers, trunks, tables, seats, and innumerable other pieces of civil and religious furniture, small architectural marvels, which, during the Middle Ages and the Renaissance, were untiringly produced in every town throughout Flanders and Brabant. This, again, is a branch of industry which is still far from being extinct in Belgium.

As for the Belgian sculptors, with whom the wood-carvers were so closely connected, their names stand written in golden letters on the scroll of the history of art, in which they have taken so conspicuous a place. To enumerate their names would occupy more space than is at present at our disposal; but by the thoughtful foresight of the Government, a superb collection of photographs of all these great works of Belgian sculptors scattered over Europe is shown in a series of turning cases, while full-sized casts of some of the more famous serve to effectively adorn the central aisle of the pavilion, in the centre of which rises conspicuously, more than 50 ft. in the air, the tabernacle of Léau. A puzzle of superposed niches and statuettes, it is one of those marvellous works of the Renaissance which, in the midst of their apparent confusion and prodigality of ornament, still preserve the character of grandeur which so frequently will be found to be wanting when the same effect is sought in more modern work. Truly Cornelius de Vriendt,—the brother of the better-known painter, Frans Floris,—surpassed himself in this beautiful tabernacle, which the Government have done well to place in the centre of the Retrospective Art Section; but recognition has been long in coming to the worthy Cornelius. A generation ago, if we mistake not, the name of the artist of this wonderful tabernacle was unknown, and local antiquaries attributed the work to some Italian artist.

Together with this superb monument there are a number of other casts; but none, unfortunately, catalogued or labelled, a fault, by the way, to be found with very much that is exposed here. In the Retrospective Art Section only a comparatively small portion of the objects has been as yet catalogued, while none are labelled; and without a catalogue even the experienced expert resembles not a little the competent captain at sea without chart, sextant, or chronometer. He may, by the aid of his log and compass, steer his way to land, but only under severe disadvantages. Why should it not be obligatory that owners should label every object they lend to exhibitions? They would then take upon themselves entirely that responsibility which the authorities are always so careful to have transferred from their shoulders, the public would gain immensely, and let it be remarked that the sale of the catalogues would not suffer, as such catalogues as these are purchased quite as much as books for future reference as *vade-mecums* during the exhibition. The want of a complete catalogue a few weeks before the close of the exhibition is an inexcusable omission.

This want in the case of such objects as casts of well-known monuments is, of course, with the initiated, but little felt, and it is easy to recognise such familiar works as the "Cheminée du Franc" at Bruges, the altar-screen of Hœckendover, and such superb works as the tombs of Charles the Rash and Marie of Burgundy from the church of Notre Dame at Bruges, or the stalls at Vilvorde, with several others equally famous, here to be seen; but among the smaller objects the absence of catalogue or label is deplorable, the more so as, in the extraordinary variety of the objects exhibited, no rigorous order has been observed. All is well arranged, it is true, but not with that methodical exactness that makes the museum of the Porte de Halle one of the gems of Brussels, a perfect encyclopædia of the art of the past. The general effect is certainly admirable, the tapestries lining the upper walls of the central aisle, itself occupied by the furniture and larger exhibits, and in the central portion of which stands a pavilion, where is shown as choice a collection of lace as perhaps, since the South Kensington Exhibition of a few years ago, has ever been gathered together. It would require, indeed, the learning of a Mrs. Bury Palliser to guide one's way, unaided as one is by catalogue or label, through the cases of Point de Flandres, of Alençon, "point" from Lille, from Brussels, from Dinant, from Bruges, from Mechlin, from Antwerp, and all the other "points" for which Flanders and Brabant are so famed, and with which our own Honiton or Bedfordshire, Lyme Regis or Devonshire, lace, some specimens of which are to be seen here, would find it difficult to compete in beauty. All the laces are here,—Italian guipure, lace from Valenciennes, from Paris, from Venice, from Holland, from Spain, from Zante, from Sweden, and from many a quiet hive of industry which the uninitiated wot not of. The cases containing a collection of embroidery, which are in this same lace pavilion, are even more bewildering in their beauty; while the various other cases, containing a priceless number of knick-knacks, snuff-boxes, watches, chains, charms, brooches, &c., all aid in transporting the spectator back, in illusion, to the strange days in which all this refined beauty was produced, and in use contemporaneously with a style of existence from which even the poorest of the present day would revolt.

Flanking the principal aisle of the Retrospective Art Pavilion are the side-aisles, from which branch out a number of recesses,—side-chapels, to continue the figure,—in each of which the cases contain the smaller objects and choice collections; musical instruments, continued by a still choicer collection of national pottery, porcelain, and faïence from Brussels, from Tervueren, from Bruges, and from Antwerp, and of which so little as yet is known; an interesting gathering of costumes, chiefly, however, of the last century; a collection of specimens of "Grès de Flandres," and the various other exhibits to which we have already devoted a collective notice, but among which we have neglected several features.

Foremost among these comes the enameller's art, which is here, perhaps, as richly represented as it has ever been before. From the early days when the artists and the workmen still came from the East and Byzantium, through the times when the art is purely national, down to its decadence, the choice art of the enameller can be traced. Among the other as yet unmentioned art-industries, let us not forget the glass, the productions in which might easily be, as they have often been, confounded with the finest works of Murano, and the existence of the manufacture of which in Belgium was, till within a short time since, entirely unknown. As for the stained glass, this hurried mention must suffice.

But not here does the simple enumeration stop. The numismatist will find a bewildering collection of coins from all the towns of Belgium, tokens, and medals, among which the work of Jonghelinck, of Conrad Bloc, of Varin, of Duvivier, and the Rottiers show how high Belgium has stood in this noble branch of art, the tradition of which she keeps alive in the work of the Wieners. A rare collection of several hundred fans range their butterfly-like coloured wings in a serious of cases that would excite the admiration of the sternest puritan, as it would the cupidity of the most honest dealer to see the choice collection of silver plate, so much of which is in the purest "Queen Anne" style, and worth a trifle more than the regulation 4s. 6d. an ounce.

The bibliophile has his eyes and mind feasted with a collection of the choicest printed books which Belgium has produced since the learned philologist Thierri Martens, the friend of Erasmus and of More, published at Alost, in 1473,—that is, about thirty years after the invention of printing, — his *Speculum Conversionis*; while among the MSS. will be found some of the rarest monuments of the caligraphist's and the illuminator's delicate art, in which Belgium, in the days that preceded printing, excelled. The libraries of the kingdom have been laid heavily

under roqnisition, and the collection of MSS. is one of the most complete,—as a national collection,—that has perhaps ever heen made. Here from a sheet of parchment, twelve hundred years old,—portion, doubtless, of an evangel written hy one of the earliest missionaries in the country, or one of the first Christians in the north of Ganl,—down to the last expiring efforts of the illuminator's art, which died a slow death, through the various periods of its existence, where it is diffionlt to say in which it most excelled, whether in the Dark Ages, in the thirteenth century, or the Renaissance, can he traced the whole history of the manuscript which led the way so nobly to the introduction of the art of painting and the invention of printing, and opened thns the great era of modern history and modern art.

MORE LIGHT ON THE LAW OF LIGHT AND AIR.

In commenting the other day on the case of The Ecclesiastical Commissioners *v.* Kino, which, as our readers may remember, was a case of much importance in regard to this question, we observed that perhaps no subject was so prolific of litigation as this. That within a short time of our remarks on the decision in The Ecclesiastical Commissioners *v.* Kino we should again have to touch on another important case shows once more how fruitful this subject is of lawsuits, and how carefully those who are interested in it should take note of the important decisions which from time to time are given in the courts of law. The name of the case, which again throws more light on the law of light and air, is that of Fowler *v.* Walker (49 *Law Journal*, Chancery Division, p. 598), and is a decision of Vice-Chancellor Bacon.

We suppose we may fairly assume that our readers are aware that when an ancient light is proved to have existed the opening a new window or the enlargement of an old one in the wall of the honse does not take away the right to the light which has been gained hy grant or prescription. In other words, the right to the entry of light into a window of a certain size is not lost hy that window being enlarged. That is a proposition which was once and for all settled hy the case of Aynsley *v.* Glover (44 *Law Journal* Reports, Chancery, p. 523) decided hy the Court of Appeal, or the Lords Justices as they were then termed, in the spring of the year 1875. Taking this hasis as settled, we now come to an important practical point which is a necessary conseqnence of this decision, and that is that when a new building is erected npon the site of that which coutained the ancient lights, the positiou of those lights must be proved in the most clear and undoubted manner hefore a court of law will give any relief to a man who claims the right to have such lights. This is, in effect, the result of the case of Fowler *v.* Walker, one which, we think, may fairly be considered of much use in showing that nothing less than clear evidence of position can assist a person who wishes to restrain anotber from building on the grouud that be is injuring ancient lights which are incorporated in a new building. At the present day, too, the simple point is one of perhaps unusnal importance, because not only in London, but in all our large provincial towns, old buildings are being continually replaced hy new ones. For years to come this change of structure is certain to continue.

By describing very shortly the facts of the present case, the example will be most noticeahle and usefnl.

It is sufficient to say that the buildings of the plaintiff were warehouses and offices in Liverpool, and that prior to 1868 the site of these premises was occupied by three cottages, ahout 25 ft. high, each cottage having three stories, each story having one small window, which was admitted to be an ancient light. Various improvements went on near tbese premises, until the defeudants came to pulling down some old buildings close to the site of the plaintiffs' warehouses and building thereon a new structure, the erection of which the plaintiffs claimed to restrain. The allegation of the plaintiffs in support of their claim was that their new wiudows were in part coincidental with the old windows in the cottages. This, as we have seen from the basis which we have assnmed, was a perfectly good claim, if, and if only, it was showu by clear evidence that the position of the ancient lights remained intact. Let ns see, then, how the plaintiffs supported their contention,—a part of the subject of great practical importance, as we have already said. According to a plan prepared by a surveyor, it appeared that the new wiudows contained parts of the old windows. The plan, however, was only made from the recollection of the snrveyor who superintended the pulling-down of the cottages and the erection of the new buildings in 1868, and from such information as he could get from persons who were acquainted with the place. This evidence was somewhat roughly dealt with in the judgment; for, said the Vice-Chancellor, "the surveyor and architect who pulled down the house and built a new one says that he has no knowledge of it (the ancient light), except a vague recollection; but he has invented a drawing, describing the position of the façade as it now stands, and he has described the particular positiou of the windows which he says were there; and his reason for saying that is, that he has collected the information from persons who could tell him where they were." Then the judge goes on to commeut on the other evidence in words which are perhaps best transcribed *literatim et verbatim* from the judgment, as they are not wholly without humour. "The other evidence npon the subject is that of three old women who were some of the inhabitants of those cottages, one or two of whom had made waistcoats or practised as a seamstress, and one of whom said that there was light enough in the windows as they existed to enable her to make waistcoats or sew something else. That is the way this case is hronght forward, and that is what I have to deal with, and I am without a particle of evidence as to the position of those windows." Then he proceeds to say that he cannot rely on the imaginary plan, and that the evidence of the tbree old women was quite insufficient.

Therefore the rule may be deduced from this judgment that the position and the existence of ancient lights in a former building must be proved hy evidence of the clearest kind. It may be said that if the right claimed in this present case actually existed, it was a hardship on the olaimant that he did not obtain the relief which he sought. But, on the other hand, it is clear that if persons actually possess valuable rights, they shonld take care in any change of structure to keep something of a memorial of their existence. As Vice-Chancellor Bacon pertinently remarked, "What reason, I have asked myself several times, could induce the plaintiffs when they acquired the site upon which those cottages stood, and had in contemplation the building of a very large structure in place of them, not to preserve evidence of this most important fact? Why did they not take some means of preserving them?" The moral to be drawu farther from these remarks of the judge, as well as from the facts of the case, plainly is, that when a building in which are ancient lights is demolished, plans and views of it should he made in which the position of these lights is clearly apparent. Then it is possible to place the windows of the new building so that they can without any donbt at all take the place of tbe old lights. And if litigation should unfortunately occur in reference to the new structure, the architect and his plan of the old building can show the position of the former lights, which can, of course, be compared with the new structure. In fact, the surveyor in the present instance locked the door after the horse was stolen, as the saying goes; for, if instead of making a drawing some years after the cottages were pulled down, and in view of the approaching trial, he had made a plan when the cottages were demolished, it might have had a very material effect on the trial. This case of Fowler *v.* Walker should, therefore, he laid to heart by every architect and surveyor in the kingdom.

The Proposed New Bridge at Battersea. The question of the most suitable site for the new hridge which is to replace the present dilapidated structure at Battersea is being discussed hy the local authorities on both sides of the river. It is believed that Sir Joseph Bazalgette at present intends to recommend the erection of the new bridge by the side of the old one, and to take down some forty houses on the Surrey side to open up an approach; hut the Battersea Commercial Club (representing the tradesmen and ratepayers of Old Battersea) has resolved npon memoralising the Metropolitan Board of Works in favour of a site higher up the river, in a line with Cremorne on one side and with Battersea-square on the otber. A new steam-boat pier is about to be erected here at this point in the river.

ON THE EDUCATION OF THE PERCEPTIVE FACULTIES IN ART.

Startling as it is to be told of a newly remarked, or a neglected faculty, a serious study of which "is one of the many pressing *desiderata* in the new science of edncation," the remark comes from a source which deserves at least respectful attention. There are few writers or thinkers who have attempted more systematically to carry tbe methods of exact science beyond the limits of that which is commonly known thau Mr. Francis Galton. If it he said that such matters as "Statistics of mental imagery," or "visualised nnmbers," or "psychometric experiments," are matters that come rather within the domain of fancy than within that of fact, it must be replied that it is on the fringe or border-land of solid fact that the chief advance of humau knowledge is to be anticipated. The engineer who, by imparting a judicious direction to the known action of flood and river drainage, wins a new province from the sea, may be said to be always paddling in marshes. But swampy and subject to constant overflow as was the area of his labours when he commenced them, he has handed it over to the farmer, as arable land, at their close. Hence the fact that a writer bas been the first to treat what was regarded as shadowy and vague with a method yielding precise results must make him to be regarded as one of the most valuable pioneers of the march of knowledge.

We cannot speak of the new observations submitted by Mr. Galton to the British Association, and referred to, rather than stated, in the September number of a monthly magazine, with all the distinctness that we could wish, in the absence of any account of the questions put, the replies collected, or the general hasis of facts, on the collection of which the writer relies. With much that Mr. Galton remarks we fully concur. And if we fail to do so with the paper as a whole, it may probably be due to the fact of his having introduced it to the world in the ephemeral condition fitted for the pages of a magazine, instead of in that more serious literary form which its importance may prove to deserve.

The subject of which the paper treats is the mode in which some persons "perceive past scenes with a distinctness and an appearance of reality that differ little from actnal vision." But connected with this faculty or habit (which alone is of great interest to observers) is mentioned something very different. "Others," says Mr. Galton, "have a complete mastery over these mental images. They can call up the figure of a friend, and make it sit on a chair or stand np at will; they can make it turn round and attitudinise in any way, as hy mounting it on a hycicle or compelling it to perform gymnastic feats on a trapeze." And yet, a little further on, we are told, "It is a mistake to suppose that a powerful exercise of the will can vivify a faint image." A little further consideration will probably explain statements which at the first hlush are thus contradictory.

The fact is, that the phenomena referred to by Mr. Galton are of two, or rather of three, distinct genera, however closely they may be allied. The first, as to which alone the paper at its outset proposed to treat, are acts of the memory. This faculty is of especial service to the artist. We see the outcome in art hy the constant repetition of the same type to represent the same idea. Thus one modern artist whom we might name appears to have made his first acquaintance with certain animal forms in museums. Whenever these animals occur in his compositions they seem to he stuffed. Other animals, probably first known by him as alive, display all the variety proper to life and motion.

This power of memory is not confined to the sight. It appertains to every sense. In proportion as one or other sense is more fully developed, its memory will be more vivid. And early impressions, especially those of childhood, will generally he most vivid. This is naturally to be expected, first because of the greater impressibility of the sensorium in yonth; secondly because of the comparatively few impressions produced in earlier years; thirdly, because of the repeated strengthening of the particular memories by repeated recalls to the attention. No doubt this vividness of memory, which differs to an extraordinary degree in different persons, is susceptible of culture. No douht, on the other hand, that the usual course of educatiou, and also the advance of life, apart froce special education, tend to dim the force of

the impression. And especially when aide to memory, ench as writing or drawing, are nsed, the hold of the mind on the past is relaxed, and forgetfulness ensues.

It ie thus quite intelligible how it is the case tbat in savage life, or among nncnltivated people, the vivid presentation of the memory, wbether of form, of colour, of sound, of sequence, or of any other pbenomenal relation, may have a reality which, to the ordinarily tanght member of a highly-civilised community, is almost inconceivable.

Quite different from this faculty of memory are "tbe visions and hallucinations that flasb into view without any connexion with the subject of conscious thought." On this branch of the question Mr. Geltou defers remark. It is one, however, of perhaps even more direct interest to the artist than the power to recall picturee of tbe past, from which it is totally distinct. As far as our own acquaintance with thie faculty goes, its action is capricious and unaccounttable. Excepting in early childhood, ite most vivid ocourrence (as far as our testimony bears ns out) is when the body is jnst sinking into sleep. Quiet and composed, and yet, ae one would say, broad awake, the recipient of tbese visione is only made aware thet sleep is at hand by the opening of the theatre of the imagination. Landscapes, faces, figures, gronps, never before seen or imagined, then pass before the perception with the reality of objective vision. This subject has been but little studied, but in the study there appears to us to lie the clue to discoveries of no slight importance.

Distinct, agein, from this fleeting and unconscious vision, ie the rare power of calling up visione at will. It is probable that the latter is a more advanced, or perhaps a cultivated, form of the former faculty. But the command is more or less imperfect. The most remarkahle instance of tbe possession of such a power of which we have any acoount is that of the painter Blake. He saw things invisible to other eyes. To him an angel on a tree was as visible as the tree itself. How far he was the master and how far the servant of this imeginative vision we are unaware. The power of compelling visions of thie nature is akin to that possessed by some persons of recalling or continuing a dream. In fact, the whole of tbese phenomena are so akin to those of true dreaming, that the term "waking dreems" is very properly applied to them.

With regard to the cultivation of the imaginetive faculty, from whicb Mr. Galton expects eo much, we do not doubt that it is possible. But we hold that, to any merked extent, it is only possible at the expense of some other faculty of the mind. If we take the case of a well-developed and healthy child, there is a certain unknown maximum of power to which it is possible that, under the most favonrable circumstances, that child might attain in body and mind. But tbe conditions oau never be altogether the most favourable. The education will never, in the present state of the world, be perfectly and evenly balanced. The more vigorous faculties will naturally grow at the expense of the less vigorous. Aud if special attention be given to the education of one, it will probably he effected at more than a compensatory starving of otbers. Thus a cereful and studied development of tbe "visualising faculties" would be likely to tend to what is called wool-gathering.

In tbe method of M. Lecoq de Boisbeudren, for the education of the picturesque, or rather of the pictorial memory, cited hy Mr. Galton, we think this danger ie avoided. The method of the teacher is that of strengthening the perceptive power, and thus implicitly strengthening the memory. He teacbes his pupils how to observe, aud then repeats the observation till the image is photographed on the hrain. It may be the case that what Mr. Galton calls the muscular memory comes in aid, bnt tbat is, to our view, a minor consideration. If a pupil is made to define in the air tbe outline of a figure, by bringing the point of tbe peucil, at a given stretch of arm, along the outline as seen by one eye—the other being closed—he will have a more distinct conception of the figure than if he has not thus successively noted each detail. If this operation be repeated, his conception of the figure will become more accnrate and more vivid. So, more or less, will be his memory. If this process be repeated from several points of view, a stereoscopic conception will be formed, and a stereoscopic image will be presented to bis imagination. Tbe education of the memory is here not directly attempted, but will be a necessary result of the education of the perceptive attention.

We hope that Mr. Galton will give the world tbe benefit of his observations and deductions therefrom in a complete and permanent form. Witbout attempting now to offer any opinion on the long-vexed question of distinct faculties of the mind (ae contrasted with distinct operations of the whole mind) we think that there can be no heeitation in admitting the fact tbat the strength of memory in any particular person is proportioned to the power and exercise of attention. When one person has a memory for form and anotber for colour, the first sees the forms and the second the colonrs more distinctly than the other, either beoause snch is the natural bent and balance of hie unconscious observation, or beceuse he takes more pleasure in one order of phenomena than in the other. For cultivating the visual memory, the first thing, then, is to cultivate the power of perception, and this is to be done by some snch methods as that of M. de Boisbaudran. The second rule we take to be not to commit tbe sketch to paper. It is true that the act of sketching may be a fresh exercise of the perception. Bnt we think there is no doubt that memory relaxes her hold from the moment that the mind is aware of the committal of observation to record.

THE GREAT HOSPITAL, MADRID.

CHURRIGUERESQUE ARCHITECTURE.

An enthusiastic young student (long may his enthsiasm last, for it will lighten and brighten while it endnres) who expresses his obligations to the *Builder* in language so fresh and unguarded that it ie quite delightful, asks us to tell him what Cburrigueresque Arohitecture ie. As a rule we do not answer questions that may at once be replied to by turning to a book. And, in this case, if the ardent querist had consulted Ford's "Handbook of Spain," part ii., or teken down the ever-useful Fergusson, and looked at his chapter on Spanish architecture, in the fourtb volume of the "History," his thirst for knowledge on this particular point would at once have been appeased. It happens, however, that we have ready for nse a view of a very well-known building in Madrid, which is an example of this awkwardly-called style, the façade of the San Fernando Hospital, and this we pnblish in onr present issue. We have, in recent volumes, given illustretions of some of the splendid Mediæval buildings whicb are to be found in little-visited Spain,—illnstrations which appear to have afforded infinite pleasure to, at any rate, a section of our readers, and it is desirable thet they should eee what sbape architecture took in that country when the Renaissance ran wild. The earlier works of this period were for the most part cold and academic, but in the seventeenth century reactiou took place, and the utmost extravagance in design was indulged in. From the name of the chief architect of the period,—some call him the chief culprit,—these works fell under the title "Churrigneresque," and may be said to be included between the years 1650 and 1750. The architect of tbe façade we have illustrated was, we believe, Pedro Ribera (abont 1726), who did many extravagant things, but few more so than this. Still, it bas its teachings.

Workmen's Diseasee.—As a set-off against the wealth which tbe sheep brings us with its golden fleece and golden hoof, must be placed a mysterious disease which but a short time ago was unknown in this or any other country. *Capital and Labour* says,—"It is called the 'woolsorter's disease'; aud the germs of the disease are believed to be contained in tbe unwashed foreign wool which arrives in this country tbe colour of ink, and, for reasons partly to be explained and partly inexplicable, as poisouous as the growing Upas tree. The woolsorter goes to bis work at the warehouse, be it in Bradford, Leeds, or elsewhere; he sorts his wool, and the next, perhaps, that is heard of him is tbat he is dead, struck down by this mysterious stealthy disease. . . . . If masters and men confront the new and subtle destroyer witb the determination to conquer, the arch-enemy in this his latest form will be 'laid,' as many a pestilence of greater magnitude has been 'laid' by means of prompt, calm, and sensible action."

CONCERNING SOUTHWELL MINSTER.

We printed a communication the otber day (p. 215, *ante*) in relation to the excursion of the Archæological Institute to Southwell Minster, now in course of partial restoration under the direction of Mr. Ewan Christian. Some further remarks on the building, and what is being done in it, may be of interest to some of our readers.

Southwell is a great name among lovers of English Mediæval architecture, yet there are perhaps a good many still who know the place only by illustrations, which are not very many or very good. Southwell is one of those troublesome places which is on a small branch line, and can only be got at by local trains. Certain details of the Early English foliage work bave been popularised by drawings and photographs,—the foliage decoration in the external arcb of the chapter-house door, for example; and hence many persons think of Southwell habitnally ae a chnrch characterised especially by rich decoration. It is so in one or two portions, exceptionally so, but the first view of the Minster is the view of a grand, eolid, bare Romanesque nave and Norman tower. We apply the term Romanesque to the nave, since it presents, more than is ofteu the case in English work, characteristics common to Romanesque architecture of a certain period all over Europe, and tbere is a very German look about tbe exterior, suggestive of the early churches of the Rhine land, in the straight lines of the western towers, the flatness of tbe buttresses, and the plain circular windows of the clearstory. Tbis German appearance would probably have been still more marked when the western towers had their square slated spires, which have been wanting for fifty years or so, and are now being replaced by the restoring architect. This foreign relationship of the architecture ie traceable, as we shall see, in one or two other points, in eo marked a manner thet one would be curious to know whether the history of the building furnished recorde of any specially foreign influence presiding over its inauguration and constrnction; but documentary evidence in regard to Southwell is, we believe, of the sligbtest.

The west front of Southwell, theu, is a perfectly simple, flatly-treated front, witb a Norman doorway, of the usnal charactor of decoration, and of no very great richness or elaboration, in the centre, and rising into two nearly similar square towers. One slight point of dissimilarity in the detail of the towers is, however, of interest. Tbe northern tower has, about two-tbirds of ite height, the form of decorative wall arcade so common in rather advanced Normen work, formed with round arches intersecting one another. The arcade in the same position on the other tower has a pointed arcade of exactly tho same design in other respects, the intersecting portion of the arches heing omitted. This looke really like giving some countenance to the old and, as we most of ns now think, exploded idea that the pointed arcb arose from the intersection of round arcbes. That it did so in this instance there can be no doubt; but this merely ornamental use of it does not invalidate the conclusions as to its structural origin when used on a large scale and as part of the constrnction of a building. The original masonry of the tower finishes with an oversailing corbel cornice, as does also the centre tower, and from these cornices sprang originally the lines of the timber spire of tbe west towers. The centre tower, we have little doubt, was originally roofed with a somewhat similar square timber spire, of mucb lower pitch, a pyramidal roof rather tban a spire. In all the tbree towers the later parapets and pinnacles have been built flush with the main wall-face, or nearly so, leaving the corbel-table projecting idly from the wall, wbere it, of course, looks particularly had in the angle view. The angle turrets of the west towers, of which those on the north-west tower were still standing at the time of our visit, are at first sight rather a puzzle. The spires were standing (a second edition of them probably) early in this centnry, so that the pinnacles could only have been added in recent times, but they are quite unlike anything that we are accustomed to find built at that time. The explanation seems to be furnished by the centre tower, the roof of which had gone long before, and which was furbished up with pinnacles apparently of late Elizabethan or Jacobean date, two of them had imitations of Gothic, two of them very like Elizabethan chimneys. When the western spires went, the west

towers were finished to match the centre one, with similar debased Gothic and chimney-pot terminations. These, which are of little historical and no architectural value, being imitations of imitations, are being removed, and the new spires will spring from their proper footing on the corbel-table. Of the propriety of thus replacing the spires we have no doubt whatever. The front is incomplete without them, and they have been in existence nearly within the memory of living men [they are shown in a view in Dickenson's "Southwell," 1819], so that to replace them is, in fact, merely to repair a catastrophe, and to substitute a fitting architectural termination to the towers in place of a piece of egregious bungling, for the present finish of the towers is no better than that. The framework of the southern spire is in its place now. As it appears, from something that was said at the visit of the Archæological Institute, that question has been made as to the towers being safe for the weight of the spires, we may add, for the benefit of "weak brethren," that any fear on that point is absurd: the towers would carry twice the weight with safety. As a question of appearance, however, we did not like the way in which it was apparently proposed to bring down the spire on the corbel-table, with a cant outwards at the foot; a completely straight line from the eaves would be more in keeping with the character of the architecture.

The stern character of the architecture is continued round the exterior of the nave and transepts; the fronts of the transepts have an almost barbaric appearance with the large rude cable-moulds to the windows, and the incised ornament of zigzags and small circles filling up the heads of the low-pitched gables; and the change is the more remarkable from this rude architecture to the beautiful Early English work of the eastern transept chapels and the choir, and the rather later and richer work of the chapter-house. The chapels were a rebuilding of the usual eastern apsidal chapels of the Norman church, parts of the Norman work of the original opening into the chapel from the transept being preserved in the interior wall. In the south transept the chapels have been removed without rebuilding, and in the north transept the communication with the church is cut off, and the former chapel is now the library. The chapter-house externally recalls a little, in the treatment of the buttresses especially, the York chapter-house, but on a smaller scale. Going round to the east portion of the choir, we are reminded still more of another cathedral,—Lincoln. The architecture here is in the purest and most refined Early English style; very reticent of ornament, but with an almost Greek refinement and delicacy in the design of the buttresses and the general composition of the lines; and in general effect, and in the detail of the buttress-heads, the base-course, and other points, is so similar to the work of the nave and south transept of Lincoln that one cannot but think some of the same hands were employed on both. A peculiarity, and not a very fortunate one, in the east end is an arrangement of an even number of windows (four), with the pier in the centre; it is interesting as a peculiarity, but does not look well. The Norman north porch to the nave is interesting for its wagon-vault or ceiling, plastered originally, no doubt, and which might be susceptible of decorative treatment in colour.

It is proposed to restore the original high-pitched external roof to the chapter-house, and this will be a manifest architectural improvement, the present roof being neither one thing nor another, and looking as if it had accidentally dropped within the walls; and the chapter-house is such a perfect bit of architectural design of its kind that it is worth while to bring it back into harmony of proportion in regard to its roof. Whether it was worth while, or even desirable, to raise the nave roof to the high pitch belonging to the late period, is another question. It has now been done, and the roof, internally, is a capital piece of solid and simple carpentry, framed with curved braces so as to form nearly the effect of a wagon-vault when seen in perspective, the bays being marked only by a strong tie-beam with chamfered edges from pier to pier: the general effect is quite in keeping architecturally, though not archæologically, with the remainder of the interior. But as the flat ceiling is to be retained in the transepts, there would have been more unity of internal effect if the nave also had a flat or perhaps a canted ceiling: and externally there is just the same objection to the high-pitched nave roof in this case as in the case of St. Alban's; the high roof of the nave abutting against the centre tower seems absolutely to require roofs of similar pitch over the transepts, in order to preserve the balance of composition of the whole. As it is done, it is useless to remonstrate, but we do not consider the game was worth the candle in this case.

Internally the nave at Southwell is a grand specimen of Norman architecture, with the characteristic that, in place of the ordinary triforium gallery, there is what is in fact a double-storied aisle, as in the great churches in Caen, the large triforium arcade opening, not on a narrow gallery in the thickness of the wall, but on a floor the complete width of the aisle, and resting on the lower aisle-vaulting. This two-storied aisle is again much more a Continental than an English feature; one or two fine specimens of its employment in German churches have been illustrated in our columns. The upper aisle is lighted by very small low windows, which form a feature in the exterior, close under the corbel-table of the eaves, the corbels being half interrupted or cut short over the window-heads to give more room. The lower aisles, or aisles proper, are covered by a simple heavy quadripartite vault, the transverse arches very much stilted, and, in fact, almost horseshoe in shape. In the transepts a singular incident is the irregular and incorrect cutting of the cable-moulds over the windows, which show that some one had blundered over his work, or had not been properly overlooked. From the north transept access is gained to the library, which, as before mentioned, is part of the former Early English chapel which was originally open to the church, and which also had, by a rather unusual arrangement, a floor several steps below the level of the church floor; probably the object of this was to gain sufficient height for the chapel without rendering the chamber over it too high up for convenient access. Mr. Christian proposes, as was observed in our former report, to lower the floor (which, for convenience of use has been raised to the level of the church) to its former level, and to re-open the chapel into the church, and restore it to its use as a chapel (placing the library above). Architecturally speaking, this will be, no doubt, a great gain to this corner of the church, and will restore to light details which are now unnecessarily hidden beneath the floor, or built up in mere walls of enclosure.

In the choir-screen we have one of the latest pieces of work in the church, Late Decorated, and very rich and beautiful in detail. The mimic vault which covers the entrance to the choir is peculiar in more ways than one; in the fact that it has vaulting ribs flying quite free of the vaulting surface (or what would be the vaulting surface if it were a genuine built vault), and still more in the fact that there is here found a decided and pronounced example of the German trick of interpenetration of mouldings; another example of this occurs also, though less marked, in the aisle vaulting at the south-east angle of the choir. To find thus an essentially Continental detail again, after a lapse of nearly three centuries, in a church which shows Continental features in its main design at an early period, is an odd coincidence, though, of course, a purely accidental one; and the example of interpenetration, elaborate as it is, may have been merely a casual experiment, or possibly due to the employment of a foreign mason on the work. There is something unusual in other details of the work, as, for instance, in the wall diaper work on the inner side of the screen, where we find a minute design dividing the wall surface, as usual in wall-diaper of this date, into small squares, but in which every square is differently treated,—a by no means usual refinement. This, again, looks as if some foreign hands had been employed on this screen, who gave their own interpretation and treatment to the orthodox English Gothic details of the period. The idea of moving the screen (for purposes of ritual), which seems to have been at least discussed, seems preposterous; it is far too delicate work to be safely pulled about, nor is there any practical reason, in regard to space, for such an alteration: the choir is quite large enough, we take it, for all the demands made upon it as a church for worship.

The interior of the choir is a very fine specimen of Early English work, worthy of the exterior, and in remarkably good preservation; indeed, both the interior and exterior of the choir show in their present state how carefully the stone must have been selected, and how well the whole has been built. Much of the external detail is nearly as sharp and clean as if new, and internally it has hardly been necessary to do anything more than scrape off the whitewash. A curious point in the interior architecture is the random treatment of the caps in the triforium arcade, some of which are carved with fine foliage in the usual style of the period, others (in the same bay) moulded only. At first, the impression is that there has been a definite intention of giving the choir a richer appearance looking eastward than westward, by carving the eastern capitals in each bay, which are of course most prominently seen when looking eastward (and such a treatment would be quite in accordance with Mediæval æsthetics); but though the easternmost bays suggest this idea, in other places the position of carved and uncarved capitals is reversed, so that it would appear to have been mere whim. From a door in the north aisle of the choir we get access to the chapter-house, which here, as in nearly all establishments of the "secular" clergy, is octagonal. The chapter-house is approached by a passage, part of which has formed an open cloister along the side of a small open court left between the chapter-house and the north-east angle of the crossing. In this little cloister we see again evidence of foreign influence. The arcade which separates it from the open court is carried by double shafts placed well apart and with a cross lintel bearing from the inner to the outer shaft, from which the arch springs; the whole having a peculiarly un-English look. The cross-lintels are carved on each face with beautifully delicate naturalistic foliage, in low relief, and mostly in excellent preservation. The beauty, however, of this little bit of architecture is at present much marred by the fact that the space between the shafts has been built up with a plain stone wall up to the level of the caps, and the space in the head of the arch filled up with glazing. This has no doubt been done for the sake of warmth during the time when the chapter-house was still in constant practical use by people who did not like draughts on their way to it; but by this proceeding the beautiful effect of the coupled columns is of course lost, and the whole thing spoilt. There can surely be no practical objection to removing this wall and opening out the little arcade again, and thus enabling us to realise the effect of a peculiarly elegant and, in an English cathedral, unusual bit of architectural composition. As the restoration work in the choir is supposed to be complete, we were surprised to find this had not been done; it would be as righteous a bit of work as a restorer could do, being simply the removal of the raw material of walling from a place where it never should have encroached.

This bit of cloister, with its peculiar treatment, confirms the idea which the chapter-house suggests, that there was unusual and possibly foreign influence at work over this beautiful addition to the building. The chapter-house dates just about the zenith of the Early Decorated or Geometrical period, while the style still retained, with the richer decoration then coming into fashion, the chastened beauty of line and the constructive truthfulness and simplicity of the Early English style. Much of the carving in the chapter-house would convey in itself the notion of a later date, for a large proportion of it is as naturalistic as the carver could make it; but it is evident that there was an original genius at work here, who would not run in the accepted paths of conventionalism, and who, by his own individuality and love of nature, anticipated by a considerable period the style of naturalism which was afterwards to develop in English architectural carving, and not only anticipated it, but surpassed it beforehand. For in the fully-developed period of decorated carving it is very seldom that we find naturalism which, as naturalism, is as fine and as complete as this, and, at the same time, as artistically treated. We give a page of sketches, showing the character of the arcading which surrounds the walls of the chapter-house and some of the details of the carving. The two capitals are specimens out of a number which are all completely distinct in character, all exhibiting the most spirited representation of natural foliage, and all deeply undercut, in some instances so boldly that they seem almost to stand entirely free of the bell of the capital. Considering how delicate the work is, their state of preservation is remarkable. The bases seem to have gone a great deal more than the caps; at least, it appears to have been thought

necessary to restore them all except one, which is tolerably perfect, and has been left as a sample of the rest. However, that is comparatively mechanical work, and so long as the capitals are not tampered with, we need not be inconsolable about the bases. The triangular spandrels above each arch of the arcade are treated with the same variety as the capitals, and are all obviously taken direct from nature, with the exception of some where grotesque animals or heads are introduced. The little sprays of foliage over each capital, concealing an awkwardness in the mitring of the mouldings, form a pretty feature in the work; these, again, are all varied and nearly all studiously naturalistic. The crockets over the gablets are treated with more conventionalism and more similarity, by a true instinct of taste, since great variety in these would have given too irregular and rugged an outline to the boundary-lines of the arcade design. There are two types of them, one derived apparently from oak-leaf, the other from some foliage with longer, thinner, and more numerous laminæ. They present the same general outline, but have sufficient variety in character and shadow effect. The crockets, though so bold in profile, are kept rather thin and sharp in section, in order to keep them well clear of the wall, and leave a space for shadow behind them; and the effective way in which the two lower ones are made to overlap in the angle of the gablets, will be noticed in the illustration. Besides this beautiful and rich arcading, there are many fine capitals and spandrel carvings in the upper portion of the chapter-house, which in fact constitutes quite a school of naturalistic architectural carving, and is worthy of the fullest and most detailed illustration.

Those who visit Southwell should not omit to go into the small open court before mentioned, adjoining the cloister leading to the chapter-house. From the north-east corner of the small court there is a most picturesque view of the parts of the building visible from thence, especially if seen, as we had the good luck to see it, on a day of bright sunshine and cloudless sky,—nothing visible but the picturesque and time-tinted walls of the choir and cloister, interspersed with beautiful bits of detail; and above, the grand mass of the central tower relieved against the blue sky.

Two remarks we may add as to custodianship of the building. The system (now happily obsolete in many of our cathedrals) still obtains at Southwell, of leaving the most interesting parts of the building under the lock and key of an official who expects a fee, proportioned to the munificence of the visitor, for showing them. This we have always protested against. The verger at Southwell is, in the matter of intelligence, a favourable specimen of his class, and has more knowledge of the building which he "ciceronises" than we have found in many cases; but it is a radically wrong principle that buildings which, artistically speaking, are national property, should be under the thumb of a person who tells you that he makes his living by showing the building. Far better to make a certain fixed charge to every one, "for the expenses of the fabric" (as a check on mere idlers), and leave the visitor free to go over it alone or attended as he pleases. The other point we may mention is that residents in the neighbourhood who take an interest in the church have an impression that too much latitude is allowed to the contractor for the restoration to do a good deal what he pleases in small matters, in the absence of the architect. It is impossible in a mere day's visit to form any independent opinion as to how much ground there is for the criticism, but we feel it a duty to give it publicity,—*sous toutes réserves*, as the French journalists say.

Tamworth.—The committee for the restoration of Tamworth parish church have received a report from Mr. Basil Champneys, architect, London, suggesting the mode in which the work may, in his opinion, best be carried out. The total cost would be 1,300*l.* As to the nave clearstory, the four eastern bays are in almost as precarious a state as those on the north side of the clearstory, and would require encasing in the same manner. The probable cost would be 400*l.* The six western bays were renewed some years since, but with a total disregard of all the final detail of the original work. Though this part of the building is not in need of immediate substantial repair, it would have to be considerably reformed to bring it into harmony with the new restoration. The probable cost would be 360*l.*

PROPOSED MUNICIPAL BUILDINGS, GLASGOW.

WE give an outline of the principal elevation of the design selected for the first premium and the plan of the ground-floor. The author, Mr. Corson, says that, in considering what particular form of Classic architecture would be most suitable for a building devoted to municipal purposes, he had to choose one of three varieties, which he distinguishes for his purpose, as Fenestral, Roman, and Palladian. After giving some reasons against the first two, he says,—The third variety, Palladian, he has adopted as the most suitable for a civic structure of many stories and varied uses. "There are many examples of this style in Italy, France, and England. The Library at Venice and many of the palaces there, the Hôtel de Ville (destroyed by the Commune) at Paris, the Banqueting House at Whitehall, and the Carlton Club in London may be cited. In this style the columns never rise through the height of two stories, but each story has its own complete order of columns with the windows between them, and the columns and pilasters are usually attached to the wall. This style has great dignity of character, is much more varied and lively than the Roman, and expresses admirably the character of a building which includes large apartments for civic hospitality as well as for civic business."

The heights of the stories, floor to floor, are as follow:—basement floor, 13 ft.; ground floor, 22 ft.; first floor, 17 ft.; and the second floor varies in height according as the rooms rise into the roof or have other rooms over them.

The principal entrance is in the centre of the George-square front, the entrance to the telling-room in the centre of the John-street front, and the two carriage-entrances are in the centres of the two other fronts in a line with each other.

The front entrance is by a lofty archway, 11 ft. wide by 20 ft. high. The porters' room is on the left, and passing through swing-doors in a glass screen the vestibule is entered. This is 25 ft. square, with large domed niches in the angles, and statuary on pedestals in each niche. As the tower stands over this vestibule the walls are made of a solidity and thickness calculated to give the necessary support. Ascending the steps, the hall and staircase are entered by another archway. The carriage entrance in the court is by an open loggia or covered arcade, 45 ft. by 12 ft., which gives admittance by numerous doors to a vestibule 60 ft. by 23 ft., in which, on the right hand and on the left, are recesses for the reception of cloaks and umbrellas. An easy flight of nine steps leads up to the grand staircase, meeting on a level the approach from George-square.

The grand hall and staircase, 62 ft. by 34 ft., contains two stairs, right and left of the hall, which is divided from them by screens of columns and arches. These lead up to the first floor, and are so arranged that the landing forms an upper hall, 34 ft. by 17 ft., with the council-chamber at one end and the reception-room at the other. The council-chamber, which is over the vestibule and loggia, is 45 ft. by 37 ft., and is arranged with semicircular ranges of seats rising from the centre table. The principal entrance to it is from the centre of the principal landing. The reception-room, saloons, and town-hall are arranged *en suite* on this upper floor.

The reception-room is entered from the grand staircase, and has also an entrance from the Lord Provost's room. The saloons would form a handsome approach to the town-hall, 30 ft. wide throughout, expanding at the angle into a square of 42 ft. The town-hall has a narrow gallery at the sides, forming on one side a series of boxes, and at the west end a deeper gallery, communicating with the upper saloons.

The cost is estimated by the author at 150,432*l.* The referee, Mr. Barry, places it at 220,000*l.*

We have received several letters condemning in strong terms the award of the referee. Considering that the one point on which a large body of the profession have agreed to insist before entering upon any competition is the employment of a professional referee, it seems unfortunate, to use no other expression, that competitors should be led to take this course on the present occasion. That the report presents an apparent inconsistency we are not bound to deny, but we will suppose that the referee could explain it away if he found occasion to do so. Some further observations will be found at p. 366.

ST. PETER'S CHURCH, UPPER HOLLOWAY.

THE new church is built at the foot of Highgate-hill, near the Archway Tavern, and the new district is formed by appropriating a portion of the parish of St. John, Holloway.

The walls of the church are built entirely of concrete, formed with Portland cement and burnt ballast, and are faced externally with red Chylton bricks, 4½ in. thick, and internally with yellow stocks, with red brick bands and arches. The facings are bonded every four courses with a row of headers.

The church is 105 ft. long, the nave is 32 ft. 6 in. wide, and the aisles are 10 ft. wide. In consequence of the width of the nave there is no chancel arch, but the nave roof runs unbroken from east to west. The aisles are 18 ft. 3 in. high to the roof-plate, and the nave is 36 ft. to roof-plate, and 61 ft. from floor to top of ridge. The clearstory walls are strengthened by buttresses, which are supported by flying arches connecting the nave and aisle walls together, and thus relieving the nave piers of some of the weight that would otherwise rest upon them. It has an open-timber roof, and the timbers are left unstained. The church is lighted by means of coronæ hanging from the crown of the nave arches, and the chancel is lighted by two massive standards, fixed at the end of the choir seats. The lighting was carried out by Messrs. Potter, of South Moulton-street. The church is heated by Grundy's apparatus. The cost of the church, including lighting and warming, will be a little under 8,000*l.* It seats about 700. The architect is Mr. C. L. Luck, of Carlton-chambers, Regent-street, and the builders are Messrs. Hook & Oldrey. Mr. J. Kaberry is clerk of the works.

APPRENTICESHIP, OR THE OLD AND NEW WORKMAN.

THE thought has occurred, and is still occurring to many reflective minds, how it comes about that, notwithstanding the great spread of artistic and scientific knowledge, and the sundry facilities now available on the part of the workman, the general mass of our artisans should understand so little, comparatively, of the principles of their respective arts.

Technical education, for the last decade at least, has been a loud cry on all sides, but it is to be feared that in several directions it is a "great cry and little wool." Technical manuals and treatises on various trade subjects are numerous, and they are also cheap; but while some are good, many others are bad, or otherwise very indifferent, or unsuited for the aims and objects the writers or publishers have in view. We are glad to know that some of our technical manuals can be and are studied with advantage by a number of our young workmen, but, generally speaking, they are unsought, and of course unstudied, by the great army of our young operatives. We need not go far to seek for this cause of the lack of interest on the part of many young workmen in matters that one would suppose intimately concern their future prospects. If the same condition that governed our skilled trades for centuries back, and down to the earlier part of the present century still existed, and was conformed to, the value of our technical literature of the day would be duly apparent, and where found useful would be pretty generally made use of by our workmen. With the changed condition of society and the greatly multiplied subdivisions of all sorts of skilled labour which have taken place, the workmen in many of our trades are reduced to little better than mere ciphers. They are no longer, as were their grandfathers in the same or similar trades, complete workmen or masters of their craft, but makers of parts. To the decline of the old apprenticeship system is directly attributable much of our inefficient workmanship, and our large body (still yearly growing larger) of indifferent and inexperienced workmen. Where one man formerly set out and finished a certain piece of work which he operated on from beginning to end, there are in some cases now a dozen hands employed. The part-workman in our large workshops has not the same inducements or stimulus to study a treatise or master the principles of his art as his predecessors had a few years ago. In rare instances he may endeavour to know all that he ought to know, or that is useful for him to know, but the general

When this is satisfactorily accomplished, the question will, in many cases, occur, "Why use the horse at all?" The animal is an admirable motor power for steady and continued motion on a level road. He is distressed,—and thus becomes a costly motor,—on hilly roads, as is seen in Edinburgh. He is also distressed, to a smaller extent, by the effort needed to start. We are, therefore, busily engaged in designing mechanical motors for hilly roads, and mechanical means for aiding the horse to start, and when we have succeeded in perfecting these two objects, the natural sequel will be to release the horse from the tramway altogether.

The recent half-yearly meeting of the North Metropolitan Tramways Company affords an example of what is doing in this minor industry of transport. The length of line worked by the company we make out from the report to be between 21 and 22 miles. The capital expended we also make out to be 735,000*l.*; so that the capital cost is about 3,420*l.* per mile. The report does not enable us to apportion this between road, plant, and live stock; but it mentions that the stud consists of 2,094 horses. The gross receipts for the half-year amounted to 137,736*l.*, which, as the receipts are stated to be at the ratio of 14·44d. per mile run, gives a mileage of nearly 23,000 miles, or rather less than 42 miles per horse per week. This fairly fits with the old rules of the best coachmasters, with the exception that from 40 to 50 miles per horse per week was maintained on the road at the rate of from 8 to 10 miles per hour, while the tramway can hardly be rated at half that speed. We thus have, then, a means of measuring the cost of the loss of power in stoppage and slacking, which is equal to at least that of the difference between the two velocities. In other words, it consumes considerably more than half the power of the animals. This, again, points in the direction of the economy to be obtained by the use of mechanical motor power.

The total expenditure was 111,767*l.*, or eighty-one per cent. upon the revenue. Out of this a dividend at the rate of seven per cent. per annum is fairly divisible. The relaying of the line with steel rails is charged to revenue, so that a reduced cost of maintenance may be anticipated. It would be interesting to have the accounts in more detail, so as to be able to compare more exactly the cost of mechanical and animal power. But the figures as herein given seem to indicate a satisfactory condition of this minor, but not unimportant, carrying company.

Within a day or two of the declaration of the 7 per cent. dividend of the Tramway Company, the London General Omnibus Company declared a dividend at the rate of 12 per cent. The accounts are not published in sufficient detail to allow of such an analysis as might prove highly instructive. But it should be remembered that the roadway is in one case provided, or, at all events, maintained, by the company, and in the other case by the public. The difference in the cost of locomotive power, that is to say in the value, keep, and management of the stud, may thus be but trivial. As compared with the Tramway Company, the Omnibus Company has one main item of capital provided, on which no interest is charged to working cost. If other things are alike, this item is worth five per cent. on the gross income of the traffic.

AN OPENING FOR CAPITAL, SCIENCE, AND SKILL.

In the twelve months ending August 31, 1880, the import of wheat into the United Kingdom reached 59,815,691 cwt., equal to 13,803,621 qrs., and when we add to this the import of wheat flour, which amounted to 10,131,726 cwt., or 2,980,493 qrs., we find that we received from abroad no fewer than 70,247,417 cwt., or 16,784,114 qrs., of wheat and wheat flour. In the twelvemonth ending August 31, 1878, the amount was 62,255,125 cwt., or 14,808,966 qrs., and in the twelvemonth ending August 31, 1879, it was 60,849,823 cwt., or 14,543,607 qrs. If we add oats, Indian corn, and barley, the gross total in 1879–80 reached 34,500,000 qrs. It is easy to calculate how many millions of pounds sterling sent out of this country this means.

Is nothing to be done with our waste lands and idle hands to make us a little less dependent on the foreigner for our daily bread,—not to speak of the desirability of giving work in their own country to some who cannot now get it? Scientific farming and improved machinery must be looked to to bring it about.

THE HITTITES AND ANTIQUE ART.

We have received from Mr. W. St. Chad Boscawen the following *resumé* of his paper read before the Anthropological Section of the British Association at Swansea. The paper dealt with the civilisation and history of the tribes of North Syria. Mr. Boscawen commenced by pointing out the important aid which the Assyrian and Egyptian records furnished to the student of Oriental history in the task of reconstructing the ethnographical and geographical divisions of Western Asia. From the hieroglyphic and cuneiform records we learn that the whole of the northern portion of Syria was occupied by a powerful confederation of tribes, who formed no mean factor in the political complications which, thirty centuries ago, agitated the then known world. In the Egyptian inscriptions these people were known as the Kheta, and in the Assyrian tents we find them called the Kattai, while we may identify them with the Khittim, or Hittites, of the Scriptures. Strange as it may seem, these people, who, more than 3,000 years ago were able to hold their own against all the hosts of Egypt, who defied Assyria for more than six centuries, and only yielded at last to a species of compromise, were, until very recent years, quite an unknown race. The name was known to us from our Bibles and from the inscriptions, but no record could be identified as the memorial of the people whose name was thus brought before us; but things are now changed. No longer is the Hittite empire a mere name. It lives in its recovered monuments, and it will, we hope, shortly speak to us by its inscribed records, and yield, as have its conquerors, Egypt and Assyria, the secrets of the bygone past.

We first find the Hittites mentioned in the inscriptions from the ancient cities of Chaldea, even before the time when Abraham left his home in Ur of the Chaldees,—when they were the opponents of the kings whose armies penetrated into Syria. We find them again at a later period, extending their rule as far south as Hebron, and it will be remembered that Abraham bought the cave-sepulchre of Machpellah from Ephron the Hittite. The fragment of history preserved in the fourteenth chapter of Genesis is one of the most valuable records extant. From it we learn that at the period of the Abramic migration, which we may certainly place at least 2000 B.C., the commercial code current in Babylon had penetrated into Syria, and was known not only to Abram, the native of Ur, but also to Ephron the Hittite. Mr. Boscawen remarked that the record given of the purchase of the field and cave of Machpellah was in almost exact agreement with the technicalities of a Babylonian contract, such as we find in the British Museum. Mr. Boscawen then proceeded to trace the various relations, warlike and peaceful, between the Kheta, or Hittites, and the kings of Egypt, as they are recorded in the hieroglyphic inscription. We find them warring against Thothmes III., Seti I., and Rameses II., the Sesostris of the Greek writers. From these inscriptions Mr. Boscawen was able to trace out the geographical position of most of the Hittite tribes who were engaged in these wars, among whom we may note of special interest to Bible students the Anaka, the Anakim of the Bible, the Katu or Kitu, the Hebrew Kittim or people of Cyprus, the Phœnicians, and the people of Hamath. One of the most interesting and valuable documents relating to this period of Oriental history was a hieroglyphic copy of a treaty made between the king of the Hittites and Rameses II., the ruler of Egypt. In this treaty we find an offensive and defensive alliance entered into, and, moreover, an agreement made to extradite all offenders from either land. This document is extremely valuable, as it furnishes many names of Hittite kings, princes, and divinities, and thus gives an insight into Hittite civilisation. The great battle fought near the city of Kadesh on the Orontes broke the power of the Syrians for some time, and induced them to enter into friendly relations with Egypt. After thus tracing the various points of contact between the Hittites and the Egyptians, Mr. Boscawen passed to consider the evidences, monumental and other, which we have of the Hittite civilisation. He then described the site of the great Hittite city of Carchemish, on the Euphrates, which he had visited and explored during his recent tour in the East. The great mound which formed the citadel, the walls, gates, and quays bordering on the river, were described, and many points of interest regarding the architectural and military knowledge of the Hittites were deduced. Mr. Boscawen next described at some length the various sculptures and inscriptions found on the site. Chief among these was a fine sculpture representing the goddess Astarte or Ashtaroth, the Syrian Venus. This work was of the greatest importance to archæology and to Biblical studies, because it furnished us with an early representation, probably of about the date of Solomon, of the goddess whose worship extended from Babylon all through the west of Asia. The goddess whose worship is described by the prophet Baruch as being one of the most abominable in Babylon, the Ashtaroth, the abomination of the Sidonians, and the Ephesian Artemis or Diana, were all forms of the same nature goddess commonly called the Asiatic goddess.

From the Assyrian inscriptions Mr. Boscawen pointed out evidence that the Greek legends of Hercules and of the Amazons were all derived from stories or religious legends which had been transmitted from Babylon to Carchemish, and thence to Ephesus and even to Troy. The next subject treated of was one of great importance, namely, the influence which the Hittite empire had exercised in the westward spread of the civilisation and art of Babylon and Nineveh. Mr. Boscawen then proceeded to show how many relics of this people were in existence in Mysia, Lycia, Phrygia, and Galatia, and in the regions of the old Lydian empire, all showing that it was to these tribes of North Syria, and not to the Phœnicians, that the Greeks owed much of their culture. The religion inherited by the Hittites from contact with Babylon had supplied the Greeks with much on which to found beautiful legends and poems, the art engendered in Carchemish had spread to Ephesus, Sardis, and even to Troy, as shown by the relics discovered by Dr. Schliemann. From Troy to Mycenæ and thence to Athens, Rome, and the far west, were all steps in that pathway of culture and civilisation which ran from east to west. After referring to the curious hieroglyphic inscriptions which had been discovered on the site of Carchemish and other Hittite cities, Mr. Boscawen concluded his paper by directing the attention of all students of Oriental history to this new factor in the problem of Asiatic history. To the Biblical student it explains much that before was obscure; to the Egyptologist, Assyriologist, as well as classical student, it is a ray of light which penetrates many dark and obscure corners in the labyrinth of Oriental mythology and art.

A WORTHY EFFORT.

Mr. Mitchell Henry, M.P., who has given notice of a motion for next session for the appointment of an Industrial Commission to aid in the development of the resources of Ireland, writes to explain that the objects contemplated are, amongst others,—

1. The reclamation of waste and semiwaste lands by the agency of labourers who would be paid weekly wages for a year, when the first crop would be reaped, and the outgoings be reduced by the food-supply obtained. Afterwards families would be settled on these lands at rents calculated on the capitalised outlay of purchase and wages, and the local congestion of the most barren and crowded parts of Ireland would be relieved.

2. The experiment of tapping some of the large, deep bogs of Ireland by the process of tunnelling at the base or outlet of the dry water-courses always found in bogs.

3. The formation of light railways as feeders to the main trunks, with which Ireland is already tolerably supplied. These would often make a difference of 25 per cent. in the value of the produce of farms now remote from railway accommodation. And lastly, the development of the fishing industries by the construction of harbours and piers. The majority of these works would be remunerative, and entail no loss to the State; but there are certain drainage operations which would require an outlay of public money.

We quite agree with him that if the idea is once grasped by the country that Ireland is an undeveloped estate, requiring only moderate and systematised outlay to make it productive, the further idea will speedily follow that the best form of national insurance will be to relieve a large part of its population from periodical famine, and its inevitable accompaniment political turmoil.

WESTMINSTER OFFICES COMPETITION.

THE Building Committee have refused to adopt the report of their referee, Mr. Barry, and the whole matter is referred to a meeting of the Vestry. While pretending to exclude the press, and making official requests that no information should be given, individual members of the Vestry are said to have assisted in making matters public. The whole affair is becoming a muddle, and one of our correspondents, "A Ratepayer," calls it something worse.

THE DONATELLO SOCIETY, IN FLORENCE.

ON Monday, the 13th, at 9.30 a.m., the exhibition of modern pictures under the protection of the Donatello Society was opened in Florence by the King of Italy in person, accompanied by his brother, Prince Amadeo, and a select body of the nobility, artists, and others. The military manœuvres near and the grand review had brought royalty to Florence, and the committee thought it expedient to anticipate the day of opening, to have the presence of the King to give greater prestige to the undertaking. Count Serristori had most generously offered a suite of rooms in his palace for the exhibition, and in great haste the pictures that had arrived were hung, and a goodly array of art presented itself to the visitors. The English and Dutch pictures have not yet arrived; rooms are arranged for their reception. The half of the pictures at present on the walls are French. Many have already been hung on the walls of the *Salon*. The object of the society is to incite Florentine artists to better work,—to raise the tone by competition with artists of other countries. If the best of each country is hung here the consequences cannot be doubted, but they must be the best, and not the refuse of *Salons*, or the aim of the society will be defeated. Many good names figure in the catalogue. Works by Meissonier and others are on the road, and some fine works, full of thought and high talent, to incite the Florentine artists to better work than of yore in their yearly exhibitions, are already hung. So with example and perseverance much may be gained by this spirited movement in aid of Italian art. The exhibition of old tapestries and other articles will be opened in October, in the large *Salle* of the Refectory in the cloisters of Santa Croce. The third, of art applicable to industry, also in the month of October. Sufficient publicity has not been given to the undertaking. We believe we were the first out of Italy to make known this Society, which has for its object the attempt to restore to artistic Florence some of the grand character it bore in days gone by as the centre for all that was highest in artistic talent.

The King takes real interest in the attempt, and examined with minute attention each work; and if good wishes can procure success, his hearty desires, expressed in cordial terms, will bring great good to Florence.

TRADE UNIONS CONGRESS IN DUBLIN.

THE thirteenth annual congress of the Trade Unions of Great Britain commenced in Dublin on Monday. About 120 delegates were present. Among the larger societies represented are the Amalgamated Society of Engineers, the Miners' National Union, the Miners' (Durham) Association, the London Trades Council, the Liverpool Trades Council, the Edinburgh Trades Council, the Glasgow Trades Council, and the North-east Lancashire Power Loom Weavers' Association. The congress also includes female representatives of the National Union of Working Women (Miss Merrick), the Bingley Weavers' Union (Miss Cordigen), the Yorkshire Heavy Woollen Weavers' Association (Mrs. Ann Ellise), the Upholstresses' Trade Society (Miss J. G. Wilkinson), The Tailoresses' Society (Miss Yeary), and the Bookbinders' Society (Mrs. E. Patterson and Miss E. Whyte).

Mr. Henry Slatter, chairman of the Parliamentary Committee, secretary of the Typographical Association of England, took the chair, and in opening the proceedings said it was satisfactory to know that the success of the present Congress would not be a falling off from that which had attended former meetings, and that this, the first meeting on Irish soil, would be memorable, not only for the largeness of the gathering, but from the importance of the discussions they should engage in. He hoped, also, it would be found successful in furthering the interests of the great cause they had at heart. Some trades had felt the long pressure of bad trade, and even the small expense of sending a delegate was found too great for them to bear. A great portion of the important work to be done would come before them in the proceedings of the Parliamentary Committee, which would be referred to in detail in the report which would be read, and from which they would find that shortly after the last Congress at Edinburgh,—shortly after it had separated,—a dissolution of Parliament was announced, and the consequence of that was to entirely disarrange the plans of the Parliamentary Committee, and the work which they had prepared for the coming session had to be abandoned then, and resumed after the new Parliament assembled. He thought there was no election which more absorbed their attention or caused them more anxiety than the one at Stoke-upon-Trent. He thought he might say for every working man and woman in the United Kingdom that they owed a debt of gratitude to the electors of Stoke-upon-Trent for returning to the House of Commons Mr. Broadhurst, who was not only known to them as their valued secretary, but who had been able to render most valuable assistance in the debates upon the Employers' Liability Bill. That measure, as they were aware, was the subject of considerable criticism when it came before the House. Introduced by an independent member, it attracted very little attention, and hostile capitalists could afford to treat it with indifference; but when it became a Government measure, all the forces which could possibly be brought to bear against it were used, with, he thought he might say, great unscrupulousness, in order to defeat it. It was now, however, passed. Probably it was in many respects less perfect than they would wish to see it, but still it was an important advance on anything that existed previously, if it recognised that the workmen had some claim against reckless and unscrupulous employers. A great part of the employers were not, he was happy to say, men of that class, and they would have little to fear from the operation of the Act, which had now been enrolled upon the statute-book, but some of the employers were of this class, and it was satisfactory to be in a position to be able to deal with them through the Act which had been passed.

On the motion of Mr. Galvin, seconded by Mr. Morrissy, Mr. J. Murphy, of Dublin, one of the representatives of the ironfounders of England, Ireland and Wales, was elected chairman; Messrs. Jones (Bristol), Shorrocks (Manchester), and Davis (Birmingham) were nominated for the vice-chairmanship. The highest number of votes being in favour of Mr. Shorrocks, that gentleman was elected.

On the motion of Mr. Salmon, seconded by Mr. White, Mr. J. Ward, of Dublin, was elected secretary of the Standing Orders Committee; Messrs. Battersby (Glasgow), Abrahams (Dublin), Smith (London), Clark (Liverpool), and Davis (Birmingham) were elected members of this committee. Messrs. Smith (Dublin) and M'Lean (Edinburgh) were elected auditors.

Mr. Slatter then vacated the chair in favour of Mr. Murphy.

The report of the Parliamentary Committee was then submitted by Mr. Broadhurst, M.P., Referring to the Employers' Liability Bill, it says:—The effect of the Bill as it left the House of Commons is shortly as follows: A workman (or his family in case of his death) is to have the same right of action against the employers for injury by negligence as a mere stranger would have, with the following exceptions—namely, 1. The employer is not to be liable unless the injury is caused by the negligence of the employer, or of some person in a position of superintendence, including signalmen, &c., on railways, or by improper byelaws or rules, or is partly attributable to the workman's own neglect including neglect to give information of danger, &c. 2. The compensation recoverable cannot exceed three years' wages. 3. Actions must be brought in the county courts, or sheriffs', or civil bail court, and within a limited time notice of the injury must be given to the employer within six weeks, and the action begun within six months of the injury or death. We have no desire to over-estimate the value of this Act. It cannot, however, fail to be of great value as a preventive against many of the accidents that now occur. If it has this effect it will mainly accomplish our purpose. We are not seeking money compensation from employers, as our chief object is to secure the preservation of the health and life of the bread-winners of the family. While we express our regret that the Government did not legislate on the lines of Mr. Macdonald's Bill, we must not forget that they have travelled as fast as public opinion would have seemed to warrant them. Many of those who now profess their preference for our original proposal were but recently quite opposed to any legislation on the question. The effect of this law will be that the defence of common employment will be swept away in a few years. The battle has been fought over this Act. Time and opportunity only are wanting for the completion of the work. In the Lords the Bill received most severe treatment. On the motion of Lord Brabourne section 3 of Clause 1 was struck out of the Bill. By a vote of a large majority of that House, and on the motion of Lord Beaconsfield, the Act was limited to two years. The Lord Chancellor amended Clause 4, by extending the time for bringing an action in case of death from injury from six to twelve months. The Lord Chancellor also omitted the words "Stock-in-trade" in section 1, Clause 1. With these amendments the Bill came back to the Commons on September 2. In the meantime your committee held a meeting, and passed a resolution appealing to the Government not to agree to the omissions of sub-section 3 of Clause 1, urging that it would be better to abandon the Bill for that session than to accept such a mutilated measure; and we have the satisfaction to report that the Government restored the lost section, and extended the limit of the Bill to seven years instead of two. This firm determination of the Government to maintain the principle of the Bill had its effect in the Lords, and on the following night the Bill passed through the House of Lords as again amended in the Commons without debate. The limitation of the Act to seven years does not at all interfere with the principle of the Bill. The limit, as every one knows, means no limitation in fact, and can even be amended at any time before the expiration of seven years. This paragraph, written at the last moment before going to press, is placed before you in order to show that the Act, as described above, is not altered in principle or scope from its power as it left the Commons after the third reading. It comes into force on Jan. 1, 1881.

We may notice some of the subsequent proceedings of the Congress in our next.

THE *DAILY TELEGRAPH* NEW OFFICES IN FLEET STREET.

THE costly new buildings rising in Fleet-street include premises for the *Daily Telegraph*. They are on the south side of that thoroughfare, a short distance west of Salisbury-court, and immediately adjoining the recently-erected, handsome, red-brick and granite block now used as the offices of the *Daily Chronicle*. The new structure is occupied as the advertisement and general business offices of the *Daily Telegraph*. It is upwards of 70 ft. in height, and has a frontage to Fleet-street of about 30 ft. The main face of the elevation is in Portland stone, red and grey polished granite, being freely introduced for ornamentation. The building contains four lofty stories and attic with dormers. At the east and west sides of the ground-floor portion of the frontage, there are rusticated piers, double-arched windows, having red granite columns, with ornamentally-carved capitals, occupying, with a uniform entrance at the west side, the rest of the frontage. A balustrade above is carried across the elevation. At each side of the first floor, which has arched windows, the head of which is filled in with carved work, there are double red granite pilasters, whilst at the angles of the second floor there are panels faced with polished grey granite. The third floor has a range of four arched windows, divided by red granite shafts and capitals. Above is a bold cornice, the elevation being surmounted by three dormers, and an ornamental iron cresting.

The whole of the old block of buildings on the north side of Fleet-street, forming Peterborough-court, which has formed the publishing and editorial offices of the *Daily Telegraph* for some years past, is intended to be taken down, and an entirely new block of buildings erected on its site. The buildings will have a frontage to Fleet-street of about 60 ft., rising to a

height of between 70 ft. and 80 ft., and when completed will form one of the most prominent features in the thoroughfare. At the west side of the frontage in Fleet-street, there will be a private carriage-entrance. The building is to extend to a depth of about 100 ft. southwards, the printing and publishing departments occupying an extensive area in the rear.

Messrs. Arding, Bond, & Buzzard, of Surrey-street, Strand, are the architects, and Mr. W. Herne, of Bayswater, is the builder.

OBITUARY.

Mr. Stephen Shute, for a number of years managing foreman for Mr. Harry Hems, of Exeter, died on the 3rd inst., of cholera. Mr. Shute was well known over a wide area, not only for his great personal skill, but also for a peculiar amount of quiet tact and unassuming good judgment, which won for him the respect and esteem everywhere of all classes amongst whom he was thrown. Mr. Shute returned home from Belgium a fortnight prior to his decease in the best of health, and succumbed after a few days' illness at the early age of 42, leaving a widow near her confinement, and nine children to mourn his loss. His funeral was attended by many hundreds of members of the various building trades and others, and he was carried the whole distance to Whipton Cemetery (two miles) by those amongst whom he had toiled.

Hermann Anschutz.—The death is announced, at Munich, of this veteran German artist, who had just completed his 78th year. He was one of the pupils of Cornelius. Having studied under Hartmann, in Dresden, and Cornelius, at Dusseldorf, he gave as the first specimen of his talent the picture for the ceiling of the Odéon, at Munich, representing the Judgment of Midas, painted when he was only twenty-eight years of age. The King of Bavaria, Louis I., was so pleased with this that he sent the young artist to Italy to study the remains of ancient painting in the Museo Borbonico, and at Herculaneum and Pompeii. Returning to Munich, Anschutz executed a series of frescos and encaustic pictures in the Royal Palace in the ancient style, after designs by Leo von Klenze and Zimmerman. In this work he was partly assisted by Nilson and Hiltensperger. He subsequently resumed oil painting. Forty years ago he was made Professor of Painting in the Munich Academy of Arts, a post which he resigned in 1872, on account of enfeebled health.

COMPETITIONS.

Broadstairs Drainage.—At the last meeting of the Broadstairs Local Board, it was reported that a number of plans and estimates had been received for the proposed drainage works. The chairman (Mr. Clark) suggested the appointment of a competent engineer to examine the plans and advise the Board as to the best scheme to be adopted. Mr. Kidd (a member of the Board) said he had a scheme, submitted before he knew he was going to be a member of the Board, and wished the plans to be inspected by the Board before deciding to consult an engineer, and moved that the plans be received and submitted to a committee with instructions to consider and report at a future meeting, such committee, if necessary, to be a committee of the whole Board. This motion was seconded and carried. Specifications and plans were sent in by the following firms, viz., Russ & Minns, London (estimated cost 6,440*l.*); Jas. Lumley & Co., Bradford (8,390*l.* 5s.); Winship & Harrison, London (11,400*l.*); Le Fevere & Co., Budge-row, London (26,000*l.*); T. Hennell, London (9,820*l.*); Rowell & Harding, London (12,000*l.*); Gotto & Beesley, London (7,560*l.*); Dudley & De Salis, London (5,515*l.*); T. Taylor, London (mains 5,874*l.*, branches 1,727*l.*, total 7,601*l.*); H. Parker (8,500*l.*),—to run it into sea at North Foreland, 6,500*l.*; Benjamin Nichols & Co., Birmingham (8,540*l.*); J. G. Clow, Dartford (22,608*l.* 13s. 8d.); Saunders & Collard, London (4,994*l.*); E. F. Griffith, London (7,900*l.*); J. Kidd, St. Peter's (6,500*l.*). Ultimately, it was resolved that the plans should be referred to a committee of the whole Board for consideration. "One who wants to know" writes to *Keble's Gazette*,—"Is it not an anomaly that a gentleman who has submitted a plan for the drainage of Broadstairs and St. Peter's, should accept a seat on the Local Board just at the time that that Board has to discuss his and other plans, and should still allow his plan to remain in competition? And is it advisable for a body of gentlemen, who are not engineers, to go into committee to discuss the merits of some fifteen elaborate plans for the drainage of this district, without the assistance of an unbiassed professional man?" To his first question we would reply in the affirmative, and to the second we would say,—Decidedly not; if the members of the Local Board take this course, the inhabitant ratepayers will very likely rue the day.

Competition for a Villa Residence. — The *Staffordshire Advertiser* says that of twenty-six sets of plans that were submitted in competition for a proposed new villa at Swansea, those of Mr. J. P. Mumford, architect and surveyor, of Rugeley, were accepted. Sad work!

GLASGOW MUNICIPAL BUILDINGS.

LETTER FROM MR. CORSON.

MR. GEORGE CORSON, of Leeds, who will receive the first premium for his design for the new municipal buildings at Glasgow, has written to the Glasgow Town Council a letter, in which he refers at considerable length to the style and cost of the new buildings. As estimated by himself and Mr. Barry respectively, he says it is evident that Mr. Barry has taken his London experience and London prices in forming his calculation of the expense. Glasgow prices are, if anything, under those of Leeds; and he has taken the cost of the Leeds Municipal Buildings, which he is now erecting, as a guide in forming an estimate of the Glasgow buildings, and as a result of one of his calculations he has added 20 per cent. to the rate per cubic foot. Thus, while the Leeds buildings are to cost 10d., the Glasgow structure would be 1s. per cubic foot. In this average he includes domes and towers.

In concluding his letter Mr. Corson says:—

"I may mention that the late Mr. Cockerell, architect, of London, who was the referee in the Leeds competition, reported in favour of my design, but also said that none of the designs could in his opinion be carried out for less than 1s. a foot. The result of the estimates accepted proved he was wrong, and that my estimate was ample. The total area covered by the Leeds buildings is 3,054 yards. The Leeds Town-hall, which cost 120,000*l.*, including land and fittings, has an area of 5,800 yards, entirely covered by buildings. The total area covered by the Glasgow buildings is 5,608 yards. In each case the area of the courtyard or quadrangle is deducted. Assuming that the above facts prove the correctness of my estimate, I venture to submit that I have fulfilled all the conditions of the competition, and that it would be manifestly unfair to select for execution, in preference to mine, any of the designs that have broken the condition as to cost. If I had thought it right to take a margin of another 100,000*l.*, I venture to think that my design would have stood first absolutely, as Mr. Barry has placed it first of such designs as adhered to the restricted cost."

The designs, still on view in the Corporation galleries, are attracting a considerable amount of attention; and before the Corporation concludes an arrangement with any architect, some exciting scenes will be witnessed in the Council chamber. Indeed, one of the daily newspapers advises the abandonment of the scheme on account of the expense, and the necessity there is for adopting a sewage scheme.

TRAMWAYS.

Southwark and Deptford.—The permanent way of the Southwark and Deptford tramway is being rapidly laid between Deptford Lower-road and the Spa-road railway station, Bermondsey, about 200 yards being, on the average, completed each week. The stabling for the company's horses and the sheds for the cars will soon be completed, and the cars are nearly ready for delivery, so that it is expected a portion of the line, between Deptford Lower-road, near the crossing of the Brighton Railway, and the Spa-road station of the South-Eastern Railway, will be opened for traffic in a few weeks.

Oldham.—It was stated on the 9th inst., at the meeting of the Oldham surveyor's committee, by the borough surveyor, that the Oldham tramway line, which has been in course of construction about nine months, is now completed. A communication has been received from General Hutchinson, who will inspect the line on behalf of the Local Government Board. The Failsworth tramway is to be inspected at the same time. The Oldham line of tramway has cost between 25,000*l.* and 30,000*l.*, and has been let to the Manchester Carriage Company, who will therefore have in their hands the through tram-line from Manchester to Oldham.

RENTAL AND SANITARY REFORM.

ON Sunday last, what is described as a crowded meeting, convened by the "Local Rights Association for Rental and Sanitary Reform," was held at the Democratic Club, Rose-street, Soho, to take into consideration the best means of advancing the objects of the Society, and to receive reports from members who had visited certain premises which it was alleged were in an unsanitary condition, and for which excessive rents were charged by the house-farmers.

The chair was taken by Mr. Duggan, who stated that the Association had appointed a commissioner to inspect the localities in which houses, and the tenements in them, were in an unsanitary state, and that morning reports would be submitted of the wretched condition in which numbers of the working classes are obliged to live. Last Saturday he visited a district, not far from where they were now met, and was invited to inspect a man's house. He did so, and, on going up the stairs, found it necessary to take two and even three steps at a time, in such a dilapidated state were the stairs. The working man lived at the top of the house, but there was not what could be called a roof on the habitation. The floor was full of holes, and the man,—it being Saturday,—was drying his clothes in the room in which he lived and slept, and for which he was paying 4s. 6d. a week. Now, that plainly showed that if the inspectors of nuisances did their duty, such a state of things could not exist. He went to another house in the neighbourhood of Holborn, and there, in a wretched hovel, he found a man suffering from English cholera, his wife having been previously afflicted with the same epidemic,—in fact, in the whole place the inhabitants had been "down" with diarrhœa and cholera, and no wonder, such were the unsanitary conditions under which the poor people lived. It was, indeed, high time that some association took these scandalous matters in hand.

Mr. E. Dunn (hon. secretary) said cases like those reported by the chairman, with scores of others, would be embodied in a comprehensive report for presentation to the Secretary of State, Sir William Vernon Harcourt, M.P., and also to the Metropolitan Board of Works. In the report no delicacy as to concealing the actual addresses of the unsanitary houses need be observed. He had during the week visited six different washhouses in the neighbourhood of Edgware-road, and in all of them there was that peculiar effluvia arising from the drains not being properly trapped. Many of the poor working classes were compelled to live near the aristocracy, because they had to work for them, and must live either in these old "shanties," or in "model" dwellings. As to the public baths and washhouses, how could women, who must bring their children with them, use these, which were filled with steam?

Other speakers addressed the meeting, which was adjourned, after a resolution in support of the objects of the association was passed.

DRAINAGE AND SEWERAGE WORKS.

Dorchester.—The Town Council (acting as the Local Board) have passed a resolution requesting the surveyor (Mr. Thomas) to prepare plans of works for the treatment of the sewerage of the town. A committee appointed by the Council had previously reported adversely to placing the works in the hands of the Native Guano Company ("A. B. C." process) or the Rivers Purification Association, on the score of expense, and recommending, at the same time, that the work should be placed in the hands of the surveyor.

Loughborough.—At a recent meeting of the Loughborough Board of Guardians (acting as the Rural Sanitary Authority) the Clerk stated that he had received a letter from the Local Government Board containing Major Tulloch's report upon the sewerage works. It appears that some months ago a dispute occurred between the Sanitary Authority and their engineer, and that in consequence the Local Government Board were appealed to to send down one of their engineering inspectors. The Sanitary Authority alleged that their engineer had selected ground altogether unsuitable for a sewage farm, the greater portion of it being above the outfall, and that the scheme had not been carried out in accordance with the plan approved by them. The letter stated that the

Local Government Board had received from their inspector, Major Tulloch, a report upon his conference with the Rural Sanitary Authority with regard to the works of sewerage and sewage disposal for the village of Sheepshed, and had learnt from Major Tulloch that the land for the purification of the sewage has not been judiciously selected, as, with the exception of eight acres, it lay too high to allow of the sewage flowing on to it unless the sewers are worked under pressure. Major Tulloch stated that he recommended the Sanitary Authority to exchange the unsuitable land for some more available, or, if this should be impracticable, to purify the sewage on the eight acres. The Board also found that the sewers had been so laid as to work under pressure, although Major Tulloch had brought under the notice of the engineer the serious objection to this being done. It being the opinion of the Guardians that it was not desirable to entrust Mr. Stephens with the carrying out of the works suggested by the inspector, it was unanimously resolved to retain Mr. George Hodson, C.E., of Loughborough, and the clerk was directed to instruct him to consider the suggestions, inspect the outfall and land leased by the Authority, and ascertain what land suitable for irrigation could be obtained in exchange for the land leased, and to report fully thereon at the next meeting.

MASTERS AND MEN.

Wages in the Pottery Trade.—At a meeting of the Staffordshire Potteries Arbitration Board at Hanley, last week, it was stated that every branch of workmen in the pottery trade had resolved to give notice to the employers for an increase of wages to the same level as they were before. Lord Hatherley, as umpire to the board, gave the award reducing the wages eight per cent. in November last. Most of the men have expressed their willingness to submit the matter to arbitration, but the men in three important branches of the trade have not yet decided to accept arbitration. Mr. Brassey, M.P., will sit as umpire in October, preparatory to the annual revision of the wages list in November.

Weston-Super-Mare. — A misunderstanding exists between employer and employed in the building trade, and the Society men are out on strike. The masters rely on filling any vacancies in their staff with men from Bristol, where, it is stated, there are many able and willing to work with but little to do.

HOW SUBURBAN DWELLINGS ARE BUILT.

HEAVY PENALTIES.

At the Edmonton Petty Sessions, on Monday last before Messrs. Abbiss and Howard, divisional justices Mr. George Preedy, builder, of 69, Mayfield-road, Dalston appeared to answer four summonses obtained at the instance of the Edmonton Local Board, which charged him with infringing the bye-laws of the said Board, which provided that the walls of new buildings "shall be efficiently and solidly bonded and put together with mortar or cement."

Mr. Moulder, solicitor and clerk to the Board, conducted the proceedings, and having briefly mentioned the facts, called

Mr. Johnson, assistant-surveyor, who deposed that in the course of his duties he visited certain houses which were being erected by the defendant at Jeremy's-green, Lower Edmonton. He noticed a heap of substance containing about 32 yards, covered with sand. He obtained a spade, and dug into the heap, and found that, with the exception of a slight coating of sand, it was common mould. He called the attention of defendant to it, who said he had purchased the heap as it stood. Witness told him that it must not be used for building purposes, and he asked to be allowed to scrape off the sand, promising not to use the soil. Witness visited the place the next day, and found that it was not being used. On a subsequent visit witness noticed that the heap had been removed from the spot where he first discovered it to another place about five yards off. He went again the next day, and found that the mould had been covered with sand as before, simply as a blind. Witness remonstrated, and defendant said it had been covered by mistake. He warned the defendant that the material must not on any account be used as mortar, and he said it should not be. On the 23rd of August witness found the mould and sand being screened together; on the 24th being mixed; and on the 25th being used as mortar in the construction of four dwelling-houses.

Samples of the material were produced, and were easily reduced to dust between the fingers.

Mr. Moulder.—Can walls be solidly bonded together with that stuff?

Witness.—No. I could easily knock all the work down with my hand.

Mr. Moulder.—What do you say that stuff consists of?

Witness.—Of about eight parts of mould to one of sand, and very little lime.

Other evidence having been given,—

Defendant said, as soon as his attention was called to the bad material he pulled the work down and built it up with better stuff.

Mr. Abbiss.—Pulling down the work under such circumstances is no answer to the charge. You should have used proper material at first. You were cautioned more than once, but you went on notwithstanding. You knew you were doing wrong.

Defendant called a witness, who said he was employed to manage the brickwork, and he had used worse material on larger jobs.

Mr. Abbiss said the case had been fully made out, and that the Local Board were simply doing their duty in seeing that houses were built that would be safe and sound. Defendant must pay the full penalty of 5*l.* in respect of each house,—20*l.* altogether,—with 1*l.* 12*s.* costs, and in default a distress warrant would issue.

PITCH-PINE WOOD FOR WINDOW-CILLS.

SIR,—I cannot agree with all the remarks that were made in the *Builder* two weeks ago, by "An Old Carpenter," respecting the use of pitch-pine wood for window-cills. Having had a large experience in the use of that wood, I have come to the conclusion that if the stuff is thoroughly well seasoned, it comes next in order of merit to English oak. Fifteen years ago I introduced pitch-pine for window-cills on a large estate, where 5 0 or 600 houses have been built, and since then nothing else has been used there for that purpose. As far as my general observation goes, these cills are all now as sound as when they were first fixed. I am in a position to say this as my business calls me into one or another of the houses daily.

This to me is sufficient proof that pitch-pine is a first-rate material for window-cills, and I should certainly prefer using it at any time to inferior oak. H. S.

EXTERNAL COLOUR.

SIR,—Some speculations and discussions that have lately appeared on the artistic colouring of houses, joined to the bare unrelieved appearance of those done in Portland cement, have suggested to me that the latter would be improved by the quoins or corners being finished with raised work done in cement of a considerably darker colour,—say, a dun-brown,—the jambs of the hall-door being made to match.

Other colours might suit different tastes; the colour of dark red sandstone for instance, or of limestone. A. BOYLE.

CHURCH-BUILDING NEWS.

Nunnington.—The restoration of All Saints' Church, Nunnington, near Helmsley, North Yorkshire, is about to be undertaken. This church was built about 600 years ago, and was partially rebuilt in 1671. It is now in a most dilapidated condition; in fact, it was condemned as thoroughly unsound thirty years ago. The proposition was first to pull it down completely, but now a thorough restoration has been determined on; and Mr. Ewan Christian, the architect of the Ecclesiastical Commissioners, has been entrusted with the work, which will include the removal of the low white-washed ceiling of the chancel and nave, the formation of a new side aisle, but putting back the north wall; building of new open roofs, rebuilding of vestry and porch, adding an organ-chamber and new organ, opening out the tower and facing the unfinished west arch, the provision of open seats and new reading-desk, and the introduction of a system of warming and ventilation. Thirty-six additional sittings will be gained in the aisle, and eighteen more in the tower, by the alterations, which, it is estimated, will cost 2,200*l.* Mrs. Rutson, of Newby Wiske, has already offered 800*l.* and some stone, and Mr. John Rutson gifts of 300*l.* value towards the restoration.

Kirkdale.—The parish church of Kirkdale, near Kirbymoorside, is now in course of restoration. A new roof, of oak, and slated, will replace the old flat one, and will be 12 ft. higher than it. A new three-light east window is to be inserted, and also one in the south wall of the chancel. The old painted seats in the chancel are being removed. A system of drainage of the churchyard will be put in, the chancel floor laid with concrete, and then covered with polished flags. In removing the old roof the supporting beams were found to be quite rotten, and other portions were very much decayed. In removing the soil near the altar the workmen came upon three lead coffins, the outer coverings of which had mouldered away. The restoration is in the hands of Mr. S. Crowther, architect, of Manchester, and the contract will be carried out by Mr. Mark Foggett, builder, of the same city.

Llawr-y-Glyn (near Llanidloes).—The foundation-stone of a new church at Llawr-y-Glyn, which is about six miles from Llanidloes, has been laid. Mr. N. Bennett Owen gave the site, which is in the valley of the Trannon. The building will be erected of grey stone, in the Gothic style, from the designs of Messrs. Jones & Park. It is to accommodate 150 worshippers, and its cost, exclusive of bells, will be 900*l.*

Noss.—On the 10th inst. was laid the corner-stone of a new church at Noss, a growing village on the banks of the river Yealm, in the parish of Revelstoke. The building is to cost about 3,000*l.*, and will be erected from the designs of Mr. J. Piers St. Aubyn, architect. His plans show a church, in the Perpendicular style, for the accommodation of 250 persons. It will consist of a tower, nave, north and south aisles, with two entrances,—a south porch, with doorway under the tower. The vestry will be under the north aisle, and approached by a flight of granite steps. The structure will be built of local stone, with granite dressings, with an oaken roof. The clerk of the works is Mr. Crosbie, and the building will be put up by workmen in the employ of Mr. Edward C. Baring (lord of the manor, who is erecting the church at his own expense.)

Old Deer (N.B.).—The foundation-stone of a tower to the church of Old Deer has been laid. The tower, which is being erected at the south-east corner of the church, is of Aikey Brae granite, from a design by Mr. Raeburn, architect, Edinburgh, and will rise to a height of 73 ft. Above the tower will be a slated spire, rising to an additional height of about 30 ft. The tower has a room for a library on the basement floor, and a bell-tower and clock above.

SCHOOL-BUILDING NEWS.

Ardwick, Manchester. — A new Wesleyan Sunday-school which has been erected in Chancery-lane, Ardwick, was formally opened on the 9th inst. The building occupies the site of the old Chancery-lane School, erected in 1817, and externally is of red brick, with terra cotta and Hollington stone dressings, the style being Gothic. The building is three stories in height, and has two entrances — one for boys, in Chancery-lane, and the other for girls, in York-street. On the ground-floor, there is a large room 60 ft. by 40 ft., and a room which has been set apart for infants, 30 ft. by 20 ft. There are also on this floor four class-rooms and a library and rooms for the librarian and secretary. The infants' school will afford accommodation for about 200 children. On the first floor, which is reached by a stone staircase, is a lecture-hall, with large vestries and class-rooms. There are eighteen class-rooms, and altogether school accommodation is provided for about 1,300 children. The total cost of the premises, inclusive of the site, has been about 8,000*l.* The work has been carried out by Messrs. R. Neill & Sons, contractors, Manchester, from designs furnished by Mr. Stevens, architect, Manchester. The entrances, it may be stated, are paved with Craven's encaustic tiles, glazed bricks forming dados to the walls on each story.

Monton (Manchester).—The Countess of Ellesmere has just laid the foundation-stone of a new school-room for the district of St. Andrew's, Eccles. The whole scheme is not yet in hand, only one school-room (48 ft. by 30 ft.) and two class-rooms being now in course of erection, but it is intended ultimately to make fuller provision for the wants of that portion of St. Andrew's district, with day and Sunday schools for both boys and girls. The site of the new building is the gift of the Bridgewater trustees, who have presented about one-third of an acre of land off Slack-lane, Monton, nearly opposite Partington-street. Mr. Lord, of John Dalton-street, is the architect, and accommodation will be afforded for about 240 children, at an estimated cost—for the completed and furnished school-room—of 1,420*l.*

VARIORUM.

THE sixth volume of "Proceedings of the Association of Municipal and Sanitary Engineers and Surveyors," recently published by E. & F. Spon (Charing-cross), contains a number of useful papers, many of which received notice in our pages at the time of delivery. The volume is edited by Mr. Graham Smith.——"The Visitors' Handbook to Gloucester Cathedral," by J. H. Billett just now published (Billing, Gloucester), is clearly and sensibly written. It includes a full account of the stalls and other wood carvings.——The very interesting paper on "Samuel Prout, Artist," by Mr. J. Hine, F.R.I.B.A., read before the Plymouth Institution in March last, has been reprinted in a separate form from the Transactions of that Society.

Miscellanea.

The Dignity of Labour.—The annual report of the Howard Association remarks:—"One-sided indeed is 'head knowledge' when it is not applied to a wise recognition of the dignity of manual labour. Both in Great Britain and America 'popular education' (so called) has not yet sufficiently taught this dignity, either to boys or girls, otherwise there would not be the present rush of the former into poverty-stricken clerkships, or of the latter away from the old-fashioned ranks of useful domestic service. One of the best of the myriad letters of Mr. Gladstone was the note written on this subject (dated February, 1877), in which that great statesman said: 'Working men should for themselves, and especially for their children, try more to elevate handicraft, and less to escape from it into the supposed paradise of pen and ink.' And if our pulpits were more practical, and less devoted to aërial generalities of transcendental theology, they would not only, as the *Spectator* wisely suggests, bring down Christianity into the practical duties of every-day life—'how to drive horses with humanity and sell even cabbages with honesty,'—but would also inculcate the truth that handicraft labour has for ever been dignified and ennobled by the participation and example of the Apostolic Tentmaker of Tarsus and Fisherman of Galilee, to say nothing of a still more august Exemplar. This conviction, and its practical recognition, becoming generally popular, the cells of prisons and the wards of workhouses would also, assuredly, tend to become far less crowded by miserable inmates."

Unhealthy Dwellings in Marylebone.—The *Daily Chronicle* reports an inquest held by Dr. Hardwicke, the coroner, concerning the death of Robert Bailey Bird, aged four years, of 1, Christchurch-residences, Lisson-street, Marylebone. The deceased, who had been to the Bell-street Board School, complained of his throat being sore, and although everything was done for him, he grew worse. There had been a good deal of illness at the schools, and the deceased some three months ago caught the measles there. There had been scarlet fever in the house, which contained twenty rooms, which were let out to ten families, each family having two rooms. The dust-bin, which was just outside the room-door of the parents of the deceased, smelt very badly, as it was not emptied often enough, whilst near to that was a waste water-pipe, down which the persons who lived upstairs emptied their dirty water, which ran into an open drain, and the smell therefrom was very bad. Dr. John Cuy Westmacott said that he had made a *post-mortem* examination, and found that death was from inflammation and ulcers of the windpipe, and from the evidence given he should say it was caused by diphtheria or scarlet fever, arising from the condition of the house. The jury returned a verdict that the deceased died from inflammation and ulceration of the windpipe whilst suffering from blood poisoning, arising from diphtheria and scarlet fever. The jury added that the sanitary condition of the house was unsatisfactory, and that a report respecting the drainage accommodation should be made to the Marylebone Vestry.

Condition and Health of Paris.—The abominable smells that pervade some quarters of Paris, and the unusual mortality of the last two months (the death-rate for July and August shows an immense increase over the corresponding period of 1879), are beginning to cause uneasiness to the Municipal Board of Health. According to the *Standard*, the medical men of whom it consists have held a meeting, the only result of which was a further illustration of doctors disagreeing. One gentleman held that the sewers were at fault; another, that the new system for utilising the contents of Parisian cesspools as manure did all the mischief. The condition of the water is also abominable, and has much to answer for. There has been no rain for six weeks to speak of, and there are 80,000 cesspools in Paris, to which the evil is to be traced. As, however, hundreds of people over the usual average are being killed, it would be gratifying to know that steps were being taken to remedy the known evils.

Scarcity of Water in Cardiff.—In consequence of the continued drought, the inhabitants of Cardiff were, on the 9th inst., called upon by placards to economise their consumption of water.

The Sanitary Institute of Great Britain.—This Institute,—the president of which is the Duke of Northumberland,—will hold its autumn congress next week, in Exeter, under the presidency of Earl Fortescue. In connexion with the meeting there will be an exhibition of sanitary appliances and apparatus, which is to remain open for more than a fortnight. The sections of the Congress are:—1. Sanitary Science and Preventive Medicine; president, Dr. De Chanmont, F.R.S. Section 2, Engineering and Sanitary Construction; president, Mr. Robert Rawlinson, C.B., M.I.C.E. Section 3, Meteorology and Geology; president, Sir Antonio Brady, F.M.S. The order of proceedings will be as follows:—September 21st., public luncheon at the Guildhall; three p.m., opening of the exhibition by the Mayor of Exeter; eight p.m., first general meeting; opening address by the president, Earl Fortescue. September 22nd, second general meeting. Section 1.—Address by the president of the section, to be followed by papers and discussions on Sanitary Science and Preventive Medicine; in the evening a *conversazione* will be held by invitation of the Bishop of Exeter at the Palace. September 23rd, third general meeting. Section 2.—Address by the President, followed by papers and discussions on engineering and sanitary construction. In the evening Dr. Richardson, F.R.S., will deliver a lecture. September 24th, fourth general meeting. Section 3.—Address by the President, followed by papers and discussions, meteorological, geological, and geographical. In the evening the closing general meeting of the Congress will be held, to be followed by a public dinner. The next day (Saturday) will be devoted to excursions.

Mural Paintings in Manchester Town Hall.—Mr. Ford Madox-Brown has just completed the second panel of his frescos now being painted in the town-hall of Manchester, and a writer in the *Liverpool Daily News* gives some interesting particulars of the work. The panel first painted (the second in order on the walls) is entitled "The Baptism of Edwin," and is illustrative of an important event in the very early history of Manchester. Panel No. 1 (the second painted) represents the Romans building a fort at Mancenion, and the subject embodies the foundation of Manchester, for although the British name Mancenion seems to indicate its locality as a centre for population, it is uncertain that anything worthy of the name of a town existed before the Roman Mancunium. The writer says,—"There may be less profusion of concentrated thought in this panel than in the other, but there is more of collateral invention, and as we half-listen to the piercing wind whistling about the limbs of the builders, and surging amongst the rich folds of Agricola's robes and of his wife's fur cloak,—the whole being wild, biting, and inveterate,—we cannot but feel that this is altogether the more satisfactory work. The cartoon for the third panel (still unpainted) represents the expulsion of the Danes from Manchester, and is a picture heaving, nay, rocking and reeling, with terrible energy, yet touched on the humoristic side also with certain curious incidents."

A New Monastery in Sussex.—Between Brighton and Worthing there is being erected a large Carthusian monastery, to be dedicated to St. Hugh, an offshoot of the Monastery of the Grande Chartreuse, in the mountains of Dauphiné. The estate is about 350 acres, of which fifteen are covered with buildings. The architect is M. Normande. To give an idea of its magnitude, it may be stated that the main court is larger than the Tom Quad, at Christ Church, Oxford, or the great court of Trinity at Cambridge, and is surrounded by a range of cloisters with stone-fretted vaults. The chapel is to be of cathedral-like dimensions.

Luminous Paint for Railway Carriages. The ceilings of carriages on the Great Northern, Midland, and Lancashire and Yorkshire railways have been painted with luminous paint, and passenger-trains composed of these carriages, when passing in the daytime through long tunnels, have not now to be lighted by means of oil-lamps, as is usually the case, there being sufficient light reflected from the luminous paint.

Mr. Rupert Kettle.—Her Majesty has conferred the honour of knighthood upon Mr. Rupert Kettle, of Wolverhampton, in recognition of the services he has for many years rendered as arbitrator in connexion with wages disputes in the iron trade and other leading industries of the kingdom.

Artisans' Dwellings in Dublin.—The report of the directors of the Dublin Artisans' Dwellings Company for the half-year ending 30th June last, states that the capital subscribed is now 33,730*l.* All the buildings on the Manor-street site have been handed over by the contractor. They consist of four two-storied cottages facing Manor-street, thirty-two of a somewhat similar size in Kirwan-street, and thirty-six one-storied cottages at the rear. The directors have in course of erection four cottages on a site in Buckingham-street. Negotiations with the Corporation are pending for a lease from them of the site known as the Coombe area, containing 4½ acres, at a rent of 200*l.* a year, commencing from the 1st of January, 1883. The directors propose to expend at least 20,000*l.* in building upon this site. A moiety of this amount will be borrowed from the Board of Public Works; one shareholder has promised to contribute 4,000*l.*, and the directors rely on the shareholders and public subscribing the balance required. The directors believe the site to be a most suitable one in all respects; it will give space for the erection of 200 cottages. The rental of the company's property up to the 30th of June, 1880, was 1,234*l.* 7*s.* 4*d.*, as compared with 1,114*l.* 4*s.* 8*d.* for the half-year ending December, 1879, showing an increase of 120*l.* 2*s.* 8*d.* The arrears of rent were 34*l.* 15*s.* 9*d.*; and out of a total number of 261 tenements, there were occupied 241. The entire revenue for the half-year, including balance of 61*l.* 19*s.* 2*d.* remaining after paying last dividend, amounts to 1,340*l.* 5*s.* 9*d.*, which, after providing for all expenses, will leave a balance of 799*l.* 11*s.* 5*d.* out of which the directors recommend a dividend at the rate of 4 per cent. per annum, leaving a balance of 127*l.* 12*s.* 11*d.*

A Reredos Difficulty.—Previously to the consecration of the church of St. John the Evangelist, Walton-on-the-Hill, near Liverpool, a memorial from a body of the parishioners was presented to the Bishop of Liverpool, calling attention to the existence of "a piece of sculpture containing in relief a full-length figure representing Our Saviour extended on a cross, with figures of the Virgin Mary and St. John at the foot of it, affixed to the wall over the communion-table." The reredos in question is the gift of Mrs. Gerard Leigh, of Luton, and was executed by Mr. J. Woolner, R.A. The Bishop of Liverpool, in reply, said,—"I do not like the sculpture over the communion-table, and I do not like the separation between the chancel and the body of the church. Speaking for myself, I should never think of adorning or arranging a church after such a fashion. But the question is not what I like personally or dislike, but what is legal, or rather what is not forbidden by the law of the Church of England. Now, I am informed by my legal officials that there is nothing in the church of St. John the Evangelist, Walton, which exceeds the limits allowed by the law of the Church of England. Under these circumstances I do not see that I can refuse to consecrate the church, whatever my own private feelings may be. If I call upon others to respect and obey the law, I must not set an example of disregarding legal decisions myself."

An English Colony in America.—Mr. Thomas Hughes, M.P., is in the United States on behalf of the English Emigration Association to found its first American colony. The Association has bought 300,000 acres of land, the tract extending through four counties of Eastern Tennessee. It is a fertile plateau in the valley of the Cumberland river; and Mr. Hughes will inaugurate the colonisation project during September by visiting the locality and delivering an address. The land has been surveyed and laid out in farms; some settlers are already there; hotels, nurseries, and fruit orchards have been started; towns are planned with extensive reservations for parks. The colonists are not expected to be of the poor classes, but will be English tenant-farmers, well-to-do tradesmen, manufacturers, and the younger sons of the gentry.

Death-rate in Dublin.—According to Dr. Cameron's report on the state of public health in Dublin during August, 1880, the deaths within the municipal area during the month were in the annual ratio of 39·27 per 1,000 persons living. On the northern side of the city the rate was 44·85 per 1,000; and on the southern side 36·82 per 1,000. The general death-rate was high, and the zymotic death-rate very high for the season.

York Minster.—Last week Mr. Street, under whose supervision the restoration of the south transept of York Minster has been carried out, paid his final visit of inspection prior to the scaffolding being removed from the southern façade. He expressed to Mr. Bradley, the clerk of the works, his warmest thanks for the excellent manner in which the work had been carried out, and also congratulated Mr. Milburn upon the satisfactory execution of the whole of the carving. The *York Herald* says it is not intended to proceed with the western aisle of the transept until the question of the new Will Office is finally decided. It is understood to be the intention of the Dean to have the ground now used as the stone-yard laid out as a grass plot, instead of being covered with gravel, as it was previously to the commencement of the restoration. It is now nearly nine years since the restoration of the south transept was commenced. The following have been the contractors:—Mr. J. Robinson, plumber, of Little Stonegate, for the leadwork of the aisle and transept roof; Mr. Rockledge, of Little Stonegate, for the new boarded ceiling, &c.; Mr. S. Thomas, painter, of Stonegate, for decorating the ceiling.

The Atmosphere of the Metropolitan Railway.—Frequent travellers by the Metropolitan Railway are not to be envied the atmosphere they have to breathe in the tunnel between (say) King's-cross and Paddington. Various plans for the purification of the air have recently been under the consideration of the company. It is stated that, in a modified form, a plan invented by Dr. Richard Neale is about to be tried on the line between King's-cross and Edgware-road. The proposal is to have a carriage, from which the ends and the greater portion of the sides are removed, fitted up with trays of lime placed obliquely, and moistened by water dripping down from the top of the carriage, and placed next the engine of the train. It is asserted that the air in the tunnel can be perfectly purified by this process, as a large quantity of impure air, coming into contact with the lime, would lose the noxious gases, and escape purified at the end of the carriage. Another proposed plan is to erect at Portland-road a screen consisting of many layers of coarse canvas, or similar material, moistened with a soda solution.

Growth of the Metropolis.—The annual report of Sir Edmund Henderson on the Metropolitan Police says that the increase of the metropolis during the year 1879 comprised 21,589 new houses, forming 401 new streets and two new squares, of a total length of 71 miles 468 yards. This makes the length of new streets added to the metropolis and handed over to police protection during the last ten years, 383 miles, 758 yards. Valuing the houses built in the year at an average of 300*l.* each, we have an investment of 6½ millions sterling.

A Canadian Cotton Factory.—The new Craven Cotton Factory, Brantford, Canada, is approaching completion. It is four stories in height, and is 175 ft. long by 73 ft. wide. The mill is being erected under the direction of Mr. Thomas Broughton. The doors, sash and window frames are supplied by Schultz Bros., and the painting by Mr. John Tainsh. The lumber is furnished by Mr. Wm. Young, and the brick by Messrs. Workman & Watt. The stone for the masonry for the ground floor and wheel house, which is substantially built, is chiefly brought from Troy, near Brantford.

Water Mstags at Hereford.—At Hereford there are in use 150 water-meters, and it is found that the quantity of water consumed where meters have been fixed does not exceed 10 gallons per head per day, whilst the average consumption all over the city is 40 gallons per head. The Hereford City Surveyor says:—"I am sure some gentlemen in this city have to pay as much as 10s. per 1,000 gallons for water used at their houses, whilst others close by do not pay 2d. per 1,000."

Reredos at Knapton.—A reredos, the gift of Mr. James Tirdall, has just been erected at Knapton Church, in the picturesque valley of the Derwent, some six miles from Malton. The church, dedicated to St. Edmund, is an old building, in the main of Early Decorated work, and consists of a nave, chancel, and north aisle. From time to time works of restoration have taken place therein, under the direction of Messrs. John Gibson & Son, architects, of Malton, who have also designed the reredos, which has been executed in English oak by Mr. Harry Hems, of Exeter.

City of London Public Works.—The following is an epitome of a tabular statement showing the loans raised by the City within the last quarter of a century for the purpose of public improvements:—For the formation of the Metropolitan Cattle Market and extension of its slaughter-houses, 1852-6 and 1873-6, 478,600*l.* For the Holborn-valley and Farringdon-market improvements, 1864-72, 2,376,000*l.* For the Metropolitan Meat, Poultry, Fruit, and Vegetable Market, site, approaches, &c., 1863-78, 1,037,000*l.* For the London Central Fruit, Flower, and Vegetable Market, approaches, &c., 581,000*l.* For the Foreign Cattle Market at Deptford (1870-79), 280,000*l.* For the enlargement of Billingsgate Market (1872-8), 272,000*l.* For the building of the Royal Exchange, 98,500*l.*; for the rebuilding of Blackfriars Bridge (1864), 300,000*l.*; for ditto and the purchase of Southwark Bridge (1867-9), 315,000*l.*; for the preservation of open spaces (1876-9), 100,000*l.* Out of the above accounts the only amounts paid off apparently are 604,100*l.* on the Holborn-valley improvements; 113,000*l.* on the Metropolitan Meat and Poultry Market, &c.; 22,000*l.* on the Deptford Cattle-market, 8,200*l.* on the Royal Exchange, and 60,000*l.* on Southwark Bridge. The total amounts due for the above-mentioned purposes stood, according to the above account, on the 31st of December last, at 5,129,800*l.*

Railway Construction in Australia.—Notification of an important change in the railway policy of the Queensland Government has been made. Until recently, the Government have followed the plan in force in the Australian colonies generally, of borrowing money for the construction of lines. Now, the *Melbourne Argus* says, they have determined to adopt the American land-grant system. During his recent visit to London, Mr. M'Ilwraith (the Premier) found that English capitalists were willing, and even eager, to make Queensland railways on these terms. Two syndicates were anxious to drive a bargain with him on the spot. So impressed was he with what he saw and heard, that he has determined now to stop the trunk lines at the earliest convenient opportunity, and to arrange for their continuation by private companies. He is quite determined not to go on with the present system of building these railways at the Government expense, and if any of them do not offer sufficient inducements to private enterprise, they will have to remain in abeyance.

The Value of our Minerals.—According to the report of Mr. Robert Hunt, F.R.S., Keeper of the Mining Records, the total value of the minerals produced last year was 55,733,967*l.*, about half a million less than in 1878. The production of 1878 was worth 2,000,000*l.* less than that of 1877, and that year showed a small diminution as compared with 1876. The figures for 1880 may be expected to be the first of an ascending scale.

The Association of Municipal and Sanitary Engineers and Surveyors will hold their Northern District Meeting at Darlington, on the 24th inst. The following papers will be read and discussed:—"Sheldon Sewage Disposal," by Mr. James Cregge; "Sanitary Appliances," by Mr. George Bell; and during the day the Darlington Sewage Farm, the Darlington Ironworks, the Park, and the Darlington and Stockton Waterworks will be visited.

Fire at a Builder's.—On Friday, the 10th inst., between eight and nine o'clock p.m., a serious outbreak of fire occurred on the premises of Messrs. Brass, builders and contractors, situated in Old-street, St. Luke's. Independently of extensive carpentry, joinery, and other workshops, there was stabling for eighteen horses, that number being then in their stables. The premises were completely gutted, and serious damage done to the surrounding property. Fortunately, the horses were got out without sustaining serious injury.

Lambeth Baths.—Mr. H. E. Pearce writes,—"I beg to inform you that my new newspaper kiosque, which is now in course of erection at the Lambeth Baths Pavilion, will be opened on Saturday, October 2nd. Will you be good enough to mention that your paper will be on sale there?"

An Exhibition of Gas Apparatus is now being held in Dublin, under the auspices of the "Alliance and Consumers' Gas Company." It includes cooking and heating appliances for use with gas, which are shown in full work. A similar exhibition is about to be held in Glasgow.

TENDERS

For rebuilding warehouse, No. 31, Houndsditch and Duke-street, for Messrs. Samuels & Co. Mr. H. H. Collins, architect. Quantities supplied by Messrs. Batstone Bros.:—

Sparks	£6,205 0 0
Ashby & Horner	6,170 0 0
Marks	6,026 0 0
Conder	5,938 0 0
King & Son	5,882 0 0
Kirk & Randall	5,846 0 0
Outhwaite	5,830 0 0
Col s & Sons	5,760 0 0
Downs	5,675 0 0
Croaker	5,585 0 0
Merritt & Ashby	5,550 0 0
Sabey & Son	5,495 0 0
Bentley	5,430 0 0
Abraham	5,384 0 0

For shops and houses to be erected at Landor-road, Stockwell, for Mr. C. W. C. Hutton. Mr. H. H. Collins, architect. Quantities by Messrs. Batstone Bros.:—

King & Son	£6,275 0 0
Higgs & Hill	6,240 0 0
Robinson	6,080 0 0
Taylor	5,937 0 0
Harris	5,904 0 0
Rice	5,850 0 0
Sabey & Son	5,824 0 0
Pack Bros.	5,795 0 0
Brass	5,687 0 0
Mitchell	5,678 0 0
Abraham	5,657 0 0
Kirk & Randall	5,648 0 0
Croaker	5,490 0 0
Colls & Sons	5,457 0 0
Downs	5,377 0 0
Sheffield & Prebble	5,173 0 0

For additions to the Rectory, at Hornsey, Middlesex, for the Rev. James Jeakes, M.A. Messrs. Wadmore & Baker, architects:—

Clark & Bracey	£1,735 0 0
Conder	1,735 0 0
Scrivener	1,710 0 0
Ashby Bros.	1,697 0 0
Shurmur	1,683 0 0
Dove Bros.	1,585 0 0
Mattock Bros.	1,177 0 0

For extension of premises, Goswell-road, for Messrs. Carter, Paterson, & Co. Mr. William Eve, architect:—

Abrahams	£4,320 0 0
Hall, Beddall, & Co.	4,095 0 0
Heiser	3,948 0 0
Lawrence	3,900 0 0
Harris & Wardrop	3,654 0 0
Hunt, St. Paul's Works, Bow Common (accepted)	3,615 0 0

For the erection of a factory at Millwall, for Mr. J. T. Morton. Mr. William Eve, architect:—

Heiser	£786 0 0
Crabb	769 0 0
Hunt	750 0 0
Harris & Wardrop	739 0 0
Wilson & Exton	738 0 0
Salt, St. Paul's-road, Burdett-road, (accepted)	709 0 0

For the erection of stabling for Messrs. Carter, Paterson, & Co. Mr. William Eve, architect:—

Eary	£490 0 0
Sweet & Loder	450 0 0
Hubble & Trott	389 0 0
Barnes	348 0 0
Nye, Ealing Green (accepted)	330 0 0

For a new fish-market, and extending and ventilating the fruit-market and butchers' market, Ashton-under-Lyne. Messrs. John Eaton & Sons, architects. Quantities supplied by the architects:—

Brown, Stockport	£7,200 0 0
Robinson & Sons, Hyde	6,950 0 0
Burton & Sons, Ashton	6,500 0 0
Castle Hall Saw-mills Co., Stalybridge	6,380 0 0
Holden, Stalybridge	6,289 0 0
France, Stalybridge	6,239 0 0
Meadows, Stockport	6,183 0 0
Haughton, Godley	6,173 0 0
Garside, Barnes, & Co., Stalybridge	6,150 0 0
Quarmby, Linthwaite	5,990 0 0
Herd, Ardwick	5,887 0 0
Napier, Manchester	5,948 0 0
Taylor, Dukinfield	5,882 0 0
Storrs, Sons, & Co., Stalybridge	5,869 0 0
Marsden, Ashton	5,850 0 0
Dyson & Sons	5,680 0 0
Holmes & Webster, Ashton	5,520 0 0
Gibson, Dukinfield	5,510 0 0
Neal, Ashton (accepted)	5,498 0 0

For Leigh special drainage works, for Martley Sanitary Authority. Mr. E. Pritchard, engineer. Quantities by Mr. E. J. Parnell:—

Contract No. 1.—Outfall Sewerage Works, Pipe Sewers, and other works.

Bell, Gateshead	£6,072 9 11
Holland, Leicester	5,391 4 0
Hobb & Glummer, Rotherham	4,487 5 11
Rayner, Liverpool	4,215 0 0
Everall, Great Malvern	4,091 10 0
Small & Sons, Gloucester	3,988 2 5
Jevons, Dudley	3,763 16 8½
Palmer, Birmingham	3,760 0 0
Hunter, Nottingham	3,715 14 4
Law, Kidderminster	3,649 0 0
Young & Nicholson, Chelmsford	3,565 6 8
Bourne, Worcester	3,510 0 0
Dewitt, Harbury	3,423 0 0
Osborn, Malvern	3,325 0 0
Cowderry & Sons, Newent (accepted)	3,278 17 0

For extra story to No. 60, Curzon-street, Mayfair, and additional works for Mr. Widdecombe. Mr. W. H. Collbran, architect. Quantities not supplied:—

Schieran	£1,5 0 0 0
Bolding	1,179 0 0
Henderson	1,097 0 0

For alterations to bar, and repairs, &c. to the Princess Victoria, Lower-road, Deptford, for Mr. Joseph Bartholomew. Mr. Henry Roberts, architect:—

Marr	£623	0	0
Banks	535	0	0
Simpson	493	0	0
Lewis	495	0	0
Godart & Co., Mile End-road (accepted)	446	10	0

For two houses, Spring-road, Bedford, for Mr. M. Hewlett. Mr. F. T. Mercer, architect:—

Moore	£459	0	0
Potter	440	0	0
Wharton (too late)	440	0	0
Boyse & Harris	430	4	7
Sparrow	429	0	0
Lilley (accepted)	427	10	0

For public house at Renhold, Bedfordshire, for Mr. Wells. Mr. F. T. Mercer, architect:—

Moore, Bedford	£490	0	0
Haynes, Sandy	475	10	0
Wharton, Bedford	460	0	0
W. & H. Sparrow, Rushden	450	0	0
Lilley, Bedford	440	0	0
Laughton, Bedford	420	0	0
Harrison, Bedford (accepted)	415	0	0

For house, Spring-road, Bedford, for Mr. E. Alderman. Mr. F. T. Mercer, architect:—

Moore, Bedford	£270	0	0
Croby & Son, Bedford	203	0	0
W. & H. Sparrow, Rushden	242	0	0
Potter, Bedford	240	0	0
Wharton, Bedford	228	10	0
Lilley, Bedford	225	10	0

For the erection of new stable and cottage buildings, Single Gate, Merton, for Mr. W. Goodyear. Mr. R. Cruwys, architect. Quantities supplied:—

Harmer, Wimbledon	£892	0	0
Johnson, Wimbledon	884	0	0
Mundy, Wimbledon	857	0	0
Templer, Merton	799	0	0

Rice, Clapham (accepted with modifications).

For roads and sewers on the first portion of the Champion Hall Estate, Lower Sydenham. Messrs. Stuart, Barker, & Son, surveyors:—

Simmons	£1,342	15	0
Harris	1,130	0	0
Blake	946	0	0
Jackson	915	5	0
W. & J. Woodham (accepted)	803	0	0

For rebuilding the Cock Tavern, Holloway-road, Islington, for Messrs. Lines & Heldon. Mr. W. J. Worthington, architect. Quantities by Messrs. Harris, Worthington, & F. Lennox Canning:—

Clarke & Bracey	£5,287	0	0
Lamble	5,230	0	0
Axley	5,200	0	0
Crockett	4,997	0	0
Hearle & Son	4,993	0	0
Marr	4,982	0	0
Outhwaite & Son	4,950	0	0
Burch & Moore	4,871	0	0
John & Henry Cocks	4,784	0	0
Clemence	4,745	0	0
Cowland Bros.	4,680	0	0
Mortar (accepted)	4,567	0	0
Chapman	4,559	0	0
Jackson & Todd	4,550	0	0

For village hospital, East Grinstead, for Mr. Charles H. Gatty. Mr. E. P. Loftus Brock, architect:—

Norman	£1,790	0	0
Nightingale Bros.	1,783	0	0
Charlwood Bros.	1,485	0	0
Godly (accepted)	1,250	0	0

For repairs and decorations to the Horse Shoe Hotel, Tottenham-court-road. Mr. Flack, architect. No quantities supplied:—

Worrall & Stevens	£1,100	0	0
Schoolbred & Co.	928	0	0
Berridge & Tuce	889	0	0
Collman & Scantlet	887	0	0
Hooman	800	0	0
McLachlan & Sons	749	0	0

For alterations and additions to St. Michael's Church, Stockwell. Mr. Thomas Dashwood, architect. No quantities supplied:—

Burmsa	£1,442	0	0
Lathey Bros.	1,048	0	0
McLachlan & Sons	975	0	0

For a pair of houses at Clement's Estate, Ilford, for Messrs. Withers. Messrs. Whitmore & Kennard, architects. No quantities supplied:—

Hosking	£1,587	0	0
Cardus	1,395	0	0
North Bros.	1,380	0	0
Hobern	1,290	0	0
Hawkings	1,168	0	0
Barnes	1,087	0	0

For rebuilding Nos. 77 and 79, Walworth-road, for Mr. P. Saillord. Mr. Benjamin Tabberer, architect:—

Sabey & Son	£4,130	0	0
Merritt & Ashby	4,097	0	0
Rider	3,948	0	0
Jarrett	3,900	0	0
Mark	3,780	0	0
Ashby Bros.	3,737	0	0
Marsland	3,706	0	0
Downs	3 673	0	0
Lawrence	3,650	0	0
Nightingale	3,633	0	0
Crabb	3,599	0	0
Conder	3,620	0	0

For house and shop, East Barnet. Messrs. Brooking & Nelson, architects. No quantities supplied:—

James, Barnet	£657	0	0
Richardson, Brixton	610	0	0
Butcher, East Barnet	594	0	0
Angood, Tolington Park	580	0	0
Howa.d & Gordon, Barnet	554	0	0
Beal, Battersea	528	0	0
Marriott, Tottenham	505	0	0
King, Hornsey	495	0	0
Ellwood, New Barnet	487	0	0
Miller, Barnet (accepted)	480	0	0
Childs, Tottenham	478	0	0

For the diversion of Pymm's Brook at East Barnet, for the British Land Company, Limited. Mr. Henry B. Michell, surveyor:—

Fizzey	£385	0	0
Dunmore	379	0	0
Acock	337	10	0
Peill & Son	320	0	0
Jackson (accepted)	290	0	0

All statements of facts, lists of tenders, &c. must be accompanied by the name and address of the sender, not necessarily for publication.

We are compelled to decline pointing out books and giving addresses.

NOTE.—The responsibility of signed articles, and papers read at public meetings, rests, of course with the authors.

CHARGES FOR ADVERTISEMENTS.

SITUATIONS VACANT, PARTNERSHIPS, APPRENTICESHIPS, TRADE, AND GENERAL ADVERTISEMENTS.

Six lines (about fifty words) or under ..... 2s. 6d.
Each additional line (about ten words) ..... 0s. 6d.

Terms for series of Trade Advertisements, also for Special Advertisements on front page, Competitions, Contracts, Sales by Auction &c. may be obtained on application to the Publisher.

SITUATIONS WANTED.

FOUR Lines (about THIRTY words) or under ..... 2s. 6d.
Each additional line (about ten words) ..... 0s. 6d.

REPLIES TO ADVERTISEMENTS,

Addressed Box ——, Office of "The Builder,"

Cannot be forwarded, but must in all cases be called for, and the Office Receipt produced

THE UNPAID FOR A BOX IS AS UNDER:—

For "Situations Wanted" Advertisements ..... 6d. per Week.
For all other Advertisements ..... 6d. per Week

PREPAYMENT IS ABSOLUTELY NECESSARY.

"." Stamps must not be sent, but all small sums should be remitted by Cash in Registered Letter or by Money Order, payable to the Post-office, King-street, Covent-garden, W.C. to

DOUGLAS FOURDRINIER, Publisher,
Addressed to No. 46, Catherine-street, W.C.

Advertisements for the current week's issue must reach the office before THREE o'clock p.m. on THURSDAY.

The Publisher cannot be responsible for DRAWINGS, TESTIMONIALS, &c. left at the Office in reply to Advertisements, and strongly recommends that of the latter COPIES ONLY should be sent.

TERMS OF SUBSCRIPTION.

"THE BUILDER" is supplied *direct* from the Office to residents in any part of the United Kingdom at the rate of 12s. per annum, *prepaid*. Remittances payable as above.

The Builder.

The Cradle of Romanesque Architecture.

THE members of the Architectaral Association who wisely intend to visit Northern Italy this autamn are to be envied their trip to "fruitful Lombardy, the pleasant gardeu of great Italy," where so many iateresting and nniqne featares will reward even the hasty inspection that can alone bo given in the intonded few days' stay in each of the historic towns which are to he visited. Tarin, with its rectilinear streets, resemhling so cariously the plan of an American city, and where that delight of Italy, the *portici*, the arcades which Napoleon after his Italian campaign endeavonred to introdace iato Paris, as we see in the Rue Rivoli, is first met with,—Turin, with its famous Palazzo Madama and its famoas Armeria, hut with little else of interest; Milan, with its thousand treasures, too numerous to epitomise, hut where the artist might revel many a happy month, studded with architectaral marvels, dating from the deepest of the obscurity of the Dark Ages up to the present day, and which will donhtless make the Lombard capital the chief centre of the excursion; Bergamo, with its Broletto and choice Romanesque gem, Sta. Maria Maggiore; Brescia, with its antique Rotunda, and many another relic of tho art of classic days, the Middle Ages and the Renaissance, not least among the latter the well-known Loggia; Cremona, with its few hnt rare specimens of the art of the past; Mantua, reflected ia its calm lake, and alive with recollections of Virgil, and with many another famous featare, too sacred to be merely hastily mentioned; Pavia, where San Michele is a miae of artistic stndy, and ia its neighhonrhood the world-famed Certosa, thickly set with jewels of Reaaissance art,—all these are to be visited, and many another qniet spot wbere lingers still, spared hy the respecting hand of time and the more rathless march of human progress, traces of the art of the days when all was so different, when the very years seem to have heen longer, and the life sach as we can scarcely picture with exactness to our mind's eye. Italy ia this respect possesses a pecnliar charm for the artist, teeming as it does with recollectious, and hegemmed with marvels of architecture, scalptnre, and paintiag, where so mach speaks of the hy-gone days, where the traditions of the distant past may still he found alive, and, ahove all, where cities differ from each other, separated hut hy a few miles of ill-kept road,—a classic soil, oa which the formation of modern Europe has left at each step its plainly-read mark, where the mind and eye are charmed with pleasnres of ever-renewed novelty,

The district to which the Architectaral Association more particalarly devote their attention is one of the most interesting in Italy. The Lombard plain, studded with its innumerable cities, fabnlously wealthy ia the past, and even now forming the richest portion of the peninsula, presents to the artist generally, he he architect, scalptor, or painter, a series of featnres that possess aa exceptional interest. For the architect more specially there are points for stady and research of the deepest professional valae. Tbe nature of the country; its situation; the history of the develonment of its culture, and consequently of its artistic progress; the elements that influenced this development, and the results that attended it, offer a series of inqniries of something more than an archæological value. Of this fact we shall he convinced when the resnlts of the excarsion will have heen made known; for Lombardy is the cradle of that strange and heautiful style of architoctnre which has heen termed the Romanesqae, one of the most important of the many steps in tbe slow development of modern from Classic architecture, the expression of the change of a belief from Paganism to Christianity with its new needs, its new aspirations, aad its new hopes.

This Lomhard origia of a special style has led to the adoption of the term "Lomhard," as applied to the architecture (helonging to a certain period) of this portion of Italy, hat the accuracy of the term may he qaestioned. The harbarians who, ia the sixth century, invaded Northern Italy, nader the dreaded Alhoin, hronght with them to the Sonth no architectaral traditions of their own; hut, once arrived in the fertile plain of Lomhardy, we can trace how the style of architecture that arose after this important event was created.

Throughout the whole extent of her widely-spread empire, Rome had left the traces of her monumental art; and after the centaries of neglect and ruin that followed the fall of the Roman rule, these same haildings formed the sole models of construction and of decoration when not themselves directly used or their materials. This influence is everywhere traceahle, bat in varying degrees; in the western portion of the empire the deep-rooted traditions of the past were too powerfal to be much affected, as we see them later on, when the capital is fixed at Byzantiam, branching out ia a parely origiaal direction, when the Greek empire was ia its tarn to influence the world, not alone westwards, hut agaia eastwards, and the recent archæological discoveries in Central Asia have shown us how far this influence extended. While in the East the new Greek art was rapidly reaching its zenith, in the West the deserted Roman art was slowly dying,—not, however, hefore it had exercised its spell on the comparatively uncultivated people to whom it formed the sole school of tradition.

Under these inflaences, Roman art daily grew more corrapt, and its precepts and rules were forgotten; slow, indeed, was the decay,—slow as was the disappearance of the purely foreign element among tbe Italiaa populations. With this faot once accomplished, and order agaiu established, the necessity for self-defence ceases to hecome the all-absorbing thought. With the attendant leisnre is developed the desire for refinement and for art. Generations are yet to pass before this desire finds its full expression, hat the seeds have beeu laid, and ia time we see them blossom forth into a distinct and origiaal art, known as the Romanesque or Romano-Byzantine, which it has heen urged, hnt erroneoasly, first had its origin in France. Northern Italy is the cradlo of this interestiag and heautiful style of architecture, and there still exist a number of rare and perfect specimens of the creations of its artists.

As the modern school of scientific research has shown us is the case with the actiou of nature, so ia art, no perceptible change is the result of accident, but is due to the effect of surrounding influenoes. What these influences were in Lombardy it is not difficult to stady. As early as the sixth century, we find the traditions of Romaa architecture affected hy Byzantine art; the former had long been settled in the country, and existed, as an art of the past, in the numerous Classic remains, aud, as a living art, in the Christian hasilicas which since the time of Constantine the new religion had industriously erected. The second, the Byzantine art, we see introdaced during the rale of the Goths, not manifesting itself solely on the shores of the Adriatic, as we see it in Saa Vitale at Ravenna, hat penetrating to the very heart of Lombardy, where in Milan itself, in addition to several basilicas of tbe foarth and fifth centuries, we see rise a superh and thoronghly Byzantine church, dedicated to Sau Lorenzo.*

What this admirable Byzantine architecture was, aad its origin, it is nnnecessary here to inquire; snffice it to say, that with the transfer of the seat of the Romaa Empire to the hanks of the Bosphorus, this new and characteristic style makes its existence known. From its timid commencement ia the second centary, at Baalhec and Palmyra, it had gained in strength and holdness, till the day when Isodorus, of Miletas, in hailding the Temple of St. Sophia, consecrated the new style which saccoeeded that of Rome. Agaia the genius of the old Greek artists seemed to have risen from its long slnmber, and if the new expression may not possess the Classic parity of its elder sister, its marvels were to astonish, as they still

* See Dartein, "Étude sur l'Architecture Lombarde, et sur les Origines de l'Architecture Romano-Byzantine," Paris, 1870, folio, with an atlas of plates; and Vitet's "Etudes sur l'Histoire de l'Art," série deux,—Moyen Age; to which admirable works, with the cross references to be found in their pages, we are much indebted. Dartein's work, after an introduction, treats in detail a number of existing churches of the Romano-Byzantine style; Sant' Ambrogio at Milan; San Celso, also at Milan; at Brescia, the basilica of San Salvatore; the little church of Sta. Maria in Valle, and San Pietro di Civate; Madonna del Castello, near Almenno; and the Rotonda at Brescia.

do, the artistic world. "For the second time the Greeks held the sceptre of the great and noble builder's art; it was from them that the Arabs received its secrets, it was by them that the first lessons reached Europe, when in the eleventh century, after 500 or 600 years of darkness, the West again sought the light, and sought it in the East."*

In the West, however, the Roman traditions still formed the sole architectural school, so rooted that when Diocletian brought back, in the third century, from his Asiatic wars, an admiration for the Eastern architecture, which showed itself in his palace at Spalatro,—a coarse imitation of the Temple of Baalbec,—the innovation was to remain unnoticed. As Vitet has well expressed it, every spark of imagination had died out in this Italy, exhausted by eight centuries of grandeur. Even when from time to time rose in the populous centres some building, the architect of which had drawn his inspiration from travel in the East, its influence was *nil*, and the mass of constructions continued the Roman traditions, each day growing heavier and coarser. The relations between the two empires became rarer every day; the distance increased by the schism in their religious belief; thus the architectural movements of the East and West long remained mutually unaffected.

A point which Vitet has shown clearly as still further aiding in the maintenance in the West of Roman traditions, arose from the differing types of the places of worship adopted by the two empires; while the West modified for their religious purposes the basilicas of pagan Rome, —a tradition long retained, as we see in the basilica of San Clemente at Rome, Santa Praxeda, and St. Martin, built in the ninth century,—the Christians of the East created a new type, and built churches. What the basilica was it is needless here, in detail, to describe; suffice it to say that in the Roman city it served as the court of law, the hall of justice. The basilica was used by the Christians in preference to the temple, greatly on the score of its superior size. The temple, soiled as it was by Pagan recollections, and closed to the use of the new religion, there remained the two courses of adopting the basilica, or creating a new type of place of worship; the less noble, less religious course was adopted by the unimaginative Westerns, and the basilica was chosen, the idea further finding favour with the bishops, who sanctioned in the old temple of justice the worship of the new faith. The change was an easy one to make, and soon the painter and the mosaic-worker had decked with their suggestive symbolic images the walls and "tribune," as the apsis was called before that Greek term prevailed. A few further modifications were necessary,—into which, however, at this point, it is unnecessary to enter, — with the addition of the exterior "atrium," with its colonnade (such as still exists in Santa Ambrogio, in Milan) to shelter during the celebration of the mysteries the as yet uninitiated catechumens,—and in the midst of which rose the simple octagonal baptistery, with its sacred vase of symbolic purification, pointing out, by its position at the door of the temple, the road by which it alone might be entered. The further addition made of the beautiful and religious conception of the subterranean "confession," where reposed the relics of the martyrs, and the pagan basilica was transformed into a Christian place of worship, to affect for many a generation yet the monkish builders. Thus we see the Roman style prevailed, and was perpetuated by this adoption of the basilica for the usages of the new worship.

It was at this position that architecture had arrived when the barbarous Goths descended into Italy, swept over the fertile plain of Lombardy and down the pleasant coast of the Adriatic, driving before them the population. It was at this time that Venice was formed on the mud flats at the month of the Piave and the Brenta. But the Goths, as so often happens with conquering nations, were to be in turn overcome by the refinement of their enemies, and the prevailing Roman taste was to influence their untaught artistic natures. We have only to mention the tomb of the learned and enlightened Theodoric at Ravenna,—at this moment so seriously threatened in its existence,—and we see how Roman is its style; and yet Theodoric had been educated in Byzantium. In building his tomb he was, however, obliged to employ Italian workmen.

* Vitet, "Etudes sur l'Histoire de l'Art,—Moyen Age," Paris, Edition 1866, 8vo., p. 296.

Let us not pass over the mention of this wise and good prince,—an early archæologist of the truest type,—without a tribute of respect to his memory. His influence was to be marked on the later artistic and literary development of Italy, and his reverence for the past led him to a holy respect for its noble architectural creations. He it was, let us not forget, who wrote to his architects, Daniel and Symmacus,—"You will repair those monuments which have suffered by the effects of war, but in such a manner that they shall not appear to have been repaired, and,"—a sentiment, he it remarked, uttered now 1,300 years ago,—"that the original construction shall alone be re-established in its primitive state."

But the rule of the Goths was to be overturned, and under the renowned and unfortunate Belisarius and Narses, Italy was again to become one of the jewels in the crown of the Roman Emperor reigning at Constantinople. Had the Greeks only kept their hold on the empire, it is more than probable that from their appearance,—that is, in the sixth century,—the traditions of Byzantium would have taken root in Italy; for it must be remembered that to this period belong the baptisteries of S. Giovanni, built by the Archbishop Neo, and the beautiful Church of San Vitale at Ravenna, both in the purest Byzantine style; but still the introduction was distasteful, and we see at a later date the Bishop Ursicinus build his grandiose Church of St. Apollinaris according to thoroughly Roman principles and traditions. The Greek influence had, therefore, not yet commenced to work when the allies whom they had imprudently called in, the Lombards, or Longobards, seized Italy.

It has been, as we have above remarked, a subject of no small discussion whether the architecture termed "Lombard" was not an introduction of these barbarous conquerors. But in the present day the question has been satisfactorily settled. The Lombards, a wilder and even less civilised people than the Goths, can scarcely have introduced an architectural style of their own. Indeed, so improbable do facts show this Lombard origin to be, that it may be dismissed without further discussion.

The Lombards, once settled down, did as their predecessors had done, and conformed themselves to the tastes and traditions they found about them. At this moment there existed in the world,—the world as it then was understood,—but two styles, which Vitet, and others before him, have concisely termed the Neo-Greek and the Bastard-Roman. The Lombards, therefore, when their refinement led them to that necessary consequence of all cultivation, the consideration of the arts, had alone to choose between these two styles, and a very indifferent acquaintance with the early architecture of Northern Italy will show that all those works attributed to the Lombards are either semi-Roman or Oriental. But it is to be remarked that it is to the former that they attached themselves, and for this fact it is easy to account. Western by birth, the Lombards remained strangers and unfriendly to the Greeks and their ways, and such, during their stay of two centuries, they continued to be. Their tastes were purely Roman; they spoke and dressed in the Roman fashion; it is therefore scarcely likely that they would have employed Greek architects; the utmost they had seen of San Vitale at Ravenna was its shining cupola on the horizon, while at home they lived in the midst of ruins and of buildings stamped deep with Roman traditions.

Such was still the Roman influence, that when the Lombards leave Italy, we trace it in the eighth and ninth centuries. San Clemente, as has been above remarked, built in this latter century, is in its general character a pure basilica. But times were about to change. The influence of Byzantinm commences to filter into the West. The German Emperor Charlemagne, Roman in his refinement, leaves, in his palace at Ingelheim and on the banks of the Rhine and the Garonne, the traces of his admiration of Oriental architecture. Vaguely he foresaw that it was thence that was to spring,—many centuries were to elapse before his prophecy came true,—the dayhreak of refinement and culture, and after seeing San Vitale at Ravenna, Aix-la-Chapelle is gifted with its wondrous temple; but for Northern Europe, with the death of Charlemagne, the light was to die out again; deeper shades still were to fall on the Dark Ages, and which alone can explain the superstitious belief which prevailed that with the fatal year 1,000 the world was to close its career; at such a moment architecture was to suffer the most seriously of the arts, and the tenth century is the saddest, the most miserable in its history, as indeed it is in that of European civilisation.

When at length opened the new century, a fresh spirit is infused into the West, particularly remarkable in Italy, under the enlightened rule of Otho the Great. The high roads of commerce were frequented again, the ports re-opened, the trade between the East and Italy flowed again West, and the rich tissues, the perfumes, the secrets of the arts and learning of the Orient became known to the West. With the increase of wealth and ease came naturally refined tastes; and the grandeur, commercial and artistic, of the Italian cities, rivalling each other in splendour, commences from this date.

Italy and the West thus prepared, Byzantine architecture again makes its appearance, not, as in the sixth century, in the midst of war and calamity,—not as in the reign of Charlemagne,—but among a wealthy community seeking for a new expression of the new needs of a new society. Penetrating by the Adriatic sea on the east, by the Arno on the west, the Venetians on one side in their basilica of St. Mark, on the other the Pisans in their superb cathedral, were the first to accept the traditions of Byzantinm. Venice and Pisa are followed by Verona, Ancona, Lucca, Ferrara, Bergamo, Parma, Milan, all the great towns of Northern Italy. Soon, writes Vitet, the Italian soil was covered with monuments more or less Oriental, at first simple and severe in their magnificence, then elegant and light, and later on more ornate, more florid each day. The new style reigned unrivalled for two centuries, till Europe, through one of those circumstances which make the history of art so noble a drama, turned with enthusiasm in the thirteenth century to another architecture which Italy alone received with coolness, the ogive architecture, which created the cathedral of Rheims, the cathedral of Cologne, the spire of Friburg, in Brisgau.*

The Oriental tradition mingling with the still existing traditions of the Roman builders, created that architectural style known as the Romano-Byzantine, or the Romanesque, which found in Lombardy the favoured land of the meeting and blending of the two influences of which it was made up. From Lombardy the monkish architects bore the new style to France, to Burgundy, and to chillier Normandy, whence in time it spread throughout France. The Norman Conquest was to introduce it into our island, where the creations of its artists, familiar to the profession, are to be found in many a quiet old-world corner of England. Germany was to receive even more directly the architectural influence of Lombardy, which showed itself markedly on the banks of the Rhine.

With the eleventh century the Church, now growing rich, was to develop its architectural zeal with an energy which, particularly noticeable in Italy, was to spread throughout Christendom, and the Romano-Byzantine style was to cover Western Europe with its characteristic productions, modified in each country by those local influences which are so invariably to be noticed in the history of architecture, and which have properly led to almost similar works belonging to the same family being denominated differently in different countries, and even provinces. In this sense of the term, "Lombard architecture" must be regarded as the purely local expression of the Romano-Byzantine style in Northern Italy. Once this fact is understood, there cannot again arise the possibility of a belief that the invading Lombards, or Longobards, introduced into Italy an original architecture. This fact is the more important to have settled, as it is in the monuments of Lombardy and Northern Italy that the Romanesque style is to be studied in its most distinctive and original character, and where it has left so many still-existing creations of its architects, all stamped with a peculiar character of striking beauty, the direct result of the honest faith in which designer and workmen toiled so steadily together. This character it is out of place to describe; it is familiar to every student of the history of art. Northern Italy is the cradle of this style, and the Architectural Association, in their present trip in Lombardy, will have many opportunities of studying on the spot the earliest creations of this intensely-interesting period of the development of their art, which was to lead to the later marvels of the Gothic architects.

* Vitet, p. 310.

There exist throughout Northern Italy a large number, comparatively speaking, of monuments belonging to this distant period, and to these more than one member of the Association will pay especial attention; the conceptions of these early architects are worth minute observation, particularly by the English student, the constructive materials used by the Lombards being precisely the same as those necessitated by the geological structure of England. The same material necessities that influenced the architects of those times regulate the conceptions of the English architect of to-day. The want of building stone, or rather the extreme difficulty of obtaining it, in Constantinople,—which, when it became the capital of the Roman Empire, saw rise in every direction gorgeous palaces and churches,—and the abundance of clay, obliged the Byzantine architects to employ brick as their building material, and in this course they had the precedent of their ancestors at Nineveh. In Northern Italy this feature of the early architectural style is peculiarly noticeable, and, let it be remarked, the noble edifices which the Lombard architects erected with the aid of honest bricks and mortar, destroy for ever the theory so often put forward that with small building materials it is impossible to create great works.

The Architectural Association will make one of their chief objects of study, during their excursion, the use of brick and terra cotta, so largely employed throughout Lombardy, and valuable results may follow their combined inquiries. How long the traditions of the use of brick and more elaborated terra cotta were retained, and what results may be obtained by their aid, we see in the graceful creations of that great architect of the Renaissance, Bramante, in his church of Sta. Maria delle Grazie, in Milan, which the Association will do well to study, as it is shortly to be handed over to restorers. In the hands, however, of such learned students as Sig. Angelo Colla, and his accomplished co-worker, Sig. Tullo Messarani, the necessary work may, we trust, be as lovingly done as could be desired.*

What other wonders the Association on their tour will see, those who know Northern Italy will remember,—wonders ranging from the Classic architectural remains scattered over Lombardy, no less plentifully than elsewhere where the Roman power was dominant, through the Dark Ages and the Revival down to modern days. It is to be hoped they will not neglect the architectural works of the Renaissance, as brilliantly represented in Northern Italy as are the still earlier and rarer remains of the Romanesque period.

MARGINS OF SAFETY.

WE recently drew the attention of our readers in the pages of the *Builder* to the unsettled state of the question of wind-pressures as affecting exposed surfaces over widely-extended areas. The absolute necessity of having some reliable data to go upon in the case of structures that are subjected to exceptional dangers from atmospheric disturbances will, no doubt, urge itself upon the scientific world, and it is to be hoped that ere long no doubtful answer will be given to the questions that are being at present asked on the part of practical engineers and the public generally, as to the necessary margins of strength that will secure absolute immunity from accidents. In the meantime, no harm will be done by looking back upon the sayings and doings of the early masters of those arts which, within recent years, have been subjecting the forces of Nature to the uses of man, and one passage occurs to us as peculiarly appropriate at the present time, not only as regards wind-pressure, but in its general bearing on the question of stability. "When we have to do with, and to endeavour to control, those powers of Nature that are subject to no calculation, I trust it will be deemed prudent not to omit in such a case anything that without difficulty can be applied, and that would be likely to add to the security." These words are Smeaton's, and are quoted by one of the most eminent engineers of our own time, as of exceptional authority as coming from the mouth of "our greatest marine engineer."

Taking the sentence we have just quoted as a text upon which to hang a few observations, it will be noticed first that there is an admission on the part of Smeaton which implies that he was himself in the habit of dealing with natural forces that were subject to no calculation. These were for the most part either wind, or the destructive agency of heavy masses of water driven violently against artificial obstructions by its fury. If an engineer is to be justified in throwing over the time-honoured maxims of his profession by distributing his materials in a manner that differs essentially from previous practice, he must be able to show that all the possible forces with which his finished structure has to contend have been exactly calculated, and a sufficient margin of safety provided for each and all of them. Where the force is of such a constant character and is subject to such a well-known law as that of gravity, Smeaton's words imply an exception. There is no reason why the calculated strains to be provided against on account of the mere weight of a structure, and of a passing load, should not be estimated with the utmost exactness; and in these cases the margin of safety may be provided for more as a safeguard against possible flaws of material than as a provision against any ignorance of the forces that are subject to established laws. Smeaton, were he still living, would no doubt have been as much opposed to unnecessary accumulations of material as the most advanced of our modern engineers. All this, however, leaves the question of uncalculated forces practically untouched, and when provision has to be made for withstanding the fury of the winds and waves, the words we have used as a text have lost none of their significance.

When writing on the subject of wind-pressure, we pointed out that there is no established rule for the guidance of engineers and architects in the case of structures that offer an exceptionally large area to the force of the winds in exposed positions. Nearly a century has passed since the days of Smeaton, and, considering the immense strides that have been made in the theory as well as the practice of engineering during the years that have intervened, it is somewhat astonishing that such a state of matters should exist. We concluded with the expression of a hope that the magnitude of the interests involved in the construction of such vast structures as those which are required for bridging the estuaries of the Tay and the Forth may soon have the effect of bringing about a full scientific investigation of the subject, and a clearing up of all doubts for the future.

Meanwhile, when we consider that the admission made by Smeaton with regard to the existence of "powers of nature that are subject to no calculation" still holds good, it would be well for engineers engaged in works of such a character to pin their faith to the second part of the sentence, and "not to omit in such cases anything that without difficulty can be applied, and that would be likely to add to the security."

The particular circumstance that gave rise to these words was the proposal made by Smeaton to use joggles in the masonry of the Eddystone Lighthouse, and it is not at all unlikely that they were used as an argument for the expenditure of more money than those who were responsible for its erection were willing to spend. It would be well if engineers, instead of making efforts to save money at the expense of stability, as too frequently happens, were rather ready to find arguments such as Smeaton's for convincing their clients that the most costly structure would more than likely prove to be the cheapest in the long run. Although the effect of nearly a century of storms has made it necessary to reconstruct the Eddystone, and to reconsider its design, the precautions of Smeaton were so far justified that he was able to state that "after a stone was thus fixed we never, in fact, had an instance of its having been stirred by any action of the sea whatever." Had the circumstances varied and the structure been exposed to still greater violence, Smeaton would, no doubt, have seen his way to making still further provision for the safety of the structure consistently with the principle laid down in the sentence referred to. Until, then, engineers and architects are in a position to estimate the maximum possible force of the winds and waves in a given situation with as great certainty as the force of gravity,—and it is exceedingly unlikely that any such perfection of information will ever be attained,—until, in fact, the "powers of nature that are subject to no calculation" are thoroughly understood, it will be well for them to provide margins of safety that are far more than sufficient to withstand any average, or even any observed, destructive force. Works that have been designed to withstand the fury of the elements frequently succeed in doing so until their sufficiency becomes a standard for similar undertakings, and it happens not unfrequently that after they have served the purpose of a precedent their destruction proves the fallacy of the argument. In the construction of masonry to act as a breakwater in exposed situations it would, indeed, be difficult to over-estimate the allowance that ought to be made for exceptional exhibitions of natural forces.

A quotation from the report by the Messrs. Stevenson, upon the effects of a storm which took place at Wick, in 1872, is an apt illustration of how wide the margins of safety, in certain cases, ought to be. "The (seaward) end of the work, as has been explained, was protected by a mass of cement rubble work. It was composed of three courses of large blocks of 80 to 100 tons, which were deposited as a foundation in a trench made in the rubble. Above this foundation there were three courses of large stones carefully set in cement, and the whole was surmounted by a large monolith of cement rubble, measuring about 26 ft. by 45 ft. by 11 ft. in thickness, weighing upwards of 800 tons. This block was built *in situ*. As a further precaution, iron rods 3½ in. diameter, were forced in the uppermost of the foundation-courses of cement rubble. These rods were carried through the courses of stone-work by holes cut in the stone, and were finally embedded in the monolithic mass which formed the upper portion of pier." . . . . . "Incredible as it may seem, this huge mass succumbed to the force of the waves, and Mr. Macdonald, the resident engineer, actually saw it from the adjacent cliff being gradually 'slewed' round by successive strokes until it was finally removed and deposited inside of the pier. It was not for some days after that any examination could be made of this singular phenomenon, but the result of the examination only gave rise to increased amazement at the feat which the waves had achieved. It was found on examination by diving that the 800 ton monolith forming the upper portion of the pier which the resident engineer had seen in the act of being washed away, had carried with it the whole of the lower courses which were attached to it by the iron bolts, and that this enormous mass, weighing not less than 1,350 tons, had been removed *en masse*, and was resting *entire* on the rubble at the side of the pier, having sustained no damage but a slight fracture at the edges." It is quite impossible that an estuary can ever be the scene of such destructive agencies as those which occur on portions of the coast exposed to the full force of the open sea, but such extraordinary phenomena with regard to the waves ought to be well considered even in the case of a comparatively-sheltered structure, when the lives of passengers, as well as the capital employed, are involved in its failure to withstand their fury.

THE ABATEMENT OF NUISANCES.

ALTHOUGH it is a maxim of the law that there can be no wrong without a remedy, it is not unusually in the nature of the law to make that remedy which it gives to a sufferer a long and tedious one. Wrongs to property, especially, are often the most difficult and expensive to obtain redress for, and a legal remedy is therefore often regarded as only one degree better than the wrong itself. But there are certain matters in respect of which the law permits a man to seek redress by his own hand, and with the utmost expedition that he pleases. This is a privilege of the highest value to owners of property; but, just as Pope stated that a little learning was a dangerous thing, so we, perhaps, may be permitted to point out that the power of private redress is also somewhat of an edged weapon, and may not improbably wound him who employs it. Perhaps, too, no persons have more interest in such private remedies than have owners of buildings and land, and it is for this reason that we propose to offer a few remarks on the question of the abatement of nuisances to show what is the power which the law gives to private persons, and consequently within what limits it is confined. A well-known legal writer has gone so far, indeed, as to state

* As to those who will more especially devote their attention to Sta. Maria delle Grazie,—with which Bramante's name is linked indissolubly with that of Leonardo da Vinci,—may we venture to refer them, while at Milan, to Sig. Colla, whose drawings of projected restoration of the church formed so conspicuous a feature in this year's architectural exhibits at the Paris *Salon*, as was noticed in these pages? To the restoration of another of the Renaissance buildings of the Lombard capital, Sig. Colla has also devoted his attention, the Palazzo Marino, now the Townhall of Milan.

that it is never advisable for a person to pursue this remedy; but we think that if employed with care and caution, and with a clear knowledge of the object sought to be attained, it need not prove so exceedingly dangerous. As regards nuisances themselves, it must be borne in mind that the legal meaning of this word is somewhat different from that which it holds in common parlance. It is used in its broadest meaning, and does not mean something offensive to the senses, which is the usual meaning attached to this word. Derived as it is from the French *nuire*, to hurt, it means something which injures and hurts property or person, and has thus a very extended range. It has also been defined as being a consequence of something not directly or immediately injurious, — injurious, however, in its effect. Thus a person who digs a channel or erects a dam on his own land does no more than what is in itself lawful; but if the effect of his so doing is to divert the water from a natural water-course, to the loss of a riparian owner below, or to turn it back to the injury of a riparian owner above, such acts become unlawful. The first point, then, in regard to this subject, which is very elementary in its nature, is that a thing must first of all be a nuisance before it can be abated. It is not enough that there must be fears or probabilities of a certain thing turning out to be injurious; it must actually have developed into this legal species before a person can take the law into his own hands. On the other hand, it is satisfactory for an injured party to know that if the nuisance is so mixed up with some legal right as to be inseparable from it, then, that this legal right may be put an end to by the abatement of the nuisance. The case of Cawkwell *v.* Russell (26 *Law Journal* Reports, Exchequer, p. 34), decided in the year 1856, and which has always been regarded as sound law, is an instance of this proposition. The result of the case could not possibly be put in briefer form than it is in the judgment of Baron Alderson, which is perhaps the most pithy judicial decision to be found in the law-books. We give the whole judgment in the following lines:—"If a man has a right to send clean water through my drain, and chooses to send dirty water, every particle of the water ought to be stopped, because it is all dirty." There the plaintiff had been suing the defendant for obstructing the drainage of his houses, and it appeared that the plaintiff had a right to let clean water run through the defendant's drains, but as he sent dirty water the defendant took the remedy into his own hands, and so completely abated the nuisance that he also stopped the flow of clean water. Hence arose the judgment which we have set out above, and which forms a capital illustration of the proposition, that if a nuisance cannot be abated without the conclusion also of some legal right, that legal right must cease. But it must also be borne in mind that it will not do in all cases to act in this wholesale kind of fashion, and that if the nuisance is abated in an unreasonable manner, the person so doing lays himself open to the unpleasant consequences of an action at law, and illustrates what we have already said that the abatement of nuisances is somewhat of a two-edged legal weapon, which may cut and injure the user of it. Let us give an example also connected, as was the last instance, with the flow of water. A plaintiff had a prescriptive right to the flow of water led by means of a gutter from a mill-stream at a point where an ancient weir was erected, and he wrongfully lengthened the gutter for the purpose of irrigating more land. Consequently the flow of water down the defendant's mill-stream was diminished, so that there then existed an injury or nuisance which he might abate. But, unfortunately, he set about doing so in too thorough a manner, for he pulled down the ancient weir, and consequently prevented any water at all from flowing on to the plaintiff's land. Such in brief were the facts in the case of Hill *v.* Cock (26 *Law Times*, new series, p. 185). The result of the action which the plaintiff naturally brought against the defendant was that the Court held that the defendant was not justified in stopping the plaintiff's excessive user of the water by means which altogether prevented his enjoyment of the water. Again we may quote from the judgment, namely, that of Mr. Justice Willes, whose decisions always command the highest respect. "The flow of water," he says, "to the defendant's mill was injured by the alteration of the gutter, and the plaintiff had thereby destroyed the measure of his right over the old course, and created a confusion of his ancient rights. If the whole of the defendant's right had been interfered with, as it was in the case of Cawkwell *v.* Russell, then the taking down of the weir would have been a reasonable mode of destroying the plaintiff's enjoyment. However, he is bound to abate the nuisance in the most reasonable manner, and subject to there being no confusion of rights created, the jury have found that it was not practically necessary for the purpose of abating the nuisance to pull down the weir. If the extent of the nuisance was so great that it was reasonably impossible to abate the nuisance, then I should say there exists a right on the part of the proprietor of the servient tenement to interfere with the whole." It would not be easy to state the law upon this subject much more clearly than is done in the two judgments which we have quoted, as they show what is the power which the law places in the hands of a person who is affected by a nuisance, and within what limits that power may be exercised. But it will also be noticed that in the last judgment Mr. Justice Willes speaks of the jury,—the great judges of fact. Hence it will be obvious that dangers arise in the abatement of nuisances by private individuals because what may appear reasonable to an aggrieved and injured individual who does not look at the matter in the calmest possible light, may appear by no means so reasonable to a jury of his countrymen, feeling at the moment great belief in the sanctity of the law of which, in that particular case, they are the temporary guardians. No doubt the owner of the mill-stream did not consider that he was doing an unreasonable thing in stopping *in toto* the flow of water, but when it came before the jury and the bench, a different opinion prevailed. Hence we have here an instance also of the necessity for not acting without careful consideration, and only going to the extent of stopping the actual nuisance. Again, to touch most briefly on another point: as a rule, no previous demand to remove the nuisance is, except in some exceptional cases, necessary. Still, we would never recommend a man to abate a nuisance without first demanding its removal; for should the matter come before a court of law, the absence of such a demand does not place the "abater," as we may call him, in a favourable light. Owners of land and buildings, if they have these main principles in their mind which we have pointed out, and if they act calmly, may thus find the abatement of nuisances by their own hand a more speedy and more satisfactory remedy than an appeal to the courts of law.

MODERN NEW YORK.

THE halo of tradition that surrounds the name of New York is by no means exceptionally attractive or important. New York is essentially a modern city, and visitors from the old world come and glance at it, not for the purpose of seeing architectural remains of bygone generations; not to gaze on archives, or monuments centuries old, but to see a modern city,—a metropolis throbbing with business life, one of the world's busiest marts, standing at the back of one of the finest harbours in the world. It is not too much to say that the foreign visitor cannot possibly see anything around the wharfs at which he may land to favourably impress him. We have no docks, really, unless the somewhat dilapidated wooden piers at which the ships land their passengers and goods can be dignified with the name. When the visitor to our city for the first time has run the gauntlet of the Custom-house officers, and protested against the extortion of the cab-driver, he gazes with astonishment on the wretchedly dirty appearance that almost everything wears. The streets, even in the heart of the city, are filthy and uneven. The best of them are paved with granite blocks, more or less irregularly laid, which renders riding in an ordinary vehicle, or walking, very tiresome. Gaunt top-heavy telegraph-posts stud the causeways thickly along the most important streets, for, with all their improvements, New Yorkers have never yet put any of their telegraph-wires underground.

When a man has fairly settled himself down to view men and things from an unprejudiced standpoint in this marvellous city, he cannot but find much to delight him. To walk from the extreme south end of the island along the Broadway in a northerly direction for six miles, and realise that the whole island was sold so recently as 1626 to the Dutch Governor by the Indians for $24,—that in 1656 it contained only 120 houses and 1,000 inhabitants,—is no easy task. The development of the city has been unique in the history of cities. It is true enough,—and no one can distinguish the fact more easily than an Englishman,—that there is a great deal of room for improvement. One of the greatest and ever-present grievances is the bad condition of all the streets. The pedestrian who walks along Cheapside, London, is inconvenienced but little by the noise of passing vehicles, owing to [the smoothness of the material with which the street is laid. But in the Broadway,—and, in fact, everywhere in New York, where there is any great amount of traffic,—the incessant noise, clatter, and rumble are well-nigh distracting to all quiet mortals who regard a continual deafening sound as one of the banes of mundane existence. Even in Fifth-avenue, the great aristocratic street of the city, along which stand the residences of some of the richest men in the country, there is no asphalte or wood-paving,—nothing but hard, badly-laid granite blocks. In all my perambulations, I have not seen a square yard of wood-paving anywhere. Why it finds no favour I can form no idea, especially when considering the vast amount of wood which the country produces.

To see modern New York at a glance, one must needs take a walk along Broadway, called by the old Dutch settlers "Heere Straat." This is the city's great spinal column, and it is the one great thoroughfare running north and south that declines to observe the arrow-like straightness which is the characteristic of most of the streets. It swerves now to the west, and then to the east, cutting across several "avenues," which, being laid out more recently than the erratic "Heere Straat," continue their course in as straight a line as men could draw. The individual who walks up this grand thoroughfare for the first time without uttering the word "magnificent" many times must be sadly deficient in his power to appreciate architectural boldness and skill. On either hand, for five miles, there is an embarrassment in the riches of gigantic solid stone, brick or iron structures, used as hotels or for business purposes. While it is not my intention to refer in detail to the noteworthy buildings of New York, I would not pass without a word concerning the oldest house in the city. It is now known as "Washington Hotel," and is No. 1, Broadway. It was erected in 1742 by Sir Peter Warren, K.C.B.—a name immortal in the annals of English maritime warfare. At the time of its erection it was the most magnificent building in the city, but it has long been eclipsed now. While 138 years is but a small period in the history of some houses in the old world, we regard Washington Hotel as a very ancient building, because it is the most ancient we have. There is an interest attached to it, moreover, in the fact that Sir William Howe, Sir Henry Clinton, and Sir Guy Carlton (afterwards Lord Dorchester) all patronised this house. Improvements are constantly being made along Broadway. Small and unsightly houses, erected before the present generation entered into active life, are gradually disappearing, and in their places buildings, fitted up with the latest improvements and appliances, are being reared to the height of seven, eight, or ten stories.

The elevated railroads, of which the English bear only fragmentary accounts, are a great boon to those who live several miles from the heart of the city, though they are a great nuisance to those past whose houses they run. They are badly managed at present, but with good and fair treatment the public would admit that they were an inestimable boon. An extension northwards, which without these railroads would render travelling from one end of the city to the other a long task, is rapidly progressing, and many fine new buildings are now being erected on ground which a few years ago was considered far into the country.

New York. T.

Penrith.—Messrs. Graham's premises, in the Market-square, are being rebuilt. The front is of local red stone, the roof being broken with half-timber gables. The new building, designed in the old English style, will present a picturesque appearance. The work is being done by Mr. Grisenthwaite, of Penrith, from the designs and under the superintendence of Messrs. Hetherington & Oliver, architects, of Carlisle.

HOUSE DRAINAGE AND SEWAGE WORK AS A SPECIALTY.

THE tenour of the evidence which has been received hy the Sanitary Section of the Society of Arts, and discussed at meetings of the society, has shown that the most fatal errors in the application of settled principles of sanitary work are committed in the construction and drainage of edifices even of the first-class in the metropolis, by architects of the highest position. I believe I am warranted in stating it as the conviction of the section, that for the public protection, the subject of house-drainage must he cultivated and practised as a specialty. This conviction will, I believe, he strengthened hy what takes place in the United States. There, the English practice in house-drainage works and sewerage is generally closely followed hy American as well as by English architects and artisans. There may he deviations from old rontine, and improvements might he looked for from American artisans, where the conditions are such as to stimulate the exercise of the suggestive faculty of ingenuity; hut there, as here, they do not appear yet to arise in common practice. A report made to the Massachussetts State Board of Health, hy Mr. Elliot G. Clarke, principal assistant engineer of sewerage works in Boston, presents such a reflex of the errors in principle committed in common British practice, most of them, no doubt, carried over from England, that I have hegged for the loan of the woodcut illnstrations, to reprint with the report, for instruction here, and the State Board has been so kind as to lend them for the purpose.

I am glad, however, to learn that sanitary science in construction is heing taken np as a specialty in the United States, and I helieve, from the report of Mr. G. E. Waring, jun., of Newport, on the condition of Washington, that if the principles he propounds are taken up hy the Government there, for putting its seat in a proper condition, as an example to other cities in the Union, the United States Government may set an example to our Government of what may he done even for the British metropolis. He shows, what has long heen shown for London, hut not done, how the damp of its surcharged site may he removed by subsoil drainage; how a system of circulation may he introduced, and one of stagnation removed. He would carry in the pure water direct hy a constant supply, without cisternage and without stagnation, and would remove all the fouled water, and all the excretory matter from the houses, hy self-cleansing drains, and from the town hy self-cleansing sewers. He would remove storm-water hy separate channels to the river, and not mix it with the discharges from the house and create a necessity for large man-sized sewers accumulating stagnant deposits, or extended cesspools such as those under the Metropolitan Board of Works or the Vestries in London, in which the putrefactive matter is kept for weeks and months, giving off the noxious products of decomposition, and diffusing them into houses and streets. He proposes that all waste organic matter should he delivered at the mouth of the sewer at least within twenty-four hours of its production. I helieve that it may he done in less time than that at Washington. To do this there must be a proper adaptation of the sizes of the drains and sewers to concentrate the flow of the fouled waters, and to make them self-cleansing. In exposition of the ignorance which is prevalent there as well as here, he states, for example, "that the particular idea of the size of a drain required to receive the drainage of a house or of a number of houses is strangely in error. A pipe, 6 in. in diameter, having an inclination of 4 in. in 100 ft., has a capacity of discharge of nearly 200 gallons per minute, say 12,000 gallons per hour, or, hetween eight and eleven in the morning, 36,000 gallons. It is usual to estimate that during the three hours ahont one-third of the daily flow is discharged. Such a pipe, then, at such an inclination, would he adequate to the removal of nearly 150,000 gallons per day. If each household averages six persons, and if the daily consumption is even 50 gallons per head, the service would suffice for 500 houses; or supposing the sewer to run only half full, for 250 houses." Here, in London, it is common to put down drain-pipes of that size for single houses. "It is to he considered, also, that it is rarely necessary to lay a sewer with so slight a fall as 4 in. in 100 ft., and that an increase of fall secures, of course, an increase of discharge. During the past year, under the direction of the National Board of Health, I have made a number of gaugings in different parts of the country, to determine the actual practical dry-weather flow of the public sewers during the hours of the greatest use." Our local sanitary authorities would do well to follow this example. He says the result of these gaugings fully sustains the estimate thus given. "Generally, where from 50 to 100 houses contribnted to the sewer, the discharge filled a 6-in. pipe from less than 1 in. to 2½ in. deep. A sewer in Milwaukie, draining an area of ahont 75 acres, and serving a population of over 3,000, had the whole of its flow through a 6-in. pipe, which it did not entirely fill. A sewer in St. Louis, draining a district of over 11,000, had its entire flow through a 12-in. pipe, which it only ahont one-half filled. The helief is very general that if a given flow of sewage can he discharged through a small pipe, it can surely he discharged through a large one. This is not true. The whole sewage, solid matters and all, will he completely removed by a small sewer, while only the liqnid portions and the smaller solids will he removed by a large one. The solid matters, heyond the capacity of the broad and deep stream to move them, remain as a deposit in the largo sewer, always subject to decomposition, and often liable to obstruct the water-way, to lessen the already slight scouring capacity, and to invite further deposits." In this metropolis, there are estimated to be upwards of 1,000 miles of sewers of deposits—extended cesspools—chiefly nnder the management of the vestries, that serve as dire demonstrations of these truths, as well as the house-drains in the common conditions described in the annexed report. It will he found in the United States that by following out the principles set forth, three houses and three towns may he generally drained well at the cost heretofore incurred in draining one ill.

EDWIN CHADWICK.

COMMON DEFECTS IN HOUSE-DRAINS.

The purpose of this paper is to state what are the common defects in house-drains, and to show the usual forms and condition of such drains as they exist in our cities and towns to-day. The statement is chiefly based on observations made in Boston while constructing intercepting sewers; hut it is assnmed that examinations in other cities and towns of the Commonwealth wonld reveal a condition certainly no better, and prohably worse. Some testimony will he offered from those whose occupation has given them opportunities for observation; and, while it is not intended to cite exceptional cases of defective arrangement or construction, a few characteristic examples will he given, such as investigation would prove to he very common.

What are the essential conditions of an efficient house-drain, one or more of which must he violated to constitute a defect?

Briefly stated, they are, that the drains must he of size and shape to concentrate its flow, smooth inside, suitahly inclined, tight, properly connected with the house-pipes and sewer, strong and durable in material. It is of great importance that the portion of the drain within the house should always be in snch a position as to admit of ready inspection at any time; it should he in sight,* and not concealed. Let us see what proportion of Boston drains reasonably fulfil these conditions.

Existence is perhaps the most essential condition of a drain; and, hy an Hihernicism, non-existence may he termed its most serious defect. Naturally, non-existence was not observed in digging for the intercepting sewers, hut there is sufficient evidence that it is not unknown.

The writer has seen a case where a drain-pipe from a dwelling ran through the walls, and there ended. Several similar cases have heen reported to him; and another, where a block of six expensive houses, occupied for months with all the customary apparatus in the way of plumbing and waste-pipes in full operation, had no drains heyond the walls to the street-sewer. Such cases are rare, and generally reveal themselves quickly; hut it is more common to find drains which are so solidly filled with earth, grease, and other matter, as to exist only in name, and which, for any good they accomplish, might just as well not exist at all. One, examined hy the writer some months since, had apparently had nothing through it for years, the whole waste from the soil-pipe having accumulated heneath the cellar-floor. The same state of things was found to exist helow the Rockland Bank Building in Boston. A case has heen mentioned to the writer where it is thought that three deaths can he directly traced to the stoppage of a drain which was so clogged as not to act. Almost every one who has been led into this line of inquiry has some similar instance to relate, and evidence could he multiplied indefinitely. Of the house-drains crossing the intercepting sewer-trench, during its construction last season, fully 25 per cent. were almost or entirely choked with sludge.

An example of semi-existence, observed while digging for the sewer in Charles-street, is worth noting, as showing the intelligent judgment sometimes exercised in doing this kind of work. It will he understood hy referring to the sketch (fig. 1). The drain was one for surface-water; and the drain-layer, in digging from the house towards the sewer, came upon a log lying across his trench, and here stopped short, chopped a hole in the log, found it hollow, and connected his drain to it without going farther. It is true, the log led to no outlet, hut then it saved trouble, —to the drain-layer.

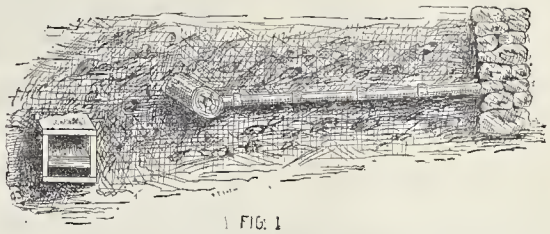

FIG. 1

As to the question of the size of drains, it was found that of 113 observed while building sewers the past year:—

11	were ahout	4	inches in diameter.		
4	„	„	5	„	„
21	„	„	6	„	„
5	„	„	7	„	„
27	„	„	8	„	„
8	„	„	9	„	„
11	„	„	10	„	„
26	„	„	12	„ or over	„

The sketch helow (fig. 2) illustrates the wide range of this diversity. Most of them drained single dwellings similarly situated; and if the

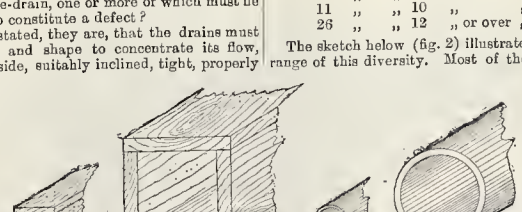

FIG. 2

* The same rule applies, of course, to soil-pipes, although that part of the subject does not come within the scope of the present inquiry.

small ones were large enough the others must have been unnecessarily large, and *vice versâ*.

But what is the proper size?

Probably nine engineers out of ten would answer, "By no means larger than 6 in."; and nine drain-layers out of ten would now say, "Never smaller than 8 in." The former argue that the drain need only be large enough to pass through it all that it can reasonably be expected to carry, and that anything beyond this tends to make the ordinary flow spread thinly over a wide bottom, without a sufficient depth to carry solid matters along with it. The latter reply that, in fact, a drain never does receive only what can reasonably be expected; and that, the larger the drain, the more storage room for the unreasonable accumulation of clothing, tin and glass ware, dead animals, &c., usually found in it. "In practice," say they, "large drains take longer to choke up than small ones, and are therefore better."

Their facts are correct, but their conclusions may be doubted. In building a drain, the object should be to prevent the beginning of a deposit; and this is much easier in a small drain than in a large one, as will be understood from fig. 3,

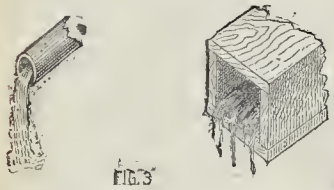

FIG. 3

where an equal quantity of water is supposed to be flowing in a 4-in. and a 12-in. drain. It might be thought (by one who thought at all about such matters) that the discharge of a great volume of water, as from a bath-tub, would tend to scour out and clean a drain. So it might a very small one. But in such a structure as our sketch represents, with a flat bottom 12 in. wide, the stream caused by such a discharge would probably meander over the bottom of the drain, and be nowhere over ½ in. deep. Let a deposit once begin, and subsequent accretions as surely choke a large drain as a small one, only it takes longer to do it. And it may even be questioned whether it is an advantage to be able to use for an additional year a drain nearly full of putrescent filth, or whether it is not better to have the evil disclosed and remedied as soon as possible. It may safely be said that three-quarters at least of the house-drains in Boston are too large, because, even if some of them perform efficient services, small ones would do as well, and be less liable to get out of order.

In respect to form, there is almost as much diversity as there is in size. Figs. 4 to 10 give the more common shapes.

The first three must be condemned at once, on account of their flat bottoms. The water

FIG. 4

FIG. 5

FIG. 6

FIG. 7

FIG. 8

FIG. 9

FIG. 10

passing through them spreads out into a thin sheet, which does not readily wash along solid matters. Floating matters also tend to stick in the angular corners more than they would on rounded surfaces. That this is so, is shown by the record. Of the 113 house-drains whose condition was noted, 45 were constructed with flat bottoms; and of these 26 were choked, or nearly so with sludge; 19 were reasonably clean. Of the remaining 68, which had rounding bottoms, 12 were full, or partly so, of sludge; 56 were reasonably clean. The common appearance of these flat-bottomed drains, as they were uncovered, is shown in figs. 11, 12, and 13. Figs. 13 represents the condition of a drain, now disused, which came from the City Hospital grounds.

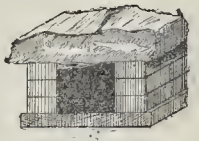

FIG. 11

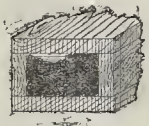

FIG. 12

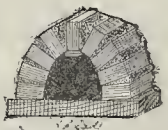

FIG. 13

The shapes shown in figs. 7, 8, 9, and 10 are unobjectionable, although, in fact, these drains were often too large, and had other defects. Fig. 8 is a kind of construction which was in vogue twenty-five years ago; and, except for liability to open joints, its angular bottom and its size is passably good. Our facts seem to show that 40 per cent. of the Boston house-drains are defective in shape.

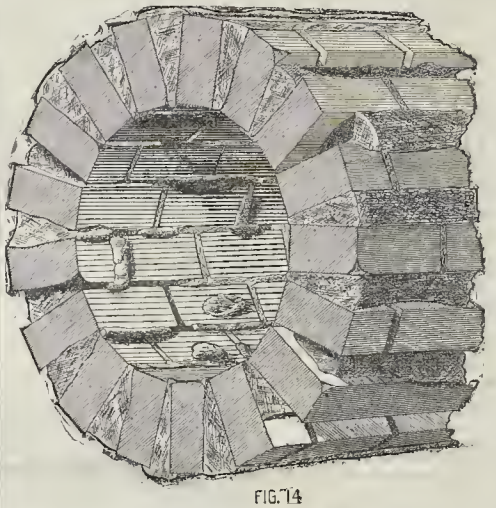

FIG. 14

A drain should be smooth, so as to afford no prominences for solid particles to lodge upon. Planed wood, slate, and brick are smooth enough. In use they soon become covered with a film of slime that makes them very slippery. Unplaned wood, which until recently has been somewhat used, is apt to be rough, and to have splinters pointing against the flow, which catch solids moving upon them. The chief difficulty in making a brick drain smooth is the care required to see that no mortar is left projecting into the drain. Fig. 14 shows the manner in which such work is often finished.

It is possible to strike each joint of the lower half of the drain so as to leave a reasonably smooth surface; but a difficulty harder to avoid is caused by portions of the mortar uniting the arch-bricks falling when the supporting centres are removed. These lumps of cement, indicated in the sketch, adhere to the bottom, and, unless carefully scraped off, harden, and form serious obstructions to the flow of sewage.

Pipe-drains, whether cement, clay, or iron are smoother than those of brick. Glazed clay pipes are especially smooth. In these, however, it is very common to find the mortar uniting the several sections of pipe projecting into the interior, forming a series of little dams which obstruct the flow. Fig. 15 illustrates this. This can be avoided by carefully cleaning the interior of each pipe, after laying it, with a swab or hoe,—a simple precaution, but often neglected by a careless drain-layer. It will not be an exaggeration to say that three-fourths of existing drains are defective as to their smoothness.

The best rule in practice for the inclination of a house-drain is to give as much pitch as is possible, and in few cases is less than ½ in. to the foot safe. A great many drains are faulty in this respect. The actual inclination of drains crossing the trench of the intercepting sewer the past year was not taken; but of the 113 met with nine are recorded as level, and fourteen as pitching the wrong way, that is, towards the house. One of these, coming from a public school building, was about 7 in. lower at the curb-stone than at the sewer. The condition of such a drain is shown in fig. 16.

The water stands in the depressed portion of the drain to the height of its connexion with the sewer, and having little motion deposits are apt to occur. In the case referred to it is but fair to say that the school-drain was clean, so far as seen. Very possibly an abundant use of water or recent heavy rains had scoured out any deposit that may have taken place. It is probable that most of this inclination in the wrong direction occurs in the street, near the sewer. The drain-layer frequently begins to put his drain simply with reference to the house, without inquiring what is the elevation of

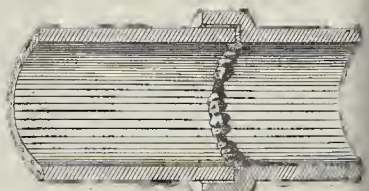

FIG. 15

the sewer into which it is to empty. He digs his trench towards the street, and lays his drain on a slope which he judges by his eye to be sufficient. This in itself is a deceptive matter, as a trench generally seems to slope down towards the observer. When the sewer is reached, it is found to be higher than the portion of drain already laid. What is to be done? It is not the drain-layer's fault that the sewer is so high. He cannot take the trouble to dig up his pipe again. It is only a few inches any way, and the pipe is run up and connected, the trench filled back, and, "out of sight out of mind."

It was stated that one of the essentials of an efficient house-drain is that it shall be tight.

Mr. Ernest Bowditch has called the writer's attention to a condition in which, at first sight, a leaky drain might appear better than a tight

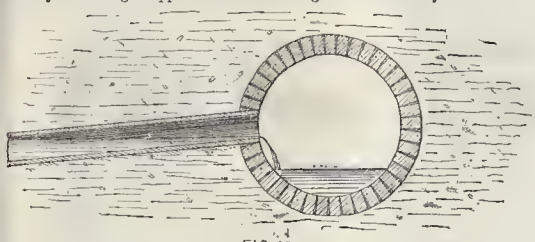

FIG. 16

one. He says, "It is sometimes noticed, when plumbing is from twenty to twenty-five years old, and where all the drains outside the cellar-walls are of open stone (technically French drains), the soil-pipe not being ventilated, that there is no perceptible leakage of sewer-gas into the house. It is reasonable to suppose that in these cases the gas generated outside the house works up through the soil, rather than force the traps of the house. The modern method of tight drains and cesspools tends to drive all gases into the house. It is frequently more important, therefore, that recent plumbing should be ventilated than that of older date.

Both tight and open drains tend to produce evils; but those arising from a tight drain can be obviated by proper ventilation of the house-pipes, while the evils from leaky ones are irremediable. Therefore, we say, drains should be tight, that sewer-gas (or what is worse, matters capable of producing sewer-gas during a long decomposition) may not escape; and also that water may not leak out, leaving the solid contents of the drain stranded.

This want of tightness is the commonest defect of all, and probably three-quarters of the annoyance from drains is due to it. In the annual report of the Boston City Board of Health for the year ending April 30, 1878, is given the result of examinations of 351 house-drains in different sections of the city. Of these, 193, or 55 per cent., are reported as defective; and in nine cases out of ten the defect consisted in the drain not being tight. This defect, more than others, affects the better kind of houses.

Mr. Theodore Clark, who has had experience with this class of dwellings, speaks thus of earthenware and cement drain-pipes:—"These, I think, rarely remain tight many years. Even where the drains are laid with the greatest care, I have observed that water will often, in course of time, make its way out around the joints between the pipe and the ring of cement. When broken it is found that the cement has taken a perfect mould of the pipe; but either from some greasiness, or possibly a little dust on the pipe at the time of laying, it has failed to adhere, and water has ultimately forced its way through. An accumulation of water caused by an obstruction in the pipes will often search out such places, which must have previously allowed gas to pass freely. Another very frequent source of trouble is the settling of the ground under and around the drain-pipes. In houses with drains originally in perfect condition, their joints will frequently, in a year or two, be found to be separated, the pipes cracked, or the branches settled away from the soil-pipes which enter them. In either case the drainage saturates the ground about the defective places with matter, whose effluvium will penetrate even concrete.

In my experience, defects of this kind are far more common than leaks in iron soil-pipes, imperfect traps, or other defects attributable to the plumber; and the earthen drain-pipe should generally be first examined in searching for the cause of unpleasant smells in any part of a house, as effluvia originating in the cellar often find their way through furnace-pipes and behind furrings to the remotest corners of a building."

In this connexion may be cited several cases recently reported, in each of which a smell was noticed whose source it seemed impossible to locate, until at last a leak was discovered in the drain, directly communicating with the cold-air supply-pipe of the furnace, which latter, of course, acted as a distributor of the gas through the entire house. A similar leak into the air-duct of the Boston City Hospital proved a source of serious illness, and probably of increased mortality, among the surgical patients, until remedied in course of the various improvements introduced by Dr. Cowles.

Leaky drains are due to a variety of causes. In a brick drain the joints between the bricks may not be solidly filled with mortar, the mortar may not adhere to the bricks (a common result of not wetting the latter before laying), the bricks themselves may be shaky or rotten, or the structure as a whole may be broken by unequal settling. In some drains no attempt is made to have tight joints. A kind much built some years ago, and of which many examples

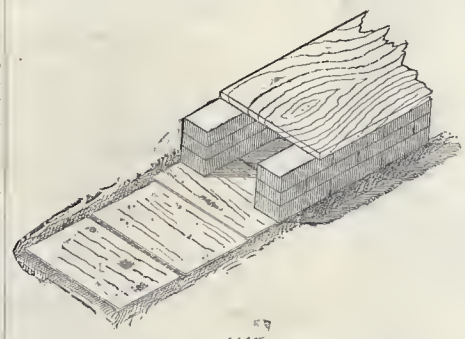

FIG. 17

remain, is shown in fig. 17. In this the bottom is made of roofing-slates placed side by side, or sometimes overlapping, but never

FIG. 18

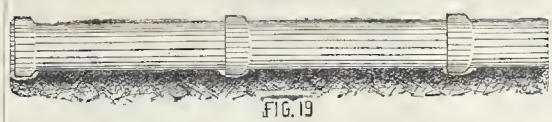

FIG. 19

with anything to prevent water percolating through the joints into the soil below. Fig. 17 reversed, with plank below and slates above,

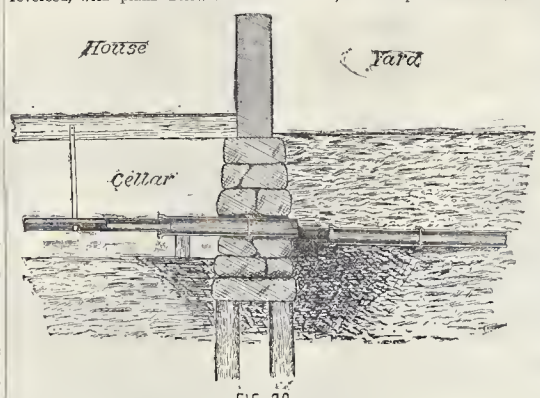

FIG 20

would resemble more than half the drains on Beacon-hill as they were originally made, and still exist. A plank drain may leak through open joints, variously caused through knot and nail holes, and by the rotting of the wood where it is not constantly wet. A pipe-drain may leak from bad joints, from flaws in the pipe itself, or because it had been broken. The breakage is generally due to unequal settling, sometimes to defective pipes, and occasionally to improper methods of laying them. The sections are sometimes carelessly or ignorantly laid on the bottom of the trench, resting merely upon their flanges as shown in fig. 18, instead of upon their entire lengths, with depressions dug out for the flanges, as in fig. 19.

In the former case, unless the dirt be rammed back beneath the pipe with unusual care, the pipe acts as a beam resting on supports 3 ft. apart, and is liable to be broken by the superincumbent earth, or by any shock, as of a body falling, or a wagon jolting over it.

As the greater proportion of leaks are caused by defective joints, it follows that a brick drain with joints every inch or two is more liable to this defect than a clay or cement pipe with joints 2 ft. or 3 ft. apart, and that iron pipe in 5 ft. lengths is less liable to it. A place where a leak frequently occurs, especially in a house built on made land, is where the drain passes through the cellar wall. If the foundation wall is supported, and the ground on either side settles, a condition of things is produced shown in fig. 20.

A drain may exist in such a state as this for months, or longer, without detection. The water follows the wall, perhaps into neighbouring houses, saturates the ground in the vicinity, and finally finds an outlet through some pervious stratum, or into some well. If the cellar be examined, little moisture may be apparent—an ill-defined odour to which the family become accustomed, and about which visitors feel a delicacy of speaking, being the only suggestion of trouble,—until finally, perhaps, may come some "unaccountable" sickness, or "mysterious visitation of Providence." Mr. W. H. Bradley, Superintendent of Boston Sewers, spoke thus of this matter three years ago, in a communication to the city government:—"The number of drains leaking under houses and into foundation walls is very large; it is almost certain to occur with every house upon made land, and is always neglected by owners and tenants till it becomes insupportable; and with sickness traceable to such causes, and continued discomfort prevailing, the parties most interested still wait for the city to carry out costly general measures, thinking thus to abate their private nuisance. As a rule, a bad smell in a house means something wrong locally, and should be stopped in a day."

The examinations of house-drains, before referred to, made by the Boston Board of Health, which aimed at the discovery of leaks by the use of strong-smelling volatile oils, show that more than one-half of the Boston drains (and

the proportion would probably not be less elsewhere in the State) are defective from want of tightness.

A drain should be firmly and properly connected to the sewer at one of its ends, and to the soil-pipe (if this connexion be within the house, as it almost invariably is) at the other. More leaks probably occur at the other place than at any other. The inspectors of the Board of Health, after pouring a little oil of peppermint into an upper water-closet, most frequently recognise the familiar odour at this point. Sometimes there is not even a pretence of making a tight joint, the soil-pipe being merely inserted loosely into the drain. In other cases the joint, intended to be tight when made, through careless construction is not so; and again having been tight when made, it may have been injured since. Fig. 21 is from a sketch made by Mr. Bradley of a case brought to his attention, existing in the house of a Boston physician. The drain may settle away from the pipe, or the pipe may settle into the drain; an iron pipe by its expansion and contraction may break the joint between them. So liable is this place to disturbance, that when possible it is well to build it so that it may be accessible to examination at any time when there is the least suspicion of wrong. Rats frequent drains, and dig into and out of them with surprising facility. An influx of rats into a house should be taken as strong presumptive evidence of a defect in the drain.

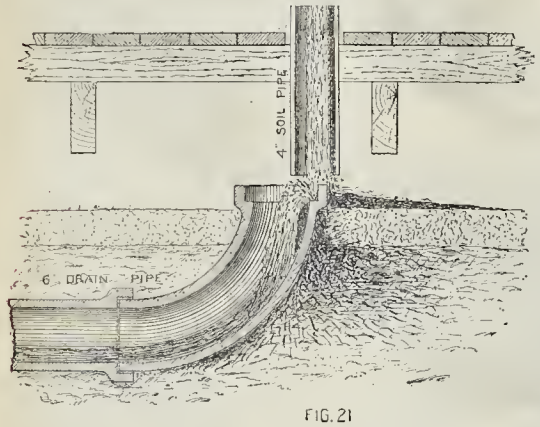

FIG. 21

The mode of connecting a drain with the sewer affects more the efficiency of the latter than it does directly the sanitary condition of the house. But as, indirectly, the condition of the sewer as to cleanliness, efficiency, and liability to generate gases, affects, through the drain, every house connected with it, the proper junction of the drain and sewer deserves a degree of attention which, till quite recently, it has seldom received.

A drain should enter the sewer either by a curve tangential to the direction of flow in the sewer, or at an acute angle with that direction, so that the contents of the drain shall unite readily with that of the sewer, and the velocity of neither be much retarded. Nineteen out of twenty drains in Boston, built previously to 1876, enter the sewer at right angles. The effect of such an entrance from the top or side it is attempted to show in the sketches (figs. 22 and 23), where the tendency to arrest the flow in both structures, and to cause eddies and deposits, is shown in a somewhat exaggerated way. Fig. 24 shows the better result attained by connecting the drain at an acute angle.

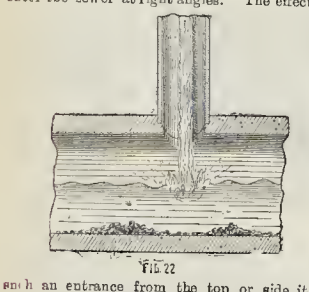

FIG. 22

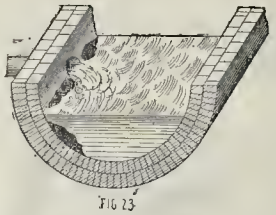

FIG. 23

It will probably be conceded that, whatever may be the mode of connexion between drain and sewer, it should be made in a firm and workmanlike manner. In practice it has generally been very loosely and roughly made. Sometimes there is no connexion at all, as shown in fig. 25, where the drain is simply brought pretty near to the sewer, and a hole broken into the latter. Of course, water from both drain and sewer soaks into the ground, and occasionally the earth falls into them. Often, as in figs. 26 and 27, a hole, somewhat too large, is cut into the side of the sewer, and the pipe pushed through, and allowed to project, more or less, into the sewer. Fig. 28 shows the rough way in which pipes are often connected with the arch of a sewer.

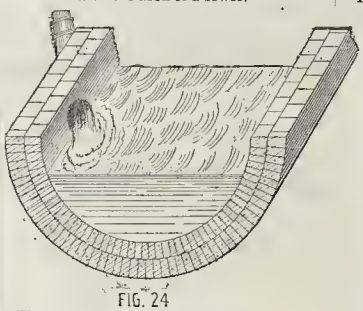

FIG. 24

The proper height in a sewer at which drains should be connected is about its ordinary flow-line. At this point the water from the drain mingles with that in the sewer with the least disturbance to both. In Boston, drains have commonly entered the sewers wherever they happen to run against them. As a general rule, they are too low (fig. 29); and water from the sewer backs into them, making a sluggish current. Their being too low might be expected from what was shown in connexion with inclination of drains; and this results largely from an effort to drain cellars into a sewer higher than the cellar floors. Occasionally, a drain-layer, having found a sewer much lower than he expected, has dug vertically to it, broken a hole in the top, and around the hole erected a chimney with which to connect his drain (fig. 30). Often the hole into the sewer is much smaller than the drain which empties through it (figs. 31 and 32). In such cases there are shoulders around the hole, on which solid matters accumulate.

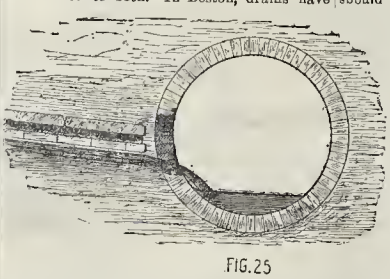

FIG. 25

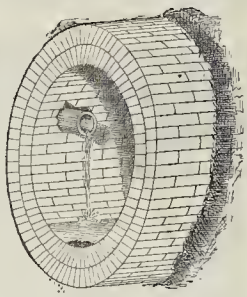

FIG. 26

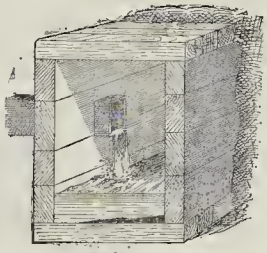

FIG. 27

The sketches that have been given exhibit what until very recently has been the method, or rather lack of method, of making connexions with the sewers of Boston; and it is supposed that the manner of doing such work elsewhere in the State has been very similar. In Boston there has been an improvement in this respect during the last three years. The superintendent of the sewers, realising how much the efficiency of his charge was impaired by the way in which house-drains were frequently connected with the sewers, obtained, against considerable opposition, authority to require that any future connexions should be made under his inspection. His regulations require junctions to be made with slants and curves, as shown in fig. 33; but of the total number of existing drains, the proportion so connected is very small. Speaking generally, it may be said that almost all the drains in old Boston are defectively connected with the sewers they enter.

The material of which a drain is composed should be durable, both on account of true economy, and, what is more important, because, being generally out of sight, any decay or failure in it is not readily discoverable. For the same reason that portion of the drain within the house should never be put where it cannot be easily examined in case there be any suspicion of trouble. The materials most generally used for drains are brick, stone, slate, vitrified clay, cement, wood, and iron.

Bricks made of good clay thoroughly burnt all the way through, are among the most enduring of building materials. But all bricks are not so enduring. From some kinds of clay good bricks cannot be made. In every kiln of bricks there are some which are not thoroughly burnt. A soft brick will rot and disintegrate in water. Therefore, while, as regards durability, bricks may be said to be a perfectly suitable material for drains, the statement is only true

provided great care is used in selecting them. Building stone and slate, often used for the tops and bottoms of drains, are generally durable (though there are instances of slate disintegrating in the course of years); but

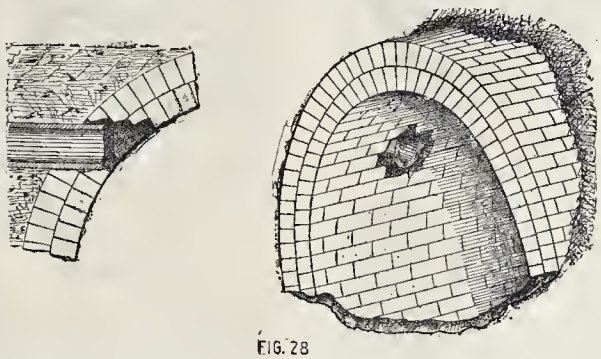

FIG. 28

there are other reasons why their use is not to be commended.

What has been said about bricks applies to the clay drain-pipe (now so commonly used), to a degree not usually recognised. Too frequently one hears Akron pipe spoken of as though it

FIG. 29

possessed unvarying qualities. It should be remembered that such pipes are burnt in a kiln very much as bricks are. Before burning they may be air-checked; like bricks, the pipes nearest the fire may be warped or fire-cracked; those higher up may be less thoroughly burnt,

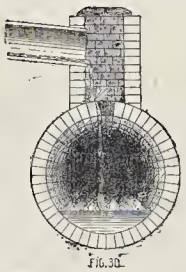

FIG. 30

corresponding to "light-colored bricks." Others may be quite soft, and imperfectly glazed, or the glazing may scale off by "popping."

Slip-glazed pottery pipes are still more liable to defects. They are made of a different kind of clay, and, being burnt at a lower tempera-

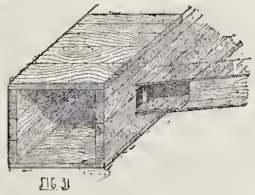

FIG. 31

ture, are usually more porous and less hard. The glazing, which is formed by dipping them before burning into a thin mixture of argillaceous earth, forms a skin over the pipe, which at times peels off under the action of frost, acids, or hard usage. While either kind of pipe, if well made, is durable enough, poor samples of each were occasionally noticed while constructing the intercepting sewer. It is important that in using them for house-drains care should be exercised in their selection.

Without going into the vexed question of the comparative merits of clay and cement pipes, it is sufficient to say here of the latter, that while they can be, and often are, made so as to be very durable, yet cases where they have failed and disintegrated are frequently reported; and it is extremely difficult to judge from their appearance whether they are good or not. In resisting the acids or alkalies, they have been proved far inferior to well-burnt bricks or clay.

It is not easy to shape wood into the proper form for a drain. If it is always kept wet, as in the bottom of a drain constantly in use, it will last an indefinite time. Where it is alternately wet and dry, as in the sides or top of a drain, it is sure to decay sooner or later. Of those seen last year, the report concerning many is, "rotten," "could not be held in place," "fell to pieces when handled," &c. The state of one such drain observed by the writer, in which the cover had partially rotted away, and earth fallen in, is given in fig. 34. Unless there are exceptional conditions, the use of wood for house-drains must be condemned on account of its liability to decay, as well as for other reasons.

The use of iron as a material for the construction of house-drains is of too recent date to permit of an absolute statement as to its durability. Thus far there seems little reason to doubt that it is suitable in this respect; and its many other merits will probably lead to its more extended use for this purpose.

Sanitary science, as it now exists, is of recent origin. Until within twenty years the arrangement and construction of sewers and drains were committed to mechanics and labourers, and were considered beneath the attention of educated men. Interest in the subject was first excited through the discovery by the medical profession, that a large class of diseases (thereafter called filth diseases) was induced by the presence of gases arising from defective drainage.

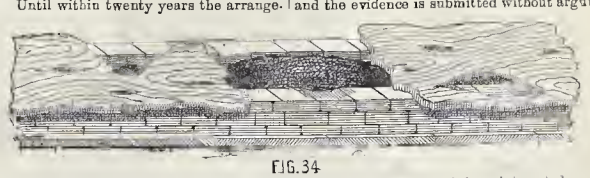

FIG. 34

To investigate and cure the inefficient methods and appliances which caused these gases, lay within the province of the engineer; and hence sanitary engineering and sanitary engineers came into existence. These latter devoted themselves with ardour to unearthing evils and devising remedies for them. Like new brooms, they attempted to sweep clean, and to purify at once the Augean stables they had discovered. But, like all reformers, they were sometimes carried away by their discoveries and theories, so that occasionally public opinion has re-acted against an exaggerated presentment of the evils of bad drainage. People have replied, "Nonsense! things cannot be in such a desperate condition, or the human race would have died

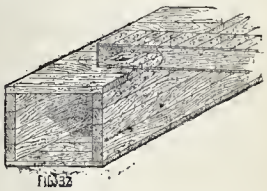

FIG. 32

out. Our fathers lived comfortably to a good old age without bothering their heads about drains, ventilators, or traps; and we are willing to take our chances."

It might be answered that our fathers did not have our intricate apparatus for drainage to bother themselves about. Neither did they put on double windows, and ventilate their houses through their cellars, nor connect their drains with their sleeping-rooms, as we do. The writer has no wish to be an alarmist. The risk from sewer-gas is probably not so great as many suppose: it is a slight risk, but a slight risk of a terrible danger. If a man thinks there is no need of insuring his house because his father lived in it for fifty years without a conflagration, he has a right to his opinion. What has been given in this paper, besides a few

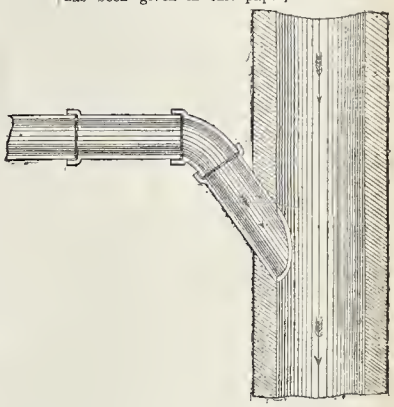

FIG. 33

general principles, is a simple statement of what exists as seen by the writer and others. The question of plumbing has not been noticed, because the writer is not especially qualified to discuss it. He merely speaks whereof he knows, and the evidence is submitted without argument for the consideration of those interested.

Should any one, admitting the evil, ask concerning a remedy, the answer is twofold. For the defective drainage which already exists, there can probably be no immediate radical relief; it can only come as people learn to

appreciate the danger of sickness and the value of health. When householders become sufficiently interested to wish to know where and what their drains are, and to make a few investigations with bottles of peppermint and otherwise, then will the better day be at hand.

As to what may be done to prevent an increase of bad work, a suggestion is offered. It is safe to assume that every man who builds a house for himself desires that its drainage shall be fairly efficient: unfortunately, it is not equally safe to assume that he will spend the time, thought, and money necessary to make it so. Now, since a defective house-drain may affect not only the owner of the house, and his family, and all who may thereafter reside there, but also the whole neighbourhood, would it infringe on personal liberty too much to require that the house-drain, if no more, shall be built according to approved plans and under municipal inspection? Merely to require that before beginning such work a plan of it should be put on record would accomplish something. In drainage, to have some plan, even if a bad one, is better than none. It insures a little thought beforehand, a knowledge of the height of the sewer, and an adaptation of the drainage to it.

In Frankfort-on-the-Maine, which has lately been sewered on the most perfect system, and with the latest results of engineering skill, it was found impossible to realise the expected benefits unless some control was exercised over house-drainage. In that city, connexion with the city-sewers is not compulsory; but if any one desires, as nearly all do, to drain into them, it is required that detailed plans in duplicate, showing everything to be done, shall be filed, one with the Board of Works for its approval, and the other to be kept at the house. The whole work is done subject to its constant inspection of materials and workmanship.

In the eighth annual report of the State Board of Health, January, 1874, pp. 130–132, are given the conditions under which buildings, &c., are allowed to be drained into the new sewerage system of Frankfort. The plans to be filed are referred to thus:—"Whenever the drainage of any house, yard, &c., is projected, the owner of the property in question must, after having signed the requisite certificate, furnish to the Department duplicate plans bearing the signature of the contractor, and containing a map of the locality on a scale of at least 1 : 2,500; a ground-plan of at least 1 : 250; and a sketch of the main drain and branches with its horizontal plane on the same scale as the ground-plan, and its profile at least 1 : 125. The certificate and one of the duplicate plans are to be kept among the documents of the Sewage Department; the other plan must be always ready for inspection by the officers at the place for which it is designed. All plans presented must contain all the works projected; the exact position of sinks, gullies, traps, and other details; the direction of the superficial water-carriers; the position of the rain-spouts, cisterns, privies, waterclosets, cesspools, vaults, wells, pumps, and other arrangements for water supply; also the levels of the surface where the works are projected, including the grades of the latter, the depth of the cellar, the lowest levels of the ground, and, where possible, the depth of the foundations,—all to be given by the standard grade."

This preparation of plans is the pivotal point about which centres the whole regulation of private drainage. Its effect is, probably, that, as the owner and mechanic are unable to make the plans with the requisite nicety and accuracy, they are prepared by an engineer familiar with the proper designing of such structures. It will be noticed that this filing of plans is not to be a mere form, but that a duplicate is to be kept on the ground, to be constantly referred to in constructing the work.

The question of sewerage is forcing itself upon the attention of all our cities and towns. Boston has appropriated between three and four million of dollars for a system of interception, whereby its sewers shall discharge freely at all times, and their contents be diverted from the vicinity of dwellings. It is the first most important step, and, as the taxpayers feel, costs dearly. If the full benefit of this improvement is ever to be realised, it will only be when the house-drains and common sewers are rendered equally efficient, and the fundamental condition of perfect sewerage,—an uninterrupted removal of waste matter from the house to its final place of deposit,—is attained.

PUBLIC WORKS IN THE COLONIES.

FROM official papers, just published, relating to her Majesty's Colonial Possessions, we get some further interesting information concerning public works. In the report which refers to *Jamaica*, we read that, last year, the sums of 8,180*l.* and 10,999*l.* were spent, respectively, upon maintenance and new works. Among these works may be noticed the following, under the head of "Maintenance":—Gas-fittings have been provided at the General Post-office. Extensive repairs and painting on the following buildings: the Supreme Court-house, Kingston; the Island Secretary's Office, Spanish Town; the Court-houses at fourteen of the principal towns and stations in different parts of the island; the Colonial Secretary's Office, the General Post-office, the Customs offices at Kingston and Port Royal. Minor alterations have been carried out to the Collector of Taxes' Office, Morant Bay, and to the Customs House offices at Montego Bay. Considerable repairs and painting have been carried out at several of the prisons and constabulary stations throughout the island; gas-fittings have been provided at the General Penitentiary and the Constabulary Barracks, Kingston. The range of thirty-two cells, for females, at the General Penitentiary, commenced last year, has been completed, and handed over for occupation. Another range of forty-eight cells, for females, has also been nearly completed. The Deputy-Superintendent's quarter, at the General Penitentiary, commenced last year, has been completed. Extensive improvements, commenced during the last year, at the Stony Hill Reformatory, have been finished. Improvements have been carried out and additional accommodation provided at certain district prisons and constabulary stations, and a new constabulary station was erected at Ulster Spring, in the interior part of the parish of Trelawny. Considerable repairs have been carried out at the public hospital and several parochial hospitals, including seven hospitals that were formerly a charge on the immigration funds. The total expenditure, under the head of roads and bridges, has been 26,873*l.*, thus divided: maintenance and repair of main roads and bridges, 22,598*l.*; new works on the main roads and bridges, 4,275*l.*; total, 26,873*l.* The average cost of maintenance has been 30*l.* 9*s.* per mile, being the lowest rate since 1871-72, although the seasons have been quite as favourable as the average. In the previous six years the rates have been, respectively,—31*l.*, 33*l.*, 37*l.*, 49*l.* 16*s.*, 33*l.* 7*s.*, and 34*l.*

With regard to *New South Wales*, we learn that the total amount expended on the finished railways of the colony at the close of the year 1878 was 9,784,645*l.* The expenditure on unfinished lines to the same date was 493,206*l.*, and the sum expended in the year 1878 was 963,351*l.* The returns of roads and bridges shows that during the year 1878 the sum of 500,745*l.* was expended. This amount includes the following items, issued to trustees from unclassified vote, 5,343*l.*; trustees from minor roads schedule, viz.,—Northern District, 10,560*l.*; Southern, 8,679*l.*; Western, 5,042*l.* Harbours and rivers show an expenditure for the year of 218,001*l.* The actual amount expended on finished works of this class was 206,320*l.*, and on unfinished works, 672,717*l.* The amount laid out by the colonial architect during the year 1878 on public buildings of the colony was 263,446*l.* The cost of furniture for the year amounted to 13,401*l.* The expenditure for the year on sewerage works for Sydney was 21,906*l.*, which, with previous outlay, gives a total cost of 639,386*l.* The waterworks of Sydney show an expenditure for the year of 63,086*l.*, which brings up the total cost of this undertaking to 1,059,019*l.* The expenditure on both of these last-mentioned works includes salaries, interest, and other expenses.

In papers relating to *British Honduras* we find incidental allusion to the various projects in contemplation at the present time, viz.:—The Panama or Nicaragua Canal, the Mexican cable to connect the ports along the Pacific, and another to connect the Atlantic ports with Cuba, the Costa Rica and Tehuantepec railways, the new steam routes recently organised to these ports, the various companies forming to commence operations or undertakings in the neighbourhood, and the recent gold discoveries in Honduras. The present appearances of the colony beyond Belize, we further learn, are hardly inviting to a stranger. There are no roads beyond a few tracks which are impassable in wet weather, and bungays, doreys, or pit-pans comprise the means of water transport; yet there are few countries which afford so many natural highways. Rivers and pine ridges intersect the country in all directions, and intervening swamps or creeks are the only difficulties to be surmounted in road-making. Nor does the place present that example of advancement or successful colonisation which seems so desirable should be the case in view of surroundings. The opinion is expressed that a loan of 100,000*l.* does not seem rash or unreasonable; the amount is only a little over two years' income, and this would build a couple of rail or tram ways,—one along the valley of the Old River, connecting Belize with the western frontier, a distance of seventy miles; the other could be made through the southern or northern district, as might be determined: the distance in either case to be limited to thirty miles,—if in the southern district, to open up the magnificent lands in the neighbourhood of the American settlement, and to give access to the highlands in the interior in the direction of San Lins and Coban; if in the northern district, as a question of defence, as much as to develope the agricultural resources of that part of the colony. A portable railway would suffice, and the following estimate has been given for 100 miles:—Cost of plant, 400*l.* per mile, 40,000*l.*; cost of clearing track, 500*l.* per mile, 50,000*l.*; contingencies, 10,000*l.*; total, 100,000*l.* The estimate for constructing the roadway may seem unreasonable, but the pine ridges, which are hard, sandy, open plains, with necessary timber (*pinus rigida*) along the wayside, could be availed of for the greater part of the distance; intervening swamps and creeks present the only difficulties, and they would form the only expensive parts of the route.

In respect to public works in *Ceylon*, we learn that the expenditure of the Public Works Department last year was Rs. 5,553,639 00¾, being Rs. 495,627 57¼, or a little less than 10 per cent., over that of 1878. The cost of the establishment, including, in addition to salaries, fixed and provisional, all salaries on account of allowances, transport, and office contingencies, was Rs. 408,891 02, or about 7½ per cent. on the expenditure upon works. Tables have been published which exhibit a classification of the expenditure, under the headings of "Establishment," "Construction," "Upkeep, Repair, and Improvement of Roads, Bridges, and Buildings," and "Irrigation Work," the funds from which the expenditure has been met, the expenditure incurred in the several provinces, and an abstract of the expenditure on the various classes of public works in each of the provinces of the island. The expenditure on irrigation works was Rs. 327,772 73¼, being Rs. 113,485 25¾ in excess of the expenditure in 1877, and it includes a sum of Rs. 33,167 26 spent on the commencement of the very important work of the restoration of the Yodi Ela in the North Central Province. The Director of Public Works reports that the Pavilion at Kandy is in good order, and that the Queen's House at Colombo and the Cottage at Nuwarra Elliya require repair. The furniture and equipment at the Pavilion and at Queen's House are in fair order. The furniture at the Cottage is not provided at the public expense. The expenditure on the breakwater, which is not included under the head "Public Works," amounted, in 1878, to Rs. 560,945 05, bringing the total expenditure from the commencement of the work to Rs. 3,188,552 05. The work was advanced by an additional length of sea-wall of 326 ft., and by an additional length of harbour-wall of 343½ ft.

According to official statistics, the sum expended on public works in the *Transvaal* during the year 1878 was 4,904*l.* 15*s.* 8*d.*, including 1,150*l.* 8*s.* 3*d.* for repairs to roads throughout the province. Nothing substantial could be shown for the whole expenditure, with the exception of a cottage built for the curator of the Botanical Gardens, Natal. This, however, is easily accounted for, inasmuch as when the country was taken over, nearly all the public buildings—both at the seat of Government and in the districts—were in such a disgraceful and dilapidated state that had the exchequer been equal to the immediate demand, it would have been far cheaper to have pulled down the majority of the buildings, and built new ones. The chief items of expenditure were for such necessary additions and "patching-up" repairs necessary to keep public offices from the intrusion of burglars and the effects of rain and dust. A large outlay had to be incurred to render the magistrates' courts and other offices

fit for habitation internally, and for providing them with such scanty furniture as was necessary to carry on the work. In like manner the sum of 1,150*l.* 8s. 3d. was expended on the roads, if one can so designate the rude tracks which have been formed by the ox-wagons. This may seem an insignificant sum for such an object in a country larger than France, but it bears a favourable comparison with the amount spent by the late Republic, which averaged during the last three years of its rule 3*l.* 6s. 8d. per annum. The sum of 150*l.* 10s. had to be paid in part payment of a contract entered into by the late Government for the construction of a water-course at Christiana which, on examination, proved to have been so far badly executed that, had it to be redone and carried out under proper supervision, it could be completed at one quarter of the expense contracted for, viz., 3,000*l.* A large annual outlay is also entailed for rent of public offices.

FROM ITALY.

A FRIENDLY correspondent writes,—I left my country abode on the 19th, and started off to Chiusi, thinking to see there the nucleus of Etruscan art in its museum, and, to my horror, found it had been sold to Palermo. A museum at Chiusi still exists, but though interesting, is not larger than many possessed by private persons. In fact, I went to the house of a private gentleman, who pays experienced diggers to dig around in the tufa, and who sells the findings at high prices, he being depended on. I then started off to Orvieto. These old Etruscan cities are all built as near the sky as circumstances will permit. I did so long to see the façade of the cathedral there, and was not one atom disappointed, as one is so often when imagination has been for years dwelling on the beauty of some particular object. The drive up to Orvieto from the station is now over a fine road, that winds round and round up to one of the old gates of the city. The façade is certainly the finest of all the Gothic façades I have seen, and the brilliant colours of the restored mosaics brought out the soft colour of the lovely columns, and all the wonderful work around the portals. And those marvellous reliefs! How beautiful the front is. I was so sorry to be seeing it alone. Then the marvels of the interior,—the Fra Angelicos and Signorelli,—a group by the former of Fathers and Saints in a compartment of the roof of the principal chapel looks as if painted yesterday. There has been a deal of bad restoration, but now there seems a loftier spirit pervading the works, and as the funds fall in they will restore the two chapels. The windows of these chapels are of thin layers of alabaster, transparent. I started off one evening at six, in a carriage, with the proprietor of the hotel as guide, to visit the Etruscan painted tombs. We drove about ten miles down from Orvieto to the plain, then up on the other side, equally high, and then we waded along narrow paths, through brushwood and over ploughed fields, till we descended the side of the hill to find narrow passages cut in the tufa leading to the tombs. The freshness of the vermilion colouring of the figures, nearly life-size, with the grand black outline, is quite startling. A glorious full moon lighted us, but we had to carry candles in the tombs. They are carefully guarded by iron doors. It would be better if there were bars only to allow the outward atmosphere to keep the tombs dry. One grieves to see these treasures neglected. On the road I went to see the chapel of an ancient Badia, where there is an altar-piece by Signorelli that must go to decay soon, and in an old palace another in perfect preservation, of great beauty. I shall never forget that drive. We did not get back till half-past ten, and the moonlight was as day. And how I had walked!—but the interest was so great that the fatigue was lessened. Then there was the glorious wine of Orvieto to refresh one, —wine such as the Olympian deities must have drunk! The next morning at half-past seven I had breakfasted, and was off with my intelligent guide to see all we could of Orvieto. We went to an old church,—San Giovinele. The priest, an intelligent old fellow, had fancied that there might be something hidden under the thickly-whitewashed walls, so he began to scrape, and found his church painted in fresco all over the walls, and columns also. The brick pavement has been raised 1 ft. above the base of the columns. Behind the altar he found incrusted in the wall a square piece of marble, of old twelfth-century work; and near, pilasters still older, which he dug out and made into an altar, and the old man described the long ceremony, fasting, he had to go through when a bishop passed, who consecrated the new altar. The pilasters are pure Byzantine,—the front piece is obviously twelfth-century work; and, sure enough, we found a piece of the same in another part with 1127, or rather MCXXVII. on it. The frescos on the wall are quite Giottesque, and one old Madonna is Cimahüé to a touch. I longed to help to scrape off all the whitewash, for not an eighth has been uncovered. Is there no one who will help the poor old canonico with a little cash?

I went to the opening of the Donatello Society in Florence, which you have already mentioned.

You know that Firenze has her king here, and 32,000 soldiers, who have been doing the grand manœuvres and the review, and the Donatello Society thought it would give *éclat* to open while the king was here. So what pictures they had they hung. The king examined them minutely, talked a great deal, hoped a great deal, and praised ditto. Prince Amadeo did the like. This is a move to do good to Florence artistically. The prime mover is Léon Gaucherel, artistic director of *L'Art*. The *Builder*, I think, is the only journal that has made the Society known in England.

WORK AND THE WORKMAN.

THIS was the subject of an address, delivered to the members of the Trade Unions Congress on Thursday in last week by Dr. John K. Ingram, Fellow of Trinity College, Dublin. Taking as a definite type of the workman's life the form it assumes in the great centres of manufacturing industry, he proceeded to consider the general conception which they ought to form of the industrial functions, the relations which had to be regulated, and the moral ideas which ought to preside over that regulation. The whole modern organisation of labour in its advanced form rested on a fundamental fact which had spontaneously and increasingly developed itself—namely, the definite separation between the functions of the capitalist and the workman, or, in other words, between the direction of industrial operations and their execution in detail. The ascendency of wealth was deplored by some and if it necessarily meant what was properly known as plutocracy, the absolute domination of wealth, the prospects of society would be gloomy enough. But the use of wealth, as of every other social force, must be regulated and moralised, a task which ought to be easier than that of controlling the rude preponderance of military force which was its historical predecessor. The active rich, if they would conceive their position aright, must rise above the purely private point of view, and must regard themselves as discharging a true public function,—that of conservators and administrators of human capital. They could not claim to be the creators of this capital; the largest part of it was the fruit of the laborious economies, discoveries, inventions, and institutions of many generations. This conception of the capitalist as a social functionary heightened his dignity, entitling him to respect by virtue of what was really a public office,—a respect which could on that ground be shown by his inferiors without hypocrisy or servility, even when his private character was entitled to little esteem. At the same time, the ideal thus presented must on good natures have an elevating effect, must tend to raise them above the vulgar abuses of wealth, and to make them regard as the greatest advantage it conferred the power of more largely and effectually benefiting their fellow-men. Our ideas of the office of the workman must also be transformed and elevated. The way in which his position was habitually contemplated by the economists, and, indeed, by the public, was a very narrow, and therefore a false one. Labour was spoken of as if it were an independent entity, separable from the personality of the workman, or it was treated as a commodity, like corn or cotton. By viewing labour as a commodity, we at once got rid of the moral basis on which the relation of employer and employed should stand, and make the so-called law of the market the sole regulator of that relation. The entire case received a different complexion when we placed ourselves at the social point of view, from which alone these subjects could be rightly studied. Labour, in the widest sense of the word, was then seen to be the continuous and combined effort of our race for the improvement of its condition and its nature, the present using the acquired knowledge and transmitted resources of the past, and handing down an augmented inheritance to the future. This was the only really human conception of labour, the only one which put employer and employed each in his right place. It would place on a solid basis the claim of the working-man to the respect and courtesy on the part of his superiors in rank; it would profoundly modify our way of viewing his remuneration. His faithful services was now too often regarded as obtaining in his wages a full equivalent return. The wages of the workingman ought to be regarded as the indispensable means of keeping him in such a state of physical health, material security, and moral quietude that he might be able to continue his service to society and to prepare a new generation for the same service. The only true recompense of the right performance of his functions lay in the conscious fulfilment of social duty and in the approbation and esteem which he justly earned from such of his fellow men as had the opportunity and the capacity for appreciating his work. The twofold conception he had presented of the capitalist and the workman brought out distinctly their duties to each other. These obligations were binding on both sides,—on the part of the workman for faithful work, as opposed to eye service, and for abstinence from all unreasonable demands; in the master, as the higher and more powerful of the associates, they involved a larger responsibility and duties of a wider range. As the appropriate motto of the feudal ages was *noblesse oblige*, so that of modern industrial society must be *richesse oblige*. The masters must subdue in themselves the base inclinations which prompted too many, while accumulating personal gain and lavishing it on their own pleasures and ostentations, to neglect their co-workers, who ought to share in equitable measure the benefits arising from their joint operations. The masters ought to be, as some of them had nobly shown themselves, the friends of their workmen, interested in their welfare and that of their families, and actively studying that welfare, in which he said he assumed the continued existence of the separation between the capitalist and the workmen. As to the so-called co-operative system, it had not yet received much cordial approbation from the working man. The co-operative stores or societies of supply were genuine efforts of the people to escape from the abuses of the retail traffic, in order to obtain good articles at reasonable prices. These had been really successful, and had done much good; but they were not true co-operative societies,—they were joint-stock companies. But the co-operative societies of production had far more widely-reaching objects, at least in the conceptions of the social speculators who had most strongly advocated them. To these they presented themselves as the true solution of the labour problem. Professor Cairnes believed that in this new organisation of industry lay the one hope of the working classes, and Mr. Thornton preached it as a panacea for the evils of the world of labour. He ought to speak with caution and modesty in opposition to such men, but he was compelled to say that in his opinion the proposed solution was an impracticable one, and that the material and moral results of any attempt to realise it on a large scale would disappoint the expectations that had been entertained respecting it. Our recent policy had been to give the security of the State for the deposits of the savings of the working classes,—a policy founded on the just idea that for them, not gain, but the prevention of loss, was the first object. The natural destination of such savings was not industrial investment, but the formation of a modest reserve to meet special domestic exigencies, or to make possible the performance of special domestic duties. It was said that the co-operative system would enable workmen to understand the difficulties of the capitalist, and so be more reasonable in their demands; but Dr. Ingram thought the lesson would be dearly bought by repeated failures, and that the same lesson could be sufficiently inculcated by observation and study. He combated the idea that the co-operative system would draw out the best qualities of the working man, and had no faith in moral regeneration founded on motives of self-interest. He thought that on the whole the effect would be to spoil the best qualities of the working-man. His large sympathies and generous impulses would

be supplanted by comparative deadness to social interests; the enjoyment of domestic life and the cultivation of the intellect would be subordinated to the pursuit of profit; and he would be likely to prolong the hours of labour on the plea that he was working for himself. He believed that the immense majority of working-men must remain to the end working-men, and that only. He further believed that this necessity admitted of being fully reconciled with their happiness and their dignity. What they ought to aim at was the elevation of their class as such without seeking to alter the basis of the existing organisation of industry. In this work they would find not only an abundant but a fruitful field for all their public spirit, energy, and sagacity. It seemed to him the merit of the trade-union movement was that it followed precisely the practical and hopeful line he had indicated. Attacked and denounced as scarcely any other institution had been, the unions had thriven and grown in the face of opposition. This healthy vitality had been due to the fact that they were a general product of social needs, indispensable as a protest and a struggle against the abuses of industrial government and inevitable as a consequence of that consciousness of strength inspired by the concentration of numbers. Under the new conditions of industry they had purged themselves from abuses which were explained, if not palliated, by the injustice of the law from which they had now liberated themselves by steady, moderate, and well-considered action. They had been instruments of progress; they had infused into the working-man a new spirit of independence and self-respect. The testimony of all who had the best means of knowing was that instead of multiplying strikes they had diminished their frequency and mitigated their violence. They should proceed further in the same path. If there were anything remaining in their rules which could not be defended on principles of the highest social morality, they ought to expunge it. They should put forward no claims that were not rigorously just. They should seek to give effect to these claims by conciliatory methods, regarding strikes as a last resource,—sometimes, indeed, necessary, but always deplorable, as intensifying evil passions and compromising many innocent existences. They should discuss all the questions that concerned them, such as those of wages, hours of labour, piecework, apprenticeship, on higher grounds than those of material class interests; they should invite the attention of the thinking public to these questions, and look to the best disinterested opinion as the judge and controller of their operations. What were the objects which the working-class ought to keep before them? First, adequate wages. It was stated that the working-class must submit to a reduction of wages in order that the capitalist might undersell the foreign competitor, and then wages would rise. The same appeal was made in Continental countries to defeat British capitalists. To judge by the language used by capitalists and their spokesmen, it might seem that the great question of industrial life at the present time was this,—what working population among civilised nations would be content to live the most miserably, in order to drive the others out of the markets of the world? He hoped the working classes would follow no such *ignis fatuus*. What was really to be desired was that the foreign working-man's standard of living might rise, and that he might maintain every increase of the wages which he had once secured. That would doubly promote the interests of our working-men, for the foreign working-man would then be a better customer for English products generally, and he less likely to be transferred from his own country to England for the purpose of reducing their wages. He thought that if any foreign country had peculiar facilities for any form of production it was desirable that they should be brought into effective operation. If each nation withdrew from those branches of industry for which its native bent or its circumstances disqualified it, choosing those for which it had special advantage, the common harmony would be greatly promoted, while the general wealth would be augmented. It was one of the greatest evils of the protective system that it stood in the way of such adjustments. The second want of the workman was a well-regulated house. Dr. Ingram advocated the cultivation of the domestic affections and duties. The wife, he observed, was the centre of the home, and in order to enable her to discharge her sacred duties she ought to be freed from the necessity of non-domestic labour, which was now too often imposed upon her. He commended the efforts of those who were endeavouring to improve the dwellings of the working-classes. The third requirement of the working-classes was educated. He dwelt at some length upon the importance of this object, and in conclusion observed that the truly vital interest of the working-men was that the whole class should rise in material comfort and security, and still more in intellectual and moral attainments.

A SIGNBOARD AND A QUESTION.

THE newspapers have given particulars of a singular dispute touching the ownership of the signboard of the Royal Oak Hotel, Bettws-y-Coed, submitted for the decision of the Bangor District Court of Bankruptcy. The sign, which is well known to most tourists in Wales, was painted by David Cox in 1847 as the signboard of the hotel. David Cox re-touched it in 1849, and in 1861, at the request of many admirers of the artist, it was placed in the hall of the hotel. The late landlady having gone into liquidation, the trustees claimed to include in the effects the old signboard, for which it was stated a connoisseur had offered 1,000*l.*, and a dispute now arose whether the painting was not a fixture, and as such belonged to the lessor, Lady Willoughby D'Eresby. The judge, after a perusal of the voluminous affidavits, decided in favour of her ladyship, directing that the costs of the application should be paid out of the debtor's estate. To make us agree in the decision as to this old sign, we ought to hear that no other signboard had been put up in its place outside.

The incident reminds us of Sir Edwin Landseer's old shutter. Mr. Jacob Bell had done some friendly commission, as on many other occasions, for the artist, and the latter desired to give him something. Bell would have nothing, but ultimately said, "Well, give me the old shutter in the stable window," a rough panel on which Landseer had partly painted a picture. For this, as he told us himself, he was afterwards offered 600*l.*

PROJECTED LOCAL BOARD OFFICES FOR SOUTH HORNSEY.

ALREADY the necessary documents in connexion with the purchase of the freehold of the site whereon stood Milton-road Chapel, South Hornsey, have been signed, and plans have been prepared for the Local Board Offices which are to be erected there. The total frontage of the land is 119 ft., and the depth, 96 ft., and this has been signed over to the Chairman of the Board (Mr. G. C. Boor) for 1,600*l.*

Mr. Fry, the Local Board surveyor, has prepared plans for the erection of a stone building, to include clerk's, surveyor's, inspector of nuisances', and other offices, Board-room, and all necessary conveniences, whilst in the yard at the rear is to be erected a mortuary with *post-mortem* room (distinct from other buildings), which is intended, in general details, to be as near an approach to the Parisian Morgue as possible. Other erections on the site will include surveyor's residence, foreman's cottage, fire-engine station, cart-sheds, tool-houses, stables, and other essentials to the work of the Board. The principal building will have a frontage of 46 ft., and an elevation of 34 ft. The Board-room will be 43 ft. 6 in. long, and 23 ft. 10 in. wide, the elevation from floor to ceiling being 16 ft. An ante-room for the convenience of committees, deputations, judicial inquiries, inquests, &c., is also to be provided, with separate lavatories for officials and the public. The surveyor's residence will be of brick, with stone dressings, as also will the fire-engine station. The heating of the building will be carried out by means of hot-water pipes to be laid beneath the basement floor, but beyond this there will be no underground operations whatever.

A special committee of the Board appointed to inspect the plans and make the necessary inquiries and arrangements, reported that they had seen similar erections to those under notice which had cost 7,966*l.* Mr. Fry submitted his plans as described, and estimated their entire carrying out at an outlay of 6,643*l.*

The Board unanimously adopted the plans, and agreed to at once apply for powers for the borrowing of 7,500*l.*, which latter sum was thought to be advisable in view of any contingencies.

CHURCH OF ST. NICOLAS, ABINGDON.

FOR many years past the restoration and repair of the parish church of St. Nicolas has been contemplated. A report as to its condition was made as far back as 1867, and the works are now to be commenced in earnest, under the direction of, and from drawings prepared by, the architect and sanctioned by the Bishop's Court this year. A new one will be placed in the nave, and the church will be newly benched with oak.

The freestone work, externally, will be of Doulting, and, internally, of Corsham stone. The church is said to have been built by an abbot of the abbey, Nicolas de Coleham, between the years 1289 and 1307. Mr. Edwin Dolby, of Abingdon, is the architect, and Mr. Edward Williams, of the same town, the builder.

PERTH MUNICIPAL BUILDINGS.

As the people of Glasgow are preparing to erect Municipal Buildings in their city, it may be specially interesting to know what is being done in that way at this time in other parts of Scotland.

The new buildings for Perth occupy the site of the old Council-chambers, and the adjoining property recently acquired by the Police Commissioners, and has frontages to Tay and High streets. The main entrance is from the High-street. On the ground-floor there is the city chamberlain's office, 25 ft. by 23 ft.; registrar's office, 19 ft. by 15 ft. The police office fronts Tay-street, and is 30 ft. by 22 ft.; superintendent's rooms, 16 ft. by 13 ft. Behind the police-office there are two ranges of cells, four on each side, entered from a large corridor, and shut out from the main office by an iron gate. Apartments are provided for the mustering of the policemen, and for a fire-engine house. The council-chamber is situated on the first floor, its dimensions are 41 ft. by 25 ft. The burgh court-room, 30 ft. by 22 ft., is on the same floor, having a public entrance from Tay-street, and a private entrance from the council-chamber, adjoining which there is a committee-room, 24 ft. by 21 ft.; and a waiting-room, 17 ft. by 13 ft. Offices are also provided for the treasurer to the Police Commissioners, and for the burgh assessor. A house for the superintendent of police occupies the second floor.

The elevations are faced with freestone from Bonfield Quarry, Fifeshire; the internal stonework has been taken from the local Huntingtower quarries. The ceilings of the council-chamber and burgh court-room are of pitch pine, and the panels are decorated with quaint stencil designs in colour. The finishings for doors, windows, and panelling on walls, &c., are of yellow pine. The main entrance doors and furniture are of oak. The council-table around which the councillors sit is horse-shoe shaped to facilitate communication with the councillors from the city clerk's desk, which is placed near the magistrates' bench.

The cost of the buildings is about 11,000*l.* Messrs. A. & A. Heiton, of Perth, are the architects; and Mr. Wells, burgh surveyor, is the inspector of works.

Lock-out in Paris.—One hundred and thirty cabinetmakers of the Faubourg St. Antoine locked their workmen out on Monday night. According to the *Standard*, this step was decided upon at a meeting of masters on Saturday, in consequence of the hostile action of their workmen. These have, it appears, been for some time in the habit of forming partial strikes by proscribing certain employers, for whom they refused to work, except on conditions settled by an executive committee. The houses in question have now agreed to close their workshops until the proscription has been withdrawn, but have appointed a committee to meet a deputation of the men for the discussion and arrangement of matters. The workmen met, and resolved to exact wages at the rate of 80 centimes per hour, and not to work more than ten hours a day. Two thousand men are thrown out of employment.

NEW MUNICIPAL BUILDINGS, PERTH.

THE NEW NATIONAL MUSEUM, WASHINGTON, UNITED STATES.

A LARGE quantity of valuable material for the development of the resources of the nation, much of which was given by foreign Governments to the United States, and from the exhibit of the United States on the occasion of its Centennial International Exhibition, lying dormant and inaccessible to the public, an appropriation of $250,000 was made by Congress, on March 4, 1879, for the erection of a fire-proof building for the National Museum, on the public grounds near the building of the Smithsonian Institution. The funds were to be expended under the control of the Board of Regents of the Smithsonian. The Regents created a building commission, of which General Wm. T. Sherman, Dr. Parker, and Prof. S. F. Baird are the members. On invitation of this Board, Major-General M. C. Meigs consented to act as consulting engineer. On March 25th following, the Commission placed the construction of the building in charge of Messrs. Cluss & Schulze, architects, whose designs had been adopted. They prepared at once plans, working drawings, schedules, specifications, and advertisements for materials of all kinds required, and, for labour in the different branches of the work, took advantage of the low prices then prevailing, and proceeded to finish the building within the limit of the moderate amount placed at their disposal.

For a description of the building we are indebted to the architects.

The building starts on the ground in the form of a square with sides of 327 ft. extreme length. This is surmounted by a cross and a dome. Within its facades, a net area of 102,200 square feet, or $2\frac{3}{4\frac{5}{6}}$ acres is covered by roofs. It contains underground the boiler-room and pipes of a steam-heating apparatus, a coal-cellar, and two large cellars for storage purposes. From one of these cellars a subterranean communication with the adjacent Smithsonian building is established, which besides ordinary uses, will serve in cases of panic, fire, or tumult.

On the main floor there are available, in seventeen halls, which freely communicate with one another by wide and lofty archways, 80,300 square feet of floor-space, and a proportionate amount of wall-space for exhibition purposes. Further, there are available on the main floor and two upper stories of four corner pavilions and eight towers, 27,400 square feet of floor-space, divided off into 135 rooms for administrative purposes, offices, working rooms, photographer, the necessary modern accommodations, &c. And, finally, about 4,000 square feet of floor-space on galleries which are intended in part for special exhibits, and in part to afford an unobstructed view of the *ensemble* of the exhibits.

On the whole, the one-story plan which has prevailed among experts ever since the Paris Exhibition of 1867, has been adopted. But by the introduction of upper stories in ornamental pavilions and towers, ample office room has been secured without encroaching materially upon the floor-space of the main halls.

The centre of the building is octagonal on the ground-floor, and is surmounted by a 16-sided polygon of 67 ft. diameter, which contains a tier of large windows, and constitutes a dome-like structure with a slate roof and a lantern, crowned by a decorated finial. This dome is 77 ft. high on the side walls, or 108 ft. to the top of the finials. Four naves of 65 ft. in width, and 117 ft. in length, radiate from the dome, and extend to the outside walls of the building; these naves form a Greek cross, over the centre of which the dome rises, and part of the spaces between the arms of the cross is fitted up with halls of 65 ft. square, and of the same height as the naves, the side-walls of both being 42 ft. high, while the height to the ridges of the slate roofs is 56 ft. These roofs are in part constructed double, for the purpose of so perfecting the drainage of the roofs that accumulations of ice and snow can nowhere obstruct it. The spaces between the high walls of and around the Greek cross on one side, and the exterior walls of the building on the other side, are allotted mainly to eight halls of reduced height, covered by lean-to metal roofs, the extreme height of which is 32 ft. By this treatment wall-spaces are obtained for the introduction of clearstory windows, which light the square halls, and assist in lighting the naves.

The four symmetrical exterior walls of the building are broken by projections in the centre and at the corners, and these have been amply utilised for miscellaneous administrative purposes, as stated above.

A modernised Romanesque style of architecture was adopted for the new building, in order to keep a relationship with the adjacent Smithsonian building, which is designed in Norman, a variety of this style. It was found necessary to modernise the style on account of the different building materials used, brick in place of red sandstone, and to do justice to the modern demands for elegance of construction, the greatest possible available floor-space, easy communications, efficient drainage, a well calculated and pleasing admission of light, free circulation of air, and other hygienic requirements.

The external architecture is based upon the general arrangement of the interior; it shows plainly the prominence of the four naves, and the careful management of the light for the central portion of the building. Four main entrances are in the centres of the façades between two lofty towers of 86 ft. in height; these act as buttresses for the naves. Between the towers, above and receding from the doorways, there are large arched windows filled with ornamented glass, and above those the gables of the naves are formed; they contain inscription plates, and are crowned with allegorical groups of statuary. The group over the northern gable, designed by C. Buberl, of New York, introduces Columbia as the protectress of science and industry. The second group, by the same artist, represents Peace with the fine arts.

To both sides of these prominent central features there are curtain walls, 27 ft. in height, which have the effect of arcades. Pavilions are placed at the corners; they are of less height than the towers, but sufficiently raised above the curtain walls to overcome the unfavourable effect which these comparatively low walls would otherwise produce.

In the rear of the curtain walls, the clearstory rises to the full height of the naves, the roofs of which terminate against the side walls of the dome. The dome is treated in a similar way, and strictly in the same character as the curtain walls above alluded to.

In addition to the windows in the solid masonry of the exterior walls, clearstory, and dome, lofty lanterns have been provided above the centres of the naves and square halls, so as to afford perfect light for this enormous space without resorting to flat skylights, which for various reasons, were avoided. These lanterns, square and oblong, together with those of the related features of the pavilion, have been so arranged, in combination with towers, groups, clearstory, and the rising dome in the background, as to produce good skylines.

All the walls above ground are composed of brickwork, built hollow, with air spaces for outside wall. To neutralise the monotony and commonplace appearance which could not have been avoided with red-brick fronts of such extent, a sufficient number of buff bricks have been introduced in panels and spandrels, interspersed with a small number of blue bricks in the ornamental work of brick cornices. A base course of granite extends all around the building. The wrought work of the main entrances, window-sills, inscription plates, copings, &c., is grey Ohio freestone. The floor-beams, girders, and roofs are constructed of rolled and shaped iron. The floors are fireproofed by brick arches and concrete. Of roofs there are no fewer than thirty-seven, many of them of complicated construction. The lanterns on the ridges of the naves are large enough to cover moderate-sized dwellings. The light but solid framework of all the roofs will be left in full view, painted in light neutral tints.

The covering of the metal roofs is laid upon fireproofed gratings, suggested by Gen. M. C. Meigs.

The slates are hung to iron purlins. In order to facilitate the heating of this building, the sashes all through the edifice are glazed with double panes, having an intermediate air-space. In all windows facing the halls, the outer pane consists of obscured glass, in order to obtain a mellow light, and to avoid the necessity of shades.

The floors of the main hall will consist of concrete, but the rooms and smaller halls will, for convenience sake, be floored with Florida pine laid on concrete.

The interior is being plastered in sand finish, washed in tints.

The wide main entrance-doors, of walnut and oak, open outward on spacious tiled vestibules, with sides and arched ceilings of ornamented buff brickwork. These vestibules are closed after hours by wide double wrought-iron gates, richly ornamented, and finished in bronze and gold.

The northern entrance is intended for general use, and hence was made prominent. A spacious tiled platform, bounded by granite side blocks in front of this entrance, is approached by broad granite steps: these are flanked by stately candelabra.

In all their steps the architects were guided by the absolute necessity not to overrun the appropriation at disposal, and hence to produce the best effect with great economy, the exterior decoration was confined to the centres of the fronts, where the art of the sculptor has been called in.

The completion of this building, in which are enclosed 3,500,000 cubic feet of space above the cellars, required more than 5,500,000 bricks, 3,250 cubic yards of rubble-work and concrete, 500 tons of iron, 31,000 square feet of glass, and so forth.

CARICATURES IN STONE.

THERE was some sad nonsense talked in the House of Commons the other day, just before the prorogation, because it had been stated in a newspaper that the corbels of one of the windows at the New Law Courts were being made to represent, one the architect of the building, and the other the "obscure" contractor. What motive the member had who raised the objection, and who must have known that such freaks were matters of every-day occurrence, it is difficult to imagine. The incident has reminded us of some grotesque modern carvings which a friend of ours lighted upon lately at Chester Cathedral, and of which we give engravings, for the amusement of our readers. These corbels will be found on the north-east corner of the north transept of the cathedral, and seem to be known locally as Political Contention and Religious Contention. In the first, Lord Beaconsfield and the late Dr. Kenealy are readily recognisable engaged in a struggle, in which a crown and a cap of liberty are concerned; and in the second Mr. Gladstone, whose likeness is better in the original than in our presentment, is using his learning as a fulcrum for the upsetting of the Romish Church.

We leave our readers, however, to exercise their ingenuity in discovering exactly what the little caricaturist desired to convey in these freaks of the obisel.

SANITARY REFORM IN THIS COUNTRY.

THE Exeter Congress of the Sanitary Institute was opened on Tuesday evening last with an address by Earl Fortescue, as president. It purported to give a history, from the writer's own point of view, of all the legislative measures which have followed the first movements on the subject, and was necessarily, therefore, very long. He objected strongly to the doings of the Metropolitan Board of Works, and to the course pursued by the present Government in respect of the Water Companies. We give the concluding paragraphs of the address:—

We have had eloquent declamation enough about the horrors of war. Still, along with the terrible amount of suffering and crime incident to it, no one can deny that war also calls forth in the nobler natures engaged in it some of the finest qualities of man,—patriotism, courage, endurance, self-denial, self-sacrifice,—not to speak of the lofty Christian heroism of men like Havelock. If peace has its victories no less than war, peace has its victims far more numerous than war. For instance, the needless waste of life in the United Kingdom during the Crimean War, was many times greater than the loss of life in the Crimean War,—a waste accompanied by the long train of physical, intellectual, moral, and spiritual evils involved in general degradation. For all experience shows that, as a rule, dirt, disease, and vice are concurrent; that with rare exceptions, families cannot lodge like pigs and live like Christians.

With regard to fresh legislation, the first Sanitary Consolidated Act of 1875 seems to embody most, though not quite all, that is wanted. The principle of distributing the cost of works, and especially of the smaller kind, over a series of years by the Improvement Rate, first sanctioned in the Metropolitan Sewers Act, 1848, has been far too little encouraged or adopted. It may seem rather complicated at first,

but we found by the aid of tables that it was easily worked, and it practically averted, to a great extent, difficult and intricate questions of ownership as regarded chargeability for such works, since the occupiers were generally satisfied that they received benefits from them worth the extra rate to be paid for them. The principle, also, of engaging an officer's whole time for the public service, and employing it in any public duties not practically incompatible, seems worthy of much more extensive adoption, not only because of the great saving in trouble and correspondence to which it conduces when co-operation between different authorities of any kind is required, but also because it removes the temptations to sacrifice public duty when it conflicts with private interest, which must sometimes arise in the case of a public officer having also private practice. Only the boundaries of unions,—which must, now that the parish has been almost wholly superseded in that respect, be regarded as the unit of local administration in England,—are in so many cases incongruous with those of the counties as to present great, though I hope not insurmountable, difficulties in the way of what I have long wished for,—the establishment of representative county boards as general intermediate authorities between the union and Downing-street. Administration is now much more in default than legislation. As the Sanitary Commission say in their Report:—

"The system of self-government, of which the English nation is so justly proud, can hardly be applied with success to any subject, unless the governing bodies comprise a fair proportion of enlightened and well-informed minds; and if this be true as a general proposition, it is especially true in regard to matters affecting public health.

In the next place, many sanitary questions of vital importance are, from their very nature, incapable of being completely provided for by any amount of legal enactment, however minute and explicit. So large a discretion must of necessity be left to local authorities as to details, that in practice much will always depend on the energy and wisdom of those who compose such authorities. Moreover, there are limits to the power of any central authority to remedy the evils produced by local inefficiency. It may control, stimulate, and in some cases supplement the efforts of local bodies, but it cannot be a substitute for them."

This has been practically recognised by the Legislature, and as Dr. Acland truly observes in his recent address:—

"On the education and voluntary action of the people depends now, before all things, their sanitary condition. They have the means of obtaining knowledge; they have the means of obtaining power. If they have the will they can obtain both. There are good books now and to spare on every branch of the question,—legal, engineering, chemical, medical, &c."

I further agree with him when he says:—

"Compulsory powers should only be exercised by the central authority in the most extreme cases, and this should be clearly understood to be the principle of action; but, as a corollary, the central authority should with the utmost freedom collect the best information, and disseminate it in the freest way. If the Treasury should not sanction the gift of reports, every local official should receive notice of all Government health publications, with the statement of the contents, cost, and where to obtain them, immediately on their issue. This would promote progress of education—and would, quite certainly, be done, and is the least that would be done, *mutatis mutandis*, by any large private company dealing with the subject. It is being done to some extent by the model bye-laws recently issued, but should be done much more extensively."

This constant diffusion of sound principles and of practical information by the wide distribution of these official reports, as well as by their general circulars and separate letters to the unions, was largely practised by the early Poor Law Commissioners. But I found, when I became secretary to the Poor Law Board, that very little more than the mere necessary formal sanctions and orders had been for some time issued from the office. The same remark applies to the change of policy in sanitary matters ever since the suppression of the first General Board of Health.

When the Treasury were stopping the former wide circulation of Reports, &c., on the plea of expense, I hardly ever recollect any member of any Government throwing any impediment in the way of the granting and printing masses of useless papers moved for in either House, however useless he knew printing them to be. The mere adoption of the system of printing large numbers long adopted by the Statistical Society of omitting the hundreds of thousands in all cases of tables of figures where minute accuracy is not required (and to how vast a proportion of them does this not apply?), would have saved over and over again the cost of continuing freely to diffuse information tending the wealth and weal, because the health, of the community. It was economising the means of economy. *Magnum vectigal parsimonia.* But refusing the useful expenditure pleased many of the same class of members that refusing the useless expenditure would have offended.

Ministers may declaim grandly about sanitation, yet we have always found honours and encouragements markedly withheld from every sanitary reformer,—*laudatur et alget.* The Local Government Board has for some time had the double charge of supervising the poor relief and the sanitary administration of the country. I am sure I am not at all disparaging the valuable public services rendered by my friend Sir J. Lambert, when I compare his in both departments with those of my valued and honoured old friend Mr. Chadwick, who took the chief part in preparing the great Poor Law Reform Act of 1834, as well as the convincing and exhaustive Report of the Commission of Inquiry, which paved the way for it; and who, after years of able and energetic work as secretary to the Poor Law Commissioners under that Act, equally prepared the way, by his masterly Sanitary Report of 1842, for the Public Health Act of 1848, and afterwards, as member of the General Board of Health under that Act, rendered such valuable services (nowhere so little appreciated as in his own country) to the cause of sanitary reform throughout the world. Not only have foreign sovereigns recognised this on various occasions, but the illustrious Institute of France years ago paid him the rare compliment of electing him into their body. Yet, while Sir J. Lambert has deservedly been made a Knight Commander, his far greater predecessor is only a Commander, of the Bath. To take another striking example, Mr. Rawlinson, sanitary engineer to the same department, of whom I have already spoken, received the same honour as Mr. Chadwick; but it was for sanitary science rendered to the army before Sebastopol, where he was under fire, not in acknowledgment of his successful work at home. Sir J. Bazalgette has also received the same distinction, and was knighted, if I am not mistaken, on the completion of his largest and most costly failure. I must add one more signal instance of official neglect,—the name of Dr. Farr, known and honoured by every zealous statesman and sanitary reformer throughout the civilised world.

As it seems clear that sanitary reform, though commended in general terms, has not received, nor is likely to enjoy, much official sympathy, and though praised in the abstract, is always liable to incur Parliamentary and municipal opposition in practice, we must endeavour, now that pretty sound legislation upon it has been obtained, to influence as far as possible public opinion on behalf not only of its principles, but its details, co-operating heartily with the many societies and associations, to say nothing of the many private individuals who have done so much to elucidate and stimulate an interest in the subject under its various aspects. We must try to enlist general administrative action in conformity with them; and in this term I would comprehend all administrative bodies, from the Cabinet down to the school managers of the country parish: and not administrative action alone, but family action and personal action, and that not of the men only, but also,—I may almost say mainly,—of the women, and especially of the mothers. Not only is there nothing unfeminine in the action we ask of them, but it is pre-eminently in their own province, and essentially womanly.

And now let me commend to your sympathy and support a most valuable and unobtrusive Association, though enjoying the patronage of some of the highest in the land,—the Ladies' Sanitary Association, which has enlisted among its helpers and counsellors various able and benevolent men, and among them the scientific, eloquent, and genial President of this Institute, but has never quitted its own modest sphere of work for one more ambitious or conspicuous. It is ready to co-operate with all engaged in the good cause, but its particular object is to diffuse sanitary knowledge and promote sanitary reform, especially among the poor; and it tries to do this very much, among other ways, distributing plain little sanitary tracts among them; instituting mothers' meetings and classes of adult girls, and giving them sanitary and domestic instruction, and establishing nurseries for motherless babes, which may serve as schools for mothers of all classes, school-mistresses and nurses. It seeks to form branch associations. I trust that it will, before long, be able to count many.

I have trespassed already much too long on your attention. But I must remind you, in conclusion, that the cause of Sanitary Reform appeals not only to enlightened self-interest, but to our feelings of humanity and sense of religious duty. The law given by God to Moses comprised regulations recognised to this day as of great practical sanitary value, and our Divine Master and Great Example not only spake as never man spake, but showed His tender regard for the bodies as well as souls of men by going about doing good while upon earth, healing the sick, making the blind to see, and the lame to walk, and ministering to bodily wants and bodily suffering.*

EXHIBITION OF SANITARY APPLIANCES AT EXETER.

IN connexion with the Autumn Congress of the Sanitary Institute of Great Britain, which was commenced on Tuesday last in Exeter, an exhibition of sanitary apparatus and appliances was opened by the Mayor on Tuesday afternoon, amidst the ringing of church-bells, the playing of bands of music, and the display of unlimited bunting. It is to be hoped that the progress of the mayor in state through the city on such an errand will duly impress the citizens and those who have charge of the sanitary condition of the city with the importance of aiming at the attainment of the best possible hygienic conditions, for at the opening meeting of the Congress on Tuesday evening his worship admitted that the rate of mortality in the city was far greater than it ought to be. The exhibition is arranged in the new abattoirs on Exe Island,—buildings which, erected at a cost of about 4,000*l.*, appear to be admirably adapted for their special purpose, and capable of minimising as far as possible the offensiveness attaching to slaughter-houses. These abattoirs have not yet been opened for use, and so are much more salubrious than the streets and lanes immediately adjacent. Although, with the view of temporarily putting a better face upon things, the streets had been gravelled and planted with conifers and evergreens at intervals, those who had charge of these arrangements apparently forgot to use some of the deodorising agents so plentifully to be met with on the stalls of the exhibition. The exhibition itself is not so large and varied as the one held in Croydon last year, but the exhibits include many improvements and novelties. As might be expected in an exhibition held so far from London, several well-known firms are not represented in the collection, but, on the other hand, many West and South of England firms are exhibitors.

In *Class I., Construction and Machinery*, Messrs. Salmon, Barnes, & Co., of Ulverstone, exhibit (No. 1) their well-known revolving shutters in iron and wood. Messrs. Steele & Wood, of Stoke-on-Trent, show a collection of decorative tiles, with vitrified colours protected by glaze, in stoneware. Mr. Henry C. Webb, encaustic tile manufacturer, Worcester, displays specimens of wood, leather, marble, tiles, and other materials stained by a novel process. It is more especially applicable to wood, in which material the effect of inlaid work is produced. The peculiarity of the process is that the colours of the patterns (and there is practically no limit to the number of colours used in each design) go right through the wood or other material operated upon. Pitch-pine is the wood used by preference. The surfaces obtained by the process when polished have a very nice effect, and promise to afford a cheap and good substitute for parquetry and other work. The same process is applicable to the staining of paper, it being possible to stain fifty or sixty sheets at a time. Mr. Webb also exhibits specimens of a new method of inlaying by pressure hardwood or

* Some of the addresses delivered and papers read before the Sectional Meetings we will notice next week.

metal in soft wood. In Section 2 ("Paints and Protectives") of Class I., Messrs. Samuel Wills & Co., of Bristol, are the only exhibitors, their stall containing a variety of varnishes. In Sections 3 and 4 ("Wall Papers and Decorative Materials") Messrs. Wm. Woollams & Co., of London, have a good display of their non-arsenical wall-papers and dado-decorations. This firm, it will be remembered, was awarded the Medal of the Sanitary Institute for similar productions exhibited last year at the Croydon Exhibition. Messrs. Goff & Gully, of Exeter, exhibit specimens of "Lincrusta-Walton," or "Linoleum Muralis," as it used more fitly to be called; so do Messrs. Cotterell Bros., decorators, of Bath and Bristol. Of the merits of this material we have often spoken. The last-named firm also make a good display of paperhangings, asserted to be non-arsenical; they are well designed, but whether they are the firm's own products is not stated. In Section 5 ("Machinery adapted for Sanitary Purposes") Mr. J. B. McCallum, the borough surveyor of Stafford, exhibits the "Excelsior" Pail or Tub-Van, designed for the conveyance of excreta in pails or tubs through towns without polluting the atmosphere and causing a nuisance. The van is non-absorbent, being of metal as far as possible. It is constructed with the view to prevent an accumulation of smells within, and the arising of noxious odour during the process of collection and passage through the streets. To gain this end ventilation is obtained through charcoal or other disinfecting ventilators. One important feature is the ample provision that is made for collecting any sloppings from the pails, thus preventing the same from finding its way into the streets. A collector is formed as a false bottom, which can be emptied by means of a screw-plug at the end of the journey. The weight of the van is apparently considerably less than that of the ordinary type. The van is made to contain twenty-four tubs; it will turn in its own length; and the openings, instead of being fitted with hinged doors, which are liable to be damaged by the wind and unnecessary wear and tear in opening carelessly, are fitted with doors sliding upward, which are made to remain open or shut at pleasure. Mr. McCallum also exhibits a revolving hand-sweeping brush and collector for road-scavenging, which is stated to have important advantages in point of economy. Messrs. Crossley Brothers, of Manchester, exhibit one of their "Otto" Silent Gas Engines at work. It is not surprising to learn that there is an increasing demand for this clean, easy-going, and economical motor-engine. Messrs. J. C. Stark & Co., of Torbay, exhibit a "Two-man" gas-engine,—a new patent; and Mr. J. E. H. Audrews, of Stockport, shows a "2-man" Bisschop gas-engine of new type. Among the exhibits in Class I., we noticed a plan for the disposal of the sewage of Exeter, involving the construction of new main sewers, and an outfall to conduct the sewage to proposed settling-tanks at Duck's Marshes, below Exeter, whence the effluent water is to pass into the tidal portion of the river Exe. The scheme has been prepared by Mr. H. Percy Boulnois, M.Inst. C.E., surveyor to the City of Exeter. Messrs. J. W. Trew & Sons, architects and surveyors, Bristol, exhibit designs for cottage hospitals and other buildings. Not included in the catalogue is a curious collection of sea-weed products from Paris, one of which, a flexible semi-transparent tissue resembling oil-skin, is capable of use (so it is claimed) for the remedying of damp walls.

In *Class II., Sewerage and Water Supply*,—Section 1 comprises water-closets. Mr. William White, F.S.A., of Wimpole-street, exhibits the "Shrewsbury" water-closet, invented and patented by him. It possesses the merits of cheapness and efficiency. Special and ingenious means are adopted to obtain a much more effectual flush-out of the pan than is attainable by the usual means. The water is discharged suddenly into the pan through a down-pipe at least 2 in. in diameter. Mr. White also exhibits his improved ball-valve and hib-cock. The makers of all these appliances are Messrs. F. Pierce & Co., of Little York-place, Baker-street. Mr. A. T. Angell, of Fulham-road, exhibits the patent self-ventilating "Disjuncta" closet, the principle of which is equally applicable to baths, sinks, &c. The space beneath the seat is so made as to prevent the passage of air through the joints of the woodwork to the interior of the house, but is ventilated direct into the open air by louvres made in the external wall. Inside this chamber or space the closet-basin is completely disconnected from the trap below, and it is claimed that all effluvium arising from the trap, and all sewer-gas that may be forced through it when the valve is opened by the uprush of air meeting the downflow of the contents of the closet or sink, will be carried outside through the louvres. A working model of the same closet is also exhibited by Dr. Churchill. Messrs. Capper, Son, & Co. exhibit Pearson's patent trapless "twin basin" closets. Mr. David Gill, of Weston-super-Mare, exhibits his "automatic action" water-closet, his patent flushing apparatus, and his "sanitary twin door." The closet is all in earthenware, and possesses the merit of being readily fixed, without breaking through or interfering at all with the floor surface. It is claimed for it that all effluvium caused while the closet is being used is carried away by a back draught at a point below the top of the basin. Underneath the pan is an outer air-chamber, with an air-passage to the front of the basin, and the air entering the closet-pan, while the latter is in use, passes over the contents of the receptacle, and through the exit air-pipe at the back. Ventilation of the closet-chamber itself is sought to be accomplished by means of air-boxes (one for ingress and one for egress, situate respectively at the bottom and top of the wall of the chamber), and these air-boxes are closed or opened by the raising or lowering of the closet-lid. When the closet-lid is up, the outer air is excluded, and the only ventilation is that through and across the closet-basin (supposing, that is, that the door is so made as to prevent the passage of air under or round its edges, for the inventor does not use the window for ventilation); but when the closet-lid is down, ventilation is going on through the room and through the closet pan as well, the inlets and outlets to each being separate, as already mentioned. For use in combination with these appliances, where it is specially desirable (as in hospitals) to take every possible precaution to cut off all passage of foul air from the water-closet to the interior of the building, Mr. Gill has devised twin doors, ventilating the space between them by special means. The whole arrangement, though perhaps theoretically perfect, is rather too elaborate and expensive for general use, but it is right to say that Mr. Gill advocates the use of double doors more as a means of securing privacy than as absolutely necessary on sanitary grounds. Messrs. Doulton & Co., of Lambeth, show their serviceable "Lambeth" valve closet and their improved side-outlet trapless closet, together with various closet-pans and other appliances in stoneware and earthenware. Messrs. Garton & King, of Exeter, exhibit Stidder's trapped "Universal" valve closet and wash-out closet and trap. Messrs. J. Tylor & Sons, of Newgate-street, show an excellent valve water-closet, and their patent "clear-way" regulator valve closet, with parallel pull. They also exhibit seat-action closets and water-waste preventers. Mr. Bostel, of Brighton, again shows his "Excelsior" water-closet. Messrs. Brazier & Son, of Blackfriars-road, exhibit their "self-acting aromatic and deodorising water-closet," which has a chamber communicating with the water in the bottom of the pan and trap. This chamber is charged with lime and camphor, and every time the closet is used the water in the chamber is renewed, without, however, letting the lime or camphor escape. In Section 2 ("Dry Closets") the British Sanitary Company, of Glasgow, exhibit their patent self-acting earth-closet, which possesses some very good points, notably the non-liability of the earth to clog together in the hopper when not quite dry. Mr. James Woodhead, of Bradford, Mr. James Wood, of Newport, Mon., Mr. H. Phillips, of Exeter, Mr. John Parker, of Woodstock, and Messrs. Wippell, Bros., & Row, of Exeter, are exhibitors of dry closets and commodes of various kinds. In Section 3 ("Urinals") Messrs. Doulton & Co., and Messrs. Tylor & Sons are exhibitors; and Mr. Henry Phillips, of Exeter, shows a cheap urinal in connexion with a large receptacle for dry earth, so as to utilise the manurial properties of urine. Section 4 is devoted to sewage treatment, the exhibits under it including Spence's patent aluminoferric cake, Mr. William Batten's patent manhole covers and ventilators (previously noticed by us), and a model of a patent "sewer gas annihilator," exhibited by Mr. H. P. Boulnois, C.E., City Surveyor of Exeter. Some of those who saw this thought that it would merely prevent the sewer gas finding vent. Mr. Isaac Shone, of Wrexham, shows a number of large drawings and models illustrative of the application of his pneumatic sewerage system to the drainage of towns. Mr. J. A. Stephan, of Worcester, Messrs. Doulton & Co., and the Sanitary and Domestic Appliance Company, of Manchester, are exhibitors of filters. Messrs. Trew & Sons, of Bristol, exhibit working drawings of farm drainage works. In Section 5 ("Traps"), Mr. J. M. Craig, of Kilmarnock, exhibits two of Buchan's patent ventilating sewage-gas traps; and Messrs. Doulton & Co. have a collection of traps, open-air receivers, and gas interceptors,—all worth attention. Messrs. Candy & Co., of Newton Abbott, exhibit two full-sized models of their registered "perfect drain ventilator, which was awarded a bronze medal at the Royal (Cornwall) Polytechnic Society's meeting this year. Messrs. Brazier & Son, of Blackfriars-road, show their fat-interceptor and drain. In Section 6 ("Sinks") Messrs. Doulton & Co. exhibit slop, mortuary, and other sinks, and Messrs. Tylor & Sons their patent enamelled iron slop sink. In Section 8 ("Apparatus for Water Supply") Mr. Joseph Willoughby, of Plymouth, shows ball-taps which have a small plug formed within the main plug, to which a lever and float are attached. Messrs. Tylor & Sons display a large variety of "waste-not" and other valves, and Messrs. Doulton call attention to their high-pressure hall and draw-off valves. Mr. George T. Tonks, of Birmingham, exhibits Meakin's patent "frictionless balanced supply valve." The substitution of glass balls for those made of copper or zinc allows of the use of balls of a larger size than usual, while they are cheaper. In Section 9 ("Cisterns") Messrs. Doulton & Co. exhibit their water-waste preventing cisterns; and Mr. Thomas Davis, of Exeter, exhibits a cistern divided into two distinct compartments, the water in the one to be used only for flushing closets, and that in the other for drinking and culinary purposes. In Section 10 ("Flushing and Watering") Messrs. Bowes, Scott, & Read, of Westminster, exhibit Mr. Rogers Field's patent self-acting flushing tanks. Messrs. Doulton & Co. also have an automatic flush-tank, and they are large exhibitors in Section 11 ("Miscellaneous Sanitary Goods"). In the same section, Messrs. Henry Sharp, Jones, & Co., of the Bourne Valley Pottery, Poole, show their "Rock-Concrete" tubes for sewerage works, and Mr. John Phillips, of the Aller Pottery, Newton Abbot, and the Kinson Pottery, Poole, exhibits his patent "access pipe" for allowing of the ready examination of a drain. The arrangement consists of two pipes, butt-jointed as to the lower portions, and meeting on and supported by a "rest"; the upper portions of the pipes are cut into so as to leave a circular hole when placed together, and over this hole a saddleback cover is made to fit, supported by the "rest" already mentioned. At the same stand are also exhibited Phillips's patent vitrified stone-ware invert brick, terra-cotta chimney terminals and wind-guards, and specimens of Devonshire faïence. The Branksea Island Pottery Company display a variety of stone-ware for sanitary purposes. Mr. W. Scammell, of Exeter, and Messrs. Candy & Co., of Newton Abbot, are exhibitors of the same class of goods. In this section Messrs. Tylor & Sons show their patent grooved joint, for fixing lead-pipe without solder.

Class III., Heating, Lighting, and Ventilation.—In Section 1 ("Heating Apparatus") of this class, Messrs. Chorlton & Dugdale, of Manchester, exhibit their "sunlight" stoves. Messrs. Doulton & Co. have a good display of their new "Lambeth Radiating Tile Stoves," in glazed fire-clay. They require little or no attention, and consume very little fuel. For halls, churches, school-rooms, &c., they are not only healthier, but, by reason of their colour, far more cheerful in appearance than iron stoves. Messrs. Carton & King, of Exeter, show Gillingham's patent heat radiator, and Mr. R. H. Griffin, of Kirby-street, Hatton-garden, exhibits eight of his patent ventilating and heating register-stoves. Mr. J. Williamson, also of Kirby-street, sends a number of stoves, hot-plates, &c.; and Mr. G. E. Pritchett, architect, exhibits examples of his cellular tile construction for warming walls and floors. In this section and in Section 2 ("Cooking Apparatus"), Messrs. Willey & Co., of Exeter, and other local firms, exhibit a large variety of gas-stoves for cooking and heating purposes, the Exeter Gas Company offering prizes for the best appliances shown,—among which we may mention Messrs. Verity's patent gas fires, and George's patent

Gas Calorigen, exhibited by B. Farwig & Co., of London. Mr. Constantine, of Fleet-street; the Wilson Engineering Company, London; and Messrs. H. C. Davis & Co., of Cambserwell, are exhibitors of kitchen-ranges and other stoves. In Section 3 ("Lighting") there is a varied display of gasfittings by Stark & Co., Torquay; Webster & Co., Nottingham; and Willey & Co., Exeter. Section 4 is devoted to ventilating appliances, the exhibitors including Mr. Thomas Lloyd, of Winchester; Dr. Hinckes Bird (who exhibits his appliances for costless ventilation as described in the *Builder* in 1862); Mr. Josiah Moore, of Clerkenwell (Moore's louvre ventilators); Messrs. C. H. Sharp & Co., of Newgate-street (who show their "Crown Ejector" and other ventilators); and Messrs. C. Kite & Co., of London, exhibit their registered dormer ventilators for church roofs. The Sanitary and Economic Supply Association, Gloucester, exhibit Dr. Bond's patent "enthermio" ventilating gas stove; and Mr. Crispin, of Bristol, shows a lean-to greenhouse, ventilated on Hunt's patent auto-pneumatic system, which is worth attention. Messrs. Robert Boyls & Son, of Holborn Viaduct, send their long-tried and well-proved air-pump ventilators and other appliances.

Class IV., Personal Hygiene, Food, and Disinfectants,—is an interesting one, but we have not space to instance the numerous exhibits in the eight sections into which it is divided.

Class V., Miscellaneous,—includes thermometers, barometers, microscopes, and other scientific instruments likely to be of service to sanitarians and medical officers of health.

In opening the exhibition,

The Mayor (Alderman W. H. Ellis) said he felt sure that from the exhibition the citizens of Exeter would be able to get a great deal of valuable information. That was the first exhibition of the kind that had ever been held in Exeter, and he believed that it was one of the best that had ever been held anywhere. In it were to be found appliances of every kind, including drain-pipes, traps, ventilators, and cooking apparatus. Exceptionally might be mentioned the gas cooking apparatus. He was happy to say that the Gas Company of Exeter had been very liberal in offering medals for the best kinds of gas-cooking apparatus, the result being that they had there one of the best collections of gas apparatus ever brought together. He believed he was right in saying that they had over one hundred exhibits entered in this class. He trusted that it would be the means of encouraging a new mode of cooking in the future. The site on which this exhibition was being held was, to his mind, the best site that could have been possibly chosen. It was the site of the old Gas Works, and it had now been utilised by the Town Council for a public slaughter-house or abattoir. He trusted that as soon as the present exhibition was over the butchers of the city would see that it was to their advantage to come there to kill their animals. He hoped that whilst the exhibition remained open it would be visited by an immense concourse of people, who would he then able to gain valuable information to carry away to their homes, and so render Exeter and the neighbourhood one of the healthiest places in the world, and one of the most desirable places for people to reside in. He concluded by declaring the Exhibition open.

Earl Fortescue thought the best thanks of the Institute were due to the Mayor and inhabitants of Exeter for having provided them with that most admirable site for the exhibition of sanitary appliances. The thanks of the members of the Institute were also due to the Mayor and citizens for the cordial reception and kind hospitality which they had received at their hands.

Dr. Richardson heartily seconded the observations of Lord Fortescue. He thought the members of the Institute were most deeply indebted for the great care and kindness evinced on the part of the authorities of Exeter in forwarding this Exhibition, and he might say that practically no part of the work of the Sanitary Congress was of such importance to the country at large as this exhibition. For many days after the congress had closed the people for miles around Exeter would have an opportunity of visiting the exhibition; and if they learnt the practical lessons to be gathered from the exhibits, the exhibition was likely to be of more benefit than would arise from all the speeches and lectures in the congress. He knew of nothing so educational to the poor as an exhibition of that kind, and for that reason he most cordially seconded what had fallen from Lord Fortescue.

The exhibition, which is to remain open from ten a.m. to ten p.m. on every week-day until Saturday, October 9th, has not yet (so far as our observation has gone) been very largely attended. Mr. E. L. Box is the curator.

THE SOURCES OF OUR COAL SUPPLY.

DEPENDENT as is the position of the kingdom so largely on the reservoir of long-stored-up power which is contained in our coalfields, the extent to which the latter are drawn upon is a subject of great interest, and this the more because of fluctuation in the degree in which we draw upon the various sources of our coal supply. Railways have "set all the towns of Britain a-dancing," according to Carlyle; and they are changing very materially the extent to which we are dependent upon specific coalfields. In the official reports of the Inspectors of Mines we have reliable records of the extent to which our coalfields are drawn upon. In the kingdom we have coalfields stretched over nearly a twentieth part of its extent. In Scotland, the coalfields are chiefly between the shores of Fife and Haddington, and of Ayrshire. In England, the great coalfield of the north is early-famed; that of the midlands stretches over part of Yorkshire and the counties that adjoin it on the south; westward is that of Lancashire and Cheshire; and there are those of North and South Staffordshire; all these, with the rich seams of Wales, comprise the great bulk of the British coalfields. These coalfields, or the collieries therein, 3,356 in number, are under the inspection of fourteen inspectors. Each inspector reports to the Secretary of State yearly, his report embodying a statement of the amount of coal produced from the mines under his charge, the loss of life in the production of coal, and other similar particulars. The reports, therefore, contain official statements of the extent to which the respective districts contribute to the total fuel supply of the kingdom.

Taking last year as a typical one, it may be stated that 133,720,393 tons of coal were produced from the collieries in the kingdom. As the collieries vary in size,—the production varying at each from a few tons to nearly half a million tons a year,—it is evident that a citation of the numbers of pits in each district would be useless to indicate the proportionate production of each. And, though it would be less unsatisfactory, even the number of persons employed would be apt to mislead; for whilst in Ireland each person employed in and about the coal-fields gives back 100 tons of coal yearly, in Scotland the average output is over three times that quantity. The number of "persons" employed in and at the mines, it may be said, is 476,810,—three-fourths being employed under ground, whilst in the number employed above ground there are 4,842 females. Taking, then, the figures of exact production, these may be shortened by being placed in the decimal form, representing the millions of tons of coal produced in the districts. Each of the inspectors divides the output into that of the distinct counties; but whilst this is generally followed, in one or two instances the slight production of one part of a district is added to that of the chief portion. The following, then, are the quantities of coal produced by the districts or parts of districts named:—Cumberland, 1·525 million tons; North Durham, 6·105; Northumberland, 5·537; South Durham, 17·155; Lancashire, North and East, 8·993; Ireland, 0·129; Denbighshire, 1·499; West Lancashire, 9·562; and Flintshire, 0·721; Yorkshire, 16·241; Derbyshire, 7·561; Leicestershire, 1·103; Nottinghamshire, 4·316; Warwickshire, 1·051; Cheshire, 0·723; Shropshire, 0·822; North Staffordshire, 4·017; South Staffordshire, 7·806; Worcestershire, 1·522; Glamorgan (part), 0·746; Gloucestershire, 1·289; Monmouthshire, 4·660; Somersetshire, 0·742; Carmarthen, 0·664; Glamorganshire (part), 11·747; East Scotland, 11·300; West Scotland, 6·160. In these, with the exceptions of one or two very small contributions, the total is made up. In the working of the mines under the Coal Mines Act, there is also produced fire-clay, shale, &c., but the quantities are small, and are excluded from those above given.

These are the official figures, and it is evident that the great coalfield of the north-east of England still takes the lead in production, for it yields nearly 29,000,000 tons of coal, a quantity not very far short of one-fourth of the total brought to bank in Great Britain. The rich seams of South Wales are being increasingly drawn upon, and they now yield over 12,000,000 tons; but as it is estimated that that basin contains one-third of the available coal supply of the kingdom, and as the present output could be maintained for more than twenty-seven centuries, the increase of that output may be expected without alarm. From the coalfield of Lancashire over 18,000,000 tons are drawn yearly; from that of the Midlands, we extract in the counties of Yorkshire, Derbyshire, and Nottinghamshire more than 27,000,000 tons,—or, in proportion to the ascertained available coal, at least fourfold that hewn from South Wales; whilst the vast beds of North Staffordshire are drawn on to a comparatively slight degree. Those of Scotland preserve a steady output of 17,000,000 tons last year.

The reports of the inspectors furnish no information as to the uses of the coal; and the only facts that are obtainable as yet from other sources show that during last year more coal than usual was exported, and that more was sent to the metropolis. It is evident, then, that the consumption in the country generally had decreased, for the output of coal has been practically stationary for the last four years, whilst it had been previously advancing for a score of years at the average rate of 3,000,000 tons yearly. If the whole of the facts could be obtained, it would probably be found that a large part of the decrease is due to the intense dulness that has prevailed in the manufacturing and more especially in the smelting industries, which has been only partly counterbalanced by the growth in the consumption for gas-making purposes and for those of steam-raising. It is probable now that there has been a return of partial activity in the manufacturing trades, that the coal output of the kingdom will again resume its normal growth.

ART, HEALTH, AND ELECTRICITY.

THE recent heat, though so great in London, was far more intense in Paris, and the sufferings induced caused a renewed outcry in favour of electricity instead of gas. In public buildings, especially in theatres, the enormous number of gas-burners requisite to thoroughly illuminate these places is now, it is urged, an unnecessary evil. The electric light throws off little or no heat, it is unaccompanied by the bad odours inseparable from gas, and the danger of explosions or fire is avoided. Others urge that the injury to the public health caused by gas would also be removed, but are met by experts who say that the electric light produces a certain amount of nitrous oxide gas which is very poisonous. In spite of this, the advantage from a sanitary point of view is probably still in favour of the electric light. When noticing the electric modes of lighting exhibited at the last Universal Exhibition, we remarked on the benefits to the atmosphere of theatres, &c., that might result from the use of electricity, and we urged the importance of extensive experiments as to its sanitary advantage. Experiments must be instituted to settle this part of the question.

M. Charles Garnier loudly demands the introduction of electricity so as to preserve from destruction the works of art with which he has decorated the Paris Grand Opera. To descend from the sublime to the comic, from the Grand Opera to the Palais Royal, this latter theatre has been entirely re-decorated, and in so remarkable a manner that it merits a few words of notice. M. Bayard has been entrusted with the work, and has painted on the walls of the *foyer* or crush-room a biographical history of the theatre. On one side we have groups representing all the ancient actors in their most celebrated parts,—the Père Amant, Boutie, Déjazet, Jules Pernon, Nathalie, and Mars. To unite the past with the present there is an allegorical group of nymphs and satyrs, and then we find the portraits of all the celebrities who still convulse the gay audiences,—Brasseur, Hyacinthe, Ravel, Schneider, &c. But we are reminded that these new and elaborate decorations, which possess the double attraction of works of art and works of history, will be prematurely obliterated if they are exposed, night after night, to the blaze of innumerable gas-burners. The Gymnase Theatre has also been re-decorated, and these facts and the intense heat must account for the revival of the old contest relating to the respective merits of gas and electric light.

UNIVERSITY COLLEGE, LIVERPOOL.

THE establishment of the proposed University College at Liverpool will be an event of much more than mere local interest, for it may be fairly hoped that it will supply an educational want which exists in the populous county of Lancashire, even though Manchester has now for a good many years done much in the cause of higher education. The subscription list which has just been issued for the first time, is as remarkable a document as we have met with for a long time. Nothing can give a more vivid and practical sign of the immense wealth of this country, or of the greatest seaport of Great Britain. Nothing, too, shows more noticeably how flourishing is the position of our great mercantile towns, in spite of the depression of trade of which we have heard so much; for we find that there are no less than five donations of 10,000*l.* each, namely, that of Lord Derby, to found a chair of Natural History; of Mrs. Grant, to found one in some branch of science; of Messrs. W., S. G., & P. H. Rathbone, to endow a "King Alfred" chair of Modern History and Literature. Messrs. A. H. Brown, M.P., Crosfield, & Barrow, also give 10,000*l.* to found a chair of Ancient History and Literature; and there is another donation of a like amount to found a chair of Experimental Physics and Mathematics. We mention these gifts *seriatim*, because they seem to be of really historical interest as exemplifying the wealth of England in the nineteenth century. There are also many gifts towards a chair of Philosophy, Logic, and Political Economy, and to found a Roscoe Chair of Art, as a monument of the most durable kind to Mr. William Roscoe, the Italian historian, and the early patron of Gibson the sculptor. More than 6,000*l.* has already been collected for this object, which is one very worthy of support, for in no part of England is it more desirable to diffuse a love of art than in the somewhat hard and busy North country. And, we observe, to turn to the point of money again, in the whole list two gifts of 2,000*l.* each, and some sixteen of 1,000*l.* each, besides many of a large though lesser amount, all of which go to still further exemplify at once the wealth of Liverpool, and a spirit which by no means is unworthy of comparison with that which actuated the merchants of Venice, albeit the inhabitants of the great Mediæval seaport may have done more as a city for the direct and judicious encouragement of the fine arts.

CHRIST CHURCH, NEWGATE-STREET, CITY.

THIS fine church, one of those erected by Sir Christopher Wren after the Great Fire of London, is now being renovated and partially restored. The site it occupies, viz., reaching from Christ Church-passage eastwards to King Edward-street, is the site of about one-half of the original Grey Friars' Church, built in connexion with the monastery given by King Henry VIII. (the gift being confirmed by his son Edward VI.) to the citizens of London for a school, now the Blue Coat School.

This original Church of the Grey Friars was of great size, and occupied not only the site of the present Christ Church, but of the whole of the present churchyard opposite to it. It had a passage-way through it, almost in the centre, leading to the cloisters of the monastery situate northwards, a small portion of which cloisters still exist. This passage-way, now open to the sky, constitutes what is called Christ Church-passage.

Wren, of course, rebuilt the church in his favourite Classic style. It may be said to be remarkable for its fine, large, lofty, and airy nave, with large side-aisles, but has no chancel proper. The columns of the nave, with the clearstory windows carried by horizontal beams over them, reach, as it were, right up to the east wall. The absence of a duly-marked chancel was probably caused by the (to a certain extent) limited length of the site not allowing both nave and chancel of good proportion: hence Wren, preferring a good nave to a well-proportioned chancel with a stinted nave, designed a fine nave of good proportion, simply marking the chancel by two steps at the line of the second column from the east, and a raised floor up to the east wall.

The lofty stone columns (about 30 ft. high), formerly and of late all coloured over, have now been scraped and restored to the original stone, which is Portland; the clearstory window openings, from which the principal light to the church is derived, have been filled with new cathedral glass in lieu of the old lead lights; the vaulting, which is only of timber and plaster, has been all recoloured, with the ornamental portions picked out. The back portions of the heavy galleries have been removed, and the internal appearance of the church is thereby considerably improved. The pewing, which is of solid oak, has been all scraped, cleaned, and varnished.

It is in contemplation, should the Blue Coat School (the boys of which now fill the galleries every Sunday) be removed to the country, to take down the heavy galleries, and clear them entirely away; also to re-pew the church with pews of moderate height. This, it is thought, will much improve the interior, inasmuch as the galleries run across the lofty side-aisle windows, and were therefore erected by Wren for the purpose of obtaining a large number of seats, at that time wanted, but now no longer required, when City people reside in the suburbs.

The works have been carried out by Messrs. Hayward & Son, builders and decorators, under the supervision and direction of Mr. Henry S. Legg, of Christ's Hospital, the rector being the Rev. Michael Gibbs, M.A.

The Lord Mayor and sheriffs attended service at the church on Sunday, the first day of opening after the completion of the works, it being customary for the Lord Mayor to attend in state on St. Matthew's Day at this church every year.

NEWCASTLE PUBLIC LIBRARY.

THE first stone has been laid of a new building in Newcastle for the Public Library, and arrangements are made by means of which it will be opened with 20,000 volumes at least. The structure, it is stated, is to be "in the Corinthian and Doric orders of Classic architecture"; but, if we may judge from a fearful illustration, published in a local paper, it will have little to do with those admirable institutions. However, it promises to be a commodious building, and includes galleries for sculpture and painting. The façade will be 167 ft. in length, 30 ft. at each end being made to project. The principal entrance is in the centre, approached through a portico with Doric columns supporting an entablature which will be surmounted by a balustrade. This balustrade will be continued along the whole length of the building. Above this, in the recessed portions, panels will be formed in which subjects may be carved in relief. The centre portion will be surmounted by a pediment with attic, below which will be formed a cornice, with blocking course, terminating at the projecting ends. The bays at each end of the building will be furnished with a modillion cornice, surmounted by a balustrade. The roof is semicircular in shape, and the centre portion of the first-floor rooms will be lighted by skylights through a panelled ceiling, and by gas sunlights at night. The basement floor will be used for the ordinary working purposes of the Library. On the ground-floor there will be a lending library, 60 ft. by 42 ft. and 17 ft. 6 in. high; a library containing books for reference, 58 ft by 36 ft., semicircular on plan, and 19 ft. 10 in. high. There will also be two reading-rooms, 43 ft. 4 in. by 28 ft., and 25 ft. by 19 ft. respectively, each 17 ft. 6 in. high. The whole of these rooms will be approached from the principal entrance-hall or vestibule, which will be 43 ft. long and 20 ft. wide. On the first floor the front rooms will be appropriated for pictures and sculpture, and will be 135 ft. long by 28 ft. wide, and from 23 ft. to 28 ft. high, divided by partition-walls fitted with sliding-doors, the whole arranged *en suite*. There will be four rooms set apart for science and art classes. These will be approached from the front street by a separate entrance, and although connected with the Sculpture and Art Gallery on the first floor, the working of these classes will be carried on distinct and separate from the working of the Library. The staircase and part of the walls of the vestibule or hall will be constructed so as to admit of extensions in case of further requirements. The light will be admitted through a large window on the staircase landing and from the roof. This portion will be 24 ft. wide, semicircular on plan, and 42 ft. high from floor to ceiling. The area of the site is 1,431 square yards, and will nearly all be covered by the building. The land and structural works are estimated to cost 20,000*l.* The architect is Mr. A. M. Fowler, the borough engineer.

THE RICHMOND SWIMMING-BATHS COMPETITION.

ANOTHER muddle! The instructions limited the competitors to 1,500*l.*, and the Committee have selected and recommended a design priced by the authors at 3,200*l.* A curious mistake, moreover, was made. The design selected was marked "Natation": so an envelope thus marked was opened, and found to contain the name of Mr. F. D. Lockwood. Inquiry, however, showed that he was not the right "Natation." Two designs were sent in so marked, and the real authors of the design selected were found to be Messrs. Elkington & Son, of Cannon-street, London.

Mr. Lockwood writes to us as follows:—"A clause in the instructions issued for the guidance of architects competing for the new swimming-baths states that 1,500*l.* is to be the limit of cost to be expended upon the works. A design has been selected which the architect estimates will cost 3,200*l.* to carry out. On behalf of the remainder of the competitors, I leave it to yourself and the ratepayers of Richmond to answer one question,—Is this justice?"

The *Twickenham Times* says:—"The plans of 'Natation' are of an attractive character, and give promise of baths that will be of great benefit to the town. To begin with the basement of the front building, provision is there made for a laundry, towel washing-room, engine-room, and engineer's workshop, two boilers, and a well with two pumps. On the ground-floor there are separate entrances for the first and second-class baths, a ticket-office, and nine first-class private baths. On the first floor there are sixteen second-class private baths, some of which are so apart from the others as to be available for ladies or special baths. Apartments for the attendant are set apart on the second floor. Corridors from the ticket-office lead to the first and second-class swimming-baths. In the first-class bath the water covers a surface 90 ft. by 27 ft. the depth increasing from 3 ft. 6 in. at one end to 6 ft. 6 in. at the other, and there are fifty-seven dressing-rooms arranged along the two sides. Behind this there is the second-class bath, with water covering a surface 51 ft. by 34 ft., the depth increasing from 3 ft. 6 in. to 5 ft. 6 in., and twenty-six dressing-rooms. The cost of the works is estimated at 3,200*l.* Several other plans were sent in, the cost varying from 1,500*l.* to more than 8,000*l.*"

THE ARCHITECT OF THE PARIS PANTHEON.

POSTHUMOUS homage has just been rendered to Soufflot, the architect of the Paris Pantheon, by exposing his portrait in one of the supplementary galleries of the Louvre. It was painted by Vanloo, and in the lower part of the frame there is a gilded plaque to which are affixed two golden medals representing the Pantheon from different points of view. Soufflot is depicted by the artist in the act of designing the monument which has immortalised his name. He wears a costume of apricot colour, and this, in the eighteenth century, was considered the pink of fashion. The portrait bears the signature, *Vanloo pinxit*, and has been given to the State by one of Soufflot's descendants.

Manuscript Architectural Work. — We find the following item in Mr. Young's Catalogue (12, South Castle-street, Liverpool). As to what the real value of the work may be we know nothing:—

"248. Fowler (J.), Domestic, Ecclesiastical, and Monastic Architecture of England and Wales, from the earliest times to the present century,

SPLENDID AUTOGRAPH MANUSCRIPT,

10 vols., most clearly and beautifully written, and profusely illustrated with about 3,000 engravings from various works (some scarce), water-colour drawings, pen-and-ink sketches, &c., of churches, castles, mansions, costumes, carvings, portraits, &c., half red morocco, holland covers, *gilt*, 10*s.*, 1825-38, folio.—This unique and interesting work must have been the labour of a life-time, as well as a labour of love. It illustrates very completely our cities, cathedrals, castles, mansions, circles (such as Stonehenge, &c.), mossics, carvings, &c. &c., and a vast number of works have been destroyed to get the engravings. From Dunn-Gardner's collection."

THE TRADE-UNIONS CONGRESS IN DUBLIN.

AMONG the subjects discussed last week at the Trade-Unions Congress in Dublin was that of steam-boiler inspection. Mr. Macduff (Glasgow) moved:—

"As a great number of accidents, caused by boiler explosions, result from the inefficiency of inspection, this Congress hereby instructs the Parliamentary Committee to urge upon the Government the great necessity of compulsory inspection."

This resolution was in reference to certificates of competency for men in charge of steam engines and boilers. They found, from a cause that lately took place in Glasgow, that while there was an engineer of experience to take charge of the machinery of the establishment, the inspection of the boiler was not thoroughly attended to; and, in fact, it appeared in evidence at the trial that some of the boilers had not been inspected for ten or twelve years, and plates that had been three-eighths of an inch thick had been allowed through corrosion and the weather to rot down to an eighth of an inch. At the explosion there were twenty-seven lives lost, and one firm had some twenty-seven boilers, all more or less, in a similar condition. That was evidence that compulsory inspection was required.

Mr. Johnson seconded the motion.

Mr. Rhodes (Dunstable) did not object to the inspection of boilers, but if it went forth that the inspection of boilers was quite sufficient for their safety it might prevent the more useful practice being put into operation, of having properly-qualified men in charge of boilers. It was much safer to have a qualified person in charge of the boiler, for his own life would be in danger if he worked at an unsafe boiler.

After other remarks,

Mr. Prior asked Mr. Macduff to add to his resolution:—

"And that it shall be an instruction to the Parliamentary Committee, in dealing with this question, to endeavour to keep it separate and distinct from the equally important subject of engineman's qualifications."

Mr. Knight said Mr. Burt, M.P., who had charge of this subject in the House of Commons, absolutely refused to separate the two questions.

Mr. Macduff said he would adopt the addition to his resolution.

Mr. Coote said he was compelled to believe these inspections were almost always useless. As a rule the inspectors saw exactly what the head of the firm, or the interested party, chose to point out to them. He would sooner have the opinion of one illiterate engineman as to the condition of a boiler than that of twenty scientific theorists.

Mr. Nixon, of Newcastle-on-Tyne, joint secretary of the Miners' National Union, moved, as an amendment,

"That Mr. Thomas 'Burt, M.P., be requested to re-introduce in Parliament the resolution moved by him in 1879 on the subject of steam-boiler inspection and certificates of competency of men in charge of engines and boilers."

The amendment was carried by 48 to 28.

The Nine Hours System.

Mr. Burnett (London) moved,—

"That the Congress, recognising the vital importance of offering the most strennous opposition to any attempt on the part of employers to extend the hours of labour, strongly advises the trades of the kingdom to unite for the common protection of the existing hours of labour, and empower the Parliamentary Committee to act, if necessary, as the medium of arranging a conference of those trades who may express a desire to federate for such a purpose."

He said the trade to which he belonged (the engineers) had undergone such vast expenditure and trouble on this question that he deemed it necessary to say a few words to the other trades on the subject. The nine-hours system had been introduced into the engineers' trade of the country in 1871, and the reduction of the hours of labour which the engineers then succeeded in obtaining was extended to other trades which previously had worked longer hours, so that the bulk of the trades in the country were interested in supporting the nine-hours system. The amount of wages which a man had to receive was doubtless one of the first questions for their consideration, but he ventured to assume that the question of the hours of labour was of greater importance than the mere question of wages. Wages rose and fell in accordance with the various laws affecting the labour market, but the hours of labour remained fixed, if not for all time, for a very great length of time, and it ought to be their object in dealing with the question of hours to bring them down to as brief a limit as possible. He referred to the operations of the Iron Trades' Employers' Association, which was the greatest organisation of capitalists in the country. Its proceedings were always conducted in private, and its reports were in the first place called private copies, and then they were afterwards told they were strictly confidential. Referring to one of those confidential documents, he pointed out that the most important portion of it related to the movement for the extension of working time. It went on to show the various steps taken by their association to increase the hours of labour, and referred with triumph to the fact that in Scotland in the beginning of 1879 the hours of labour were extended from 51 to 54 per week. It also referred to the fact that a conference had taken place between employers and men with the view of still further extending the hours of labour. If a time of temporary depression should enable the employers to extend the hours of labour, they should remember that a time of prosperity might enable the men to wrest back the hours of labour. The disputes at Huddersfield and Bradford were the principal disputes on the time question in which they had been engaged. In Huddersfield several of the shops had conceded the terms of the men, and were now working on the short-hours system. In Bradford the hours had been extended from 54 to 56½ per week, and now, after a strike of nearly eighteen months' duration, their society had only within the past few weeks achieved a complete victory, and, with a few exceptions, all the shops in Bradford are working on the short-hours system. They wanted to point out to the trades of the country that although they were able to supply the sinews of war from 20,000*l.* to 25,000*l.* in addition to the ordinary benefits of the society, other societies might not be so strong and well able to resist, and therefore they urged upon them the necessity of joining in this combination to protect the hours of labour.

Mr. Guile seconded the resolution. The employers had set them such a very good example of united effort that it was just as needful,—nay, more so on their part,—that they should combine and protest against being robbed of this one hour privilege each day, as it was for the employers to enforce it again on the working men of this country. If the employers got ten hours' work out of them for nine hours' pay, they could go into the market retaining the same margin of profit on their capital as heretofore. He would say the time was coming when, if all who ought to work did work, not nine hours', but six hours' work would be sufficient to supply the wants of the country.

Mr. Ashton thought the hours of labour question was a more vital one than that of wages He held that with the improvements in machinery, which enabled work to be performed in a shorter time, the labourer should have a benefit in reduced hours of labour. He pointed out that although Mr. Burnett's trade might boast that they were working only nine hours a day, yet the members of his trade, as well as others, were always ready to work overtime when they got the chance of earning a few shillings by it. He held that if they had to work a certain number of hours per day, they ought to cease labour at that time, and refuse to work overtime under any inducement.

Mr. Thom (Edinburgh) suggested an amendment, and

Mr. Burnett subsequently put his resolution in this shape:—

"That this Congress, recognising the vital importance of offering the most strenuous opposition to any attempt on the part of the employers to extend the hours of labour, strongly advises the trades of the United Kingdom of Great Britain and Ireland to unite for the common protection of the existing hours of labour where they have been reduced, and to take the earliest opportunity of equalising them with the lowest basis which has been obtained; also to empower the Parliamentary Committee to act, if necessary, as the medium of arranging a conference of trades which may express a desire to federate for such a purpose."

Mr. J. Ward (Dublin) seconded the amended resolution which, after a long debate, was unanimously carried.

On Friday, the following resolution, in favour of apprenticeship, was carried, and is a direct confirmation of the views put forth in the article upon the subject in last week's *Builder*. Mr. Nanetti (Dublin) proposed,—

"That this Congress is of opinion that a regular system of indentured apprenticeship, extending over stipulated periods, is the best means of developing technical knowledge, and increasing the skill of workmen in the United Kingdom."

Mr. Avens (London) seconded the motion.

Mr. Clarke thought this was a question for each individual society to deal with, and not for the Congress at all.

Mr. Fitzpatrick (Liverpool) concurred with Mr. Clarke.

Mr. Davey moved an amendment, to the effect that the question could not be adequately dealt with by the Congress, and could only be dealt with by the separate trades.

After a lengthened discussion, the amendment was rejected and the resolution adopted.

The Congress was brought to a close on Saturday last, when the next place of meeting was considered, and the following places were voted for:—Durham, 20; London, 19; Manchester, 15; Belfast, 8; Swansea, 7. The final division lay between Durham and London, and the latter received 35 votes, Durham getting 30.

The subject of strikes and lock-outs was then considered, and the following resolution passed on the motion of Mr. Coote, of London:—

"That in the opinion of this Congress, the time has arrived when measures should be taken to bring into closer union the somewhat estranged relationships of capital and labour, and to place them upon a basis that will, in the future, prevent strikes and lockouts from paralysing the industry of the country. With this purpose in view, the Congress recommends to the consideration of all interested in the welfare of masters and workmen the desirability of establishing local and central courts of arbitration throughout the United Kingdom for the purpose of settling all trade disputes upon the principle of equity to all concerned."

On the suggestion of Mr. Sedgwick, who seconded the motion, the word "employers" was substituted for "masters," which was deemed offensive.

THE STATUE OF ROBERT RAIKES ON THE EMBANKMENT.

WITHIN the last few days passengers along the Embankment between Waterloo and Charing-cross have had their attention attracted to the taking down of the statue of Robert Raikes, the founder of Sunday Schools, which was erected only some two or three months ago, on the occasion of the Sunday School Centenary. The statue itself, as well as the granite pedestal on which it stood, described in our columns at the time, have been removed from the site, and the former taken away and placed under lock and key, pending the permanent foundation and basement works now in progress. The explanation offered of the removal of the structure is that its erection was only of a temporary character, in order to admit of the inauguration of the statue during the centenary week, and that for this occasion the pedestal and the statue were erected on blocks of timber. The entire structure having now been removed, the site upon which it will permanently stand in the Embankment Gardens has been excavated for the foundations to a depth of about 20 ft., and a portion of the area, about 20 ft. square, has been filled in with concrete, upon which the pedestal and statue will be permanently erected. Messrs. Mowlem, Burt, & Co. are executing the work. If the explanation given be correct, certainly it is the oddest proceeding that we have heard of for some time. Ordinary people would fancy that a temporary wooden pedestal, removable with little trouble and expense, might have been made to serve the immediate purpose.

Convalescent Hospitals.—By the aid of a generous donor (who gives 6,500*l.* conditionally on the establishment at once of a seaside branch home), the Committee of Management of the Metropolitan Convalescent Institution has secured a freehold site at Bexhill-on-Sea, near St. Leonard's, and plans for a building capable of accommodating 100 inmates have been prepared and approved by the Board. The cost of the land, building, and furnishing complete, is estimated at about 12,000*l.* The Committee of Management have already entered into a contract for the erection of so much of the building as will receive fifty inmates, and they ask for funds to enable them to fit up and furnish that portion, and also to complete the rest of the building at once. Mrs. T. Brassey has promised to lay the foundation-stone of the new building early in October.——The Princess Christian has consented to open the Convalescent Hospital for the county of Hertford, at St. Leonard's-on-Sea, on October 21st. The Marquis of Salisbury, the Earl of Chichester, and a large number of county gentry are expected to be present.

WESTMINSTER PUBLIC OFFICES COMPETITION.

ON Tuesday last, at a vestry meeting of the united parishes of St. Margaret and St. John, Westminster, Mr. George Andrew Spottiswoode in the chair, the report of the referee, Mr. Barry, on the ten designs submitted for new offices, was considered. The referee had selected three designs, and placed them in the following order:—No. 1, "Stet"; No. 2, Portcullis in circular strap; and No. 3, Black Star.

The estimated cost of the vestry offices alone (*i.e.*, exclusive of the Large Room), in each case is as follows:—

	Author's Estimate.	Mr. Barry's Estimate.
"Stet"	£16,032	£15,779
Portcullis	15,000	16,188
Black Star	15,000	16,493

After discussion, the report was adopted, and the letters accompanying the designs being opened, the respective authors were found to be—

No. 1. Messrs. Lee & Smith, 7, Queen Victoria-street.
No. 2. Mr. John E. Trollope, Elm Field, Streatham.
No. 3. Messrs. Hunt & Steward, 3, Victoria-street.

The cost of the Large Room is thus estimated by Mr. Barry:—In the case of No. 1, 6,313*l.*; No. 2, 7,547*l.*; and No. 3, 4,705*l.*

It was decided to exhibit publicly all the designs as soon as possible, and it will be then, of course, open to any of the architects to affix their names to their designs, should they so please. The matter was referred to a committee for further report.

Mr. J. E. Trollope, the second prizeman, is a younger son of Mr. Trollope, of Parliament-street.

THE CHURCH OF THE PASSIONISTS (ST. JOSEPH'S), HIGHGATE.

THIS (R.C.) church, which was opened on the 12th ult., has been elaborately decorated. The base of the nave walls is of black and gold marble; above this, to the top of the confessional arches, the walls are stencilled with the various emblems of the Passion in green on a lighter ground of the same colour, the whole being surrounded by a fretwork band of a reddish colour. On either side of the nave are recesses containing the confessionals, worked in pitch-pine and varnished. Between the tops of the Confessionals and the moulding under the windows are panels in various shades of colour. Above this are the new stained-glass windows, with ornamental panels between them, and a painting of the Crucifixion. The ceiling of the nave is panelled in various shades of grey. The cornice is decorated, and has the fascia relieved with a running pattern of passion-flowers and leaves in natural colours. The lighting is effected by means of star pendants. The font, of a carved Gothic design, stands in a chapel, which also answers the purpose of a baptistery. The Lady-chapel and the Chapel of St. Paul of the Cross stand on either side of the sanctuary, and form the transepts. In the Chapel of St. Paul of the Cross a new altar has been erected, and a stained-glass window of the Agony in the Garden fixed in the side wall. In the lady-chapel there are two more stained-glass windows, one representing Our Lady of Lourdes, and the other the Annunciation. Both chapels have paintings over the altars, and are decorated in gold and colours. The sanctuary and high altar glitter with gold and colour. On the left-hand side of the sanctuary is a pulpit of inlaid wood, and on the opposite side the altar of the Sacred Heart. The stalls and seats are of pitch-pine, varnished.

The architect is Mr. Albert Vicars, of London; the contractors are Messrs. Kelly & Son, of London. The painted and other windows, the painting of the Crucifixion, and the medallions, were painted on zinc by Messrs. Mayer & Co., and the new altar was erected by Mr. Thomas Heath.

Sanitary Prize Essay.—The Government of India has offered a prize of 100*l.* for the best "Manual of Hygiene," to serve as a text-book for the use of the British soldiers in that country. Works submitted in competition for this prize must be sent in by their authors to the Secretary to the Government of India in the Military Department at Calcutta, so as to reach his hands not later than the last day of next March.

MOULDED BRICKS: RED TERRA COTTA.

WE cannot pretend to mention all the makers of terra cotta who have sent us drawings and specimens of their ware, but it is certainly satisfactory to learn that if architects desire to use this material, or to introduce moulded and ornamental bricks, they will not find much difficulty in obtaining what they want, whether it be in having their own drawings carried out or adapting ready-made articles. As amongst the best of the specimens that have reached us, we may mention some red terra-cotta work and ornamental bricks of the same colour sent by Messrs. Arthur Gee & Co., of Stafford. The material appears to be excellent, and good taste evidently presides over the preparation of designs for stock.

THE LIABILITY ACT.

SIR,—Now that the Employers' Liability Bill has become law, in what way does it affect the liability of servants to the masters for damage done to furniture in customers' houses during the execution of works? During the past month my workmen, while decorating rooms, have broken two glass chandeliers, which, of course, I have had to replace. Can I make the workmen pay the whole or part of the cost?

Also, if workmen catch cold while repairing roofs or other outside works, and are obliged to be at home for a day or two, in order to get well, am I bound to compensate them for this loss of time? AN EMPLOYER.

GLASGOW MUNICIPAL BUILDINGS COMPETITION.

SIR,—As one of the competitors who have adhered to the condition requiring absence of colour and etching, I consider myself entitled to ask how Mr. Barry can justify evasion of this stipulation on the part of so many of the competitors. The condition was distinctly geometrical outline; and the shading of windows in first and second premiated designs and in so many of the others, violates the spirit of that requirement. I presume this was not sanctioned in reply to any query from intending competitors, otherwise the Council would have seen their way to issue amended conditions to every competitor, so that all might be on the same footing.

It is true Mr. Barry or any professional man of skill and probity would give no weight to the adventitious effect thus obtained; but it is not in human nature to avoid being influenced by effect as well as merit, and we all know there is such a matter as the art of putting things which in this age of superficial judgment is by no means to be ignored.

However this may be, the fact remains that the first and second premiated designs have had advantages which were by the conditions inferentially forbidden. Another and more important point of objection to Mr. Barry's award consists in the architecture of Mr. Corson's design, which I should imagine scarcely seconds the wishes of the Council that the style employed should be of a broad and dignified rather than florid character. The style chosen may be appropriate for a comparatively small building, but, his own design being witness, does not easily lend itself to an extensive subject.

Note the repetition of stories, none being in reality dominant, the absence of breadth, the repetition of similar parts, which of itself is calculated to destroy interest; the fact that there is neither base nor crown in the proper sense; the fact that the style does not afford a tower of the form employed, and Mr. Corson has therefore had to touch the border-land of Gothic architecture, with a resulting incongruity. The fact, however, that Mr. Corson has followed Mr. Carrick's plan in its chief features is, I think, a merit, in the light of the conditions issued, apart from the question whether that plan was the best or not. With this, as competitors accepting certain conditions, we had nothing to do. Undoubtedly, a finer plan can be produced, and has been by some of the competitors (to whom it would be invidious to refer), and so afforded them opportunity of conceiving most excellent elevations.

It is gratifying that Mr. Barry has recognised this condition, and limited himself, in choosing, to those designs which adhered to it; for it is evident that those who disregarded this stipulation, working free of its fetters, enjoyed an advantage not really conferred by the conditions, however desirable it may have been.

MENDELSSOHN.

GRAINING AND MARBLING.

SIR,—In answer to the letter in your issue for September 11th, from "A Poor Grainer," will you allow a very old hand at the trade to state what he believes to be the principal causes of the decline of what "A Poor Grainer" considers art? I have always thought that art, technically speaking, was and is something more than learning to copy such inanimate subjects as woods or marbles, no matter how beautiful the colours or forms they present.

To call such work "art" is just as much out of place as to call the thousands of very poor imitations by poor artists that we see exposed for sale artistic.

What I consider one of the causes of what was once, no doubt, appreciated is that like most new-fashioned things, it has had its day.

Your correspondent must not forget that marbling and graining is only a profession of modern growth, little more than a lifetime since first invented; but, like other trades, it may take more than a lifetime to bring to perfection. No doubt there are some really clever men in the trade who show an amount of artistic feeling for their work; but for one of that class how many hundreds are there who have not the slightest idea of what they are supposed to be imitating, never having taken the trouble or incurred the expense of procuring the smallest specimen of either the woods or marbles requisite?

There are a large number of the so-called grainers who endeavour to perfect themselves by attending a public school,—no doubt, very large and cheap, viz., walking round the shops on Sundays.

I feel quite sure that, were it not for the supposed economy in having work (graining being varnished) that would hide the dirt or bear the scrubbing-brush, we should never have had so much graining in use.

Architects and decorators seem to be getting a little better educated in such matters than they were, and are falling back on the old-fashioned honest work that was in existence before graining and marbling were thought of.

In the old style of decoration for interior work there was some really artistic work required and done, which, let us hope, may be done again, and enable the numerous artists to get a share of the employment their natural abilities and education may entitle them to.

Another very decided cause for the decline of the trade is the action of grainers themselves, who are entirely responsible for the effect; that is, the system of piece and measurement work so generally in vogue. How is it to be expected that the system of making grainers, adopted by the so-called grainers to the trade, could be otherwise than prolific in the supply of "poor" grainers? A grainer succeeds in getting a connexion among small builders, painters, and others by giving his services at a lower rate per yard than usual, and, to enable him to make a profit sufficient to live by, he has to employ at first one boy, to be supplemented by a number more, each in a few years to compete with his late master and each other, thereby overstocking the trade with a very large amount of very poor grainers in every sense of the word.

J. M. G.

GILDERS AND PREPARERS.

AN APPEAL.

SIR,—At a very crowded meeting, held in the theatre of the Charterhouse, as already mentioned in the *Builder*, on Monday, September 6th, on the very great depression in the above trade, the Rev. Stewart D. Headlam, B.A., in the chair, on a show of hands being called for, it was proved that nearly one-half of the gilders and preparers in that meeting were out of work, many of them having been out of employment for four or five months. It has been proposed to form a Gilders' and Preparers' Society for the East End of London. This will cost some amount of money, not only in forming the society, but to relieve the men out of work. We, therefore, ask for some little assistance to enable us to get over the present depression in the gilding trade. We do not make this appeal so much for ourselves as for our wives and families. We humbly ask your readers, previously to sending money to the poor in foreign nations, not to forget the poor gilders and preparers in the East End of London.

Subscriptions will be most thankfully received by the Rev. STEWART D. HEADLAM, B.A., Charterhouse, Goswell-road; or by your humble servant,

GEORGE RYAN,
Secretary *pro tem.* of the Provisional Committee.
19, *Berwick-street, Oxford-street.*

DISCREPANT TENDERS.

SIR,—I much regret seeing the tenders for Tehidy Villa made public, and consider it very bad grace on the part of the contractor, who, unauthorised, has taken upon himself to publicly expose what I believe must have been errors on the part of his fellow competitors, and which compelled me to accept an estimate my experience teaches me to be reasonable.

Considering the inconvenience caused by the limited time, &c., allowed for the preparation of the estimates, it was my last wish that any discrepancy on the part of the contractors who so kindly obliged me with tenders should have been offered to public criticism.

G. T. HOWELL.

P. S. I shall feel greatly obliged if you will allow my opinion to be known publicly.

EASTBURY HALL, NEAR BARKING.

SIR,—As the proprietor of the largest share of this family estate, I should be much obliged if you would correct the inaccuracy in the history of the title to it given in the account published in the *Builder* of September 4th last. The history is correct down to 1557, when John Keele sold the property to Clement Sisley,—not Sisby,—who probably built the house. Thomas Sisley parted with it to Augustin Steward in or before 1608. Martin Steward sold it to Jacob Price in 1628, and George Price sold it in the year 1646 to William Knightley, whose widow conveyed it in 1659 to Sir Thomas Vyner, alderman of London. In 1714 his representatives sold it to William Browne, whose nephew, William Sedgwick, parted with it to John Weldale in 1740. This is the last time the estate was sold. Anne Weldale, daughter of the above John, by her will bearing date 1773 devised it to her relative Mary, wife of the Rev. Wasey Sterry, with remainder to her issue; and the property is still in the possession of her descendants. There was a Mr. Brushfield tenant in 1796; but this fact hardly accounts for the statement in the *Builder* of September 4th, that "the manor was sold by Mr. Brushfield in 1845 to Mr. Sterry."

If I do not notice one or two other statements in your report which do not concern the title to this property, it must not be supposed that I admit their accuracy.

I may add that on the termination in the year 1875 of the farm tenancy of Mr. Whitbread, referred to in your article (which tenancy commenced in 1858), a sum of upwards of 1000*l.* was laid out by the freeholders in repairs then found necessary to the mansion-house, buildings, and fences on the farm; and during the last two years other large sums have been similarly expended by them on this estate. FRANCIS STERRY.

Poltimore Rectory, Exeter.

RAILWAY ACCIDENTS.

SIR,—Of late there has been an undue prominence of these "accidents," and there appears to be a desire to place the matter on a wrong issue.

I submit, they result in a great measure from original faulty construction, *i.e.*, sharp curves and steep gradients, and also from excessive speed,—a matter requiring attention.

As regards "faults" in construction, I can predicate on certain points where these so-called accidents from preventible causes, bad construction and high speed, may occur.

The remedy lies in these two directions, principally in the former, and to this legislative attention should be directed; all the break power in the world will be nugatory, and, in fact, it is a question whether injury to the permanent way is not effected by a too-sudden application of break power. NEMO.

PERSONAL.

SOME of our old customers having been misled by some one having started another firm in the name of J. Smeaton & Sons, at our old address, Nos. 9 and 10, Wych street, Mr. John Smeaton, so long connected with the firm of Messrs. W. Smeaton & Sons, Howland Mews, Howland-street, Tottenham Court-road, W., and 24, Moorgate-street, E.C., will be glad if you would notice in your columns that he has no connexion with any other firm than the undersigned. W. SMEATON & SONS.

Miscellanea.

Statistics of Accidents.—The manager of the Accident Insurance Company, of Bank-buildings, has published details of the accidents the company in question has paid for during the last ten years, and they furnish ample testimony of the usefulness of insuring against the casualties of every-day life, apart from those that arise from risky occupations. 11,703 claims are accounted for as follows:—5,418 in riding, driving, and walking; 2,974 in business and professional accidents; 1,555 home and domestic disasters; 417 cases in travelling by sea and land; 271 injuries through animals, birds, and insects; and 1,038 through sports and pastimes.

Ecclesiastical Art Exhibition, Church Congress, Leicester.—The Loan Collection is larger than last year, and embraces upwards of 400 separate exhibits. Embroidery, both ancient and modern, is largely represented. Mr. C. Watkin Williams Wynn shows two missals, printed at Paris in 1501 and 1503, and the corporation of Leicester have sent a copy of the Sarum Missal, belonging to the Old Town library. No one subject is so thoroughly illustrated as that embraced by Mr. William Bragge's collection of Russo-Greek "Icons," or religious pictures.

The Printers' Almshouses, Wood-green. The new blood introduced into the management of the Almshouses at Wood-green is patent, not only by the fresh vigour with which subscriptions have been raised and the necessary repairs are being carried out, but by other signs, one of which it affords us sincere pleasure to notice. However healthy and comfortable almshouses may be, the inmates will not be much benefited if their daily rations are insufficient in quantity or quality; and yet this is (perhaps we should now say, has been) the fact in some cases. The Biggs Charity is an unspeakable boon, and when added to the endowment-money makes enough for an old couple to live upon; but when, as often happens, the husband dies and leaves the widow deprived of the Biggs annuity, she may, and often does, find herself reduced suddenly to live upon 5s. or 6s. per week. Strongly feeling that no inmate of the almshouses should have less than 9s. or 10s. per week for maintenance, a few friends have subscribed together and have arranged that, for the next six months at any rate, such a state of things shall be remedied. Full investigation has been made in each case, and Mrs. W. H. Collingridge having received the promise of assistance from other ladies, has thus far kindly acted as almoner. This movement promises to lead to a systematic and friendly visitation of all the female inmates, which will result, we believe, in much good. We think that in every case where by the death of the husband the widow who remains in the almshouses has a less total income than 10s. per week, the next Biggs annuity for women should be awarded her.—*The Printing Times and Lithographer.*

Fall of a House in Oxford-street.—About half-past six o'clock on the morning of the 17th inst, the inhabitants of Oxford-street, in the neighbourhood of the Princess's Theatre, were greatly alarmed by hearing a tremendous crash. This was found to have been caused by the fall of the premises, No. 72, Oxford-street, adjacent to the theatre, in the occupation of Messrs. Cook & Burchett, goldsmiths and jewellers, which utterly collapsed. The building was a perfect wreck, and the stock of Messrs. Cook & Burchett, worth several thousands of pounds, is buried among the *débris*. Fortunately the inmates of the house had time to escape unhurt. It seems that a house on the west side of it had been demolished, to improve the entrance to the theatre (now in course of construction). To this is ascribed the downfall. The escape of the occupants appears to be due, under Providence, to their own watchfulness and energy. The aspect of the place the next day was terrible; joists and tables, partitions and chairs, "in one dread ruin blent." Such an occurrence, although fortunately no lives were lost, ought not to be allowed to pass by without a searching inquiry. Were the premises, after the removal of the adjoining house, insufficiently shored up, or had the foundations been tampered with? When we saw the ruins some of the adjoining premises seemed to us to be in a risky condition.

Art and Health at the Social Science Congress.—In the Art Department, the discussion on the first special question, "Ought there to be a School of Dramatic Art subsidised by private subscription, or endowment, or by the State?" will be introduced by a paper by Professor Fleeming Jenkin; and Mr. Hubert Herkomer, A.R.A., will contribute a paper on the second question, "How far would the revival of the old system of 'master and pupils' be of advantage, and tend to promote the growth of historical art in the country, and the fitting use of painting and sculpture in our public buildings?" Professor Jenkin will also read a paper on the following question in the Health Department, "What is the best mode of amending the present laws with reference to existing buildings, and also of improving the sanitary condition, so as to render them more healthy, having due regard to economical considerations?" And in the same department, the discussions on the special questions, "What are the best areas for sanitary purposes, and how far should there be a revision of the mode of electing and continuing the services of the officers under the Public Health Acts?" and "What are the means which should be adopted for the prevention of the pollution of streams, without undue interference with industrial operations, and for the preservation of pure sources of water supply?" will be opened with papers by Sheriff Spens, of Glasgow, and Dr. Stevenson Macadam, of Edinburgh.

University College, Bristol.—The new buildings in Tyndall's Park will be ready for use on the 1st of October. In the old buildings the complaints of overcrowding have been frequent, and must have materially hindered the progress of the college. But nothing will be heard of the complaints in future. The new buildings are, indeed, only a small part of what are required to complete the plan, but they do provide all that is necessary for health and for some degree of comfort. The experimental courses of instruction, those of chemistry, physics, and engineering, are to remain for the present in Park-row. The reason of this is that, as the new buildings would not give comfortable accommodation for all, it was thought best to retain in the old buildings the classes in those subjects for which separate rooms are required. Thus four rooms will now be set apart for chemistry, two for physics, and two for engineering. But in the new buildings each of the rooms will, as a rule, be used at different times of the day by several professors and lecturers. Thus five rooms will be made to do duty for mathematics, geology, zoology, botany, political economy, modern history, English literature, Hebrew, French, and German. But the same room will never be used for more than two hours consecutively; and all the rooms are 16 ft. or more in height, and are ventilated on Mr. Haden's system, by which the bad air is all drawn off into a high ventilating shaft; so that the students can feel that they are sure of always having a good supply of fresh air. The new buildings will be open to the inspection of the public for the first six days of October. Mr. Hansom is the architect.

Clerkenwell Workhouse.—The guardians of the Holborn Union have received a letter from the Local Government Board, stating that they had considered the proposal of the guardians to erect a new workhouse, clerk's offices, relief offices, and dispensaries, on the site of the old Clerkenwell workhouse in Farringdon-road (formerly Coppice-row). The Board say that they have given this proposal their most careful consideration, but regret that they are unable to concur with the guardians in thinking it desirable to provide on so small a site as that of the Farringdon-road Workhouse, in addition to various offices, accommodation for so large a number of paupers of the aged and infirm and acute sick classes as that proposed. It appears to the Board that on so limited an area it would be most objectionable to erect a building of such an unusual height, and to appropriate the five upper stories thereof to the accommodation of the classes of paupers above mentioned, the three lower stories being set apart for administrative and other offices. Moreover, the proposal includes in the lower stories an extensive washhouse and laundry, a kitchen, and a furnace room for the supply of hot water, &c., from which vitiated atmosphere would necessarily be conveyed, by means of the lift-shafts and staircases, to the upper part of the premises. The Local Government Board fully recognise the great care and skill which have been bestowed on the preparation of these plans; nevertheless, having regard to the large number of sick and infirm people whom it is proposed to place in so large a site, and to the fact that the site is partially appropriated to other purposes, the plans appear to the Board inadmissible. The Board feel that they have no alternative but to request the guardians to look out for a more suitable site.

Fever at Wormwood Scrubs Prison.—Evidence was given at a recent inquest that prisoners at Wormwood Scrubs have been suffering from typhoid fever, attributed to the pollution of the air by piggeries in the neighbourhood in a shocking state of filth. These piggeries have long been known and condemned, but their agency in the present case is by some denied. How is the prison drained?

Royal Institute of British Architects.—The last published part of "The Transactions," No. 12, consists of notices of deceased members, all foreign with the exception of the late Professor Edward M. Barry, and including J. P. Cluysenaar (Brussels), Pascal Coste (Marseilles), and Joseph Louis Duc (Paris). They are very well done, and very interesting.

Church Restoration at Sheffield.—The parish church of Sheffield, which has been closed for several months for the purpose of undergoing restoration, has been enlarged and beautified at a cost of 20,000*l.* The church will be re-opened on the 26th of October, when the Archbishop of York will preach.

Accident on the South-Western Railway.—When one accident happens others are always heard of. The terrible accident at Nine Elms on Saturday night (the 11th inst.) was followed by another early on Tuesday morning, on the London and South-Western Railway, between Brookwood and Farnborough, and about two miles from the former, which, however, was happily unattended with loss of life, though much damage was done to the rolling stock. The *Surrey Advertiser* says,—At a portion of the line near the Aldershot Junction, and close to Curzon Bridge, the Basingstoke Canal and the railway run parallel, and the canal being on a higher level they are separated by a brick wall, 12 ft. high and 300 or 400 yards long. The canal is being cleaned out, and in order to render the operations practicable was dammed up at this part. On Monday night the rain was very heavy, and, it is supposed, caused the canal embankment to give way. Nearly 40 yards of the wall was broken down by the sudden rush of water, and the *débris* fell on to the up-line, whilst the rails for some little distance were covered with about 9 in. of water. About half-past one the 5·15 p.m. up goods train from Yeovil, made up of an engine, two guards' vans, and upwards of thirty trucks, laden with general goods, one cattle-truck, carrying some eight or nine beasts, came along, and the night being very dark, the engine ran right into the fallen brickwork, being lifted bodily from the metals and sent on to the embankment, where it rested on its side. Twenty of the trucks, with one of the guards' vans, were also thrown off the rails.

The Art of Old Japan: its Uses and Abuses in England.—A lecture was delivered on Monday evening, at the Masonic Hall, New-street, in connexion with the Birmingham School of Art, by Mr. C. Pfoundes, of London (for many years resident in Japan), the subject being "The Art of Old Japan: its Uses and Abuses in England." Mr. J. H. Chamberlain presided, and there was a large attendance. The lecturer, in the course of his very interesting address, said, that the true Japanese art was greatly abused, there being in the imitations gross errors, not only of misconception, but also in the adaptation of Japanese design, resulting in one mass of heterogeneous incongruities, that had only the merit of being novel and "the fashion." There was nothing patchy or "scrap" in Japanese true works of art when they thoroughly understand the subject, but there was a great deal that was patchy and "scrap" in that copied Japanese ware which came from Stafford and Worcester. It was not desirable that they should become mere copyists, and he was not going to point out a royal road to pilfering novelties from an alien art while their own faculties were permitted to lie dormant. He appealed to them rather to take to heart a lesson from the Japanese, and rouse themselves to original thought, to the study of the great book that was always open before them, and, whilst carefully bearing in mind the precepts of their art instructors, to avoid blindly following paths they knew not of; to do as the Japanese had ever done,—train their minds, and exercise their natural faculties to be observant of the beauty that always surrounded them.

George Stephenson.—A marble tablet was placed with ceremony in the Turin Railway station on the 10th inst. to commemorate the fiftieth anniversary of the opening of the first railway between Liverpool and Manchester.

Wood-working Machinery in Australia. We notice that in addition to the medals awarded at the Sydney Exhibition, Messrs. F. W. Reynolds & Co., of Acorn Works, Blackfriars, have received a special prize at the Brisbane Exhibition.

Inner Temple.—The greater portion of the old block of buildings on the east side of Tanfield-court, Inner Temple, is now in course of demolition to make way for extensive additions about to be made to the library of this society. Plans have been prepared by Mr. Edis, and the works will be commenced immediately.

Tunnelling the Alps.—The boring of the Arlberg tunnel through the Alps is in active progress on the Austrian side of the mountain, and ground will shortly be broken on the Swiss side. The St. Gothard line in its entire length is expected to be in running order in April next.

Frome.—A stained-glass window has been placed in Holy Trinity Church, in this town, in memory of the late Mrs. W. C. Cruttwell. It is by Mr. Morris, and consists of one light, containing a full-length figure of St. John the Divine.

TENDERS

For erecting two warehouses at Homerton, for Mr. W. Chapman. Quantities not supplied:—

Tooley	£1,123	10	0
Trench	862	0	0

Williams & Son, Islington	4,446	0	0
Greenwood, Tooley-street	4,300	0	0
Roberts, Islington (accepted)	4,189	0	0

TO CORRESPONDENTS.

Dispute Between Architect and Builder.—If the case be precisely as stated, responsibility would not attach to the builder. A builder who carries out instructions given by specification and drawings, under the eye of the architect, and who, moreover, expressed his dissent from the course ordered, would certainly not be held liable for the consequences of that course. As to the second question, we may discuss it on some future occasion.

Centrolinead (information on this subject will be found in Mr. W. F. Stanley's Descriptive Treatise on Mathematical Drawing Instruments, p. 171, except that lines are drawn by the side of the drawing at right angles to the horizontal lines on which the studs are placed at equal distances apart. By fixing the arms with the rule on the horizontal line, of course they will exactly connect with this. To make them correspond with other lines to the same vanishing point may be soon attained by making the arms of more or less acute angles, always setting them on the horizontal line. It takes a practical draughtsman about a minute or so to do it).—J. M. S. (very few modern examples. Look to drawings of some of the Moorish remains. See court of the Alhambra at the Crystal Palace).—Constant Reader (should look to the published account of the memorial).—Juvenis (we cannot decide bets, though they do relate to sizes of buildings).—R. & R. (not in our journal).—W. S. E. (we do not remember it sufficiently).—Civis.—Competitor.—Mr. F.—C. E. D.—S. & B.—H. & O.—G. W. D.—H. J. N.—J. J. & Son.—S. F. C.—F. D. L.—O. S.—Constant Reader.—W. B.—J. U.—J. D.—J. S.—C. S.—F. E. J.—M. P.—E. L.—F. & H.—H. L.—R. G. M.—W. W. & Sons.—W. H. H.—P. J. W.—J. F.—J. T.—C. S.—W. & E.—H. W.—J. T. B.—G. V.—C.—W. O. B.—M. Bros.—F. H.

All statements of facts, lists of tenders, &c, must be accompanied by the name and address of the sender, not necessarily for publication.

We are compelled to decline pointing out books and giving addresses.

NOTE.—The responsibility of signed articles, and papers read at public meetings, rests, of course with the authors.

The Builder.

Architects and Sanitation.

CHARGES have been made against the architectural profession at the Sanitary Congress in Exeter, as well as elsewhere previously, which a large proportion of the profession will do well to consider seriously. It has been asserted, and the assertion has been accompanied by circumstantial statements, that certain buildings erected in quite recent years are no better off in sanitary provision than those of what may be called the pre-sanitation period: that buildings of a class which ought to have presented specially healthful conditions,—hospitals or convalescent institutions, public offices, and other large establishments of that description, built under the superintendence of architects of standing,—have been found so deficient in the requisite provision for, amongst other things, efficient drainage, that they have had to be closed, and the drainage system reconstructed within a very short period from the time of their being built, to prevent them from becoming institutions for fostering and spreading disease rather than contending against it. We have not the names of the architects given, and it is quite possible that if we had them, we might find they were not among those who are recognised as leading members of the profession; though we must not feel too sure even of this. When we hear, as we have done, of an eminent "art-architect" declining to visit the site of an intended house before planning it, as it was a matter of no consequence, we can hardly refuse to believe any statements of the kind we have alluded to on the ground of inherent improbability. It appears, at any rate, that there were recognised architects employed in the cases brought forward by Mr. Burdett in his communication, and that in two of these cases, at all events, the architect had unlimited funds at his disposal, and was free to do as he pleased. Yet we are told (and Mr. Burdett, a member of Council of the Sanitary Institute, made himself responsible for the truth of the statements) of drain-pipes beneath the building, soil-pipes inside, baths, lavatories, and sinks opening directly into the sewer, many of them untrapped; and no plans of the drainage existing. Drains laid with irregular falls, and in some cases falling the wrong way, formed other items in the indictment. This latter defect (one of very frequent occurrence) is, however, not one of those which in general can be rightly charged upon the architect. He, almost as a matter of course, will direct that the drains be laid with a 'proper" fall, if not a specific minimum fall; but for the observance of such directions he is necessarily at the mercy of workmen and clerks of works. An architect cannot examine and test the levels of all drains in a large building as they are laid; and if clerks of works are negligent, or if workmen will do things clumsily or dishonestly, the fault is with them, and not with the architect, who is entitled to expect at least a decent amount of common honesty and comprehension of their business on the part of the contractor's foremen and labourers, and proper attention on the part of the clerk of works to ensure that his orders are properly carried out.

In such matters as the latter, therefore, the architect may be, and often is, unfairly blamed for what is due in reality to bad or dishonest workmanship. But in regard to other charges brought in Mr. Burdett's paper, those which involve the employment of a right or wrong system in the contrivance of drainage, the architect is unquestionably the responsible person, and we fear he is in many cases very responsible indeed for a great deal which he ought to have prevented. We may say that we do not very much doubt the general correctness of the facts mentioned by Mr. Burdett in regard to the three specimens of building which he mentioned. It would, however, have been more thoroughly in the interests of truth to have specified the buildings by name, so that charges might have been met or answered where there was good ground for answering; but this might have made the reader of the paper answerable for libel in the eye of the law. A man making statements in regard to a case which is not named or defined is under great temptation to "put it strong," and to make charges in a sweeping manner which may in reality be only true partially and in detail; and we must allow for this in regard to the remarks we are now commenting on.

Statements such as those made were, of course, followed by a general abuse of architects, an amusement which sanitary reformers, editors, and leader-writers never want much encouragement to enter upon. We may be allowed to caution indignant sanitarians and their audiences, however, against supposing that all architects are ignorant or careless about sanitary arrangements, because very bad charges have been preferred against "some person or persons unknown" in the profession. In reply to the general persuasion that seemed to be adopted by the members of the Sanitary Institute, that the architects are at the bottom of all the bad drainage and ventilation, or are at best indifferent about it, we may be allowed to say that a large proportion of the sanitary reforms of the day were originally inaugurated in the pages of this journal, conducted by an architect, and that many of them were urged by us over and over again, through long years, in the strongest terms, before any notice whatever was taken of them. And if those newly-enlightened enthusiasts among the press and the public who think they are empowered to lecture the whole architectural profession on their duties, were to be a little more careful about facts and justice in their accusations, they would find that there is a proportion at least of the architects who are fully alive to the importance of sanitation, give it every attention, and are the inventors of arrangements bearing upon it. But they are always forgotten or ignored when the subject comes up, and the whole profession are attacked as if they were all alike indifferent to the subject.

This is certainly not the case, and it is only our duty to our natural clients, the architects, to say so plainly. But, on the other hand, we should be equally wanting in duty to them and the public if we did not also say that there is obviously among a proportion of the profession a lamentable and almost culpable indifference in regard to this important branch of practical architecture. The reason for this is, to a great extent, to be found in the turn for the picturesque in architecture which has been developed in so marked a manner of late years. There has been a curious series of changes in the way in which the practical and the picturesque have been regarded by architects at different periods. During the time when what we now call picturesque architecture was being produced,—when castles and monasteries were built,—the picturesque was probably hardly in the thought of the designer, in the case of castles more particularly; the building was simply the best that could be done, and the sanitary arrangements were probably also the best that could be provided with the slight knowledge and rude means which the period allowed. There is evidence that, in conventual buildings, great regard was paid to sanitary arrangements as far as the removal of refuse is concerned (though personal cleanliness may have been little regarded), and the very absence of our contrivances of traps and pipes obviated also some of the dangers against which we have to guard. In the flat period of architecture which followed the fall of Mediæval art, the picturesque, conscious or unconscious, for a while disappeared; but there was, during this period, more sound and honest building, on the whole, than at any other time, and the sanitary side of the question seems to have been properly taken into account still, so far as the knowledge of the period extended. In the present generation we find a conscious effort at picturesque architecture, combined with a frequent indifference as to sanitary provisions, at a time when far more knowledge and experience, and far better machinery, are available for sanitation than at any time previously.

The root of this indifference to so important a part of the architect's work is to be traced, we really believe, in a great measure to the taste for "picturesque" and imitative architecture which has possessed so large a portion of the profession, and which is much fostered and encouraged by the portion of the public who profess to have a taste. With those so influenced, architecture, instead of being the study how to build best for practical needs and for appearance combined, is the study how to turn to account a number of sketches from old buildings, and

how to realise their peculiar effect most faithfully. Those who make this the one object find a large public to encourage them in it, a public which is very indifferent how a house is planned, drained, or ventilated, so long as it presents the peculiar kind of picturesqueness which is desired; and a public which displays this taste can hardly complain if its demand is supplied, and must at least share some part of the blame with the architect, though it is true that the latter ought to endeavour to educate his public rather than be led by them; but that is easier said than done.

In short, the want of attention to sanitary conditions on the part of some architects is simply one of the many ill results of looking at and practising architecture from a radically wrong point of view, from the sentimental and not from the practical point. If the young architects who fill sketch-books with bits of picturesque building for "home consumption" would, before running after this ornamental part of the profession, however commendable in its turn, fill note-books with practical and sanitary observations; if they went abroad to see where to get hints for improving construction, arrangement, ventilation, and drainage, instead of merely to obtain new "notions" in the picturesque of gables and turrets, there would be some chance that the former would receive proper attention when the results of study came to be put into practice. As it is, the study is merely on the picturesque, and when facility in that has been acquired, sanitary matters have to be looked to as a more afterthought, or trusted to the experience of the builder. This sounds very hard, but we repeat that the public who demand the seeming rather than the real in architecture, and make no demand for sanitation, cannot reasonably complain if they get what they demand. But the remedy is that architecture should be regarded as it always was in the best times of its cultivation, as a matter of practical building in the first instance, and of beautiful expression in the second instance only. The idea of turning over sanitary questions to engineers or specialists, and leaving the architects in undisturbed possession of the picturesque, which has been suggested, is the very worst that could be entertained, and the most utterly suicidal thing which the architectural profession could do. People may get tired of the picturesque, or change their ideas and tastes about it; but they are likely to become increasingly exacting about sanitation, sound construction, and economic requirements; and these are considerations which will always remain the same. Let the architects be content to relegate the picturesque to its proper place, and direct their minds towards attaining well-placed, well-planned, well-built, well-drained, and well-ventilated buildings in the first instance, as the *sine quâ non*, after satisfying which they will be at liberty to look after the picturesque with a clear conscience. Unless they restore this true balance of professional work, and do it speedily, they will have reason to repent of their shortcomings; for the public are gradually being awakened to the pressing need of improvement in the sanitary construction of buildings, and they will insist on having it.

A Big Picture in Guildhall.—The Lord Mayor last week ordered a painting, 100 ft. long and 30 ft. deep, containing over 1,000 figures, to be hung in the Guildhall. It was painted by Sir R. Kerr Porter, and presented to the Corporation in 1819. Porter was born in 1775, and in 1790 obtained admittance as a student of the Royal Academy through Sir Benjamin West, then president. In 1792 the boy artist received a commission to paint "Moses" and "Aaron" for Shoreditch Church. In 1794 he presented an altar-piece of "Christ allaying the Storm" to the Roman Catholic Chapel in Portsea, and in 1798 he gave to St. John's College, Cambridge, a picture of "St. John preaching in the Wilderness." In 1800 he exhibited an immense picture, 120 ft. long, in the Lyceum Great Room, representing the Storming of Seringapatam, and in the same place, in the following year, another gigantic battle-piece, "The Siege of Acre." These were followed by a third colossal work, "Agincourt," which he presented to the City of London, and which is the picture now disentombed. Some years ago it hung in the Guildhall, where it is now again exhibited in three portions, and in a somewhat ragged condition. A committee has been appointed to consider as to cleaning and restoring it.

A NEW CHAPTER IN ART.

The discoveries made by Sir Henry Layard in Assyria and Babylonia opened up a new chapter in the history of art, and they have since been supplemented by the discoveries made in Cyprus, Phœnicia, and on the sites of Troy and Mycenæ. These discoveries have shown us that Greek art, long believed by some to be like its great patroness, Minerva, a full-born product of the land of Zeus, was but the culmination of a long series of art developments extending over centuries of time. Just as we see in geology some lofty table-land which seems, as it were, to be a huge altar of nature's God, built up layer by layer by the slow bricklaying of centuries, so the art which culminated in the divine sculptures of Phidias and Polycletus was but the last of a stratified series of art periods, each one developed from its predecessor.

The more we regard the discoveries of the last few years in almost every branch of research, either of the historical or natural sciences, the more we see the extent to which the law of development and evolution is applicable. The application of the doctrine of comparison, and the birth of the comparative sciences, is establishing each day more surely our knowledge of the laws which govern and guide the growth of art and religious culture.

Some two years ago * we pointed out the importance of following out the new evidence thus afforded to us of the westward spread of art and culture, and we indicated at the same time that there were other than Phœnician channels which conveyed the art, mythology, and civilisation, the "learning and wisdom of the Chaldees," to the shores of the Ægean sea and to the early seats of Greek civilisation.

The important explorations made by Dr. Schliemann at Hissarlik and Mycenæ have revealed to us the substrata of pre-Hellenic, and the first strata of Hellenic, culture which underlie the acropolis of Greek art. In these treasures of early Trojan and Greek art we find forms and modes of decoration similar to those current in Babylon, and evidently borrowed from the Chaldean artists. The presence in Greek mythology of legends of the gods and goddesses which are manifestly echoes of the mythology taught in the schools of the Babylonian prophets again is a point which needs explanation. Whence comes this similarity? Was there any historic contact? Is there a chain which connects Troy and Mycenæ to distant Babylon?

The ancient historians all agree in stating that long before Greek influence had penetrated into Asia Minor there had existed a comparatively high degree of civilisation among the states of the barbarians. The Teucrians, Mysians, Dardanians, the allies of the Trojans, were all skilled in the art of war, and were no mean contrast to the beleaguers of Troy. The Lycians, Carians, and the tribes of Solymes and the Cilicians had come in contact with the mariners of Sidon, and thus may have contracted many germs of culture; but in the interior of the peninsula, on the banks of the rivers Sangarius and the Halys, there were tribes who had developed some degree of civilisation, and attained to a fair standard of culture, as shown by their monumental remains. These were the tribes of Phrygia and Galatia, and the precursors of the Lydian empire. Whence came the civilisation of these tribes, and what part did they play in the westward spread of culture?

The annals of the kings of Egypt and Assyria, which have been recovered from the graves of buried temples and palaces, have not only restored to us the history of their own lands, they have also thrown much light on the history and civilisation of the neighbouring nations with whom they were brought in contact. These copious annals from temple and palace wall, from lengthy papyrus rolls and polygonal cylinder, are moreover, supplemented and illustrated by a vast picture-gallery of painted or sculptured tableaux, all of which help the more to bring before us the types and characters of those with whom the great kings warred. The long and accurately-compiled lists of spoil and tribute which defeated barbarians rendered to the conquering king furnish us with important data as to the products, both natural and artificial, of the lands of the defeated ones.

From these monuments we learn that more than eighteen centuries before the Christian era the highlands of Syria, the fertile districts to the west of the Euphrates, and the plains watered by the Sadjur, Ifrin, and the Orontes, with the slopes of the Amanus and Taurus mountains, were occupied by a powerful confederation of tribes. These people, known to the Egyptians as the Kheta, and to the Assyrians as the Kattai, are the Khittim, or Hittites of the Hebrew writers. They were a race who had been almost obliterated from the roll of history, and yet we find them a civilised and highly-cultured race, and no mean factor, not only in the politics of Western Asia, but also in the spread and development of civilisation.

The earliest record of these people is in the astronomical and omen tablets of the time of Sargon I., the king of Agane, a district of Babylonia. This monarch warred in Syria, and even carried his arms as far as "the land in the midst of the sea of the setting sun," by which we may recognise the island of Cyprus. Scanty as are the fragments relating to the history of this energetic and warlike king, we shall find that his reign was an important epoch not only in Babylonia, but in Western Asiatic history. From the Hebrew book of Genesis we learn that at the time of Abraham's settlement in the land of Canaan, the Hittites had a settlement at Hebron, and Abraham purchased the cave of Machpelah from Ephron the Hittite. The record of this transaction, as recorded in the twenty-third chapter of Genesis, is very important, as it would seem to indicate that contact with Babylon had left its impression in the adoption of the commercial code of Babylon. The minute specification of the land, and the details of purchase, read remarkably like the text of a Babylonian contract tablet.* The silver tariff, and the market-place being the gate of the city, all seem to indicate that Babylonian commerce, and with it the laws and precedents of trade, had been brought into Syria, and were familiar not only to Abraham, the native of Ur, but also to Ephron the Hittite. The chief city of the Hittites was the city of Carchemish, called by the Egyptians Qir-Qamash, and by the Assyrians Kar-Gamis or Gargamis. This city was situated on the Upper Euphrates, about ten miles above the month of the tributary Sadjur, the Sagur of the inscriptions, and on the west bank. The importance of the site was first recognised by Mr. Skene, the English consul at Aleppo, and afterwards by Mr. George Smith, upon whose recommendation the trustees of the British Museum commenced a series of explorations of the site, which have brought to light many antiquities of the Hittite founders. The modern name of these extensive ruins is Jerablûs, a name which is manifestly a corruption of the Greek name of the city, Hierapolis, "the sacred city" of Atargatis, the Asiatic goddess. The ruins are over 8,000 ft. in circumference, and there are distinctly to be traced the walls, gates, and citadel or acropolis, all marked by lofty ramparts of earth, the graves of fallen Carchemish. The city was bounded on two sides, the north-east and south-east, by the broad stream of the Euphrates, which washed the quays, now some distance from the water, owing to the rapid growth of the alluvial. The city was protected on the land side by lofty walls and gateways in the strong flanking towers. In many respects the site chosen is one admirably fitted to be occupied by a great city such as the Hittite capital was. The river affords a broad highway, down which passed the rich mineral and other products from the regions of the upper Euphrates. At Carchemish was gathered all the wealth of Syria, Phœnicia, and Asia Minor to be transmitted by the Euphrates to Babylon and the cities of the Chaldees. Here a mile or so south of the city is the ford where the caravan which passed to Nineveh and the cities of the Tigris crossed the stream, and from its position we can plainly see how fitted Carchemish was to be the emporium of Syria. Not only from the above considerations is the spot fixed on suited to be the seat of a great city. From a military and strategical point of view, few sites were better fitted to be the capital of a nation. Situated as it is on a promontory jutting out into the Euphrates, from its lofty Acropolis which towers a hundred feet above the water, an extensive view is obtained of the course of the river and of the country on either bank. An inspection of the ruins at once shows them to be the work of a people who were skilled not only in offen-

* See vol. xxxvi., p. 1161, "Syrian Archæology."

* There are contract tablets dated in the reigns of Eriaku (Arioch) and Kudur Lagamar (Chedorlaomer) in the British Museum.

sive but also in defensive warfare. The most important feature in the topography of the city is the mound-built Acropolis, which is on the north-east face of the city. It is interesting to find these mound-built citadels forming so important a feature in the topography of the Hittite cities, as we have long been familiar with them in the plains of Babylonia, where in every city they are to be found; and we may suppose that in both systems of building they had a similar origin. In Babylonia we know they were the work of the Akkadai or mountaineers, who, when they descended to the plains of Babylonia, built these lofty towers in remembrance of their mountain home, and there are many facts which lead us to assign a similar origin to the towers of the Hittites. Excavations on the sites of most ancient cities, such as Troy, Mycenæ, and others, have shown that, as in geology so in archæology, the *débris* is, to a certain extent, deposited in regular strata. We referred to this in a former article, and suggested that when explorations should be made on the site of the Hittite capital we should find ruins of many occupants. The city, whose foundation was probably as remote as that of Nineveh, has had for its occupants and possessors almost every one of the great nations of antiquity. Egyptian and Assyrian, Babylonian, Persian, Greek, and Roman, have planted their banners on the walls of the city, and each has "thrown down and dug up" the palaces and temples of his predecessors. It is, therefore, not surprising that we find the ruins of a most chaotic nature. Standing within the inclosure, the ruins can be described by no other term than "confusion on confusion heaped." Here an open excavation reveals to us the relics of the early Hittite founders, in quaint bas-reliefs; close adjacent are the bases of Roman and Greek columns, and the remains of an ancient Arab town cover a portion of the ruins. Amid such a sea of *débris* no plan can be traced with any degree of certainty, but, nevertheless, excavations have shown that through all disturbances, relics of the Hittites have been preserved to tell of those who, centuries ago, built on this spot the "city of Kemosh."

To pass now to the excavations which have been made, and to relics of the past which have been recovered. The chief and most extensive excavation has been made on the south-east face of the great mound, a short distance from the base, and within the *enceinte* of the city. Here the workmen have laid bare a long narrow corridor resembling those in the palaces at Nimrod uncovered by Sir Henry Layard. The portion uncovered is about 60 ft. long, and from 18 ft. to 20 ft. in width. It appears to have been a long flight of steps leading down from the palace mound to the city. The west wall can be distinctly traced by the plinth which remains, and on which some sculptures are still found *in situ*. The east wall has been destroyed, and many fragments of broken and crushed sculpture are found on that side of the excavation, but the line of the wall could not be traced. Near the southern extremity of this corridor a doorway is found in the line of the east wall which admits into a small chamber only partly excavated, in which is a fine sculpture standing on its plinth. Before proceeding to describe the sculptures found in these excavations, it will be necessary to say one word about the material used. In the majority of cases these Hittite sculptures and inscriptions are cut in hard black basalt, which has been brought from considerable distances. The stones bearing the so-called Hamathite characters, found at Hamah, the sculptures at Carchemish, with two exceptions, and the work at Tel Arjad, the ancient Arpad, as well as the Hittite remains at Eyuk in Galatia, are all cut in this hard stone. The cutting is of a peculiar character; it does not present an appearance of tooling, and there are but few marks of the chisel; the stone has a peculiar pulverised appearance. This is especially noticeable in the inscriptions which are cut in relief. As there are now examples of this sculpture in the British Museum, it may be of interest if they were examined by some expert, as they certainly exhibit a surface-working different to any yet seen. It is strange, indeed, to note this preference for the hardest material which is exhibited by the monument-makers of primitive nations. The Egyptians present us with the Sphinx carved out of solid granite, so hard that the best English tools turn upon it. The early Babylonians cut statues in black basalt and black granite of the hardest possible texture. The great statue of Gudea, one of the earliest kings of Babylon, whose date is probably nearly contemporary with the reign of the eleventh Egyptian dynasty, is carved in solid basalt, so hard that after more than four thousand years of wear hardly a character in the inscription is illegible. Among the sculptures at Carchemish are two cut in limestone, but there does not seem to be any difference in date of any great importance between the art periods of either class of sculpture.

The first sculpture to which we will direct attention is a large limestone bas-relief, measuring 9 ft. by 7 ft. 6 in. when perfect, but now unfortunately broken in half. The sculpture, when perfect, represented two figures,—deity, and an attendant priestess who adores or worships the goddess. We see here a very interesting tableau, evidently illustrative of the worship of the great goddess of Carchemish Dea Syria,—Atargatis or the Asiatic goddess. This is evidently the Hittite goddess whose name is given in the treaty between Rameses II. and the Kheta as "Astartha of the Kheta." The figure is nude, and full face to the spectator. The goddess wears the Hittite headdress, which consists of a lofty conical cap, the apex of which is decorated with a horned crescent, and in some cases with the solar disc in the centre of the crescent. From the shoulders rise a pair of wings. The hair is braided in two long plaits, and falls over the breasts and shoulders. The arms and hands are well carved, and the latter support the breasts of the goddess, which are represented as full. The face is much mutilated. The priestess who ministers to the goddess is represented as clad in a long kind of robe, which covers the head and the body, being confined at the waist by a girdle. This dress appears to have been the ordinary costume of the Syrian or Hittite women, as we find it frequently represented in the Assyrian sculptures.* The girdle which circles the waist is the most curious feature in the sculpture. It consists of two cords, or a double cord, which circles the waist, and is fastened behind. This was evidently the sacred cincture or girdle of the priestesses who were dedicated to the worship of the goddess. Both the priestess and goddess wear long locks and bracelets on the arms. The sculpture now recovered explains the source whence came the cult of the Asiatic goddess which the Greeks found established in Asia Minor, and which they identified with the worship of Artemis. The chief centre of this worship in classic times was Ephesus, where the Ephesian Artemis, Diana of the Ephesians, had her temple. It has long been known that originally the cult had its origin in Babylon, in the worship of Anat, or Anatis, the consort of Anu, the Babylonian Zeus. In her temple at Babylon we learn from both Greek† and Hebrew‡ writers that the women sat in the courts with cords about their waists, and burning bran,§ awaiting release by sacred prostitution from their vow to the mother goddess. It was this distinctive cord which we see worn by the priestess of the goddess here represented. Istar, "the goddess," was the daughter of Anat, and in time usurped many of the attributes of her Babylonian mother. Under the Assyrians, however, the worship of Istar received a mythology far more elaborate than either that of Istar of Babylon or Anat, and many of the stories which were current of the Phœnician Astarte and the Cyprian Venus were of Assyrian origin, and essentially related to Istar as the goddess of love and pleasure.

Still, however, we find Istar intimately relates to one important cycle of Babylonian legends, namely, the stories of the hero Gisdubar, of Nimrod. In her war against Gisdubar and the chieftains of Erech we have a proof that she was the soldier queen. In this character she appeared to Assurbanipal, and presented him with the sacred bow which was to lead him to defeat his enemies. Here she resembles very closely the Amazon queen, Omphale, the companion of Heracles. We now see, by this brief *résumé* of the myths of Istar and Anat, the importance which this Hittite sculpture receives, because, by its presence, we may consider that, as the worship of the Babylonian goddess came to Carchemish, so did many of the myths relating to her.

The question now arises, what historic connexion is there between the Hittites and the tribes of Asia Minor, which would lead us to assign to them the introduction of the worship of the Asiatic goddess into Asia Minor?

In the reign of Rameses II., the Sesostris of the Greek writers, a powerful confederation of Syrian and Western Asiatic tribes opposed the advance of the hosts of Egypt through the gateway of North Syria, the valley of the Orontes and Litany. From the Third Saltier Papyrus,* we gather an account of the great battle which took place near Kadesh, and ended in the total defeat of the allies. The papyrus also gives us a full catalogue of the forces of the Hittites and the allies. We have "the chief of the Airatu, the chief of the Masu, the chief of the Iruna, the chief of the Leku, the chief of the Tautani, the chief of the Kaskash, and the chief of the Kairkamash and the Khirahn, the allies of the Kheta all banded in one, 2,500 chariots"; and from other fragments we learn that there were the tribes of Patasu, Asi, and the land of Maton.† The researches of M. Lenormant and the Vicomte de Rouge have done much to identify the people who thus were allied against the Egyptian conqueror. We find the Arvadites (Airatu), the Mysians (Masu), the people of Ilion (Iruna),‡ the Lycians (Leka), the Dardani (Tautani§), the people of Asos (Asi‖), and Pedasos (Patasu), with the Matieni (Maten‖). These are the tribes which we see united with the Kheta, the people of Carchemish and Helbon (Khirabu). This identification would seem somewhat uncertain were it not substantiated by an interesting monumental discovery that proves the presence of the Hittites in Lydia, near Sardis. During a tour in Asia Minor last year, Professor Sayce saw on one of the pseudo Sesostris which are carved on the rocks in the woody pass of Karahel, on the road between Ephesus and Sardis, an inscription written in curious hieroglyphic characters. The inscription consists of seven characters, and of these seven six are to be found on the monuments from Carchemish. There are two of these figures, but on only one does the inscription remain. Herodotus records these statues, but the good and credulous old man seems to have confused his notes regarding them. He states with regard to the statues that he was unable to tell who had erected them until he came to Egypt, then all was made clear to him, and he assigned them to Sesostris. Oh, strange reversion of fact, when archæology now proves them to have been erected by the opponents of the mighty Egyptian, the vile Kheta or Hittites. A broken bas-relief of Hittite soldiers and a figure of an archer in the British Museum, all from Carchemish, furnish every detail of the statues at Karabel. The conical or Phrygian head-dress, the turned-up shoes, the short kirtle, and the peculiar form of bow, are all found in Carchemish sculptures. Thus on the very meeting-ground between Greek and Asiatic culture we find a statue of these Hittites, whose capital was one of the chief seats of worship of the Asiatic goddess.

From the classic writers we know that the Ephesian Artemis was represented as having many breasts, and to which were represented clinging lions, cows, stags, bees, and crabs. This was but an exaggerated form of the full-breasted "mother goddess" of Babylon, whose statue we find at Carchemish. Many statues of this goddess are found in Babylon, where they were deposited as *ex votos* in the temples of the goddess. The whole cultus of the worship of the "Asiatic goddess," or of the Ephesian Artemis, exhibits many peculiar features, all indicative of its non-Hellenic origin, but none are more striking than the strange construction of the hierarchy attached to the temple of the goddess.

From Pausanias¶ we learn that the chief priest attached to the temple of the Ephesian goddess had the title of Essen (Εσσήν) "the king bee," while the priestesses, the prototypes of the Amazons, had the title of Μέλισσαι, "the bees."

It is evident that this hierarchy was a sur-

vival from pre-Hellenic times, and we see that it has left its mark on the art of Ephesus, by the bee, as the sign on the coins of that city.* Many attempts have been made to explain the origin of this hierarchy and symbolism, but, until now, no satisfactory explanation has been afforded. The discovery of Hittite art and inscriptions as applicable to the early civilisation of Asia Minor has afforded us a solution.

It will be remembered that one of the most interesting, and, at the same time, most prolific classes of Western Asiatic art remains are the small engraved cylinder signet seals.† From Babylon, Nineveh, Phœnicia, and Cyprus we have obtained examples of this class of art-workmanship. Among the specimens of this work in the British Museum are some of Hittite persons, probably merchants trading in the marts of Assyria. In the possession of Signor Tomassini, at Aleppo, there are several very interesting specimens of this class of gems, and as these have been mostly obtained from Arabs and merchants in the locality, they are the more important.

The gems have been arranged in three classes, Babylonian and Assyrian, Phœnician, or composite. There is a class of these gems which exhibit a curious blending of the styles of art in vogue in both Egypt and Assyria. We find this incongruous fusion of the arts of two or more countries chiefly in the gems of Phœnician origin, and examples of these are found in most museums. Some very curious ones were discovered by Gen. di Cesnola in Cyprus. In this class of gems the skill of the artist would seem to have been employed to the utmost extent in producing as strange and *outré* a mixture as possible. In one case a Babylonian cylinder has been the basis, but Egyptian griffins and figures have been introduced into the scene, and by a process of conventionalising a cuneiform inscription has been turned into an artistic border. In another example an Egyptian inscription is treated in a similar manner. It has been usual to class all these complex or mixed style seals as the work of Phœnician artists, as we know they were in the habit of producing most bizarre fusions of styles to suit their patrons, as shown by the bronze bowls from Nineveh, Cyprus, and Palestrina. But some of the gems in Sig. Tomassini's collection exhibited symbols and forms not hitherto met with in their class, and thus furnished us with a new division. Several of the seals contained scenes illustrative of the adventures of the goddess Istar, the type of the Hittite Astartha. In one we see the goddess nude, with pendent locks and hands supporting the breasts, standing on the back of a couchant bull. She is placed in a species of shrine, above which is the winged solar disk; on either side stand a priest and priestess in adoration. The priestess is clad the same as the figure from Carchemish. She has the long locks, and the sacred girdle showing her dedication to the worship of the goddess. The figures here are almost exactly similar to those met with at Carchemish. We now pass to a second gem of Hittite origin. In this we have represented the adoration of the sacred tree,—the palm in Babylonia, the pine in Assyria and Syria. Here the tree is represented with the winged solar disk above it, and a group of attendant priests, priestesses, and worshippers attend it. The priest wears the lofty head-dress similar to that worn by the goddess at Carchemish, and by the Pseudo-Sesostris at Karabel. He has turned up shoes, and *is standing on the back of a bee.* It will be remembered that one of the forms of worship which the Asiatic goddess assumed was that of Cybele, whose worship, like that of the Ephesian Artemis, was of pre-Hellenic origin, and whose great temple was at Sardis. As the nature goddess, the Asiatic "mother goddess" had the tree for her symbol, and the early statues of the Ephesian goddess were the trunks of trees, and her shrine in the hollow tree; while Atys, the Phrygian and Lydian Adonis, who offended Cybele, was changed by her into a fir-tree. Again, we note that the early statues, or symbols, of Ashtaroth, the Sidonian goddess, were pillars of wood or trunks of trees. We therefore find here in the Hittite country a seal representing one important phase of the worship of the Asiatic goddess as current at Ephesus under the form of Artemis, and at Sardis as Cybele, while the symbol of her priesthood is that of the Hittite priesthood. The discovery of these art-remains opens up a new chapter in the art of pre-Hellenic Asia Minor, and throws new light on the discoveries at Troy and Mycenæ.

We are not going to review the war which has raged over the heads of Hera-Boopis and Athene Glankopis, but there are some points connected with the worship of the former on which these new-found Hittite antiquities throw additional light.

We have shown that the worship of the Asiatic goddess was a compound of the two systems of Anat and Istar, which had been blended by the Hittites into one, and those myths relating to either goddess became the property of the Asiatic goddess. Hera, the wife of Zeus, corresponds to the Babylonian Anat. In the war between the gods and the giants, when the former took the form of animals, Hera took the form of a white cow.*

When Istar waged her war against Gisdubar, the Babylonian Hercules, the father of giants, Anu and Anat created for her a bull which should destroy the hero.† In the gems, both Babylonian, Assyrian, and Hittite, we find Istar represented standing on the back of the sacred bull. In the temple of the Asiatic goddess at Eyuk, in Galatia,‡ the bull appears as a symbol. In Mycenæ, the seat of the worship of Hera, Dr. Schliemann has found a fine work of art in the head of a bull,§ and also a number of statuettes of Hera, with full breasts and a polos on the head. May not this worship have had its origin in the assignment of the bull as a symbol of Istar, and he a survival of the bull created for her by her mother Anat, the Babylonian Hera? At Ilion, again, the cow or bull-headed emblems of the Asiatic goddess were found by Dr. Schliemann. So it may be that the Iruna, or Inana, allies of the Kheta, may have borrowed the symbol from them. Among the objects of tribute received by Thothmes III. from the Kheta was a "silver vase in the shape of the head of a bull."

The stag, the emblem of Artemis, and, possibly, the descendant of the gazelle, which attends the Babylonian Istar, appears on the whorls found by Dr Schliemann at Troy, as does also the fir-branch pattern found on the robes and in the inscriptions from the Hittite country; while on the seal found by Dr. Schliemann, at Mycenæ, we have an interesting representation of a feature in the cult of the Asiatic goddess; but this will be best considered when, in another article, we deal with the questions of the introduction of these legends into Asia Minor.

On the data which have thus been gathered from the art-remains furnished us by explorations in Carchemish and other primitive cities, we may conclude that certain phases of Babylonian and Asiatic culture were communicated to the Greeks by other channels than the Phœnician,—by whom, and through what channels we hope to consider in our next article, which will form the continuation of this new Chapter in Art.

* Head's Coins of Ephesus.

† The cylinder seal was introduced in Egypt about the time of the 12th dynasty, and was probably of Asiatic origin.

* Ovid, Metam. v. 330.

† In the sixth legend or labour of the hero Gisdubar (W. A. I. iv., pl. 45).

‡ See Perrot and Guillaume, "Exploration de la Bithnye et de la Galatie."

§ The head discovered by Dr. Schliemann is undoubtedly that of a bull, not a cow.

A PATRICIAN VILLA.

Perhaps few more remarkable instances of the successful collaboration of the architect, the painter, and the sculptor,—a custom of the past too much neglected in the present day,—exist than is to be found in the Villa Barbaro in Venetia; for here the sister arts have all combined to produce that general effect which it should be the endeavour of every work of art to attain.

The Villa Barbaro is a building not unfamiliar to many members of the profession: it has more than once been cited as a specimen of the luxurious life led in the sixteenth century by the Venetian nobles; not a "villa" such as seems to be the ideal home striven at by successive generations of builders for the residence of equally successive and successful generations of honest *bourgeois*, but a villa many of whose practical features are worthy of consideration and adoption at a time when it is evident in every city that the number of persons who desire to live out of town is largely on the increase.

It is at no great distance from Venice, this villa of which we speak, and only a comfortable drive from the town from which we at present write, on the fine old high road which runs from here to Montebelluno, and so into the Venetian mountains, on whose southern slopes the villa is delightfully situated.

Nor is the approach less enchanting as one reaches the skirt of the plain and gradually ascends. When the visitor has left the gently-rising hill of the dark and now bare Montello, he spies in the distance, duly pointed out, the villa at Maser. It is a luscious country side, for here are the vineyards that produce the famous Rosolio, which the last generation held in such esteem. Soon appears, growing more and more distinct, the villa Giacomelli, the gardens, surrounded by their low walls, adorned with numerous statues, the hill-side covered with trees and vines, from which peep out here and there the white houses of the peasants, forming a landscape so varied that the mind and eye alike are charmed with the skilful union of nature and of art. In the midst of this ideal scene one is carried back in imagination to the period when Paul Veronese, Palladio, and the humbler, though no less gifted, Vittoria, aided by Marc Antonio Barbaro, were completing their united work. Andrea Palladio had drawn out the plans, had guided and inspected all the architectural portion of the work; Alessandro Vittoria had wielded his skilful chisel among the varied ornaments; and Paul Cagliari had beautified the walls with his master hand.

From the extraordinary pleiad of artists which Venice in the sixteenth century contained, Marc Antonio Barbaro and his brother Daniele, the patriarch of Aquileia, — that intensely Roman colony to whose past grandeur the modern town, or rather village, offers as striking a contrast as perhaps exists,—had chosen Paul Veronese, Palladio, and Vittoria to build and decorate for them a villa in the Venetian hills, and the work promised additionally to be a masterpiece of taste and design, for both the patriarch and his brother were fervent patrons of the arts; Daniele had, indeed, translated and commented on Vitruvius, while his brother Marc Antonio possessed no mean plastic powers.

The spot chosen for the erection of their villa by the brothers was on the southern slope of the last range of Venetian hills, the very range of gently undulating eminences on which the old town and castle of Asolo are situated.* It was a lovely spot, with the shallow blue Piave placidly flowing past on its way to the lagoons at no great distance, at the foot of the then well-wooded Montello, and slightly raised above the dead level of the great Trevisan plain. Here more than once the patriarch and his brother must have come to reconnoitre the future situation of their pleasant summer dwelling, in company with Palladio and Paul Veronese, whose handsome dogs gambolled round him, or followed the exciting scent of some frightened hare, disturbed in this then almost untouched solitude.

At length, after all due consideration, the site was settled, for no hasty affair was then the building of a house, and soon Palladio and his band of men were hard at work. Their first care completed,—the cutting in the hill-side (on which the site had been chosen) of a large step, so to speak, the height of the first story,—the house was built on this in such a manner that both stories had one side at least on a level with the ground, the first on the front, the second on the rear.

To the south, the sun darting his genial rays directly on the façade, the warmth and light were concentrated in the autumn days. To the north the shadow of the house was thrown upon the hill-side, protecting it from the sun, and here in the midst of the greenest and freshest grass plays the sparkle of the fountain, refreshing the whole air around. In this ingenious manner warmth was obtained on the cold days, and cool shade for the hotter; and so successfully has this intention been carried out, that while before the house rise, in summer, in all the varied and delicate shades of their green, the oleander, the olive, and the aloe, in the rear of the house prosper more than one retiring and shade-loving plant, and thick moss brightens the trunks of the dark green pines, wandering through which, by the paths winding amidst the overarching trees, one gradually ascends the mountain-slope, at whose summit lie stretched before one the superb panorama of the whole of the Venetian hills and the great plain far below.

* See *Builder*, vol. xxxvi., pp. 1166, 1259; and vol. xxxvii., p. 385.

Nature and art thus agreeably called upon to help each other, Palladio's next duty was the disposition of the interior in accordance with the varied needs of villa life, the apartments for the family, for the guests, for study, and for general gathering; then the arrangements for the out-houses, the kitchen, the pantries, the servants' rooms, the cellars, the granaries, the stables, and the hay-loft. Each was situated by Palladio's care with due regard to the requirements of all. Pure water from the mountain springs was conducted to the kitchen for domestic use, whence it was led partly for purposes of irrigation, partly to the well-stocked fish-pond. The principal building he extended in the form of a cross, so as to obtain a large room from which the whole panorama of mountain and plain scenery could be enjoyed. Externally an Ionic character was given to this; and flanked with two galleries, through which runs a long file of rooms; each gallery is terminated with a pigeon-cote, completing the design and harmonising with the whole, the charming occupants enlivening the scene by fluttering round in clouds or grouping cooing together on the cornices. Nor is the interior less grandiose than the exterior; the cruciform *sala* is lighted with ample windows, to the south overlooking the wide space of the plain, on the north looking on to the towering mountains; and a semicircle in the midst of which rises a Neptune's grotto and a fountain ornamented with various figures and *jets d'eau*, which play upon the flowers and grass around. At the same time as the villa, was erected the temple or church which meets the eye at the entrance, further decorated with fountain and statues, with festoons of flowers and fruit modelled and chiselled by the fantastic hand of Vittoria.

Palladio's work completed, his friend, Paul Veronese, came in to decorate the wall-spaces he had left him for his designs, and there we may imagine the figure of the painter of the "Marriage of Cana," on the simple scaffolding, with masterly decision, placing on the walls those superb colours which infused such life into the inventions of his genius. The magnificence of the Barbaro family, the sumptuousness of their dwelling, the criticisms of Palladio, Vittoria, and Marc Antonio, awoke in him all his best powers, and his facile brush peopled the walls of the villa at Maser with all the mythical personages of poetry, with loves and nymphs, and gods and goddesses, and flying Cupids perched upon the cornices, showering flowers heaped high in their rosy laps; overlooked by graver figures, Nobility, Power, Honour, and Magnificence, emblematical of the family of the Barbaro; Flora, Bacchus, Ceres, and Vertumna, representative of the products of the soil; the elements personified; and the rural arts, all ending to the joyous country life.

In the great *sala* are eight figures in various positions; these Count Algarotti has believed to represent the Muses, while between the columns may be seen, placed there as if by chance, lances and numerous other arms. From half-opened doors peep at one persons who seem alive. On the chimney-pieces, huge as furnaces, are heaped, in painting, various mythological groups; in each room new pictured marvels strike one, of that luxuriant taste which squandered magnificence on everything it touched or used; superb stuffs, scarlet velvets, golden cups, chiselled ewers, vases of perfumes, pearls, gems, flowers, fruits, and leaves adorning the hair, the bosom, and the arms of his lovely painted dames, resplendent in their decorous nudity. The painter loved contrasts, and he employed them with judicious skill, and more than once by the side of muscular heroes, with their rugged features, we see placed the graceful form of some pale goddess. But it was to the painting of the Olympus that he gave especial care, and here has introduced, with all the wealth of colour of which he was so profound a master, the most familiar of the numerous gods and goddesses.

While thus the architect, the decorator, and the sculptor were intent on their several portions of the work, the owner of the house, Marc Antonio Barbaro, was modelling the statues which were to figure in the fountain of Neptune; and when the evening sun set under the dark-blue haze of the horizon, in the direction of Padua and Vicenza, the workers met round the hospitable table of their host, and it is not difficult to imagine how the cultured wit flowed under the excitement of the honest wine of the hills, and more than one sharp Boccaccio-like jest must have waked the laughter of the group.

Many generations have passed away since those friends and professors met, till at length the gorgeous Villa Barbaro fell into the hands of the last Doge of Venice, the unfortunate if not guilty Ludovico Manin. Here this ruler of the already defunct republic enjoyed a few years of happiness; but after his death, the villa fell into hands, alas! unworthy of its possession. The abandoned home fell to pieces, the fountains played no more, the fire in the noble hearths died out. The loves and nymphs and all the gods of Olympus vanished under a thick veil of dust, and the descendants of Arachne, and Mahomet's kind spider friend, spun their magic nets across and over the beautiful cornices and statues; the squalor of neglect threw its curse over the abandoned house, and as the twilight descended, the bats flitted capriciously round the shades of Andrea, Paul and Alessandro, with their patron Marc Antonio, still sitting round the silent table.

But human vicissitudes are obliged to follow the stern laws of nature, and after the long darkness of ignorance broke the day-spring of appreciation. Signor Giacomelli purchased the Villa di Maser, and, making it his home, restored to his country and the world a precious jewel of the art of the new learning.

A new colony of artists met again at Maser; the dust and cobwebs disappeared, the gods of Olympus shone out again in all their glory, and in every part the villa was restored to its original freshness. Angelo Giacomelli, entrusted by his uncle with the supervision of the work, prevented any touch of Paul Veronese's hand from being injured, and the work was simply washed, re-appearing in all its original beauty, though mellowed, as one would say of ordinary pictures, but of frescoes, chastened by the patina of time.

Again the gardens shone with flowers, among which played the old fountains; the hills were planted with new vines, and the orchard resembled its description by Palladio, when it was "full of the most excellent fruits and various shrubs." The doves returned to their nests; again the welcome flame shot up in the old kitchen-fire; new artists sat round the table of the new proprietor in the room hallowed by the memories of their more famous predecessors, to whom they drank more than one toast, rendering homage to the intelligent generosity of those who employ nobly their wealth, restoring to works of genius their antique splendour, and thus causing to re-flourish those fine arts which act so potently in refining the manners of a nation, and in making life agreeable.

Treviso.

EMPLOYERS' LIABILITY AND WORKMEN'S SAFETY.

We have recently been silent on the subject of Employers' Liability. Our silence has been due, not to any undervaluing of the great importance of the question, nor yet to any hesitation as to the counsel we might have been able to offer, but to the fact that the discussion had passed into another arena than that of literature, and that one in which other considerations than those of calm reason were for the time but too likely to be predominant.

Now, however, that the strife of party has, for the moment, been brought, as far as regards legislation on this subject, to a close, and that a new departure is attempted by certain self-styled advocates of the interests of labour, without waiting to test the outcome of the change really effected in the law, silence is no longer needful, nor we think, altogether becoming. If the steady and wide-spread support which is given by so many members of the industrial classes to the *Builder* be a source of satisfaction to us, it imposes on us, at the same time, the weight of a great responsibility. And all the more confident do we feel that the disinterested, and we trust consistent, advice of an old friend will have more permanent weight with our industrial brothers than that of any violent advocate of extreme and one-sided courses.

The point now before us is the attempt made to induce the working-men so to deal with this new position as to make it only a step in a course that is based on the dangerous fallacy that the interest of the owner of live labour is opposed to that of the owner of stored-up labour; or that, in any trade, the interest of the workman is opposed to that of the employer, or should be urged without any regard to the effect it may have on that of the latter. Any counsel or any action based on this dangerous fallacy can only, as far as it has any effect at all, have an effect altogether disastrous.

In the discussions that have so widely taken place as to the mode of adjusting fairly the subject of the liability of the employer in case of injury to his servants, it has not, as far as we are aware, been brought forward with proper clearness that two totally distinct principles are involved in the question. These are, that of penal infliction, and that of compensation for injury. Each demands attention; but when the two are, as has hitherto been the case, jumbled together, it is little to be wondered at that accord between the different parties concerned has been found to be so difficult.

We are not of opinion that penal infliction is altogether an evil. On the contrary, although the cost to an employer of any serious catastrophe in his works is in itself a penalty for want of care, we think that the law cannot be altogether indifferent to the protection of human life and limb, and that its protection should be afforded to the workman, not only in giving him compensation for injury, but in directly punishing neglect. In the same way should that neglect be punished if it be that of the workman himself. Thus in any case of the conduct of large works under inadequate precautions, or with inadequate machinery, as well as in any case of disobedience to precautionary orders, we think penalty should follow. We would punish the owner of a mine who used a rope when it was no longer safe, just as we would punish a miner who unlocked a safety-lamp in a fiery mine. And we should rejoice to see an efficient penalty inflicted in each case, or in any similar case, entirely irrespective of the question whether any serious mischief did or did not ensue from an act of negligence or foolhardihood. And thus far, we think, the law should be penal.

On the other hand, as to the compensation that should be given in any case of injury to the sufferers, the question of penalty must be laid aside. Not, as we before said, absolutely; for it should be settled on its own merits. But as far as the provision of the compensation itself goes, the only question is, How shall it be made most easy, most adequate, most certain, and most just?

It is certain, whatever any one may say to the contrary, that all such compensation must ultimately come from one source,—the profits of the trade. From no other quarter is a penny to be expected, except from the ever-flowing and sometimes much-abused fountain of public charity. But the pension of the wounded, the widow, or the orphan; or the compensation,—whatever be its form,—to the sufferer by an explosion, or collision, or any other casualty, must come out of the profit of the business in which the sufferers are engaged.

This simple fact is overlooked by those who now hastily counsel workmen "not to consent to contract themselves out of liability." Such counsel is surely, in the first place, premature. It would be time to give it, if any proof were at hand that injustice is meditated. Above all, it is narrow and short-sighted, because it looks at only one portion of the question. It is based on that most false of all assumptions, that in any particular trade a certain quantity of work *must* be done, and that the workmen, by declining to work more than a certain time for a certain pay, can fix the price of their work. No view can be more Utopian, more idle, or more false. Insurance, some of the friends of the workman say, will be a tax upon wages. But the rate of wages will not depend on whether they are nominally taxed or not. The net wage,—that which the man will receive clear of all deductions,—will depend on two things, and, in the long run, on these alone. These are, the profit of the trade, and the relation between the labour offered and the labour supplied in order to carry it out. And these two elements must be regarded together, as influencing one another. If we look at one alone, we shall be liable to err. Thus regarded, it is certain, first, that any compensation to the workman must come out of the profits of the trade; and, secondly, that such compensation will be the fullest, and the most readily obtained, when it is charged and divided in the most regular and provident way upon those profits.

We are not now about to suggest in what manner this should be done. It is possible that different expedients may best suit different occupations. But it is to the solution of this important question that the best efforts of the ablest men in the different departments of our

productive industry should now be directed. In these efforts we should like to see the workman take an intelligent part. His hasty counsellors urge him either to take no part at all, or to take an unintelligent part. "Don't put a finger to the wheel," they say; "throw the whole onus on the masters. They are now liable; don't remove the liability from their shoulders." Can anything be more foolish? Can anything more surely tend to the ruin of a trade than the effort to throw as much stress as possible on one portion,—and only one portion,—of the machinery? Is there any difference in the solemn folly of the man who says, "Make capital bear all the risk," and that of the other who says, "Let the labourers look out for themselves?" If a trade has to be carried on at all, it will only be continued so long as it makes a certain profit. No one manufactures for the sake of manufacturing; no one,—for long together,—carries on a business only for the sake of paying so much wages. The moment the profit of a trade declines, the shoe begins to pinch all round. Interest on the capital falls, rate of wages falls; expenses contract themselves in one way or another, until either a living profit is made, or the trade is given up. Out of this living profit casualties have to be paid for. What may be the form in which the payment is made will matter little to the amount in the long run. The more certain be the mode adopted,—the less room for dispute or for litigation,—the better for the workman and the better for all parties.

Let us suppose the case of an exceptionally dangerous business,—say, a year or two hence. Let us imagine one employer who says, "I pay such and such wages, and in any case of accident on my works the men may take legal advice, and I shall do the same. I shall, of course, do my best to resist any claim on me, and I give you fair notice to that effect." Another employer says, "I pay such and such wages, out of which so and so is put by for an insurance fund, to which I contribute so much myself, and in any case of injury compensation will be made out of the fund at rates fixed and published." Can there be any doubt which employer would have the pick of his men? Whether the second would pay nominally higher or lower wages than the first would depend more on the anxiety of men for work than on anything else. The workman would feel certain in the one case, he would be quite at sea in the other. Bearing in mind the item of lawyers' bills, there can be little doubt that the second of the two supposed masters would be able to pay higher wages than the first, and that he would, at the same time, find men ready to come to him at lower wages. For the second business, in the long run, would pay only the ascertained and agreed cost of casualties. The first would have to pay, more or less accurately, for the cost of casualties; it would also have to pay the cost of fighting for the apportionment of the same; and it would be likely to have more casualties for which to pay in consequence of the less harmonious working of all the members of the establishment, as compared with that secured in the other case.

We say, then, to the working men, "Turn a deaf ear to those who, from whatever motives, advise you to meet the new law as to employers' liability in a narrow and antagonistic spirit. See what is proposed, ponder what is best, listen to the promptings of your own good sense and good feeling. But distrust all who would hound you on to an unreasoning and improvident hostility to whatever may be proposed in the common interests of your trade."

Artisans' Institute.—Technical classes for the practical and scientific instruction of apprentices and workmen in various trades, such as carpenters, joiners, bricklayers, masons, modellers, and metal-plate workers, will be opened on Oct. 4th, at 29, Castle-street, St. Martin's-lane. This is the seventh year during which the Institute has been in operation, and the special value of the instruction afforded has received increasing recognition from workmen, employers, and educationists. The City and Guilds of London Institute for Technical Education have given it their special support. Mr. Samuel Morley, M.P., Sir Harcourt Johnstone, M.P., and Mr. Hodgson Pratt are the trustees, the last-named acting as treasurer, with a general supervision over the management. Mr. C. T. Millis is the secretary, and information may be had from him at the Institute.

OLD LESSONS REVIEWED AND NEW LESSONS CONSIDERED.*

Sanitary science may be said to be both old and young. It is so old that we know nothing of its commencement, simply because we know nothing definite of the origin of the human race. The cave inhabitants were skilled in art; but at how distant a period they lived, or in what other respects they were skilled, we have little means of knowing; of this, however, we may be certain, that they would suffer from disease, and would use medicines and enchantments in some form to relieve their suffering.† At whatever period of this earth's history intelligent man appeared, diseases would afflict him; and when remedial measures were invented and applied, then *sanitary science commenced*.

There are problems in natural history which can only be speculative; as, the origin and constitution of matter; the origin of life; the origin of disease. The human intellect is powerless to fathom these profound mysteries, and if revelation is rejected, there can be nothing but a blank impenetrable darkness. There is minuteness below the search of the best microscope, and a range in magnitude very far beyond the combining power of the best telescope. One law alone is clear and certain, namely, the universal law of motion, which is change—combination and disintegration these never cease. That we call life or death pervades the universe; and the life of a system—sun and planets—though extended to millions upon millions of years, is, in the roll of eternity, no more than the life of an emmet, which is born and dies in a summer's day. As old systems perish, new systems replace them, to run their appointed course from birth to maturity, and from maturity to decay. I have neither time nor inclination to attempt to summarise ancient and modern theories as to ultimate atoms, if, or, if not, such exist; as, also, if or not, each atom is sensuous, and that, as a consequence, all bodies have developments of sensuousness in a degree—the combination of atoms in man developing sensuousness in the highest degree; matter combined in living forms other than animal life develops properties very like consciousness, as plants shrink from poisons, and, with apparent avidity, seek wholesome food, in this respect showing an intelligence superior to many forms of animal life. I, individually, should like to believe that plants can think.

But to the purport of this paper,—"Old Lessons in Sanitary Science Revived, and New Lessons Considered." The most reliable starting point I will take may be found in Leviticus xiv., beginning at the thirty-third verse, where the plague of leprosy is described afflicting the house. Without extracting the whole, the sanitary engineer will recognise "the walls with hollow strakes, greenish or reddish, which, in sight, are lower than the wall." Here is vividly described a tainted subsoil, wet and rotten with saturated filth. The modern remedy would be, entire removal of the tainted subsoil, to be replaced by lime concrete, removal of the tainted walls, underpinning with new material, and the introduction of a damp-proof course. Leprosy (or the equivalent of leprosy) affects houses at this day in all parts of the world inhabited by man, from European palaces to the hut of the Esquimaux.‡ In this malarrangement the savage fares better than the civilised man, as nomad tribes can leave a tainted site, whilst dwellers in villages, towns, and cities remain fixed on sites filth-tainted to supersaturation. Seeds of disease ripen in the polluted huts and houses of India, China, and Europe, and the North American cities have not escaped this general contamination. Australia and New Zealand have already polluted the sites of their cities to a dangerous extent, so that the mortality returns are no better than those of the old country.

In England we have apparently banished plague, which, however, prevails in the East,—Russia, Egypt, and the cities of Asia; but England has ripened the "*germs*" of cholera very recently, and typhus, typhoid, and other forms of fever commonly prevail. That these diseases can be prevented our model prisons bear witness, and modern sanitary works have also materially improved entire town communities. I have used the word "*germ*" as applicable to disease, without in the least being enabled to explain satisfactorily what is meant by it. That types of disease can be introduced and spread will be readily admitted; but that the origin, in each case, is a *germ* is not so easy of proof. It has been suggested that cholera must be conveyed to the human system in water; as, also, that tainted water and tainted milk produce typhus and scarlet fevers; and some say that fluids are necessary to the introduction of those forms of disease into the human system, periods of time being fixed for incubation. There are, however, some facts against this theory being received in its entirety; as, for instance, troops and travellers on the march into a virgin country previously unoccupied by man, develop these forms of disease much beyond the assigned period of incubation, and which, under the surrounding conditions, cannot be due to man-tainted earth, air, or water; so that the germ theory fails, unless we can imagine that germs of every form of disease which can afflict men or animals are as eternal as matter, and are dormant in matter until conditions for development are brought about. According to this idea, soil, water, and air, and every human body, must contain germs of every disease, but dormant, until brought into contact with conditions favourable for development.

The cleanest-looking places are not necessarily the safest. A clean looking country house or village, surrounded by pure air free from coal smoke, may have hidden dangers worse than any in a town. Visible dirt is not always the most dangerous, as the rain washes it, the wind blows over it, and the sun dries it. The presence of rats, either in country or in town, is a certain indication of danger, as rats live on garbage. They are usually diseased, and can convey the seeds of disease. It is not possible to predict, in all cases, as to what shall cause disease in excess in any given locality, as filth under peculiar and unknown modifications, or plus an unknown factor, may be sufficient to cause typhoid, without the so-called specific germ from a previous case. A telluric influence or an atmospheric influence, which we can neither control nor analyse, in combination with great elemental disturbances, may produce disease in excess. . . . . .

Past history has, for the most part, consisted of details of the birth, life, and death of kings, of their wars and conquests, with a very slight glimpse of the state of the people. In the future, true history will note and record the condition and doings of the people, as constituting the power of the state; but at present the world is very far from this condition. When in this age of general improvement in arts, manufactures, and commerce, we find Europe in arms to a greater extent than at any former period, and the people under a load of expenditure the heaviest in the world's history, thoughtful men must pause, wonder, and look for some practicable solution. The taxes now being levied and expended on soldiers, armaments, arms, and ammunition, would more than serve to abolish every city slum and wretched town tenement, admit of the re-arrangement of every city sewer, and pave every street, drain every house, provide a full supply of pure water at high pressure and constant service, and pay for daily scavenging. When history can detail these things as accomplished facts, it will be worth reading. Sanitary science is new, but it is not, as yet, popular. To remove filth, to promote health, and to prolong life, gain little of a statesman's notice in the battle of politics; the work has, however, commenced, and is being taken up, both at home and in our dependencies. The Americans are also becoming earnest sanitarians.

There are poverty, vice, and crime in Great Britain which, when contemplated in detail, are quite appalling; and these are the outcome of defective statesmanship,—and this after years of political freedom and so-called enlightened government. We sanitarians, however, hold that statesmanship which leaves the largest numerical mass of the population in hopeless misery must be defective. This condition of society is not a sound one; and, consequently, is not a safe one. To see the results of despotism and neglect in their most aggravated forms, we must, however, cast our mental vision over the empires of China and Russia, where millions of men know nothing of political and civil freedom,

---

* From a paper by Mr. Robert Rawlinson, C.B., read at the Exeter Congress of the Sanitary Institute.

† There are dwellers in caves at this day in parts of Great Britain and Ireland, as, also, in other parts of the world,—probably as many as ever in any age occupied such places for residence.

‡ It may not be strictly proper to use the word "leprosy" as being common to houses; the meaning is, that houses are filth-tainted to an extent which causes rottenness capable of producing disease.

the results being civil commotione, rebellione and civil slaughter, wholesale arrests, wholesale condemnatione, wholesale transportations, and wholesale decapitations, which effect nothing worth the trouble. Because the wretched people have no cessation to their persecution, they exist in misery, and have no hope.

True sanitary science recognises the unit, men,—looks at the individual, the single family, the single house, the village, the town, and the city, as these constitute nations, and as are the individuals, so must be family, town, and nation. If, therefore, there is ignorance, wretchedness, and vice amongst the lower orders of the people, the leaven pervades the entire nation.

These questions may be termed political, and it may be said that sanitarians have nothing to do with politics. Our reply, if questioned as to this, must be that to govern men is the prime duty of a statesman. But what are the definitions of the word "govern"? To a deepot there is only one definition, and that is, repression; which implies every form of cruelty which man ever devised and practised. To a British statesman I hope it means to care for the whole people, to educate and protect them in all honest dealings, to repeal all laws which tend to the commission of crime, to abolish class legislation, and to know nothing of party if it leads to faction.

The domestic side of sanitary science deals with home comforts, and the unit in this case is the house, then the village and the town. Houses must be planned, constructed, and regulated to afford means of health and morality to the occupants. Villages and towns must be so arranged, built, sewered, paved, and scavenged, as to preserve the purity of the soil below and the air above for the benefit of the inhabitants. To secure such ends there must be sewers, drains, pavements, scavenging, and a water supply. Sewering is ancient beyond written records; sewering scientifically is, however, modern, very modern, as some of those who presided at the birth of the modern system of town sewering are happily now living. Edwin Chadwick, C.B., though not a civil engineer, has, through the aid of engineers, done more to found and promote the true principles of town sewering than any other single individual in this generation.

There were sewers and drains in the cities of Asia which are now heaps of ruins. As in these days, so then, where large areas were covered with buildings, and men were aggregated, there would be sewage; and this would be removed by open channels and covered conduits, necessity having been the mother of invention. These ancient cities were, however, not wholly sewered, but only partially. It is very easy to be positive on this point, namely, that sewers and drains were not general, as there are no remains beneath great areas covered by the common people, and the ruins of which would have been found if sewer and drain-pipes had ever been laid.

Rome sewered and drained her cities, public buildings, baths, and palaces from a very early period of her history, and the ruins are there to this day. Pliny describes sewers in some of his letters to the Emperor Trajan. There were not only sewers, but there was also river pollution. The great cloaca sewer of Rome emptied sewage into the Tiber; and Pliny directs the attention of the emperor to a case in a provincial city, where certain banished men resided, apparently living in ease and idleness. There were sewers in the district, and a polluted stream flowed through it, which had become a great nuisance, and was complained of by the inhabitants. Pliny, in this case, suggests that the idle, easy-living, banished men should be more fittingly punished by being made to cleanse the foul sewers, and for the future prevent river pollution. Trajan at once consents to so reasonable a proposition. These letters by Pliny are most interesting in showing how actively he performed his duties, and how minutely informed he kept the great Emperor.

At Sinope, on the Black Sea, money had been advanced to the municipality for a theatre. A bad site was, however, chosen,—a swamp,—and the building became a ruin before completion, and the money was wasted. Subsequently, a memorial was sent to Rome petitioning for money to construct waterworks. Pliny, in this case, cautions the emperor, and advises that, if the request is entertained favourably, an engineer be sent with the money, that the local authorities may not job it away, as in the case of the ruined theatre. I suppose the emperor did send an engineer, as, in 1855, I saw the ruins of the service reservoirs, which, but for man's destruction, would have been as entire as on the day of their completion, the walls now remaining being sound and massive as when first constructed.

The making of earthenware vessels by means of the potters' wheel is of very ancient date; and the work of the potter has, amidst all the ruins of ancient cities, been the most enduring. The vast collection of bricks, tiles, tablets, pipes, and vases placed in European museums testify to this fact. At some early period earthenware pipes were thrown on the potter's wheel, having sockets for jointing similar to those now made in England. I saw samples in Asia Minor, in 1855, evidently new. They were about 13 in. in length, and 5 in. internal diameter, having a socket of about $1\frac{1}{2}$ in. in depth. They were being laid at Kulali, situate on the Bosphorus, to form a conduit to bring water to the barrack hospital. The natives were at work laying the pipes on a contour line, a considerable length of trench being open. I did not at first see any arrangements for ventilation and wash-outs, and was questioning the engineer officer upon these points, as to whether or not they had been provided for, and making a rough diagram, scratching on the ground with a stick to illustrate my questions. The engineer officer could give no information; but one of the native workmen, who had been listening to and watching us, touched me on the shoulder, and, with a sparkling countenance, said "*bono, bono*," immediately taking me along the line of aqueduct, and pointed out the structural means I inquired about, both for ventilation and for wash-out.

Aqueduct making is a very old Eastern practice, aqueducts, fountains, and wells being common all over the inhabited parts of Asia. Water, as one of the elements necessary to life, was, in a warm climate, sought for and stored carefully. A very meagre history of springs and wells would form a large book, and might be as interesting as the most vivid romance. There are holy wells throughout Asia, and there are also holy wells and fairy wells in Europe, novelists having with great effect availed themselves of these superstitions, and woven them into their descriptions of supernatural phenomena. There is, in fact, an enormous amount of superstition, romance, and poetry connected with springs. Magical virtues are attributed to many waters, a belief in which leads to incalculable injury.

There are shrines in India within which are reputedly sacred waters, to be washed with, and to be drunk by the pilgrims to secure eternal salvation. On certain days in the year thousands of the natives assemble and encamp round these sacred shrines. The approach to the holy water is by a flight of marble steps, down which perspiring natives, many of whom are crippled and diseased, throng to have a cupful of the fluid. The practice is to pour a cupful over the head of each native, to flow back to the tank, and this hundreds of times repeated during the day, so that it ceases to be water and becomes a vile compound,—the washings from the bodies and feet of natives, and this horrible decoction the priests in attendance administer to be drunk by the poor besotted votaries. Cholera usually breaks out amongst the pilgrims at these gatherings, and it would be contrary to the known laws of sanitary science if it did not do so.

Recently there has very properly been a rage for water analyses, many thousands having been made in Great Britain and in British India, and very startling conditions have been revealed. Water which has been considered pure by the inhabitants of English towns has been found to contain a dangerous proportion of polluting matter, to the effects of which they appear to be stupidly apathetic; but the researches in India reveal a state of things almost too terrible to contemplate. The natives of India are expert diggers of wells and formers of tanks to supply and store water for use; they are also careless of life, committing suicide with apparent avidity, death by drowning being common. It had been observed that at certain Indian stations British soldiers were liable to be afflicted with virulent types of disease,—as cholera, fevers, and, at Delhi, carbuncles and sores, the Delhi sores having become a recognised affliction. Inspection was ordered, when it was found that within the province there had been about 1,700 carcasses of human beings removed from tanks and wells, the water from which had been regularly used for human consumption. Some of the worst wells were ordered to be cleansed, when many human bones were removed from them. The tanks in use are open, and the surrounding ground slopes towards the water; over the surface human excrement is spread, and the natives both wash clothes and bathe in the water they use for cooking and drinking. High caste apparently affords no protection, but acts in a contrary direction. Calcutta is supplied with filtered water, but high-caste natives decline to use it. A native water-carrier was observed filling his skin at a stand-pipe with filtered water, but when about three-parts filled, he went to the nearest puddle, and with his hands proceeded to fill his vessel. An Englishman, observing him, asked what he was doing, when he replied, "Making Ganges water for master."*

Some medical men state that pure water is absolutely necessary to health; others send their patients to drink the most abominable compounds at English and foreign spas. Pure water is a rarity in nature, and where it is found it must be protected with great care, as it is a powerful solvent and greedy of impurities. The solvent property of rain-water, which is the nearest approach in nature to pure water, is probably amongst all the elements the most powerful agent in moulding and disintegrating the solid earth. By way of illustration, the river Thames may be taken. The water of this river contains, in round numbers, about one ton of bicarbonate of lime in each million of gallons, when the water is clear, bright, and sparkingly transparent. The daily supply pumped into London is now about 135,000,000 of gallons, so that 135 tons of bicarbonate of lime is combined with the supply of each day's water, or upwards of 49,000 tons per annum. The average flow of water down the Thames may be taken as 1,000,000,000 gallons per day; so that about 365,000 tons of bicarbonate of lime is washed down per annum from the Thames alone. About four-fifths of the dry land of the earth contain lime, or are limestone, upon which this dissolving action of rain-water is unceasing; so that the whole of the solid earth above sea-level may be silently washed and wasted down into the great salt ocean. Soft water being so powerful a solvent, is economical for washing, but it is vapid for drinking, and it is liable to produce diarrhœa when peat-tainted. It has not been proven that hard water (hard as Thames water) is injurious to health: it has, however, been demonstrated that it is a great protection to health when it has to be brought into contact with metals,—lead, zinc, and some other substances. It is the duty of the sanitarian to obtain clean water, and to preserve it fresh, cool, and clean; but pure water,—in the full sense of the word "pure,"—I do not believe to be necessary to health,—as spring, stream, river, and well waters necessarily contain salts of the rocks they come into contact with, and these are the waters which are the most largely obtained in nature, and in by far the most cases can alone be obtained, and must, therefore, be accepted. Contaminated water must be dangerous, and should always be avoided. Contamination is not, however, the most dangerous when the water is most visibly polluted. The turbid waters of the Nile, in Egypt, and of the Ganges, in India, are taken for use in preference to all other water. These mighty rivers are, however, usually turbid, the suspended silt acting as a disinfectant.

The filthiest and most dangerous water to drink is well-water, human excreta tainted, which water may be clear and sparkling. Surface-water flowing down brooks and rivers, though visibly polluted, does not appear to be as injurious as tainted well-water, earth and air being purifiers of surface-water. Water, when included and stagnant, as in wells, pipes, or small unventilated tanks, and especially when affected by liquid or gaseous impurities, becomes stinking and unwholesome. In water-works the water to be impounded in reservoirs should be gathered from the cleanest possible sources, and should be preserved clean. Sand-filters should be close to the service-reservoire, which should be covered and fully ventilated. The supply from the reservoir and the supply-mains should be direct, and the mains should be so laid and connected as to produce continuous circulation, as water retained a long time dormant in "dead-ends" rapidly becomes deteriorated. The best water-supply will be one which secures the

* Great improvements have been made at stations throughout British India in improving and in guiding water-supply sources, both tanks and wells, to prevent pollution; these improvement works are now going on.

purest source, and by the works of storage and distribution preserves it the purest up to its delivery for use.

Bathing and washing are necessary to health, but there are many towns in Great Britain and Ireland without adequate means for bathing and washing; and, as a consequence, the people do not bathe and are not clean. Baths are common in better-class houses, though by no means as common as they should be. The "tub" is, however, used as a substitute. The poor cannot provide their own baths. These ought, therefore, to be provided for them by the municipal authorities in the best and cheapest form, and in the most convenient positions. With the baths should be wash-houses, where water, soap, and all the apparatus necessary for clean and rapid washing, drying, mangling, and ironing should be made available at the least practicable cost, and if sites are judiciously selected, and there is no extravagance in the construction and management, there need be no loss. But a small rate in aid, if required, will be a saving indirectly in promoting cleanliness, sobriety, and improved health.

A writer I have before quoted remarks that in Japan bath-houses exist in great numbers in the towns, where warm water is provided at a small cost. These baths are for the benefit of the poorer classes, who use them in great numbers; as regularly as evening comes crowds of Japanese men and women go to bathe. There are ranges of box-shelves where the clothes are placed, whilst the individual steps into the bath, emerges from it, well rubs the skin, dresses, and departs clean in person. In Great Britain, at this day, thousands upon thousands of the poor are never washed clean from their birth to their death, unless they go to prison or to the workhouse. There is no bathing accommodation provided. At all schools there should be baths, and complete washing should be a part of education, as those who are accustomed to regular personal washing in youth will not subsequently abandon it.

Sanitary science has, during the last half century, probably made most progress in England; but then this island is a very small spot on the globe; and even England,—free, rich, compact, and educated as it is,—only progresses slowly. It may, however, be interesting to this meeting to learn that there is an Association of Municipal and Sanitary Engineers and Surveyors to the number of 205, and that 197 towns and districts are represented by the members. The extent of work executed might be indicated by the make of earthenware pipes and other sanitary articles, if a reliable return could be obtained. The Messrs. Doulton are making about 1,300 miles of drain-pipes per annum, besides many thousand soil-pans; and this may be about one-tenth of the entire English make of sanitary articles. There is not time in a public address to deliver a closely-reasoned essay, and a popular address is not, I assume, expected to be other than discursive. The following remarks may interest the public, though they may not teach much to the educated engineer.

Sewers and Drains.

There are good and bad sewers and drains, and the public should know some of the reasons why this is so, and then they may refrain from condemning sanitary works in general. Sewers and drains have been formed which are so defective as to be a cause of serious nuisance: they are too large, have wide and flat bottoms, the materials are bad, and the construction worse. It is possible to damage a town by defective works, and so bring discredit on sanitary science. I will attempt to describe how a town ought to be sewered, and how houses ought to be drained, to fully answer the purposes intended. Correct plans and sections are required upon which to lay out the system of sewers and drains to be constructed; the depths of the cellars should be figured on the sites of houses; the relative levels of the streets may be indicated by contours, and on the sections the strata should be shown by colours. A careful engineer will test the strata by boring and trial holes. Full details how to lay out sewers in right lines, both on plan and in gradient, are given in the "Suggestions" published by the Local Government Board.

An engineer should settle at the commencement what duties the sewers will have to fulfil. If the town has manufactories consuming and polluting much water, the question may arise, if or not this polluted water is to be removed by the town sewers; there will also, in some cases, be a question of injurious fluids, such as tan-pit refuse and pickle-waste from brass-founders, lacquer manufacturers, and tin-plate workers; there are also dye waters, and soap-waste from woollen manufactories,—some of these fluids can be treated on the premises to precipitate the solids and disinfect and clarify the fluids, and, consequently, where there is no land available for sewage filtration, the manufacturers may reasonably be called upon to clarify their polluted liquids,—and not pass them in their crude state to the sewers. There are wet and dry subsoils. Sewage will, upon good gradients, flow to any point required by gravity; in other cases there may be a flat area with a wet subsoil, and a swamp for an outlet, or this may be below the river or sea level. In such cases pumping may have to be resorted to, and then it is desirable to reduce sewage to a minimum. The subsoil should have independent drainage, and the sewers and drains should be water-tight, surface water, including rainfall, being otherwise provided for.

To construct water-tight sewers and drains requires the best materials and the most careful workmanship, but these, indeed, are necessary under all conditions. In a wet subsoil land-water should be excluded; in a dry subsoil, the sewage should be prevented from leaking out of the sewers. In the foregoing remarks extreme cases of wet and dry are contemplated. If sewage has to be pumped, and has to be clarified by irrigation, the volume to be dealt with should as near as practicable be a constant quantity. If, however, there is a free outlet by gravity, the sewers may be allowed to partially receive both subsoil and surface water; only, however, to some known and limited extent. It is an advantage to have a wet sewer rather than a dry one. Sewage flows intermittently during portions of each day, when the inhabitants are using most water; if there is no subsoil water, the sewers at intervals may be comparatively dry, admitting of deposit. A steady continuous flow of water through sewers sufficient to maintain a regular current, and not more than a few inches in depth in the main sewers, will be an advantage. Main sewers should ordinarily be laid at a depth sufficient to admit of the deepest cellar being effectively drained, the invert of the branch drain being at the least 1 ft. below the cellar floor, the fall of the house-drain being not less than one in sixty, and entering the main sewers not lower than half its diameter. These remarks are of course general, and cannot in all cases be acted upon, as many towns have low sites which cannot be effectively sewered and drained without special means (air-valves) to prevent cellars being flooded by back-water from the sewers, or by special pumping. House drains, as a rule, should be outside the basements of the houses. But where houses are built in streets, and the kitchens are at the back, the drain must cross the basement, unless back drainage is adopted, when no drain need enter the basement. Much has been written and said both in favour of back-drainage and against it. I have had twenty years' experience of back-drainage, and know nothing but good of it. It has been said that it is an interference with the rights of private property; that the drains will choke, and then there must be trespass to find out the point of failure. My reply is that back-drains may be so laid that nothing but gross usage, amounting to wilful action, can choke them; and even in such a case they will be freed and cleansed without trespass, as manholes and flushing will enable them to be so cleansed. To enable sound sewers and drains to be constructed, the trenching must be true, and the bottom to receive sewer or drain must be absolutely sound and solid. There must be no mistake here, or the work will soon be a nuisance and a ruin. Sewers and drains may become broken-backed; then there will be leaking joints, or saturated subsoil, and a choked sewer or drain will bring discredit upon sewering. If the bottom of a sewer or drain-trench is not sound, it may be made so by cement concrete, and in loose wet quicksandy ground sewers and drains should be covered with concrete. Sewers and drains will work better, and be maintained in better order, if subjected to regular and properly-graduated flushing at short intervals. It is possible to overflush, and so injure the sewers. As much water as will give a velocity of about 6 ft. per second may be admitted; greater force, to give a quicker velocity, will be liable to injure brickwork, and blow or force open pipe joints.

Waterclosets and sinks should be against outer walls; should not have continuous flue-like connexions with the sewers, but have a severed connexion, and means for full external ventilation. Every public building, however large, and every house, however small, should be so drained as to afford no possibility of sewage-gases entering, and they should stand absolutely free from the sewers, though perfectly connected with them; this might be a law without any exception. At present almost every public building and house in London is in direct communication, by the drains, with the sewers, so that sewerage-gases pervade them; there are open sewer ventilators in the streets, which serve to dilute the sewage-gases, and the enormous number of houses perform a similar purpose, and it is this dilution which prevents the full amount of mischief from being experienced; but there is a danger in it, and this ought to be avoided. This is to be done by absolute isolation, and external ventilation above the roofs of the houses. In Leeds, for a population of 320,000, there are upwards of 20,000 openings from the sewers acting as ventilators, which have been in use more than seven years. This is an example other towns may follow with advantage. Perfect sewering requires perfect street-paving and perfect street-cleansing. Scavenging must, in all cases, be a work of the municipality, or other local governing body. Contract work should be avoided. The work of scavenging should be paid by rate, and this rate should be general.

Waterworks should, in all cases, be in the hands of the local governing body. The service should be constant and at high pressure, with fire-service provided for. Water should be laid on to every house and to every tenement; there should be no exception. The service-pipes may be of wrought iron, with screw joints, and all the taps should be "screw-down." If the services are taken within the houses and tenements, and the service is high-pressure and constant, there will not be much wilful wasting of water, and house-taps will not be stolen, as waste of water, when at high pressure, will be very disagreeable within a house. Fix stand-pipes in streets and roads, as is done now, and the waste will continue to be unceasing, because it will not inconvenience any one, as when it is within doors. The poor cannot have a full and fair use of water if it is alone obtainable from external stand-pipes, as this involves carrying and storing within the tenement. It should also be remembered that one gallon of water weighs 10 lb., and that fifty gallons weigh 500 lb., and this will be only ten gallons per head for a family of five persons. The labour required to carry 500 lb. of water each day, or eighty tons per annum, will simply be enormous, and ought not to be expected from the poor tenant. Serve the water within the house, have necessary supervision, and take charge of repairs; the inhabitants will then be properly supplied with water, and cannot easily waste it. Before closing these brief and imperfect remarks I may glance at a few works recently executed, or which are now in progress.

Calcutta has been partially sewered, Bombay is now in course of being sewered, and preparations are in progress for sewering and draining other Indian cities. Sewerage works at Berlin are also in progress, to be completed with sewage irrigation. Dantzig has been completed, with sewage irrigation added; and main sewerage plans are being prepared for other Continental cities. At Warsaw, with a population of 350,000, the estimate for sewers is 600,000*l*. Buda Pesth, population 270,000, main sewering under consideration. St. Petersburg, population 670,000, estimate for sewers 3,000,000*l*., to include pumping and sewage purification. Munich, population 250,000, estimate for sewering, 600,000*l*. Düsseldorf is to be sewered by Messrs. Liudley, of Frankfort. Messrs. Lindley have sewered Frankfort-on-the-Maine, population 125,000, cost 380,000*l*. Out of 6,800 houses, 5,200 have been completely drained, and in the town there are about 22,000 water-closets. At present, the sewage goes into the river Maine, but it is to be intercepted and clarified. The Prussian Government insists on sewage clarification, which, at present, is stopping sewering on the Rhine cities, where it is very much needed. The water of the Rhine is, however, used for domestic purposes by the population on its banks, and it ought, therefore, to be preserved free from sewage.

French and Belgian towns remain with cess-

pools; even Paris and Brussels, with their enormous and costly main intercepting sewers, are cities of cesspools, and I do not know of a single well-drained city in Italy. We are met here in this ancient city of Exeter to discuss sanitary science and preventive medicine, engineering and sanitary construction, meteorology and geology—to give information and to receive information on subjects which we consider to be of vital importance to each individual man, to each town, and to each nation; but when we read the current newspaper literature of the day, we seem as men beating the air. Statesmen pay very little attention to our subjects, but starve labour by conscription, impoverish populations by taxation, and, at enormous cost, provide the most refined and terrible weapons for human destruction. We are in the midst of a war *furore*, and sanitary works can have no solid and satisfactory progress under existing conditions. There is over the length and breadth of Europe a rampant military spirit; armies, armaments, ironclads, and 100-ton guns, attract most attention. The people are summoned from far to witness autumn manœuvres conducted by emperors, as if soldiers were the beginning and ending of human progress and civilisation. The Americans appear to be the only sane nation. The governments of the Old World are drunk with military ambition.

WOMAN AS A SANITARY REFORMER.*

Two of the wisest of men, and by necessity, therefore, both of them sanitarians, Solomon and Xenophon, have laid down rules bearing on the duties of women who rejoice in being called wives as well as women. "A good wife," says Solomon, "worketh willingly with her hands." "She is like the merchants' ships, she bringeth food from afar." She is an early riser, and sees that every one has an early breakfast. "She riseth while it is yet night, and giveth meat to her household, and a portion to her maidens." By exercise she strengthens her limbs. "She layeth her hands to the spindle, and her hands hold the distaff." She knows that where there is poverty there can be neither health nor happiness. "She stretcheth out her hands to the poor; yea, she reacheth forth her hand to the needy." She provides against the cold. "She is not afraid of the snow for her household; for all her household are clothed in scarlet." In clothing herself she combines artistic taste with usefulness, as every woman is bound to do. "She maketh herself covering of tapestry; her clothing is silk and purple." "She maketh also fine linen and selleth it." "Strength and honour are her clothing." She combines common sense with gentleness. "She openeth her mouth with wisdom; and in her tongue is the law of kindness." She is watchful and busy. "She looketh well to the ways of her household, and eateth not the bread of idleness." And these, says this wise sanitarian, are her rewards:—"She shall rejoice in time to come." "The heart of her husband doth safely trust in her." And, light of perfected happiness! "Her children rise up and call her blessed." The second of the wise sanitarians, Xenophon, tells his story of the good wife in somewhat different terms and manner, and indeed with difference also of detail. He makes Socrates and Critobulus hold a discussion which comes to this general understanding,—that the ordering of a household is the name of a science, and that the science becomes the order and the increase of the house. Socrates, the master, recounts to his pupil that he once held a communication with a man who, indeed, might be called a good and honest man. He had already seen and studied the works of good carpenters, good joiners, good painters, good sculptors, and had seen how they attained to excellence; and so he desired to find out how those who had repute for goodness and honour attained their excellency. He looked for such a one first amongst those who were handsome, but it would not do; for he found that many who had goodly bodies and fair visages had ungracious souls. Then he bethought him to look for a man who by general sentiment was reckoned upon as good, and at last he found Ischomachus, who was generally, both of man and of woman, of citizen and of stranger, called "the good." Socrates is made to discover Ischomachus sitting in the porch of a temple, and, discussing with him many subjects, asks him how it is he is called a good and honest man. At this Ischomachus laughs. "Why," he replies, "I am called good when you and others speak of me I cannot say. I only know that when I am required to pay money for taxes, priests, or subsidies, they call me Ischomachus; and indeed, Socrates, I do not always bide in my house, for my wife can order well enough whatever is wanted there." "And did you yourself bring your wife to this perfection," asks Socrates, "or did her father and mother teach her?" "As she was but fifteen when I married her," returns Ischomachus, "she had seen very little, heard very little, and spoken very little of the world; and therefore,"—he continues some way further on,—"I questioned, and then instructed her." "Methinks," says Ischomachus, "that the God hath caused nature to show plainly that a woman is born to take heed of all such things as should be done at home, and these are the reasons for the belief. He, the Maker, hath made man of body, heart and stomach, strong and mighty to suffer and endure heat and cold, or privation, to journey, and to go to the wars. Wherefore, He hath, in a manner, charged and commanded him with those things that he done abroad, and not of the house. He, also, remembering that He has ordained the woman to bring up young children, has made her far more tender in love towards her children than the man. And, whereas He has ordained that the woman should keep those things which the man getteth and bringeth home to her, and knowing also that to keep a thing safely it is not the worst point to be doubtful and fearful, He has dealt to her a great deal more fear than He did to man; while to man, who must defend himself and his own, He has dealt out more boldness. But because it behoveth that both men and women should alike give and receive, He has bestowed on them alike remembrance and diligence, so that it is hard to discern which of them has most of those qualities. He has, moreover, granted them indifferently, the power to refrain from doing that which is wrong, so that whatever either of them does better than the other is best for both; and because the natures and dispositions of them both are not equally perfect in all these things, they have so much the more need the one of the other; for that that the one lacketh the other hath. Likewise the law shows, and the God commands, that it is best for both to do their part. It is more correct for a woman to keep house than to walk abroad; and it is more shame for a man to remain skulking at home than to apply his mind to such things as must be done abroad." Some lessons of economy are first to hand. The wife is to have that that which should be spent in a twelvemonth be not spent in a month. The wool that is to be brought in is to be carded and spun, that cloth be made of it; and the corn that is brought in must be most carefully examined, that none which is musty and dirty be eaten as food. Above all, the same instruction that Solomon insists on is enforced with special fervour. The wife is to be most particular, if any of the servants fall sick, that she endeavour herself to do the best she can, not only to cherish them, but also to help that they may have their health restored to them. A little further on the Philosopher touches on the importance of perfect order in the house as connected with the health and wealth of it. From these lessons he teaches his wife, and thereby all wives, matters that are more particularly of a sanitary kind. A house, he says, has an ordination. It is not ordained to be gorgeously painted with divers fair pictures, though these may be excellent, but it is built for this purpose and consideration that it should be profitable and adaptable for those things that are in it, so that, as it were, it bids the owners to lay up everything that is in it in such place as is most meet for the things to be put. Therewith he disposeth of places for things in due form, and assigns the uses of the various parts of the establishment, in such manner that the woman who presides over the whole shall know the parts in a truly scientific way. The inner chamber or room, because it stands strongest of all, is to be the strong room in which the jewels, plate, and every precious thing in the belongings of the house must be securely located. The driest places are to be places for wheat; the highest places for such works and things as require light. The parlours and dining-places, well trimmed and dressed, are to be cool in summer and in winter warm. The situation of the house is to be towards the south, so that in winter the sun's light may fall favourably upon it, and in summer it may be in goodly shadow. The wearing apparel is to be divided into that intended for daily use, and that required for special or grand occasions. Everything belonging to separate service,—to the kitchen, the bakehouse, the bath-room,—is to be assigned to its own place and use. All instruments which the servants use daily are to be shown to the servants in their right places, and are to be kept there when they are not wanted. Such things as should not be made use of except on holydays and rare occasions are to be left in special charge of an upper servant, who should be instructed beyond the rest of the servants to observe the same rules as the mistress herself would carry out. "At last, good Socrates," said Ischomachus, "I did express to my wife that all these rules availed nothing unless she took diligent heed that everything might remain in perfect order. I taught her how in commonwealths, and in cities that were well ruled and ordered, it was not enough for the dwellers and citizens there to have good laws made for them, unless they chose men to have the oversight of those laws. In like manner, then, the woman should be, as it were, the overseer of the laws of the house as the Senate and the Council of Athens oversee and make proof of the men of arms." Finally, Ischomachus touches on the mode by which his wife should maintain her own health. He observed about her, as a very strange habit, that upon a time she had painted her face with a certain unguent that she might seem whiter than she was; and with another unguent that she might seem redder than she was; and that she had a pair of high shoes on her feet to make her seem taller than she was. Whereupon, "Tell me, good wife," said he, "whether you would judge me worthier or more beloved if I explained to you what we are precisely worth, keeping nothing secret from you, or if I deceived you by declaring I had more than I really had, showing you false money, chains of brass instead of gold, counterfeit precious stones, red instead of scarlet, and false purple instead of pure and good?" She replies, "The gods forbid that you should be such a one." He then recalled to her her own deceptions, and when she inquired how she should be fairer in reality, and not appear so only, he gave her as counsel, that she should not sit still like a slave or a bondwoman, but go about the house like a mistress, and see how the works of the house go forward; look after all the workers and sometimes work with her own hands, by which exercise she would have a better appetite for food, better health, and better favoured colour of her face. While likewise the sight of the mistress, more cleanlily and far better apparelled, setting her hand to work, and, as it were, striving at times with her servants who should do most, would be a great comfort to them by leading them to do their work with a good will instead of doing it against their will. For they that always stand still like queens in their majesty will be only judged of by those women who are triumphantly arrayed. "And, now, good Socrates," continued Ischomachus, in conclusion, "be you sure that my wife lives even as I have taught her, and as I have told to you." Good wives of the type of the wife of Ischomachus would, in one decade, make domestic sanitation the useful fashion and order of the nation they purified, beautified, and heatified. I quote this basis of wifely work and duty, because I feel more deeply, day by day, that until it is admitted, and something more built upon it, sanitary progress is a mere conceit, a word and a theory, instead of a thing and a practice. It is in those million centres we call the home that sanitary science must have its true birth. It is from those centres that the river of health must rise. We men may hold our congresses year after year, decade after decade; we may establish our schools; we may whip on our law-givers to action of certain kinds; we may be ever so earnest, ever so persistent, ever so clever; but we shall never move a step in a profitable direction until we carry the women with us heart and soul. Adam had no paradise in Paradise itself until Eve became the helpmeet for him. We ought not to blame woman-kind because it seems that women are behindhand in the work. They are not, in point of fact, behindhand at all; they are rather the forerunners in the race. Long before the word "sanitation" was heard of, or any other word that conveyed the idea of a science of health, the good, cleanly, thrifty housewife

* By Dr. B. W. Richardson. A lecture delivered in the Victoria Hall during the Exeter Congress of the Sanitary Institute.

was a practical sanitary reformer. Nay, if we come to the question of organisation itself, we have in this country, in that admirable Institution, the Ladies' Sanitary Association, the first of the great sanitary societies, which by its publications, its practical aid to mothers, its out-door recreative parties to the stived-up children of the metropolis, and by various other means, has set an example which will one day be historical as a part of the great movement in the promotion of which we are engaged. There is not, therefore, one single difficulty in the way of making the woman the active domestic health reformer. The only thing that requires to be put forward is the method of bringing her universally into the work, and, if I may so express it, making the work a permanent custom or fashion, to neglect which would be considered a moral defect. There are in England and Wales alone six millions to be influenced. The first suggestion is that the beginning of the crusade shall be a beginning that shall not drive, but lead; that shall not dictate, but patiently suggest.

"Women should ne'er be taught a thing unknown,
It should be credited as all their own."

Nor can any finer or nobler occupation be imagined than is implied under this head of domestic care and nourishment of health. There are women who think it the height of human ambition to be considered carers of human maladies, content at best to take their place with the rank-and-file of the army of medicine, and not perceiving that the only feature in their career is its singularity,—a feature that would itself become lost if the wish of the few became the will of the many. I press this office for the prevention of disease on womankind, not simply because they can carry it out; not simply because it pertains to what Xenophon describes as their special attributes, their watchfulness, and their love; but because it is an office which man never can carry out; and because the whole work of prevention waits and waits until the woman takes it up and makes it hers. The man is abroad, the disease threatens the home, and the woman is at the threatened spot. Who is to stop it at the door, the man or the woman? The house is her citadel. The majority of women will ask hy what process of training can we help towards a triumph of science so beneficent? I devote myself from this point of my discourse to give some answer to that question.*

THE ROADWAY OF THE THAMES EMBANKMENT, AND THE NEW CITY OF LONDON SCHOOLS.

Simultaneously with the commencement of the works on the site of the intended new City of London Schools, on the Thames Embankment, the Metropolitan Board of Works are at present constructing the additional width of roadway which is to be thrown into the Embankment for some distance westward of the Royal Hotel. The roadway will be widened to the extent of about 20 ft. at the western boundary of the hotel, gradnally tapering along the Embankment to the extent of about 180 ft., until the curve, at that distance, works itself ont into the present footway of the Embankment. The widened roadway is being formed on the strip of land adjoining the Embankment, immediately in front of what will be the boundary-wall of the new school gronnds. It will rest on a series of piers and walls, or arches, erected upon the walls and arches of the Metropolitan District Railway, which rnns immediately under it about as far as the hotel, as the railway is carried nnder and across New Bridge-street, Blackfriars. There will be twelve of these piers and vaults, besides a number of wider openings near the hotel, of a special construction. Several of the piers have already been erected, and the roadway will shortly be completed, and the new wall dividing it from the gronnds of the City of London Schools built, but it is not expected to he opened for public traffic until the long-standing dispute between Mr. De Keyser and the Corporation has been settled, and the unsightly hoarding in front of the hotel removed. The roadway is being constructed by Mr. Webster, under the superintendence of Mr. Rowell, as clerk of the works.

Messrs. Hill & Higgs, the contractors for the foundations of the City of London Schools, are actively proceeding with this preliminary portion of the works. The greater portion of the excavations at the west side of the site have already been got out, and a considerable area of the concrete foundations has been laid. Several hundred cubic yards of earth work have been removed, and shipped away in barges from the wharf immediately under Blackfriars Bridge, the tramway under the Embankment, between the old gasworks and the banks of the river, having been utilised for the purpose; it is likewise used for conveying the concrete materials to the site.

* The conclusion in our next.

THE BEDFORDBURY AND GREAT WILD-STREET IMPROVEMENTS.

NEW PEABODY BUILDINGS.

A large portion of the two areas lately cleared in the neighbonrhoods of Bedfordbury and Drury-lane, and known as the Bedfordbury and Great Wild-street improvement schemes, will shortly be covered with new blocks of industrial dwellings, erected by the Peabody trustees, who have taken possession of the land and are now proceeding with the buildings. The making of the new and widened street in Bedfordbury, between Chandos-street and New-street, has for some time been in progress, and is now nearly completed, the greater portion of the paving and curbing having been laid. The sewerage of the street was one of the heaviest portions of the work. The thoroughfare is now nearly double its former width, the carriage-way, exclusive of the foot-paths, being 30 ft. wide. We understand that upon the site, which until recently was occupied by narrow confined alleys and repulsive hovels, of which we gave particulars long ago, there will he four blocks of industrial dwellings extending the greater part of the distance between Chandos-street and New-street, nearly the whole of the east side of Bedfordbury heing ocenpied by the west walls of the several blocks, one of which is already in an advanced state. Messrs. Cubitt & Co. are the contractors. Similar blocks of buildings are likewise in course of erection on the extensive area lying between Drnry-lane and Great Wild-street, where such a large number of old and dilapidated dwellings were some time ago demolished. The buildings will extend from east to west between Great Wild-street and Drury-lane, and the foundations of the several blocks are now being got in. When completed the buildings on the two sites will contain a very large number of tenements, having accommodation, it is stated, for a population of more than 3,000 persons.

NEW PANORAMA BUILDINGS IN LEICESTER-SQUARE.

A large circular building is at present in course of erection at the rear of the north side of Leicester-sqnare, a site long unoccupied, immediately opposite the gardens, and between Leicester-street and Leicester-place, which is intended for panoramic purposes. It is designated the "Royal Panorama," and will shortly be opened for exhibitions of this character. The architect of the building is M. L. Dumoulin, of Paris, Messrs. Cubitt & Co. being the contractors. The building is covered in, and nearly ready for occupation. It is lighted from the top of the dome. Tho principal entrance will he along a wide corridor, approached from the Square.

THE BUILDING TRADE IN GLASGOW.

The statistics which Lord Dean of Guild Mirrlees, of Glasgow, gave in his annual statement last week present a fair idea of the poverty of the building trade in the commercial metropolis in Scotland during the past three years. The trade had had a long spell of prosperity, which was not in any sense diminished by the passing of the School Board Act. But too much prosperity is often a had thing, and so it proved in the building trades. Tho success of ono man pnt another on the *qui vive;* and in a very short time a building mania commenced in Glasgow, and lasted for several years. Even Edinburgh people, who have no reputation for money-making qualities, joinod in the speculation, and helped the builders of the West on to temporary ruin. Glasgow got over-built, and one adverse circumstance after another, crowned by the City Bank failure, brought about a complete collapse at the end of 1876 and the beginning of 1877. Rents havo fallen, and in some instances undertakings, commenced years ago, are not yet completed. But for a few public buildings, the trade, indeed, has been almost at a standstill, and there is no sign at present of a revival. In every corner of the city there are numerous blocks of empty honses, and in somo parts of the suburbs complete rows of shops are untenanted. We get at the facts by consulting the Dean of Guild Court's figures. Mr. Mirrlees makes out that the last was the worst of the three years of depression, Two years ago the estimated value of the buildings for which "linings" were granted was 755,717*l.*; while last year it was 431,970, and this year, 355,430*l.* The average of these three years came to 514,000*l.*, whereas the average of the five years preceding came to 1,612,000*l.* In other words, the entire value of the building operations in Glasgow, during the last three years, did not come np to the average of a single year of the five years preceding that time. These figures have a deep significance, and though Mr. Mirrlees is uncertain as to the cause of the great falling off, there can be no question that speculative building by non-capitalists, backed up as these gentlemen too often were by legal firms, had a great deal to do with the state of chaos into which everything fell. The greatest diminution during the past three years has been in the rearing of shops,—a now too common commodity in Glasgow; and next come houses for the working-classes. We hope for a revival in the building trade as well as other trades, but we are afraid some time must elapse before there can be room for any great impetus. A curious fact is that, ahout two years ago, more than a half of the debtors in Glasgow prison had been connected with building speculation, and a significant fact was that the great majority were the builders themselves.

THE PUSCHKIN MONUMENT, MOSCOW.

The monument erected in memory of Paschkin, the well-known Russian poet, which was unveiled not long ago hefore a vast concourse of spectators, is after the model of the Academician Opekuschin. The bronze figure,—the head slightly inclined forward, the features lighted up hy a scarcely perceptible smile of sadness which plays round the half-opened lips, the right hand hidden in the breast, while the left holds behind the back a wideawake hat,—stands npon a pedestal of polished red and dark grey granite, rising 18 ft. above the pavement. Besides festoons, which wind round the base, the latter is adorned hy a laurel wreath, with a pen, round which a ribhon is twisted. The front of the monument bears but one word, "Puschkin"; the hack has the inscription, "Erected 1880." The total cost of the monument is said to have been 83,000 roubles.

The Black-hole of Hammersmith.—Dr. Hardwicke, the coroner, has properly directed the attention of the Fulham District Board to the rider to the verdict of a jury on the body of Matilda Marchant, who had died in Clerkenwell prison after being confined in the cells of Hammersmith Police Court. The rider was to the effect that the Medical Officer of Health for the district should be requested to inspect the cells. Dr. Collier reported that he had complied with the request, and had also inspected the Police Court. He said—"It appears that the woman Marchant was retained in the police cells at a time when some sanitary alterations were heing carried out; but I cannot say whether she contracted the fever of which she died at that time. There are only five cells for the reception of all the prisoners taken to the Court. Each cell contains an area of 481 cubic feet, which is not more than sufficient accommodation for two persons, whereas as many as eight prisoners are at times confined in a cell. There is literally no ventilation except a small iron grating over the door, which is quite inadequate for the purpose. With eight persons confined in a cell, there would be only 96 cubic feet of air space for each prisoner. . . . . There is an apartment termed the 'strong room.' It contains an area of 6,655 cubic feet. It is used at times for the reception of as many as 94 prisoners and 60 constables. This gives only 79 cubic feet of air-space to each person. Such an amount of overcrowding is highly prejudicial to health. The Court itself is quite inadequate for the purpose for which it is used."

THE PUSCHKIN MONUMENT, MOSCOW.—M. Opekuschin, Sculptor.

ALL SAINTS', HIGHGATE: NEW MISSION HOUSE.

CHURCH OF ST. GEORGE, PERRY-HILL, LEWISHAM, KENT.

This church was consecrated early in the present year, and was erected at the sole cost of the patron, Mr. George Parker, J.P., of Lewisham House. The tower is about to be raised, and the exterior views show it as it will then appear. The cost of this will be defrayed by Mr. Parker, thus making the total outlay about 9,000*l*. The church consists of a nave 85 ft. in length, with clearstory of two-light windows in couples, and north and south aisles, with a three-light traceried window in each bay; these are divided from the nave by piers and moulded arcades, the pier-columns being of red Mansfield stone, and the bases and caps moulded and carved. The seating for the congregation in the nave and aisles is of yellow deal, and will accommodate about 600 persons. The choir and clergy seats in the chancel are of oak.

The baptistery is placed at the west end of the nave, and is an octagonal apse in plan, with a two-light traceried window in each bay, and wooden groined and ribbed roof, with a moulded arch leading to the vestibules on either side, communicating with the inner and outer porches on the north and south sides of the west front, and these latter communicate with the nave and aisles, and, together with the somewhat unusual treatment of the circular west window, produce an original effect. The arms of the patron, and a figure of St. George and the Dragon, are carved in vesicas in the porch gables.

The font is thus placed at the extreme west, and immediately opposite to the Communion-table. It is formed of Caen stone, enriched with marble shafts and jewels, with carved caps and emblems.

The pulpit is placed on the north side of the chancel-arch, and is also of Caen stone, arcaded, and with marble shafts, with a figure of St. George and the Dragon in a central niche.

The chancel is 40 ft. in length, and the same width as the nave, viz., 27 ft. 6 in., and is multi-angular at end in plan, with timber-groined roof, supported on marble shafts, with symbolical carving in the caps. It is approached from the nave by three steps, with four additional steps to the sacrarium, including the altar-pace. In the north wall is a credence, and in the south wall a sedilia.

The vestries are spacious, and are placed upon the south side of the chancel, that for the choir communicating with the south aisle, and the other with the chancel. The clergy vestry contains a piscina.

On the north side of the chancel is placed the organ-chamber, with furnace-room beneath, and tower rising above it to a height of about 90 ft. (when completed), with a pinnacle at each angle; that over the belfry-stairs rising to a further height of about 33 ft.

The outer walls are faced with Kentish rag-stone, laid in horizontal, though drop courses, the dressings being in Bath stone. The style adopted is early fourteenth-century English Gothic, and is consistently embellished. The builder is Mr. B. E. Nightingale, of Albert Embankment. The architect is Mr. William C. Banks, of Gracechurch-street, London. The tile paving was executed by Messrs. Hawes & Co. Mr. Robert Smith executed the pulpit and font, and Messrs. C. P. Kinnell & Co. supplied the heating apparatus. Some stained-glass windows have been set up in the church by Messrs. Lavers, Barrand, & Westlake.

MAUSOLEUM, WINDLESTONE HALL, DURHAM.

We give a sectional view of the Mausoleum which has been erected at Windlestone Hall from the designs of Mr. J. Dick Peddie, architect. The dome is supported by deeply recessed arches, and the whole light comes from the lantern and the piercings in the dome. The upper portion of the recesses is intended to be decorated with wall-paintings or mosiacs, the space below being reserved for mural monuments. The mason was Mr. Jas. Harkness, and the cost about 3,400*l*.

ALL SAINTS', HIGHGATE: NEW MISSION HOUSE.

The woodcut shows the view from the North Hill of the new Mission House for the district of All Saints, Highgate, which was dedicated by the Bishop of Bedford on July 21st of this year. Hitherto the work of the mission has been carried on in a small hired house, which for some time past had proved insufficient for the purpose. The work of the sisters in charge is to visit the sick and poor, and to dispense all the relief required in the district. Classes and guild meetings are also held here under the direction of the sister in charge, and the vicar, the Rev. Edgar Smith. Here is also a small convalescent ward for children either from the neighbourhood, or from poor parishes in London. The one-story building at the back is not yet built; it is intended for an assembly-room to be used for guild and parochial meetings, Sunday-school, &c., its place being at present occupied by a temporary building, which has long been used for these purposes.

The house contains, on the ground-floor, a sister's sitting-room, common-room, waiting-lobby, kitchen, scullery (fitted with soup-boiling apparatus, &c.), pantry, larder, stores, and other offices; on the first floor an oratory, four bed-rooms, and water-closet; and above, a small convalescent ward and dayroom for children, with nurses' room and lavatory.

The walls are of stock brickwork, faced throughout externally with Portland cement rendering and rough-cast panels and smooth margins. The plinth and chimney being of red brick, and the roofs tiled. The whole has been substantially built at a cost of about 1,300*l*. by Mr. Wheeler, of Highgate, from the designs of Mr. C. H. M. Mileham, of Gower-street, London.

SIR JOSIAH MASON.

AN ENCOURAGING CAREER.

The Josiah Mason College in Birmingham, of which we have before now given some particulars, will have been opened for work when this reaches our readers, and in a succeeding number we shall show what the building is like. In the mean time, a Birmingham correspondent sends us a sketch of the founder's remarkable career, the perusal of which may give heart to many a struggling brother. The moral of it is, Persevere.

Josiah Mason was the son of a journeyman carpet-weaver at Kidderminster, whose wife eked out the slender resources of the family by keeping a small shop, and by making and baking tea-cakes, in which art she possessed much skill. Josiah's first employment was assisting his mother in the shop and carrying round the cakes morning and afternoon to the houses of his mother's customers. The school-teaching he had was but slender, but it was supplemented by his mother's wise teaching and by the instruction he received in a Wesleyan Sunday-school, at which he was a regular attendant. When of sufficient age he became a Sunday-school teacher, and it was at this time that his peculiar mental acuteness of perception and his manipulative skill were first manifested. Writing was taught in connexion with the schools, and of course in those days the writing had to be done with quill pens. The attrition of the pen

and paper soon made the points of quill pens so blunt and rough that fair and good caligraphy required that the pens should be frequently "mended." This was an operation that few persons could manage successfully, but Josiah Mason soon became noted as a skilful pen-mender. So much was this the case that the pens from all the Wesleyan schools for miles round were sent regularly to Kidderminster for "Si" Mason to mend.

Josiah Mason's earliest mechanical employment was as a shoemaker, in which trade he acquired some skill, and in which he embarked in business on his own account while still a mere boy. For some reason, he abandoned this occupation and came to Birmingham at seventeen years of age in search of something different. He does not appear to have been successful, for he returned to Kidderminster and worked as a carpet-weaver for a year or two. He finally threw up that trade also, and came again in search of fortune to Birmingham, being then about twenty-one or twenty-two years of age.

At first Mason seems to have been singularly unfortunate in his endeavours to obtain employment. At length, however, he was engaged as a labourer at the Bagot-street Glassworks, where he was employed for some months wheeling-in coals and emptying the "caves," or tunnels under the furnaces, of ashes. Although employed in this menial capacity, he kept himself respectable, and having made the acquaintance of the daughter of one of the book-keepers of the establishment, he married her, and commenced housekeeping in one of a row of small houses, still standing, opposite the old glasshouse in Bagot-street.

Opportunity shortly offering, he left this uncongenial employment and worked at the gilt-toy making. Here his acute powers of observation, his delicacy of touch, and his manipulative skill, soon made him a superior workman, enabling him to earn good wages, and to make his little home comfortable. But after a time there came a period of commercial stagnation and a coincident change of fashion, so that Josiah Mason, in spite of his great skill, could get nothing to do, and became almost penniless. Wandering one day in a listless manner, a thought of his earlier days occurred to him, and he remembered his mother's skill in making tea-cakes. Going home and addressing his wife by the familiar name of "Tet," he asked "What coppers she could raise." Between them they "raised" 9d., which capital he thereupon invested in the purchase of materials for making some tea-cakes. Following her husband's directions, "Tet" made the cakes, which "Si," taking a basket, went out and sold, realising sufficient to double the invested capital, and to provide some food for himself and his wife. The next day, having a larger stock, his journey was extended, and he persevered until it was exhausted. Continuing this from day to day, he soon secured a "connexion," who looked for his daily coming, and bought his cakes readily. The frugal couple saved money.

Trade revived, and Mason went back to the gilt-toys, devoting his attention mainly to chains, rings, and other fittings for watch appendages. For these purposes he required a large number of split-rings, both of steel and of brass, for gilding, and those he had to purchase. He always bought them of a Mr. Samuel Harrison, a maker of these goods. Mr. Harrison was a man of most kindly and generous disposition; of simple and unobtrusive habits; of sterling integrity and of large mental endowments. He united great mechanical skill with considerable scientific knowledge. Dr. Priestley soon found out his capabilities, and for that great philosopher Harrison made an improved air-pump, and other elaborate scientific appliances. This brought Priestley frequently to Harrison's place, and the acquaintance between the two men ripened into a friendship so cordial that they generally spent two or three evenings a week in each other's society.

Mason's frequent purchases of rings brought about a degree of friendliness between him and Harrison, and the latter acquired a liking for his active and intelligent customer. In the course of conversation, Harrison one day told Mason that, having secured a competency, he was desirous of retiring from trade. Mason, with characteristic acuteness, caught at the idea, and a day or two afterwards told Harrison that he should like to have the business, but he had no capital. Harrison advised him to look up his friends, particularly his wife's father, to see if he could get assistance. Mason did so, and returned to Harrison to say that his father-in-law declined, and that he found it impossible to find a friend who would help him with a shilling. "Never mind, Mason!" said Harrison, "I've taken a fancy to you, and I've made up my mind you shall have the business; you shall pay me when and how you can." This was soon ratified, and the year 1823 saw Josiah Mason, without giving bond or other security, settled in Lancaster-street in succession to Harrison as a maker of split-rings.

Amongst other "odds and ends" left by Harrison, Mason found some curious bronze and steel pens which had been made half a century before by one Richard Parkes, a highly-skilled artificer, to whom Harrison had been an apprentice. He also found the duplicate of a pen made by Harrison himself for Dr. Priestley.

Some little time after this discovery, Mason, walking in Bull-street, saw in the shop-window of Mr. Peart, a stationer, a steel pen exposed for sale, which he bought at the price of two or three shillings, and took home. His early experiences as a pen-mender enabled him to estimate the deficiencies of this hand-made steel substitute, and the idea occurred to him that he could produce by mechanical means a far better pen at much more reasonable cost. Quietly and secretly working out this idea, he at length produced a pen which satisfied his ideas of completeness, and with which he found he could make a cleaner up-stroke than he had ever seen before. How to make his invention profitable to himself by bringing it before the public was his next difficulty.

At that time James Perry, a Manchester man who had removed to London, was actively engaged in agitating school reform, and in urging the employment of improved school books and appliances. He had already produced some pens, shaped by hand from ribbon-steel, which were on sale under the name of "Perry Pens." Josiah Mason, taking a few of his pens in his pocket, went to London and showed them to Mr. Perry. At that time Mason had no conception of any other use for his pen than as a school adjunct, but Mr. Perry, with commercial acuteness, saw at once that it must eventually supersede the quill. Arrangements were soon made by which Mason was to be supplied with ample capital; the pens were to be called "Perryian" Pens, and Messrs. Perry & Co. were to have the exclusive sale in England. This was in 1828; and the connexion then formed has been continued, with occasional modifications, ever since.

Josiah Mason continued in the penmaking business, the trade gradually extending, until the year 1876, when, being eighty years of age, he sold his business to his old friends, the Perrys, who combined with it two or three manufacturing firms, and formed a limited liability company under the name of "Perry & Co., Limited." This company has greatly extended the productive capabilities of the concern, their present production of steel pens being between forty and fifty thousand grosses per week, or something like a million of pens every day!

About the year 1840 Mr. G. R. Elkington took out his first patents for electro-plating, and in 1842 Mr. Josiah Mason, who by that time had become a rich man, joined him in partnership, introducing capital to the amount of 30,000*l.* The name of the firm of Elkington, Mason, & Co. is known all over the civilised world. Mr. Elkington died a few years ago, but Mr. Josiah Mason had previously retired from the partnership.

Mr. Alexander Parkes, the well-known inventor of "Parkesine," was at the time of the establishment of the firm of Elkington & Mason engaged by them in a series of experiments connected with electric deposition. In the course of his researches he made some discoveries which led him to think he could greatly improve upon the methods of producing "vulcanised" India-rubber. In the joint names of Parkes, Mason, and Elkington, a patent was taken out for these improvements, to which the name of the "cold" process has been given. Mr. Parkes, — who singularly enough is the grandson of the Richard Parkes who was the originator of the split-ring business, and nephew of Harrison, Mason's predecessor,—sold his share to Elkington & Mason for 5,000*l.* Soon afterwards they sold the patent to Mackintosh, of Manchester, for 80,000*l.*

One way or another Mason, in the course of years, became enormously rich. He was not blessed with children, and the question as to what was to become of his vast possessions became an anxious one, which was often discussed between him and "Tet."

At the time of the electro-plating and india-rubber experiments Mr. Parkes was a frequent visitor at Mr. Mason's house, sleeping there two or three nights a week. One evening, in Mason's absence, Mrs. Mason mooted the question of the ultimate disposal of their property, mentioning that Mr. Mason desired to do something for the elevation of women. Parkes, without much time for consideration, suggested that as orphan girls were often left in great destitution, and were exposed to peculiar temptations, something might be done for them. Within a fortnight of that evening the plans for the original orphanage in the village of Erdington had been prepared by Mr. Isaac Newey, and the project was set on foot.

Notwithstanding his many benevolences, riches poured in upon Mr. Mason from all quarters, and the great Orphanage at Erdington was at length determined upon. About 320 orphans, of whom 200 are girls, are boarded, lodged, clothed, and educated at this noble institution.

It is unnecessary to repeat in this place the details which have been published in connexion with Sir Josiah's last great institution, now opened. The Scientific College, entirely erected and endowed by Josiah Mason, is a fitting crown of his many munificent works. They were noble words that he spoke at the laying of the first stone:—"I have great and, I believe, well-founded hopes for the future of this foundation. I look forward to its class-rooms and lecture-rooms being filled with a succession of earnest and intelligent students, willing, not only to learn all that can be taught, but, in their turn, to communicate their knowledge to others, and to apply it to useful purposes for the benefit of the community. It is in this expectation that I have done my part, thankful to God that he has given me the means and the will to do it; hoping that from this place many original and beneficial discoveries may proceed, and trusting that I, who have never been blessed with children of my own, may yet, in these students, leave behind me an intelligent, industrious, truth-loving, and truth-seeking progeny, for generations to come."

GLASGOW MUNICIPAL BUILDINGS.

A NOTE.

Daniel Defoe visited Glasgow in 1727, "a large, stately, and well-built city," he remarks, and in reference to the Tolbooth, the municipal building of his time, says,—"Here the Town Council sit, and the magistrates try such causes as come within their cognisance, and do all their other public business; so that it will be easily conceived the Tolbooth stands in the very centre of the city. It is a noble structure, of hewn stone, with a very lofty tower and melodious hourly chimes." The "grand stane" foundation of the above building was laid on the 15th of March, 1626, on the site occupied by the old Tolbooth, for the taking down of which the wrights and masons received the sum of 250 marks. The work went on without break or hindrance, the civic power grudging no reasonable outlays. There was no stint of drink-money. John Neill contracted to supply the Tolbooth with a great new clock for 600 marks, but on the finish of the undertaking, the Council, finding Neill was a loser, added 300 marks to the sum, for "the clock was worth the whole sum." For "brass and copper to be the cock and vanes to the Tolbooth," 47*l.* 6*s.* were given, and William Duncan received for the "workmanship," 20 marks and the clippings. "One hundred pounds money" is given to James Colquhon in part payment of working the king's arms in stone "gilting"; and Valentine Ginkiug receives "thirty pounds" for gilding the cock, the thistle, crown and sceptre above the king's arms, and also gilding the town's arms above the entrance to the gable of the Tolbooth. One of the contracts connected with the Tolbooth is peculiar. In three weeks after the laying of the foundation stone, "Gabriel Smith undertook to sharpen the whole mason irons [chisels] during the time of the building of the Tolbooth and steeple thereof until the work be ended, for forty pounds money," and in case he should be a loser, "he refers himself to the will" of the council.

Morer, writing in 1689, says, "Glasgow has the reputation of the finest town in Scotland";

and Defoe, thirty-eight years later, writes of it, "In a word, 'tis one of the cleanliest, most beautiful, and best-built cities in Great Britain."

Doubtless, when John Boyd, maissoun, "bewed" out the town's armos 250 years ago, as he traced out the motto "Let Glasgow Flourish," he looked forward to the growing prosperity of the western capital of Scotland, which years after strives to maintain its olden reputation,—"the finest town in Scotland."

THE CAMBERWELL PROVIDENT DISPENSARY BUILDINGS.

At the bottom of Camberwell New-road, with a second frontage and entrance in Camberwell-road, facing the Green, a new Provident Dispensary is in course of erection, from the designs of Mr. Dank, architect, of Leadenhall-street. The building is being erected with red Berkshire brick. The windows and principal entrance in Camberwell New-road have arched heads in red Mansfield stone, and the elevation is surmounted by a carved cornice in Portland stone, above which is an ornamental parapet. The interior of the building contains a large central waiting-room, octagonal in form, lighted from the roof by an octagonal dome, above which is one of Boyle's ventilators. The other apartments in the building consist of consulting-rooms, and private rooms for medical men, together with drug-stores and dispensing-rooms at the rear of the building.

Messrs. Rider & Sons, of Union-street, Borough, are the builders.

RECLAMATION OF WASTE LANDS IN SCOTLAND.

Recently, the members of the Glasgow Town Council, on the invitation of the Cleansing Committee, paid a visit of inspection to the reclamation operations at Fulwood Moss. During the winter of 1879, when great distress prevailed among the working classes of Glasgow, and when extensive arrangements were being made for the relief of the unemployed, the question was mooted whether the Corporation could not find some work for those who had been so suddenly thrown idle. Among the many proposals made was one for the reclamation of Fulwood Moss, near Houston. A more unpromising piece of ground could scarcely have been selected. It was really and truly a large peat-moss, over which it was almost impossible to walk with safety. The idea was, however, taken up, and, after negotiations, Lord Dunglass granted a lease of that portion to the north of the Caledonian Railway, a short distance west of Houston Station. The lease is for thirty years, at a rent of 1s. per acre for twenty years, and 5s. per acre for the remaining ten years. It was looked upon principally as a shoot for the mud and surplus manure which was lying in the various scavenging depôts and threatening to be a nuisance to the city. It would also, it was urged, give employment to a large number of unemployed, who were then thronging the streets, and whose relief was a problem of difficult solution. As soon as all the preliminary arrangements were made, upwards of 300 of the unemployed were taken down to Houston and set to work on this most unpromising task. Thirteen acres next the main line of the Caledonian Railway were first operated on, the idea being to have this part planted with potatoes, so as to secure seed for the next season. In this Mr. James Young, who had charge of the works under the Cleansing Committee, was successful; for not only did he secure a crop sufficient to seed the 95½ acres to be cropped next season, but was able to sell a considerable quantity. During last summer a service railroad was laid, and this has been so placed that all parts of the extensive moss can be easily reached. Draining was also accomplished, and this has been so successful that already the moss is 2 ft. lower than it was before operations were commenced. In the course of the work a staff of men were employed reclaiming the remaining part of the moss, the average number so occupied, from February, 1879, till the 25th of May this year, being seventy. Since the work of reclamation was commenced no fewer than 1,882 wagons, or fully 12,000 tons, of Glasgow rubbish have been placed on the moss. The railway and its adjuncts cost 1,214*l.* 19*s.* 4*d.* A movable bogie railway for the purpose of facilitating the spread of the manure and the ingathering of the crop cost 99*l.* 12*s.* 11*d.* There was spent in ditching and draining 1,784*l.* 5*s.* 10*d.*, and for trenching and hoeing 956*l.* To these items have to be added 483*l.* 16*s.* 7*d.* paid for the fares of the workmen to and from the moss, so that the total sum expended on the reclamation of this ninety-eight acres of moss has been 4,538*l.* 14*s.* 8*d.*

DISCLOSURES RESPECTING SUBURBAN DWELLINGS.

At the Edmonton Petty Sessions, before Messrs. Abbiss, Howard, and Doe, divisional justices, James Henry Etheridge, builder, 17, Heaton-place, Peckham-rye, was summoned, at the instance of the Tottenham Local Board of Health, for infringing the 10th bye-law of the said Board, which provides that the foundations shall rest on solid ground or upon concrete or other solid substructure. Louis Etheridge, builder, of 252, Lower-road, Rotherhithe, was summoned for a similar offence, the houses in respect of which the proceedings had been taken being situate in Circular-road, Stoneley South Estate, Upper Tottenham.

The case against Louis Etheridge was taken first.

Mr. de Pape, surveyor to the Board, deposed to his attention having been called by the building inspector to the material used in the foundations of the houses in question; he visited them on the 2nd of September, and found that the walls were being erected upon improper foundations,—first, upon other than solid ground; and, secondly, on an artificial foundation, made up of loose material not suitable for the purpose. The ground was but little firmer than turf, and the so-called concrete consisted of brick rubbish, spent lime, and other materials from old buildings, and had been put in dry. Notice was served upon the defendant that the material being used was contrary to the bye-laws, and on the 6th of September witness made a further examination, and took samples of the foundation under each wall.

The defendant considered the justice of the case would be met by his promise to amend. Besides, his foreman was absent through illness.

The Bench imposed a penalty of 5*l.* and costs.

The features of the case against the other defendant were similar to those above reported, and he was also ordered to pay the full penalty of 5*l.* and costs, Mr. Abbiss remarking that the Local Board were simply doing their duty in prosecuting.

THE DOCTORS AND THE ARCHITECTS.

Sir,—I think attention should be drawn to some matters which should not be left unnoticed in the *Builder*. There appears to be a sort of concerted action on the part of a certain section of the medical profession of late to weaken the influence of architects and engineers in drainage and sewerage matters, and, indeed, in sanitary questions generally. I have had my eyes upon this movement for a considerable time past, and I have good ground for my suspicions that some sanitary organisations have been started, two chief objects of which have been to assist a section of the medical profession to rule the roast in sanitary leadership, and make architects to play second fiddle to them. Some of the medical journals are also assisting. This move has been worked in Dublin as well as in London, and is being worked at present; and one sanitary association across the Channel has been worked with energy, and has succeeded in its object of pitchforking its prominent members into official appointments.

Take note of some medical men's opinions at the late Exeter Sanitary Congress, and particularly observe the impertinent allusions of Mr. H. C. Burdett anent architects and the Institute of Architects.

The Local Government Boards in London and Dublin are worked to a great extent by the medical element, and the Poor-law doctors in connexion with, or under, that institution, if they are allowed to go on with their wings unclipped or unchecked, will soon be betraying effrontery enough to snub architects and engineers generally.

It appears to me that architects and engineers are allowing the doctors to lay their eggs like the cuckoo's, and with the usual results. It is time that a wholesome check should be put to medical men's dictation and abuse in house construction and drainage matters, and that they should be kept as far as possible to their legitimate spheres. If curative medicine is becoming a non-paying game, the doctors should not be allowed an undisputed claim for the new departure in respect of preventive medicine, a cause in which you yourself have worked for more than half a lifetime, with a few other veterans.

The great body of the medical profession were not merely inert when the *Builder* was first pointing out existing evils in our towns, and the necessity of sanitary improvements, but many of its members, as I well remember, were sneerers at the movement, and even positive obstructors. The communication from Mr. Chadwick, which you published in the last issue of the *Builder*, *re* drainage and sewerage work as a specialty, is very good in its way as an exposition of bad drainage work, but, in my humble opinion, it would neither be prudent nor advisable to aid the organisation of a class of specialists. It would lead to the further sub-division and weakening of the architectural and engineering professions, who have already, and can have in future, sufficient capable members of their bodies to grapple with all the problems of drainage and sewerage work as part of their general practice. Do not let the architectural profession be weakened or cut up at the bidding of doctors, few of whom know anything practically of drainage work. H.

THE EDUCATION OF THE WORKMAN.

Sir,—Many things in recent numbers of the *Builder* interest me much.

Respecting the "dignity of labour," speaking as the father of a numerous family, now for the most part out in the world, I have felt that it was my first duty, after providing for their immediate wants, to teach them such a trade or calling as would practically make them independent. I hold that it is the first duty of every parent to teach his child some useful trade by which he or she may get its living. Mere quill-driving by no means satisfies this condition, nor does mere buying and selling goods. I have, therefore, put each and all of them to a handicraft trade, as is the excellent practice in Germany; and so both hand and eye are educated, and if they possess brains and energy besides, they may rise to be in the end captains of industry. In no case are they likely to become drones in the hive.

Whether the handicraft trade should be taught under the conditions of an apprenticeship, or otherwise, is a matter very difficult to decide. There can be no doubt that in small works, where the master takes an active part in the conduct of the work, and being himself a competent workman taking an interest in his men, as was almost always the case in times gone by, then it was right and proper to apprentice the learner. But in large works, where the master is probably only a managing director, with little practical knowledge of the work, and the youth is put to an already overcrowded trade, where every workman is jealous of any addition being made to the number of his competitors, and has no inducement given him to teach; where the foreman has much the same feelings, and no time for teaching, having to strain every nerve to get the utmost out of both men and machinery to keep his place, and satisfy his managing director, and earn a large dividend,—where, in fact, no one below the foreman is taught to think, but only to obey, then it is an open question whether apprenticeship is desirable. I know it is largely practised under such conditions, and the boys are put to do one particular thing, which they soon learn, and they are kept thereafter to that only for the remainder of their term, to their own detriment and their employers' profit. I took the liberty, some years ago, of remonstrating with the managing director of a large machine-works in the North about this practice, but I only obtained for answer that he had got a dividend to earn, and must not be too particular how he earned it.

The lament of the decay of the useful general workman is by no means new. Some thirty years ago the late Sir William Fairbairn, in the preface to his "Mills and Millwork," pointed out how the old millwright had been superseded by the fitter, the turner, the machine-maker, *et hoc genus omne*, and was consequently, to a great extent, dying out. The same division of labour has taken place in the building trades, though to a much less extent. The mason is now a hanker hand or setter, seldom both. The carpenter *and* joiner is now very frequently dissociated. The "three-branch hand," plumber, painter, and glazier, is only to be found in remote districts. But the man who has to direct all these, in the superintendence of any important building works, must have as practical, although not as manipulative, a knowledge of the several trades, as though he had been taught each of them separately. The eye and head have been taught, in his case, without the hand. And so it has come to pass, that for those who are intended from the first to take a

leading position in mechanical engineering, special schools have been opened, like that at the Crystal Palace at Sydenham, for the purpose of teaching the hand as well as the head, and this teaching is stimulated by the scholarships established by Sir Joseph Whitworth. The result of all this is that our mechanical engineers who occupy positions of authority, are able to maintain that pre-eminence they have always held as regards general knowledge. Not so the rank and file. Very frequently these are reduced to the level of mere machine-tenders, and are paid little if any above the ordinary labourer.

Whether it would be possible to establish special schools for those who are to direct building operations is open to question. I have not yet heard that it has been attempted in England. Theoretical knowledge can be and is largely in use, but nothing can supersede the practical knowledge only to be gained by experience on the works, which are of such infinite variety, that we never build twice alike, and the conditions under which the works are carried out are never twice alike. Hence, doubtless, the catastrophes, &c., to which you allude. That the average workman in the building trade is not so good a workman as his predecessors in the past, is, in my experience, undeniable,—a fact due in great part to the wretched system of paying all alike, and so leaving no room for emulation; and also to the fact that many—perhaps most—of the men waste their leisure in music-halls and other equally enervating and unprofitable amusements; and the main reason why their wages have not been reduced, as those of the engineers have been, is that hitherto machinery has not been profitably adapted to do the work.

E. G.

ALTERATIONS IN AND ABOUT NORWICH CATHEDRAL.

Sir,—In expressing my gratification at the honourable mention made of my remarks on the supposed Saxon remains attached to Norwich Cathedral on the occasion of the visit of the Architectural Association to East Anglia, I hope I may be allowed to express also a regret at the passing over in silence of some remarks which I ventured to make on the wanton mutilation of the billet mouldings over several of the arches of the cathedral. Over the west door in the inside, and in part of the nave and the transepts, they have been entirely removed; and, what is in still worse taste, over the arches between the organ-loft and the jambs of the tower they have first been hacked and mutilated, and then covered with a coating of plaster. Thus a sham circular moulding is produced, like nothing that can be found in any work on architecture. This spurious moulding had been previously noticed by Mr. Brown, the architect, and by Mr. Spanl, who also pointed out the entire excision of the billet mouldings in various places. I should mention also that the Dean had concurred in a representation which I made to the Dean and Chapter on the subject, and exhibited his good feeling and judgment by ordering the billet moulding to be replaced over one of the arches on the north side of the nave at his own expense.

Now in advocating this restoration of Norman work, which has been wantonly innovated upon, I will add that I will yield to no one in my desire to retain, as far as possible, the joint works of different periods in our venerable ecclesiastical buildings. They ought to be regarded as historical monuments, blended and associated together, and frequently producing a harmony exceeding that of the original uniform design; but a line must be drawn against such alterations when they are utterly uncalled for, as in the destruction of the billet mouldings in Norwich Cathedral; and I beg to point out another still more glaring instance of demolition perpetrated, when two of the jambs of the tower were cut back about 2 ft., in addition to the removal of the pilasters, which were carried down to their Norman basis, making not less than 3 ft. of the solid masonry and support of the tower and the spire. It appears as if the architects of the time were desirous to show experimentally how much of that support might be withdrawn without endangering the finest part of the edifice. The pilasters, when truncated, were stopped by moulded drops of plaster or cement, and the plane of wall, when cut away, was covered by carved woodwork, forming stalls for the Precentor and the Minor Canons of a later date than the carved stalls of the Honorary Canons. I endeavoured to represent at the visit of the Architectural Association that the tower jambs, which at present suggest the painful idea of insecurity of the fabric, ought to be restored; and my object in now addressing you is simply to crave your influence in bringing about this embellishment to our cathedral. An argument in its favour is that no injury or loss will be sustained by the removal of the stalls, as there is room for the Precentor and the Minor Canons in those appointed for the Honorary Canons.

John Gunn.

WIND PRESSURE.

Sir,—I have found it useful to note down any account of violent storms, and possibly you may consider the following worth notice.

The *Elgin Courant*, about thirteen years ago, published the following:—

"The wind recently blew a hurricane at Keith, and the focus of the storm was at the Isle Mills, near the railway station. The wind lifted one of the roofs, the outside one, 100 ft. long and 30 ft. broad, and without a plank falling. The whole was borne 20 ft. high in the air, and was carried over three houses, when it came in contact with the engine-stalk, and knocked it over from the foundation. The stalk was 50 ft. high. Without it being in the slightest degree arrested in its progress through the air, the flying roof passed over the ruins of the engine-stalk, and, coming into contact with a cloth and yarn warehouse two stories high, smashed the slates of it, carried away its chimney, and then spread over the road in pieces, involving the railway telegraph-wires in the ruin. The roof flew,—body bulk, as the phrase goes,—more than 60 yards before it came to the ground, and, what is even still more surprising, it rose from a one-story house, and passed over two-story houses."

Mr. Peter Carmichael, in his paper on Factory Chimneys, read before the Institute of Engineers in Scotland, states that in 1864, at Dundee, there was a violent storm of wind, worse than had been experienced for twenty years previously. This gale considerably damaged some shafts which he describes.

On the 16th of December, 1873, the *Sheffield and Rotherham Independent* published an account of "a gale which swept over Sheffield and neighbourhood, almost unparalleled for intensity and violence," it blew down nine large chimney-shafts, and doubled up the principals of an iron roof being erected at the gas-works, and caused a great loss of life, of which they give the details.

In June last I had the following sent me:—

"Professor Tice, of St. Louis, has recently disclosed the results of a tour of inspection he has been making over the track of the tornado which wrought such havoc in the Valley of the Missouri some time ago. This terrific 'wind,' as everybody supposed it to be, performed some astounding feats. It bore off a factory-chimney for a considerable distance, and literally demolished a large number of buildings, while its effects on trees and shrubs were of the most curious character. In many instances it did not tear them up by the roots, but tore off the bark from their stems, and that not only on the side exposed to the storm, but all round them, while the ends of branches were stripped of their leaves and split up into fibres. Professor Tice affirms that all this was the work, not of wind, but of electricity; that, in fact, it was not a tornado of wind at all, but a terrific electric disturbance. The chimney just mentioned was carried off by the storm, though the building from which it was wrenched was left almost untouched, the fact being that the chimney was an iron one. In many cases the Professor found that buildings with iron roofs were rent in pieces, while others directly in the path of the storm, but which had ordinary shingle roofs, were left untouched. The action on the trees he explains by assuming that the sap and moisture of their trunks and branches were by the electric current passing down them converted into steam, the sudden expansion of which tore the bark and twigs into fragments. He notices, too, that for 145 miles the storm followed the track of a railway, and, as it were, swallowed up all the water in its course. All the facts he discovered tend to convince him that there really was no wind in this tempest, but electricity only, and that, as we understand it, he takes to be the case with cyclones generally. If this view is supported in the law courts, it will no doubt be found that the damage done by such tempests must be compensated for by those who insure against 'lightning.'"

The late Professor Rankine paid great attention to wind-pressure, as may be seen from his account of the chimney at the West Cumberland Hematite Ironworks, and other writings.

I trust some of your numerous correspondents will continue this important subject.

R. M. Bancroft,
Mem. C. & M. E. Society.

Is it True?—The *American Architect* says: "A cablegram from Scotland states that a joint stock company which has been forming in Great Britain for the purpose of purchasing timber and controlling the lumber market has been completed, and has now control of Messrs. Cooke & Grant's 'limits.' This is a beginning of a gigantic scheme, which will throw a large amount of British capital into this country."

WATER SUPPLY OF BRADFORD.

The Barden reservoir works, which are being constructed for the Corporation of Bradford, in order to give additional supply of water to that growing town, have been in progress for about four years. The new reservoir will cover an area of from 70 to 100 acres, and will have a couple of hye-channels (one at the north and the other at the south), by which waste or unnecessary water may be let off. It will be somewhat of a triangular shape, and will require a bank on one side only, as the natural formation of the earth will form the sides of the basin on the remaining portion. It is this single bank which has caused so much work and labour, for at its base it is several hundred feet in width, whilst in some places it will rise to the height of over 100 ft. above ground (to say nothing of the great depth below) and will be something like 30 ft. in width at the top. For a long time past the energies of the staff have been devoted to this bank, which has a central portion of concrete of considerable thickness, then puddle on either side on account of its effective resistance to percolation, and then, outside the puddle, massive coverings of stone, the whole forming an immense boundary-wall, which one would think sufficient almost to withstand a second Deluge. This artificial embankment is upwards of half a mile in length. There are two principal streams by which the reservoir will be filled, namely, those of Yethersgill and Fadmire Syke; whilst two channels will also connect Gill Beck and Lumb Gill with it. When completed it is estimated to hold 800 million gallons, and the contract for the work is 200,000*l*. The work has been going on for about four years, and it is hoped it may be completed in a couple more years. Mr. Easton Gibb is the contractor, his principal assistants being the manager (Mr. Alexander Riach), Mr. Malcolm, C.E., and Mr. J. H. Smith, C.E. The reservoir is being constructed from plans by Mr. Binnie, engineer to the Bradford Corporation; and the interests of that body are looked after by Mr. Yourdi, C.E. (their resident engineer), and Mr. Johnson, who inspect and measure the work as it progresses.

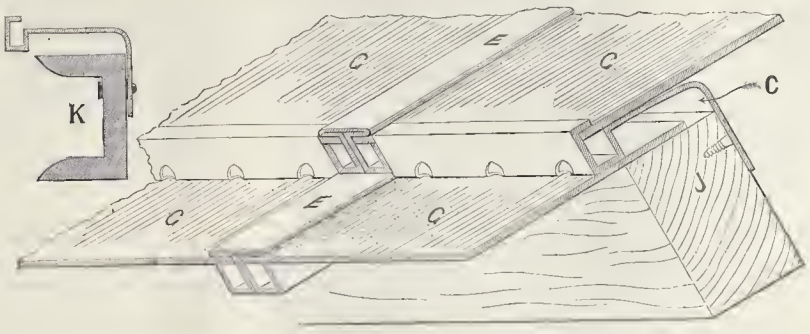
PROVINCIAL NEWS.

Stafford.—At a special meeting of the Stafford Town Council, plans were approved of for the erection of a new wing to the Borough Hall. The new building, which is estimated to cost something under 2,000*l*., is destined to hold the free library, which was sanctioned by a public meeting of townspeople some time ago, the Wragge museum, and the school of art, which has outgrown the present accommodation provided in the Borough Hall.

Smethwick.—The new building erected for the purposes of a free library and reading-room at Smethwick, and recently opened by Mr. M. A. Bass, is situate at the rear of the Gas Offices in High-street. Its main room, which is to be used both as a reading-room and library, is 52 ft. long by 24 ft. wide. It is light and airy, and is fitted up with the usual reading-desks, tables, and stands. The building, which was designed by Mr. Yeoville Thomason, of Birmingham, has been erected by Messrs. Harley & Sons, Smethwick, the cost being 1,800*l*.

Carlisle.—The large new hotel on the Victoria Viaduct, Carlisle, is approaching completion. Externally it is in the style called "Queen Anne" or "Free Classic." The ground-story is entirely of red stone. The south-east corner is corbelled and carved, and the effect is heightened by the mixture of red and white stone throughout the façade,—the white being from Lazonby, and the hardest building stone in the district, while the red is the sandstone of the district, from Aspatria. On the eight pilasters there are carved illustrations of Æsop's fables; and on the east front are two large panels, one showing the heraldic arms of the city of Carlisle, namely, a cross and four roses surrounded by a floral device, with the legend, "Be just and fear not"; the other showing a device of the rose and thistle intertwined, with the date, "1880," on a shield. The building is finished with a Mansard roof, out of which project dormer windows. There are no fewer than 126 rooms in the hotel, upwards of eighty of them being bedrooms. Though the rooms are so numerous, they are arranged on a simple plan. On each floor they open upon the central corridor, which, like the passages and staircases, is built of stone and concrete; and the whole of the

RENDLE'S NEW PATENT "ACME" GLAZING.



C. New Patent "Acme" Horizontal Bar.
E. New Patent "Acme" Vertical Bar.
G. The Glass.
J. Wooden Purlin, showing method of fixing Patent Bar.
K. Channel Iron Purlin, dispensing with wood of any kind.

walls are brick on iron girders, and hydrants for use in case of fire are placed in each lobby. On the ground-floor, on entering, is the coffee-room, 34 ft. by 20 ft., on one hand, and the commercial-room, 44 ft. by 20 ft., on the other; also the bar, smoke-room, bar-parlour, manager's room, still-room, billiard-room, 46 ft. by 25 ft.; and billiard and smoke room, 33 ft. by 20 ft., &c. On the first floor there is the ladies' coffee-room, the assembly-room, 46 ft. by 25 ft.; lavatories, &c., luggage-room, and suites of sitting and bed rooms for families. The first, second, third, fourth, and fifth floors are appropriated for bed-rooms. The hotel stands upon a part of the old city wall.

Eccles (*near Manchester*).—The foundation-stone of the new Town-hall was laid on the 13th ult., by the chairman of the Local Board. The building is of the Classic style of architecture, and comprises,—in the basement, hall-keeper's residence, heating apparatus, coal and store cellars; on the ground floor, a board and committee room, with ante-room, hat and cloak room, lavatory, &c., adjacent. Rooms are also provided for clerk, surveyor, collector, and inspector. The upper floor comprises a public room, with gallery and platform, affording accommodation for 1,000 persons, also retiring-rooms and other requirements. The principal elevations will be faced with stock bricks, relieved with Huddersfield stone to the doors and windows, &c. The contract has been undertaken by Thomas Moore & Sons, builders, of Eccles, at the sum of 4,000*l*. The architect is Mr. John Lowe, of Manchester.

RYAN'S PLUMB-RULE.

The ordinary plumb-rule with its leaden "bob" always getting out of gear, and the string twisting in wet weather, and sometimes breaking in dry when not expected, is an awkward instrument. Feeling this to be the case, an ingenious bricklayer, John Ryan, has devised, and protected, a plumb-rule to which these objections do not apply. In a sinking on the face of an ordinary "straight-edge" a thin metal rod, weighted, is hung pendulum-fashion, and its point, gravitating over a certain number of divisions marked below, shows not merely when the rule is or is not upright, but the exact extent of deviation, so that it also becomes particularly useful in building chimney-shafts or giving the right batter to a retaining wall. The rod is covered with a thin plate of metal to keep it in its place, the point only being shown, so that however the rule may be thrown about, it cannot get out of order. It may be had for a few shillings, and we are led to go a little out of our way and say that the inventor has made a number of them, and that his address is No. 50, Lockington-road, Battersea Park.

Art Classes for Ladies.—We are glad to hear that Mrs. E. M. Ward's classes are well supported. They will re-assemble on October 15th next at 6, William-street, Lowndes-square. Mr. Calderon, R.A., Mr. Alma Tadema, R.A., and Mr. W. P. Frith, R.A., are the visitors for the term.

RENDLE'S NEW PATENT "ACME" GLAZING.

The "Acme system" is the title given to the arrangement of glass roofing lately patented by Mr. Rendle, and the accompanying diagram will serve to explain it. The advantages appear to be that the lap is greater; and there being no clips, the water runs freely away; further, the channels of the vertical bars are square, thus filling the slot in the horizontal bars, as will be seen in the sketch; and the purlins are narrower, giving increased light. The new bars can be used without wood (see fig. K), thus giving an indestructible roof both inside and out. Another advantage is that there is no drip from condensation, the moisture running into the patent bar and on to the out-side of the roof. The system has been adopted at St. Bartholomew's Hospital.

STATUES.

Robert Burns.—The bronze statue of Burns for New York has just been completed by Sir John Steel, R.S.A. The statue represents the poet in a sitting posture, and the figure is colossal, being about 12 ft. in height. The incident in Burns's career which the artist has represented is that when, on the anniversary of the death of Highland Mary, he composed the pathetic poem commencing, "Thou lingering star with lessening ray," &c. The poet is represented as seated on the trunk of an elm tree, attired in the garb of a husbandman of the period, with a plaid thrown loosely round his shoulders. A replica of the statue has been bespoken for Dundee. The statue was unveiled on the 21st ult.

Denis Papin.—On the 29th of August a statue of Denis Papin was unveiled at Blois, where he was born in 1647. Papin, who was a Protestant, spent the greater part of his life in exile, living sometimes in London and sometimes at Cassel and Marburg, where he invented the celebrated steamboat on which he ascended the Weser, to the horror of the native peasants, who seized it and broke it up, believing it to be the work of the Evil One.

STAINED GLASS.

London.—The old windows over the communion-table in the Church of St. Katherine Cree, Leadenhall-street, are being replaced by a series in stained glass, emblematical of flowers, which Mr. W. M. Pepper, of Euston-road, is supplying. They are five in number.

Addiscombe.—Messrs. Britten & Gilson have just now executed and fixed a stained-glass window at St. Mary Magdalen's, Addiscombe, Croydon, for the Committee, in memory of the late Mr. Theodore Lloyd, the subject being the Ascension. We hear that it is very boldly treated.

Kingston (*Surrey*).—A window has recently been placed in the parish church to commemorate the late Mr. H. Shrubsole, formerly mayor of Kingston. It is designed to illustrate the latter part of the twenty-fifth chapter of the Gospel according to St. Matthew, with more especial reference to the fortieth verse, part of which is inscribed under the subject. Our Lord, crowned, and bearing in his hands and feet the marks of his Passion, stands in the central light of the window, and on either side of him are the blessed whom he is calling to inherit the kingdom prepared for them from the foundation of the world. The groups consist of men, women, and children, and an angel is conducting them into our Lord's presence. The figures are placed under canopies of tabernacle work, designed in accordance with the character of the masonry of the window, which is of the fourteenth century, and in the tracery or upper lights there are figures of angels bearing scrolls, on which a portion of the text referred to is written. A memorial brass tablet is in course of preparation, and will be erected upon the wall beneath the window. The window and brass are the work of Messrs. Lavers, Barraud, & Westlake.

Coventry.—A four-light stained-glass window has just been placed in the west end of Holy Trinity Church, in memory of the late Mr. W. Chater, organist of the church. The window illustrates Christ's teachings in the two great commandments, "Duty towards God and duty towards your neighbour." The window was designed and executed by Messrs. Heaton, Butler, & Bayne, of London.

CHURCH-BUILDING NEWS.

Walton-on-the-hill (*Liverpool*).—On the 10th ult. the new church of St. John the Evangelist, Walton-on-the-Hill, was consecrated by the Bishop of Liverpool. The foundation-stone of the church was laid on Easter Monday, 1876, by Lord Skelmersdale, now the Earl of Lathom. It was opened for service, under the licence of the Bishop of Chester, on May 17th, 1878, but was not consecrated owing to the debt upon the building, which has now been removed. The portion of the building now completed accommodates about 600 worshippers. When carried out in its entirety according to the plan, it will consist of chancel, nave, and side aisles, with five bays, two vestries, and lofty tower at west end. The total length of the church when completed will be 131 ft., the nave being 33 ft. 6 in. wide, and 60 ft. high, and it will then accommodate about 1,000. The contractor is Mr. Hugh Yates, the architects being Messrs. Aldridge & Deacon. The style of the building is an adaptation of thirteenth-century Gothic, treated in a simple manner. The materials of the walls outside are local red-stone, the interior stonework being entirely of the variegated red and white stone from the Runcorn quarries. The chancel is divided from the nave by an elaborate wrought-iron screen and gates, and is paved with marble mosaic. It still awaits decoration, permanent choir-stalls, and organ cases. Foremost among the ornaments of the church is the costly reredos given by Mrs. Gerard Leigh, of Luton. This consists of a polished and inlaid red marble framework rising to a height of 14 ft. 6 in. above the sanctuary floor, and enclosing a white marble panel 6 ft. wide by 4 ft. 6 in. high,

in which is sculptured in high relief the subject of the Crucifixion. At the foot of the Cross kneels the blessed Virgin, looking up at the dying Christ, whose face is turned towards her. Her hand is placed on the Cross for support, while on the other side kneels St. John, watching the Virgin Mother in readiness to receive her if she fall overpowered by the scene. This group is the work of Mr. J. Woolner, R.A. The altar is of dark carved and panelled oak, richly decorated hy the architects witb conventional roses, lilies, and passion-flowers on a ground-work of gold. The nave is enriched by several stained-glass windows, the gifts of various members of the congregation, Mr. Holiday having designed those on the south side, while the two on the north side are the work respectively of Messrs. Forrest & Sons, of Liverpool, and Mr. Holt, of Warwick. The cost of the church, exclusive of the reredos, was a little over 6,000*l.*, and an additional 4,000*l.* is required to complete the edifice.

Maghull (Liverpool).—Dr. Ryle, the bishop of Liverpool, has consecrated the new church of St. Andrew, at Maghull. The new building is in marked contrast to the small structure which it supersedes, and consists of a chancel to the east, with transepts at each side, the north transept being used as a chapel for the school-children, and in the south transept is placed the organ. The style is Gothic of the Early English period. The walls of the chancel internally are lined with polished ashlar stone. The arches, strings, label moulds, and jambs of the arcade and windows are deeply moulded, and finished with carved capitals and bases. The altar-cloth, the gift of Miss Hollingshead, is from the factory of Messrs. Jones & Willis. The nave has an arcade of five bays on each side, and a lofty clearstory. The roofs of nave, aisles, transepts, and porch are open-timbered, of pitch pine, varnished. The various dimensions of the church are:—Total length over all, 127 ft.; total width, not including porch entrance, 54 ft. 6 in.; the nave, 68 ft. 6 in. by 24 ft.; north and south aisles, 68 ft. 6 in. by 12 ft. 9 in. each; vestry, 14 ft. square; tower, 21 ft. square by 72 ft. high; the height of church to apex of nave roof, 45 ft.; the chancel, 29 ft. 6 in. by 20 ft. 6 in.; organ-chamber and chancel, 15 ft. 6 in. by 13 ft. The whole of the work has been carried out from the designs of the architect, Mr. James F. Doyle, assisted in the superintendence of the work by Mr. S. Gunning, clerk of the works. Mr. James Lesley was entrusted with the sole contract, the joiners' work being executed for him by Mr. Samuel Webster, of Bootle. The glazing in the chancel is by Messrs. Edmundson & Co., of Manchester; the tiling by Mr. Laidly Brown; the mosaic pavement by Messrs. J. Rust & Co., of Lambeth; the heating apparatus and lightning-conductor by Messrs. J. R. Cooper & Sons, Liverpool; the lamps and ornamental metal work by Messrs. Freeman & Collier, of Manchester; and the carving in the church is by Mr. Joseph Rogerson, of Liverpool.

ASSOCIATION OF MUNICIPAL AND SANITARY ENGINEERS.

On the 24th ult. the first conference of the recently-formed Northern District Branch of this Association was held in Darlington. The President of the Association, Mr. A. W. Morant, borough engineer of Leeds, occupied the chair. Mr. P. W. Thompson, C.E., of Willington Quay, who has taken an active interest, along with Mr. Hall, Stockton, in forming the Branch Association, was unanimously elected district secretary, and it was agreed, after some conversation, that there should be no hard and fast rule in the settlement of the boundaries of the Northern District, which, it was understood, will now include the North Riding of Yorkshire.

Mr. Craggs, of Shildon, read a paper on the scheme suggested by him for the disposal of the sewage of the Shildon and East Thickley Local Board district. The population of the district is 10,000, but sufficient capacity has been provided in the outfall drain for 50,000. Provision is made for rainfall and surface water by a separate set of drains, which are exclusively used for this purpose. There are two subsiding tanks, each 150 ft. in length, 9 ft. wide, and 6 ft. deep, built of 9-in. brickwork in lime mortar, the sides having a 3-in. batter upon them. The paper described the under-drainage and the surface preparation, in respect of which latter it was said that the twenty acres of land used for sewage disposal were divided into four parts, arranged upon three different levels, each plot having a gradient of 1 in 400. The cost per acre of laying out the land was about 190*l.*, which included the main drain, nearly a mile long. The number of acres of land they were laying out for the purification of their sewage was twenty. There were not more than half a dozen water-closets in the district, but nearly all were middens, such as are usually found in the mineral districts. It was the wish of his Board that they should be constructed. Nothing came into the sewer save the surface water from the yards and sewage. The land was of a somewhat clayey nature, with some gravel. It was held on lease for forty years, at 7*l.* 10*s.* per acre. The cost of the purification works would be about 100*l.* per acre.

Mr. George Bell, surveyor to Felling Local Board, then submitted a paper on "Sanitary Appliances." He said he had introduced a system of disposing of ashes and privy refuse, which would eventually be a boon to the public at large, especially the working classes. It comprised a self-acting water-closet and a dry ash-pit combined, designed and patented by Mr. A. M. Fowler, borough surveyor, Newcastle.

Mr. Hall said they had recently commenced to adopt Mr. Fowler's system at South Shields, and there it seemed to answer admirably.

Mr. Vawser confessed that as an occasional observer of the working of Mr. Fowler's system, he was highly pleased with its efficiency. The tub system, in his opinion, did not meet the difficulties of the situation.

The members then visited the Darlington Iron Company's works, in the office of which luncheon had been provided. They next proceeded to the Darlington Corporation Sewage Farm, over which they travelled under the guidance of the borough surveyor, Mr. T. Smith, who fully explained the engineering features of the scheme. At present the farm covers some 225 acres, though at the end of the year the corporation will come in possession of ninety acres more. 1,153,000 gallons of sewage on an average are dealt with every twenty-four hours. The farm, as a farm, about clears its working expenses. The party finally visited the works of the Stockton and Middlesbrough Water Board, at Tees Grange, about two miles and a half from Darlington Market-place, the water being drawn from the Tees, which is here about forty-seven miles from the source, and the same distance from the mouth. Mr. Simpson, the secretary of the Board, officiated as conductor. The land occupied by the Board at Tees Grange is twenty-seven acres in extent, eighteen acres of which are covered by works. The total area of the filtering beds is 142,000 square feet, while there are two tanks holding 2,500,000 gallons each, and one tank containing 1,500,000 gallons. The population of the district supplied is 130,000. About 50,000,000 gallons per week are pumped, 32,000,000 of which go for manufacturing purposes.

In the evening the members dined together at the King's Head Hotel.

SCULPTURE.—BLACKFRIARS BRIDGE.

The Chairman of the Bridge House Committee has objected, and the majority of the Court of Common Council have concurred in thinking it undesirable, that the regulations to govern this competition should be made known and well-considered and discussed before sculptors are invited to compete, and probably nothing more will now be heard of the matter until it is too late.

It is not often that so grand an occasion to encourage the noble art of sculpture arises, and there are, no doubt, many like myself, who, with no personal ends to seek, no particular artist to patronise, anxiously desire that the result may not be a failure, like so many other art competitions, but a great success, alike to the Corporation, who, to their honour, so liberally defray the cost, and for the artists who may be engaged in the work.

If the Chairman really thinks, as he said, that it is sufficient merely to invite sculptors to send in models, or that crayon sketches may be requested in the first instance to select from, I say unhesitatingly, disappointment will ensue.

A sculptor's sketch is made in clay; he does not affect the pencil, and the sketch in clay is a long and rather expensive matter from first to last. No artist of eminence will be likely to waste his time upon it, unless carefully-framed instructions put all competitors on a general footing, which, while leaving the artist free to express the idea put before him as his genius may suggest, will regulate the work by such a sufficient definition as will insure a general harmony in the result, so that the work of one,—excellent, perhaps, in itself,—may not have to be rejected, because it may not harmonise with some others. To illustrate what I mean, I think that instructions to competitors should determine the leading points as follows:—

1. The competition to be for four groups, of not less than three figures in each, illustrating the following subjects:—

   a., *b.*, *c.*, *d.* } The committee should select the subject (historical, not allegorical).

2. The arrangement of each group to be pyramidical, and no equestrian figure to be introduced.

3. The figures of each group, if standing, to be 12 ft. high (some may think 10 ft. better).

4. The scale of the models to be one-third full size.

5. The material to be Sicilian marble.

6. Sculptors may compete for any one or all of the four groups.

7. The successful competitor to be entrusted with the work, for which £ will be paid.

8. Second and third premiums for each group, of 150*l.* and 100*l.*, will be awarded.

Let me add that I have outlined the above, not for a moment supposing that what I suggest may not be improved, added to, or altered for the better; but only to bring to the surface some of the points requiring to be considered, and I hope sculptors will not fail to criticise and make their own views known through your columns, for it seems no other opportunity will be afforded before the first steps are taken, and then, of course, it will be too late. It is unfortunate that sculptors are not represented by any central body, Academy, Institute, or Society, which could speak in the name of the whole, and individuals, of course, are reluctant to make themselves prominent. I feel sure any good suggestions in this most important and interesting matter would be received by you in all confidence, and must be allowed due weight.

James Edmeston.

THE LONDON AND PROVINCIAL STEAM LAUNDRY.

We must congratulate the company associated under this title upon the possession of what seems to be a very complete set of buildings for their purpose. They are erected in the Battersea Park-road, and cover more than an acre and a half of ground, Mr. Ernest Turner, of Regent-street, having been the architect, and Messrs. Scrivener & Co. the contractors. The machinery has been supplied and fitted by Messrs. Bradford & Co., of Manchester. The works were opened to visitors on Wednesday last, and we had an opportunity of seeing all the working details. The arrangements appear to be excellent, apartments for the various processes succeeding each other, so that the articles treated continually move on until they reach the van by which they are to be returned to their various owners. The general washhouse is a lofty apartment, with an area of about 50 ft. by 30 ft., having down the centre a double row of Bradford's "Vowel A" washing-machines of various sizes. Along the north wall is a range of large-sized pigeon-holes or racks, each capable of containing, when duly folded, just so many socks, napkins, shirts, or what not, as can be introduced at one time into the open mouth of the washing-machine, thus greatly economising the time occupied in charging them. Along the opposite wall is a range of washing and boiling troughs for such articles as may require these methods of handling, with a tramway arrangement by which manipulation is much facilitated. At the north end are the tanks of boiling soap solution, compounded after a recipe which, without the use of chemicals, produces, in some half-dozen turns of the ponderous machine, a lather of proper thickness and fineness. At the opposite end are the "hydros," in which, when washed and rinsed, the various articles are whirled round at the rate of about 400 revolutions per minute, till every drop of extractible moisture is driven off through the open wire sides, without, it is maintained, any of that straining or rending of the fabric

inseparably attendant on the primitive process of wringing. How far this is the case we must leave time and the housewives to determine.

We cannot now pretend to describe the establishment, but will mention a few points that deserve attention.

The ventilation of the boiler-house is unusually complete, and the same may be said of the entire building, special attention having been given to this essential point by the architect.

For infected linen there is a separate department. The infected articles, being collected, not in baskets, but in open wire-work crates, are inserted bodily, without unpacking, into the disinfecting chamber, where they are subjected to dry heat, and the washing, &c., are carried on in the same isolated house.

On the opposite side of the yard are the stables, a fine and well-ventilated range, accommodating at present ten horses, but capable of extension as circumstances may require. Beyond this again is the van-shed, where the white vans of the company, with their blue lettering and smart scarlet wheels and shafts, make a handsome show.

A well, over 400 ft. in depth, has been sunk in the yard, at a cost of something over 600*l.*, and extending into the chalk, from which it extracts a supply of water running, if required, to 15,000 gallons per diem, and described by Professor Hehner, of the Analytical Sanitary Institute, as singularly good for the purpose.

As to the sewerage, great care has been taken. Every drain throughout the works runs into a central channel effectively cut off from the common sewer by ventilated manholes, and is thoroughly approachable for inspection and cleansing from end to end. The amount expended may, we understand, be called about 15,000*l.* for the buildings, and 10,000*l.* for the machinery and fittings.

DECORATION OF ST. PANCRAS CHURCH.

During the last two months this well-known church has been in the hands of Messrs. Crace, and it will be again opened for service on Sunday next, October 3rd. An important change has been effected in the aspect of the interior, which, with its walls of "Pompeiian" red, no longer produces that gloomy impression which it before shared with many of its "Classic" sister churches in London. A building with a flat ceiling, 117 ft. long by 60 ft. broad, and only 40 ft. high, may be said to present distinct difficulties to the decorator; but these have been boldly met, and not without success. The ceiling in question is originally divided by very wide margins into a great number of very small panels or shallow coffers, containing at intervals pendent rosettes. The margins are kept light, of a quiet stone tint, and the panels mostly blue, with a Greek star in each, only those being coloured red which emphasise the general design. The proportions of the panels are improved by carrying the blue or red somewhat beyond their own limit. The cornice, which has the demerit of consisting of a great number of small mouldings, without any frieze or leading feature, has been brought out with firm colour and solid gilding. The walls above the galleries are painted a bright, luminous red, whilst below the galleries so much of the wall as is not occupied by the numerous marble tablets is of a darker tone, the window and door dressings throughout being kept light. The gallery fronts are also light, with bronze and gold mouldings, and are divided by ornament into spaces which accord with the columniation below them. The dwarf columns which support the galleries are also treated as bronze, and relieved with gilding. The apse or "tribune" (which already contained three good but somewhat dark stained windows, is now made rich and effective by a series of wide horizontal bands of fine Greek ornament, on gold ground, which well relieves the six heavy verd-antique scagliola columns. These columns are said to be the largest ever made in scagliola, and will be remembered, by those who know St. Pancras, as the leading features of the interior. The topmost of these gold bands bears words (from Isaiah), "Come ye, and let us walk in the light of the Eternal." The high plinth below the columns is decorated principally in a rich morone colour and gold ornament, which is made to connect and frame the white marble tables of the Decalogue, Prayer, and Creed, which already existed. The oak seating remains, and has been renovated. New warming-apparatus, on Grundy's system, has been introduced, and, under the supervision of Mr. Salter, architect, the surveyor of the fabric, other general repairs have been executed. The cost of the works has been undertaken by a committee of the congregation, who have relied entirely upon private subscription. The church was designed by Inwood, and built in 1820-22, at a cost of 76,000*l.* The renovation will cost over 2,000*l.* The Rev. the Hon. Canon Spence is the present vicar, who has actively promoted the work.

WESTMINSTER VESTRY-HALL COMPETITION.

Sir,—As, with your usual courtesy, you complied with the request of the Vestry not to notice these designs until they had been examined by themselves; and as they have now come to a decision without affording you an opportunity of previously expressing an opinion, I ask you, in the interests of justice, which you have ever upheld, to consider and give your opinion as to the decision arrived at. Mr. Charles Barry, it is true, advised it, but strangely ignored the principal condition imposed upon the competitors. This was, that 15,000*l.* was to be the limit of expenditure, inclusive of such a large ball as could be provided within that sum.

Nevertheless, he adjudged the three premiums to three designs, two of which, according to their authors' reports, failed entirely to include the said hall; and the third design, obviously more costly in character than either, ought equally to have been put out of court by Mr. Barry on that ground, as also the elevation sent with it to double the allowed scale.

It will be obvious to you, Sir, that other designs which fulfilled the above-named conditions must have been placed at a disadvantage with these.

In other respects, also, the report which has been published, and the designs themselves, deserve careful consideration, and should be studied in connexion with the instructions to which the competitors were bound to adhere, and which have been treated as a dead letter.

John P. Seddon.

PROFESSIONAL REFEREES IN COMPETITIONS.

Sir,—Now that some architects are trying to prove that the appointment of an architect of eminence produces unsatisfactory results, taking as examples the recent competitions at Glasgow and in Westminster, I think it well to call your attention to a case in which the result has been perfectly satisfactory. Referring to the tenders published in the professional journals last week for the erection of a New Market Hall at Over Darwen, it will be seen that the accepted tenders amount to 13,417*l.*, or about 1,600*l.* less than the estimate of Mr. Charles Bell, the architect.

The competition designs were invited last year, and Mr. A. Waterhouse drew up the conditions as well as a report on the designs. The Corporation accepted, without question, the award of Mr. Waterhouse. Mr. Bell was formally appointed architect, and the amount of premium did not merge into the commission.

I think that the memorial to the Institute of Architects by Mr. Cole Adams and his colleagues can do but little, although I was One who Signed It.

P.S.—What a dreadful disappointment to the Richmond Vestry, after selecting a design marked "Natation," believed to be by a local resident, to find "Two Richmonds in the field."

DRAINAGE AND SEWERAGE.

West Bromwich.—A special meeting of the West Bromwich Improvement Commissioners was held on the 16th ult., to consider the sewerage scheme which it is proposed to adopt for the town. Mr. Reuben Farley presided. A plan and explanatory report with reference to the scheme were presented by the town surveyor, Mr. John J. Eayrs, C.E. The report set forth that the returns for the year 1879 showed that the population of the township was 53,639, and for the purposes of his calculation Mr. Eayrs had taken the population at 54,000. In the year referred to there were 10,800 houses. At present the sewage and surface-water was discharged into the River Tame, Birmingham and Tame Valley Canals, and certain watercourses. The estimated quantity of sewage per twenty-four hours was 1,609,950 gallons, and with the estimated increase it would be 2,414,850, which would have to be provided for. In the opinion of Mr. Eayrs the "separate system" of sewerage would be the best for the township. The plans provided for the drainage into the Westbromwich system of 270 acres of Smethwick, with a present population of 2,985, and an estimated increased population of 4,475. The land proposed to be purchased for the purification of the sewage was known as Friar Park, and was situated at the western extremity of the parish, adjoining Bescot Station and land about to be purchased by the corporation of Walsall for the disposal of sewage. The area of the land for Westbromwich was 287 acres, provisionally purchased from the Right Hon. the Earl of Dartmouth, tithe-free, for 20,000*l.* The system of intermittent downward filtration was recommended for the disposal of the sewage of the parish. The report further set forth that it was proposed to carry out the drainage scheme in three sections, and the plans now drawn up provided for the first section, which, it was estimated, would cost 54,726*l.* 11s. 9d. A resolution was passed approving of the plans and first section of the scheme drawn up and presented by Mr. Eayrs, and requesting the sanction of the Local Government Board to a loan of 60,000*l.* from the Public Works Loan Commissioners, the repayment to be spread over a term of fifty years.

Nairn.—A system of drainage has lately been completed at Nairn, at a cost of about 3,000*l.* Instead of running the sewage into the sea, it was resolved to apply it to the irrigation of a piece of waste ground for the growth of grass or other produce. The drainage had to be carried across the river, and for this purpose two piers, consisting of iron cylinders filled in with concrete, were sunk. The pipe,—an 18-in. iron pipe,—was laid upon them, and with footboards and hand-rails on the top of it, the pipe has been converted into a foot-bridge, which has proved a great public convenience. The level of the pipe being higher than the ground on the other side, a large embankment was raised, in which the pipe is embedded, and the top of the embankment is utilised as a public walk. The place selected for the sewage farm was known as the Salt Marsh. The soil was very thin and poor, and the subsoil consists of sand and gravel. The place was let for a few pounds as a grazing outlet to a neighbouring farmer. The first work of the engineer was to devise means to keep back the tide. This he has succeeded in doing by building in the heart of the embankment a dyke of clay, going down to the rock. At present only ten acres are being treated for the utilisation of the sewage. Its distribution is carried on by a series of channels cut in the ground, and is completely under control, one part being treated one day and another the next. The cost of the work in disposing of the sewage, including building, &c., is about 1,542*l.*, of which 200*l.* has been expended in levelling the ground.

SCHOOL-BOARD SCHOOLS.

Great Grimsby.—The second new school erected by the Grimsby School Board was opened a few days since. It is in the West Marsh, on a fine open site given by the Corporation. It has two main fronts, to South Parade and Fildes-street. It accommodates 260 boys, 260 girls, and 260 infants, and each department contains a large main school-room and three class-rooms, together with teacher's rooms, &c. A caretaker's house is placed at the angle of the two fronts. This has an octagon slated roof. The buildings are of good local pressed bricks; the windows having Bath stone lintels and sills, with blue brick bands. The roofs are slated, with red ridges. Each of the playgrounds is tar-paved, and has a covered playshed. The desks are all on the dual system, made in the town from Messrs. Colman & Glendenning's pattern. The total cost, including fencing, paving, playgrounds, fittings, architects' commission, &c., but exclusive of site, has been 5,377*l.*, or less than 7*l.* per child. The architect is Mr. Charles Bell, and the builders are Messrs. Riggall & Hewins, Grimsby.

Newcastle-under-Lyme.—The School Board here is erecting schools in the Barracks-road, to accommodate 1,000 children. Messrs. Chapman & Snape, of Newcastle, are the architects, and Mr. John Gallimore is the contractor, the amount at which the contract was taken being 3,847*l.*

At the Exhibition just held in Leyden, Holland, a gold medal was awarded to Messrs. Worr & Lewis, of 11, Lawrence Pountney-lane, Cannon-street, London, for their improved hand-power circular and band-sawing machine, and for their mortising and boring machine.

Books.

A Handbook for Painters and Art Students on the Character and Use of Colours, their Permanent or Fugitive Qualities, and the Vehicles proper to Employ. By W. J. Muckley. Baillière, Tindal, & Cox, London, 1880.

Most persons on noticing the title of this book and its publication at the present juncture will have supposed, as we did, that it was a kind of corollary to the protestation which has recently been made on the subject of colouring materials by certain painters. The author, however, specially mentions that it was in the press some weeks before Mr. Holman Hunt read his paper on "Painters' Materials" at the Society of Arts in April last. Mr. Muckley seems to have done eminently good service in bringing out a book of this kind on such a subject—a book short, concise, and practical, giving not a word more than is necessary, and based on long practical experience. The treatise is preceded by a brief preface by Mr. Poynter (to whom it is dedicated), expressing his concurrence in the views of the author, and his high opinion of Mr. Muckley's judgment on the subject. For the many readers who go by names it may no doubt have been necessary to provide the book with some such warrant from an artist of established fame, and Mr. Poynter, as the official head of the Government schools of art, was on other grounds a peculiarly suitable referee. Those who have knowledge of the subject will at once perceive that the author understands it; but then they are not the people who most need the book.

The author rightly urges, in his own preface, that the artist has no right to neglect the subject of permanence of pigments and allow himself to be careless about it as a prosaic matter. If he does not care about his own future fame, he has no right to disregard the interests of those to whom he has sold pictures, under the supposition that they will be permanent possessions, and he incurs a culpable responsibility if he wilfully neglects all care about the stability of the materials with which they are painted. *Caveat emptor* cannot rightly apply here, because the buyer is exactly the person who cannot know much about the matter. Even if the purchaser knows anything about the chemical composition and action of pigments, vehicles, and varnishes, he cannot know what the painter has used, and how he has used it. "It therefore becomes all the more imperative on the painter's part that he should thoroughly deal with it as a necessary part of his education and practice, or in ignorance he may lay himself open to the charge of supplying to his client that which he did not bargain for."

Mr. Muckley first ranges under the head of "Permanent Colours," the colours which he thinks can be justly so called, subdivided under the heads of whites, yellows, reds, blues, greens, and browns. The constitution of each colour, whether vegetable or mineral, is briefly mentioned, and any particular quality in it, either good or bad, which requires special attention. The only deficiency we find in this portion of the book is that the author does not clearly state whether all his remarks refer equally to the behaviour of the colours whether used as oil or as water colours. In general they probably would apply equally to either, though there must, we should imagine, be some cases in which a pigment may be permanent with oil and not with water, or *vice versâ*. We appear to be worst off in the matter of yellows, in regard to which Mr. Muckley seems to be generally sceptical; for though he says lemon yellow is the only yellow the painter can use with safety, he afterwards speaks very disrespectfully even of that: indeed, his remarks on it are contradictory. "It is the only colour of the kind on which we are at all able to rely, and this varies so often,—both as to purity of colour and density, that it will rarely ever serve the purpose of a primary. It should therefore be regarded with suspicion." It is certainly not a very powerful or effective yellow, as the author elsewhere admits. Cadmium yellow, the most powerful of yellow pigments, is placed by the author among the colours of inferior permanence. Yellow ochre he believes in, and Naples yellow "under all ordinary conditions." It again, however, seems rather a contradiction to be told that the old masters used yellow ochre a great deal, and elsewhere to read that "no permanent true yellow pigment appears to have been discovered by the ancients suitable for the painter's use." "The transparent vegetable yellows have been used during the last three centuries, in combination with blues, to form greens. In all cases these yellows have flown away, and only the blue colour with which they were originally mixed has remained." The opaque yellows from arsenic have gone in a different way, from damaging the colours combined with them. Altogether, the advice in regard to using yellow seems nearly to amount to that once given to people about to marry,—"Don't." However, people will go on marrying, and painters will use yellow, and perhaps both will get along somehow.

The reds and the blues are better behaved colours. The madders and vermilions used by the early painters have retained their power and purity, Mr. Muckley finds, down to the present day; though one result of this is that they now appear far too strong and brilliant for their surroundings. "Many reds," adds the author, "have been added to the old list, but they are either ineligible, or require the greatest care in the use of them." Among reds of inferior permanence, which change certainly when combined with others, and probably when alone, an old and much-used friend, crimson lake, is gibbeted. Carmine is even in worse case, the old colour; but madder carmine may be trusted. Of the decided red colours the author recommends vermilion, Venetian red, and light red, the latter being, in fact, "yellow ochre calcined to redness." Of the blues, ultramarine, of course, the queen of colours, takes the lead, and cobalt and French ultramarine stand well. Smalt, Prussian blue, Antwerp blue, and indigo are all condemned,—a sad levelling of old and respectable reputations. We must leave the reader to look up greens, greys, and browns, and study the remaining matter in regard to the primaries, in the book itself, which most people who have to make practical use of pigments will probably purchase. At the end of the chapters on the choice of colours are given three tabular lists,—the first, of permanent and reliable colours; the second, of those doubtful and unreliable; the third, of colours so fugitive that they should never be used; "and if colour-makers would cease from manufacturing them it would be of the greatest importance to the art." Among these last are found such well-known and often-used colours as Indian yellow, rose pink, chrome green, &c.

To this part of the book succeeds a very useful and tolerably full consideration of vehicles or mediums and their use and abuse, followed by other general suggestions in regard to the use of the painter's tools, some of which are comprehensive and very pithily expressed. Mr. Muckley recommends the habit to be early formed of using large brushes. The student will thus be obliged to work slower and with more deliberation. "When painting with large brushes, every stroke must be well guided, or confusion and emptiness will soon be the result. Every touch, when well directed, will probably be the just embodiment of the eye, the mind, and the hand, which last should ever be the obedient servant of the two other agents. The hand should never be permitted to work on its own account, a habit which we so constantly see. . . . . The use of small brushes favours poor work. They do not require so constantly directing as large ones do." The spirit-rapping "medium" in Mr. Browning's poem says about pens,—

"Who knows if you drive them or they drive you?"

and Mr. Muckley, without being a "medium," seems to suggest that the question may reasonably put as to brushes. The attention of architects may be directed to the remarks as to the lighting of studios for various classes of painting, and the treatment and colouring of the walls (pp. 73-75).

In regard to the preparation of colours and materials, the author comments on the very different condition under which painters work now, when everything is supplied to them ready made, and the artist may, as *Punch* suggested, "have nothing to do but just shove the colours on," as compared with the time when painters occupied a great deal of their own time and attention in preparing canvasses, brushes, colours, and vehicles. Under those circumstances an artist at least knew pretty well what he was working with, and Mr. Muckley seems to think, not unreasonably, that this practical work was not without its good effect on the artist, "sharpening the appetite of the real student, making him doubly eager to follow the more pleasant part of his occupation when the time arrived for him to do so." We may add that to every man whose main occupation is æsthetic or ideal, some degree of practical occupation is most valuable, as preserving the balance of the faculties and the character. We are not expecting that artists will take to mixing their own varnishes and vehicles again, or grinding their own colours; but the fact that it is all done by tradesmen for them now has at least this drawback, that the interest of the tradesman is merely to sell colours; he has no direct interest in making them permanently fitted for their work in the best way; whereas the painter who mixed his own colours had the ultimate result at heart. But the same dealer sells, indifferently, permanent and fugitive colours, and cares not which, so long as he does sell them. Now, says Mr. Muckley, "Let some colourman begin anew, by taking special care that all the materials which come into his hands are pure, and that the washing and grinding of certain pigments be as perfect as possible. Let him also supply only those colours which he knows to be of the best quality and permanent. Or if he chooses to sell those which are semi-permanent, let this be indicated on the usual label attached to the tube or cake, so that painters may be made aware with what they have to deal. The price of such materials might be raised according to the extra time and care given to their preparation. There can be no doubt that any colourman who would take up the business in this form would soon have the best part of it to himself, for at the present time no such person exists. The formation of a body or society for the preparation of painters' materials, under the immediate control and direction of painters of repute, would doubtless be still better." The mere additional cost of making colours carefully should count for little or nothing in the matter, when we consider the importance of the subject to art and artists, and when we realise that "from a few tubes of colour, of small comparative cost, a work of the value of hundreds, and sometimes thousands of pounds, is often produced." With which practical quotation we take leave of a very practical and useful little book.

VARIORUM.

"The Electric Light for Industrial Uses," by R. E. Crompton (Mansion House-buildings), although only a pamphlet, and having to some extent a personal motive, gives some plain, straightforward information on the subject, which many are seeking for.——Mr. John H. Webber has published, on a sheet, sketches of some of the numerous memorials of eminent Nonconformists to be found in Bunhill-fields burial-ground.——The *Magazine of Art* has a touch at our ugly street-lamps:—"A lamp in Paris or Brussels is an elegant object, of a sort of bronze, tapering up, with a little half-raised decoration of leaves running round, and crowned with a pretty lantern. The lantern is the chief and all-important feature, the post being merely to support it. But here some kind of glass "thing" is perched on the top of a massive cast-iron pillar. Then this bulk is a waste of strength and emphasis. So, too, with the newly-introduced lanterns in the City, made in the shape of cylindrical cups out of one piece of glass. This was suitable in the case of the old oil-lamps hung out by a branch from the wall, and when the light was cast downwards; but here the absurdity has to be introduced of breaking a hole in the lower spherical surface to introduce the gas-jet. This clumsy device actually interferes with the light."——In the first number of the new serial, "Egypt" (Cassell), readers are reminded that the ancients took pains in laying out their cities. This is the course that was followed in laying out Alexandria:—"Orders were given for the measurement of the ground and foundations, and the architect, Dinocrates, was commissioned to prepare a plan. This took the form of a Greek *peplum*, or of a fan, and the work of indicating the direction to be followed by the roads, and the extent of the market-places, was begun by strewing white earth on the level ground. The supply of this material falling short, it was supplemented by the assistants of the architect taking the meal which had been provided in abundance for the labourers. The legend goes on to say that hardly had this been sprinkled on the soil when numbers of birds came flying down to feed on the welcome supply of food. Alexander hailed the appearance of these feathered guests as a favourable omen, signifying the rapid prosperity and future

wealth of the city."——"The art of Fan-painting," from the French of the Baronne Delamardelle (London: Lechertier & Co.), gives information which will be found useful by those who desire to attempt the practice of this pleasant and sometimes profitable art.

Miscellanea.

Sale of the Royal Dramatic College.—This ill-starred building found a purchaser in the person of Mr. Chabot, the "expert" in hand-writing, to whom the trustees, under an order of the Charity Commissioners, have sold it for a very small sum over the reserved price of 5,000*l.* Considering that the building has been sold along with the grounds, containing ten acres of freehold land adjoining the South-Western Railway, the purchaser is said to have secured a bargain. Mr. Chabot has bought the building entirely on speculation. Last week the furniture and fittings of the twenty dwelling-houses of the pensioners in the college, together with those in the great central hall, and the out-door effects were sold. The pictures, drawings, and a variety of other gifts of considerable value, together with a library containing upwards of 1,500 volumes will shortly be sold in London; and it is stated that the Charity Commissioners have directed that the proceeds of the sale of the college and effects are to form a fund for the benefit of the pensioners of the college.

Fall of Buildings.—On Thursday in last week, about half-past nine in the evening, the greater part of the back of the premises, No. 34, Knightrider-street, Doctors' Commons, suddenly fell into the roadway of Peter's-hill, completely blocking up the thoroughfare with the *débris*.—— A singular accident occurred about a quarter to ten on the previous evening in White Hart street, Drury-lane, where the pavement in front of the shop of Mr. Prendergrass suddenly fell in without any warning. It would appear that the pavement is built on a succession of vaults, although the houses have no connexion with them, the foundations of the latter being quite independent. Some two months ago the parish had occasion to repair the drain in the immediate neighbourhood of this shop, and this is believed to have interfered with the stability of the wall between the fallen vault and the one next to it. Fortunately no one sustained personal injury by either accident.

Profit of Public Works.—M. de Labry has written an essay, in which he discusses the various advantages of public improvements to invested capital, to adjacent regions, and to the Government, showing that the dividends to stockholders and the direct revenues of Government constitute only a small portion of the benefits conferred by increased facilities for travel and the transportation of merchandise. He thinks that both self-interest and duty should prompt the inhabitants of regions which have been well developed to contribute towards the opening of new districts. Even if the contributions appear to be sunk, the increase of trade and of general prosperity will, almost without exception, amply repay all the outlay.—*Ann. des Ponts et Chauss.*

Tramways, Great Grimsby.—The Provincial Tramway Company are now laying about four miles of line in this rapidly-rising seaport, which will no doubt be a boon to the inhabitants. Messrs. Davis & Emanuel, of London, are the engineers for the works, which are being executed under the superintendence of Messrs. Manghan & Cuxson, of London and Grimsby (as resident engineers) by Messrs. Riggall & Havins, contractors, of Grimsby. It is expected that the lines will be opened early in January next.

Candidates for District Surveyorships. At the meeting of the Metropolitan Board of Works, on this Friday, Oct. 1, the Board are to consider a letter from the Royal Institute of British Architects, stating that they are desirous of improving the character of the statutory examination of candidates for certificates of competency to perform the duties of a district surveyor in London, and that they have discussed the advisability of imposing a moderate fee upon each candidate, and inquiring whether the Board would acquiesce in such a course.

Arnold Sewerage Works.—Mr. Frederick Jackson, C.E., Nottingham, is the engineer for the above works, the tenders for which we printed last week.

Defective Gas Mains.—Large street excavations have just been made in the Mile-end-road and other East-end thoroughfares on account of the discovery that a very considerable quantity of gas was escaping at some points of the gas mains into the street sewers. It became absolutely necessary to make an immediate examination, and, as the subway system is not in operation in the district, the streets had to be opened up in order to get at the defective parts of the mains so as to make them gas-tight.

Exhibition of Gas Apparatus, Glasgow. Under the auspices of the Philosophical Society of Glasgow there is now being held an exhibition such as has never previously been held in Scotland, and such, indeed, as has never been equalled in the United Kingdom, if we consider its extent and variety, and the great degree of scientific interest attaching to the collections of exhibits in several of the departments. Briefly it may be called a Gas Apparatus Exhibition, but it is that and a great deal more.

School of Art Wood-Carving. — Free studentships in both the day classes and the evening classes of the School of Art Wood-carving, at the Royal Albert Hall, Kensington, are at present vacant. These studentships are maintained out of funds provided by the City and Guilds of London Institute for the Advancement of Technical Education. Forms of application and prospectuses of the school may be obtained on application to the Secretary.

Brixton.—A stained-glass window has been presented to St. John's Church, Angell Town, by Mr. Charles Mansfield, of the Burton-road, in memory of Sarah his wife, who died on the 1st of May last. It is a two-light window, and the subjects represented are scenes at our Lord's Resurrection. The work has been executed by Messrs. Heaton, Butler, & Bayne, under the superintendence of Mr. Harley M. Grellier.

Cemetery for the Parish of St. Mary Cray.—Designs for chapel, mortuary, lodge, laying-out roads, &c., are invited in competition. More than one correspondent have pointed out that the stipulated expenditure, 1,200*l.*, is too small for what is asked for, and that designs cannot be prepared properly by October 16th as required.

Hanley School of Art.—The Hanley School of Art, which has done much useful work in promoting good design in English pottery during the last quarter of a century, is about to be re-opened, after the enlargement of its buildings at a cost of about 2,500*l.* The committee appeal for subscriptions towards meeting this outlay.

Safety of Canterbury Cathedral.—Attention has been properly drawn to the dangerous condition of the staircases leading to the top of the central tower through the accumulation therein of inflammable matter carried in by birds.

Dublin.—The erection of the (R.C.) church of St. Agatha, North William-street, Dublin, has been commenced. The new church will be 154 ft. in length, 45 ft. in width, and 33 ft. in height. Messrs. O'Neill & Byrne are the contractors, and Mr. Toole is the architect.

Photographic Society of Great Britain. The private view of the annual exhibition of photographs will take place this Saturday, October 2nd. It will be opened to the public on Monday, the 4th inst.

Sewer Gas.—Five men have been killed in clearing out a short length of sewer in Paris by the foul gas which it appears to have contained.

Clonakilty.—The opening of the (R.C.) Church of Mary Immaculate, Clonakilty, took place on the 25th ult. It has been built at a cost of 29,000*l.* from designs by Mr. Ashlin, of Dublin.

TENDERS

For forming new roadway and sewer in Adpar-street Edgware-road. Mr. Gundry, architect:—

	Sewer.	Road.
Williams & Co.	£749	£960
Mowlem & Co.	710	795
Nowell & Robson	650	849
Keeble	620	800
Boyer	670	782
George	645	800
Killingback	644	755
Neave & Son	669	750
Burford & Ball	590	750
Alldred	468	728

For building five warehouses on Great Saffron-hill, for Mr. John Jaques. Messrs. J. & S. F. Clarkson, architects. Quantities not supplied:—

Langmead & Way (accepted).

For the erection of new stable buildings, Great Enton, Witley, Surrey, for Mr. F. E. Eastwood, J.P. Mr. Henry Peak, architect:—

Martin, Wells, & Co., Aldershot and London (accepted) £2,147 0 0

For range of glass houses, potting-shed, and garden walling, Great Enton, Witley, Surrey, for Mr. F. E. Eastwood, J.P. Mr. Henry Peak, architect:—

Martin, Wells, & Co. (accepted) £767 5 0

For new stable and coachhouse, "Greylands," Horsell, Woking Station, for Mr. J. P. Fitzgerald. Mr. Henry Peak, architect:—

Gale, Woking Station	£665 0 0
Wilson, Woking Station	583 0 0
Butt, Woking Station	545 0 0
Harris, Woking Station	486 10 0
Sheers, Maybury (accepted)	350 0 0

For house, Seven Sisters-road, for Mr. E. Jarrett Messrs. Lee & Tregelles, architects:—

Conder (accepted) £1,570 0 0

For workshops, &c., Southampton-mews, Euston-road for Mr. T. Hughes. Mr. G. P. Raggett, architect:—

Grover	£2,683 0 0
Patman & Fotheringham	2,543 0 0
Macey & Sons	2,404 0 0
Bird	2,395 0 0
Conder	2,367 0 0
Scrivener & Co.	2,294 0 0

For roads and drains, Oakfield Estate, Ashtead, Surrey. Mr. John Norton, architect:—

Ford & Co.	£5,999 0 0 !
Dyer	4,880 17 6
Norris	4,884 12 10
Sibsey	4,570 0 0
Crockett	3,335 0 0
Burford & Ball	3,199 0 0
Impey	2,980 11 10
Bloomfield	2,776 0 0
Catley	2,715 9 9
Blake	2,665 18 0
Strachan & Co.	2,603 19 11
Woodham Bros.	2,505 0 0
Botterill	2,499 0 0
Bell	2,389 0 0
Peill & Sons	2,345 0 0
Rigby	2,150 0 0
Hancock, Jun.	2,075 0 0
Cole	1,926 6 0
McKenzie & Co.	1,810 0 0
Kavanagh	1,736 0 0
Caulton	1,627 14 0
Taylor & Co.	1,493 7 6
Putney	1,386 0 0 !

For new Congregational Church, Widmore-road, Bromley, Kent. Mr. J. Sulman, architect. Quantities supplied:—

Austin	£7,646 0 0
Higgs	6,859 0 0
Reading	6,517 0 0
Linzell	6,560 0 0
Staines & Son	6,194 0 0
Hollidge & Stuart	6,230 0 0
Hobern	6,050 0 0
Lowe	6,153 19 0
Bowyer	6,186 19 0
Smith & Son	6,074 0 0
Batley	5,900 0 0
Garrud	5,651 0 0
Arnaud	5,688 0 0
Beale	5,525 0 0
Crossley	5,495 0 0
Grubb	5,235 0 0
Stephens & Bastow (accepted)	5,299 0 0

For the erection of Nos. 3, 4, and 5, Wychombe Studios, Haverstock-hill:—

Nash	£2,230 0 0
Gregory & Bruce	2,224 0 0
Gould & Brand	2,098 0 0
Langmead & Way	2,050 0 0
White (accepted)	1,989 0 0

For alterations and additions to the Royal Oak Tavern, York-street, for Messrs. Murrell. Mr. W. E. Williams, architect:—

Edgar	1,663 0 0
Perkins	1,433 0 0
Yeo	1,321 0 0
Marr	1,287 0 0
White	1,249 0 0
Mark	1,223 0 0

For alterations and additions to the Green Man Public-house, Edgware-road, for Mr. John Hancock. Mr. Josiah Houle, architect:—

Temple & Foster	£1,288 0 0
Mark	1,239 0 0
Canning & Mullins	1,177 0 0
Langmead & Way	1,130 0 0

For re-erecting a part of the Royal Oak Brewery, Croydon, for Mr. F. Overton. Messrs. Scamell & Colyer, engineers. Quantities by Messrs. Curtis & Son:—

Morter, Stratford	£2,347 0 0
Smith & Sons, Islington	2,329 0 0
Boiler.	
Horton & Sons	£385 0 0
Copper Coil, &c.	
Pontifex & Sons	604 0 0
Millwrights' Work.	
Thornewill & Warham	663 0 0

For roads and sewers, Abbey Lodge Estate, New Wimbledon, for Messrs. Teuten, Robottom, & Co.:—

Martin & Welmarsh	£1,999 0 0 ! !
Ellis	1,340 0 0
Blackmore	1,050 0 0
E. & W. Hes	1,041 0 0
Harris	894 0 0
Jackson	866 0 0
Pizzey (accepted)	858 0 0
Taylor	587 0 0 ! !

For a school on the Limes Estate, Croydon. Mr. Charles Henman, architect:—

Bellham & Co., Buckingham Palace-road	£955	16	0
Taylor, Croydon	925	10	0
Laing & Co., Parliament-street	913	0	0
Holt, Croydon	884	16	4
Marriage, Croydon	869	10	0
Clark & Bracey, Coleman-street	839	0	0
Smith & Sons, South Norwood*	763	0	0

* Accepted.

For a residence, Birdhurst-road, Croydon. Mr. Charles Henman, architect:—

Humphries, Sutton	£2,670	0	0
Laing & Co., Parliament-street	2,468	0	0
Glaskin, Croydon	2,390	0	0
Williams & Son, Canonbury	2,360	0	0
Taylor, Croydon	2,319	0	0
Bellham & Co., Parliament-street	2,202	1	8
Marriage, Croydon	2,200	0	0
Smith & Sons, South Norwood*	2,117	0	0

* Accepted.

For a residence, Radcliffe-road, Addiscombe. Mr. Charles Henman, architect:—

Goddard & Son, Farnham	£4,265	10	0
Jarrett, Croydon	4,100	0	0
Macey & Sons, Strand	4,010	0	0
Marriage, Croydon	3,970	0	0
Laing & Co., Parliament-street	3,960	0	0
Glaskin, Croydon	3,887	0	0
Smith & Sons, South Norwood*	3,709	0	0

* Accepted.

For the erection of five cottages and corner shop at Hemel Hempstead, Herts. Mr. Walter T. Feldon, architect:—

Monk	£1,300	0	0
Flint	1,100	0	0
Horn	1,060	0	0
Philbey, Hemel Hempstead*	835	0	0

* Accepted.

For villa residences at West Heathfield, Twickenham, for Mr. D. W. Palmer:—

	One Pair.	Two Pairs.
Pillar	£795	£1,585
Potter	700	1,400
Cordery	709	1,380
Coney	764	1,358
Collier	700	1,340

For erecting shop at Old Southgate, for Mr. T. Sugden. Mr. William Smith, architect:—

Shurmur	£492	0	0
Harper	476	0	0
Dunford & Langham	466	0	0
Newby	456	0	0
Steele Bros.	460	0	0
Larke	443	0	0
Wheeler	427	0	0

For proposed additions to Wycliffe Hall, Oxford. Mr. Wm. Wilkinson, architect:—

Castle	£3,280	0	0
Dobson	3,275	0	0
Frankland	3,080	0	0
Wyatt & Sons	2,916	0	0
Symm & Co. (accepted)	2,777	0	0

For erecting seven shops adjoining the Upland Tavern, North-cross-road, Crystal Palace-road, East Dulwich, for Mr. W. Sayer. Mr. G. Treacher, architect:—

Gill, Wandsworth-road (accepted)	£4,550	0	0

For alterations and repairs at the North Pole, Shadwell. Messrs. Perry & Reed, architects:—

Mark	£720	0	0
Staines & Son	688	0	0

For sundry repairs and re-decoration of Mayfield Chapel, Dalston:—

Repairs to Exterior.

Barber & Co.	£357	0	0
Jarvis & Sons	270	0	0
Shurmur (accepted)	189	0	0

Re-decorating Interior.

Goodman	525	0	0
Snook	419	0	0
Campion	393	0	0
Jarvis & Sons	300	0	0
Shurmur	279	0	0
Barber & Co. (accepted)	238	0	0

For addition to swimming-bath, Public Baths, Maidstone. Mr. Edward W. Stephens, architect:—

Smith, Maidstone	£429	0	0
Naylar, Rochester	409	0	0
Bartholomew, Maidstone	405	10	0
Cox, Bros., Maidstone	391	0	0
Elmore, Maidstone	390	0	0
Avard, Maidstone	386	0	0
Wallis & Clements, Maidstone	386	0	0
Simmonds, Maidstone	377	0	0
Vaughan, Bros. (accepted)	339	0	0

For fittings, &c., at Cheshire Cheese, Addle-street, Cheapside. Mr. H. J. Newton, architect:—

Hockley	£378	0	0
Shurmur	333	0	0
Lascelles	283	0	0
Auley (accepted)	215	0	0

New Counter.

Warne	£144	0	0
Hellings	137	10	6
South	134	0	0
Sanders & Son	119	4	0
Paddon (accepted)	119	0	0

Plate Glass and Embossing.

Gibbs, Blackfriars-road (accepted)	141	0	0

For erecting smoking-saloon and enlarging polo-pavilion, decorating dining-room and saloon, at Hurlingham, for the committee of the Hurlingham Club, Fulham. Mr. Joseph S. Moye, architect:—

Saala (accepted).

For the erection of new spinning-shed at Shafteshury House, London-fields. Messrs. Leo & Walton, architects:—

Rider & Son	£353	0	0
Barrett	345	0	0
Boyce	328	0	0
Jarvis & Sons (accepted)	310	0	0

All statements of facts, lists of tenders, &c. must be accompanied by the name and address of the sender, not necessarily for publication.

We are compelled to decline pointing out books and giving addresses.

NOTE.—The responsibility of signed articles, and papers read at public meetings, rests, of course with the authors.

CHARGES FOR ADVERTISEMENTS.

SITUATIONS VACANT, PARTNERSHIPS, APPRENTICESHIPS TRADE, AND GENERAL ADVERTISEMENTS.

Six lines (about fifty words) or under ..... 4s. 6d.
Each additional line (about ten words) ..... 0s. 6d.

Terms for series of Trade Advertisements, also for Special Advertisements on front page, Competitions, Contracts, Sales by Auction, &c. may be obtained on application to the Publisher.

SITUATIONS WANTED.

FOUR Lines (about THIRTY words) or under ..... 2s. 6d.
Each additional line (about ten words) ..... 0s. 6d.

REPLIES TO ADVERTISEMENTS,
Addressed Box —, Office of "The Builder,"
Cannot be forwarded, but *must* in all cases be *called for*, and the Office Receipt produced.

THE CHARGE FOR A BOX IS AS UNDER:—
For "Situations Wanted" Advertisements ..... 3d. per Week.
For all other Advertisements ..... 6d. per Week.

PREPAYMENT IS ABSOLUTELY NECESSARY.

*** Stamps must not be sent, but all small sums should be remitted by Cash in Registered Letter or by Money Order, payable the Post-office, King-street, Covent-garden, W.C. to

DOUGLAS FOURDRINIER, Publisher,
Addressed to No. 46, Catherine-street, W.C.

Advertisements for the current week's issue must reach the office before THREE o'clock p.m. on THURSDAY.

The Publisher cannot be responsible for DRAWINGS, TESTIMONIALS, &c. sent at the Office in reply to Advertisements, and strongly recommends that of the latter COPIES ONLY should be sent.

TERMS OF SUBSCRIPTION.

"THE BUILDER" is supplied *direct* from the Office to residents in any part of the United Kingdom at the rate of 19s. per annum, *prepaid*. Remittances payable as above.

The Builder.

CONTENTS.

Decorative Suggestions from Natural Forms.

THE part played by natural vegetation in architectural ornament is very obvious in some of the best-known and most prominent features in past styles of architecture. The water-lily leaf in the Egyptian capital, the acanthus in the Greek capital, are specimens of architectural decorations in which the natural form on which the decorative treatment is founded is perfectly recognisable, and in the case of the Egyptian example is, indeed, hardly conventionalised, except in regard to its orderly and symmetrical arrangement around the capital. The Greek acanthus is conventionalised a good deal more than this; it is, to begin with, a more irregular and broken leaf in its natural form than the lotus, and had to be reduced to a conventional irregularity of form to adapt it to the spirit of Greek ornament; and as it was not used in flat incised treatment, like that of Egyptian work, but in relief, it was necessary to impart to it a comparatively solid and heavy appearance, and to get rid of its thin edges and sharp points, in order to give it sufficient weight and mass to harmonise with the architecture amid which it was placed, as well as to have some appearance of giving, at least, partial support to the angles of the abacus under which it curled. Thus the transition from nature is, after all, pretty well marked, and those who had been shown merely an acanthus-leaf in a state of nature, and told that this was elaborated into the decoration of a capital by the Greeks, would probably by no means expect to find a piece of carving so decidedly removed from imitation of nature as the Corinthian capital unquestionably is.

Other ornament in connexion with Greek architecture is even more decidedly removed from nature than this, though it may be observed that when Greek ornament is founded on natural forms the principle of the growth of nature is almost invariably retained and correctly expressed. Greek floral ornament is developed from a leading idea; it is not merely formed applied thoughtlessly and illogically. Roman floral ornament has a character and often a sumptuous effect peculiar to itself; it is still further from nature than Greek ornament, as it not only does not imitate the character of nature, but it frequently ignores altogether even the principles of nature in regard to growth and development of design; it shows us large thick masses of foliage of a somewhat heavy cauliflower type, which do not grow upon any recognisable principle, but seem to be applied in unwieldy twists and spiral bunches, mainly with the view of producing an effect on the spectator by mere massiveness and richness, and by highly-elaborated surface carving. This remark does not apply so much, of course, to the Roman capital, but then the merits of that are chiefly due to the Greeks.

Romanesque carving is oddly mingled of purely naturalistic attempts to represent foliage and small animals in as real a manner as the carver's skill allowed, and of purely abstract ornaments, looking often like classical reminiscences more or less coarsely carried out. When we arrive at the earlier complete Gothic, in this country especially, we then, for the first time, find an application of nature to ornament which is carried out on the same principles as Greek ornament, and with often nearly equal excellence, though in a very different style of execution. In the later Gothic style we find more realistic imitation of nature than we have noticed in any leading architectural style previously, and also a greater variety of vegetation introduced, especially in some exceptional cases, such as that of the chapter-house at Southwell, on which we were commenting the other day. But in general, even at this freer period of Gothic ornament, we find that prevalent types are very much repeated in the floral ornament, and only a comparatively few of Nature's types, and those among the most common and easily accessible, are pressed into use by the Mediæval carvers.

We have named the leading styles of the world, and if we look at subsidiary architectural styles we do not find any larger use of natural types of ornament, but rather less. The Arabic and most of the Oriental styles, it is needless to say, are almost entirely abstract in their architectural ornament. In Indian work it is only in worked ornament that some suggestion of Nature's comes in, and sometimes even direct imitation of nature; but that, as far as we have observed, is but seldom. When the Renaissance gave a new direction to architecture in Europe, ornament went even further from nature than ever. It developed into something founded on Roman ornament, which itself had been founded on Greek, and the reference to nature, even in the case of forms and designs which pretended to imitate nature, became thus very distant indeed, and seemed all the more so from the curious way in which the quasi-natural forms were blended with or ran into all kinds of imitations of artificial objects or unnatural chimeras. Yet one merit must be conceded to the Renaissance ornament, in which it was superior to the Roman; its foliage, however far-fetched and artificial, has a clearly-marked principle of growth and development from a root or a centre, according to the principles of natural growth, and in this respect it is more allied to Greek than to Roman taste in ornamental design, and approaches Greek ornament also in the beauty and decision of its curves. Its types, however, are even fewer than in Classic ornament, and much fewer than in Gothic; the Renaissance designer only recognising one kind of leaf and one kind of growth, combined and massed in various ways, certainly, but always the same kind of vegetation, an artificial scroll, half leaf, half stalk, derived from the Roman acanthus, reduced to more slender proportions, and employed on more definite and carefully-constructed lines.

In modern Gothic work considerable attempts have been made to introduce a greater variety of natural vegetation into architectural ornaments, and many churches have been decorated with capitals carved from knots of flowers and ferns and other vegetation, brought together for the purpose, and in some cases that we know of carved from Nature's models, placed before the eye while the work was in progress. And it is creditable to the profession of architectural carvers that in some cases this trouble has been taken not at the bidding or suggestion of the architect, but spontaneously, and from pure love of the work.

It must be observed, however, that merely carving flowers and vegetation from models is not designing ornament, and that something more of thought, more of adaptation of the form to the circumstances and the material, must be displayed to justify the claim of the work to be called ornamental design. This is what we do find to perfection in Greek and in early Gothic ornament; it is not the mere imitation of nature, but the application of natural form, retaining much of its original characteristics, to the production of ornament in a style suited to the peculiarities of the material in which it is executed, and the final form of which is the result of considerable thought, not of the mere cleverness of the hand and eye in realistic reproduction. But it is remarkable how few natural types seem to have been used in the production of ornament of this thoughtful class, and how little attempt there has been to evolve any new ones in the same class of ornament. We have gone on reproducing the Corinthian capital over and over *ad infinitum*, without it having apparently even occurred to any one that the same general form would be susceptible of varied treatment by using other leaves instead of the beautiful but well-worn acanthus, and that this variation might even be carried out in the same building with good effect, preserving the general aspect of the capitals alike, and varying the details. In the case of that beautiful production the carved Early English capital, again, we have been content to go on copying and reproducing it (very seldom with anything like the success of the Mediæval inventors), with no attempt to apply the same free yet conventional treatment, so admirably suited for execution in stone, to any other derivation from

vegetable form. It may, we confess, be doubted whether the Early English lobed foliage is adapted from any precise form in the vegetable world; whether it is not, in fact, evolved from a reminiscence of the volute of the Classic capital, which took this lobed form in the Romanesque French capitals, while still retaining its original angle position as in the Classic capital, but which the later carvers, in England more especially, adopted as the prevalent feature in the carving of a capital, introducing it with the same freedom and absence of order as if it had been a natural growth. The feature is so complete in itself, and so individual in character, that it seems difficult to touch it without spoiling it, and perhaps any effort to adopt the Early English capital with another form of detail could hardly be successful. But other forms of Gothic capital might be reproduced with foliage different from that which was used as their model by the Mediæval carvers. And if the characteristic distinction of the Classic and Gothic type of capital be kept in mind, there is no reason why the same type of vegetation might not be equally suggestive for either type of capital (or of ornament generally), and be used with totally different expression in the Classic or the Gothic manner. The radical distinction, it must be remembered, between Classic and Gothic floral ornament is that the former is geometrically and symmetrically arranged; the latter is free, and, for the most part, unsymmetrical, and imitates the irregular growth of nature even when, as in the Early English capital, it does not absolutely imitate nature in detail. This difference between symmetrical and unsymmetrical in the relation between ornament and nature is conveniently expressed in the terms "Classic" and "Gothic," the signification of which, in relation to such a point, every one readily understands; but, in reality, the distinction is a much more typical one, since the whole of ornament which is based on natural foliage may be divided into these two great classes,—that which is irregular and more or less naturalistic, of which Gothic work shows the best types, and that which, in adapting natural forms, compels them to assume an artificial and bi-lateral symmetry, and results in the type of ornament which we call Classic, and of which Greek ornament furnishes the highest and most perfect examples.

Now, considering that we have always these two essentially different methods of treating a *motif* in ornament, and that behind these we have the almost infinite variety of nature to furnish us with types and suggestions, each of which may be treated not only in one or other of these two leading methods, but may be also susceptible of several sub-variations in character arising out of the different nature and requirements of different materials, it seems strange that there has been so little effort, if not to evolve new forms of ornament, at least to give new character and treatment to old forms by taking fresh suggestions from nature. Of course all the varieties of natural form are not sufficiently marked and individualised to afford each a separate type of ornament: a good deal of similarity of character runs through many species of *flora* when taken in detail, and when taken as a whole a plant or a tree is commonly a subject for the painter rather than for the ornamentist. But even admitting this limitation, there is a variety of form in the *flora* of this country alone which is eminently suitable and suggestive for ornament, and which has never been used; and a far wider range is given if we include among our suggestive types those which are to be found in the vegetation proper to other climates, and which have scarcely been applied at all in architectural and ornamental design. Considering how frequent is the complaint of want of novelty in architectural ornament especially, and deficiency in marked character, it would seem worth while to try if new hints may not be taken from nature by way of furnishing the basis for more variety of treatment in the ornamental detail of architecture, or in ornamental work which is accessory to architecture. We propose, by way of giving these remarks a practical turn, to give sketches of some bits of natural detail such as seem specially suitable and suggestive for this purpose, and such as have been little if at all previously used in architectural detail. In doing so, we shall endeavour to draw somewhat upon exotic types of foliage, not only because these are novel in their application to this purpose, but also because there are to be found among these a good many forms peculiarly suitable thereto; forms which are more precise in their design, and more bold and free in line, than are generally to be found among the natural productions of our own temperate zone, where nature seems to work in a quieter and less exuberant style than under a tropical sun. To the sketches of nature's detail we will take leave to append, always in a spirit of modest and tentative suggestion, one or two examples of the manner in which these may be applied in the formation of architectural detail, or of ornamental detail in one of the forms which may be regarded as subservient to architectural design. The application of mere natural types to one or two different materials may also furnish opportunity for illustrating some ideas as to the manner in which ornament should be affected by the nature of the material in which it is executed, and which often in itself may almost necessarily suggest considerable varieties of treatment and of design, founded on the same initial form. The specimens of natural detail which we may be able to give will perhaps be of interest to some who have not time to collect such "cribs" from nature themselves, and if our suggestions in treating them do not meet with the approval of all, they may at least afford hints on which the taste and fancy of others may exercise themselves further.

The example we offer in this number is from a tropical shrub of very characteristic formation. The leaves have the appearance, at a little distance, of being cut short off; but in reality, as will be seen from the full-sized sketch of the end of the leaf, they are very carefully and delicately modelled. The section of the leaf is like that of a ridge-and-furrow roof. This section, with its edges and depressions, gives a great many fine lines of light and shadow, and this, as well as the flat character of the leaf and the fine and delicate curve of its lines, seem to point it out as very suitable for treatment in rather flat carved work in such a material as marble, in which the delicate curves and sharp edges can be rendered with precision. It is accordingly here adapted to a carved capital supposed to be in that material, the general form being borrowed from a semi-Byzantine form of Romanesque capital found in early French work. It may be observed that the specific epithet, *Licuala horrida*, is not to be taken as implying anything "horrid," but simply means, in the original signification of the Latin adjective, "prickly" or "thorny," referring to the stem of the plant.

Such a design as is here given might be rendered more effective in execution by picking out the lines of the leaves with gilding, either on the margin, or (better, perhaps) applied to one bevel of each ridge, leaving the alternate bevels plain.

THE BOARD OF TRADE AND THE RAILWAYS.

The circular letter of the 20th of September to the railway companies, signed by Mr. Calcraft on behalf of the Board of Trade, betrays a certain amount of tension in the relation between the administration and the managers of the various lines. It may be held to show something further, namely, the conviction entertained by the Board of Trade of their own powerlessness to exert any efficient control in the existing state of the law. Little as it is consistent with the dignity, or we might even say the utility, of a Government department to reiterate, year by year, in its official reports, that complaint of the inadequacy of the returns laid before them, which was a stereotyped feature of the reports of Sir Henry Tyler, and which has been repeated by Messrs. Calcraft & Giffen in their latest annual report, the public may be thought to have become used to it. "The companies will not furnish a word more of information than is contained in the forms authorised by Parliament," it might be said. "Some of them, as, for example, the London and North-Western, will not even do this. It is of no use to make any complaints; without new legislation the companies will defy the Board of Trade. And new legislation will not depend on the real requirements of the case, but on political or class interest conditions." So, on the principle of not crying over spilt milk, the public has left the companies masters of the field.

The alarm generally occasioned by the sudden outburst of a new crop of railway accidents seems to have inspired the Board of Trade with the idea that their hands are, at all events, morally strengthened. They have put categorical questions to the companies, the replies to which would, no doubt, be matter of public interest. And they have done this, pointedly and firmly, without having any power to enforce a reply. If the companies choose to ignore the questions, or to say that they are not bound to furnish the replies, the Board of Trade can do nothing but say that, in that case, they must go to Parliament to ask for further power. That this will be the upshot of the contention is, we think, most probable. Supposing the companies to furnish the Board of Trade, as now requested, with an alphabetical return of all the stations on their lines, showing whether the points and signals at those stations are, or are not, interlocked with one another, such returns can have no practical utility except as furnishing a basis for further requirements on the part of the Board of Trade. The general condition of the lines in this respect is well known. In 1876, on the English lines, 69 per cent. of the mileage was worked with interlocking points and signals, and the same percentage of railway was worked on the block system. In Scotland the proportions were 49 and 52 per cent.; in Ireland, 25 and 2 per cent.; and in the United Kingdom 64 and 57 per cent., respectively. By the end of 1878 the proportions had risen to 77 per cent. of interlocking, and 75 per cent. of blocking, in England, and 71 and 63 per cent. in the United Kingdom. The desideratum, therefore, for the Board of Trade is not so much to ascertain the exact localities of that quarter of the average length of the English lines on which these precautions are not yet taken, as it is to see how they can ensure the dealing with these exceptional cases in the mode which prudence points out to be desirable. The Brighton, the Chatham and Dover, and the Metropolitan District railways were the only three great lines on which, in 1878, the absolute block system was universally adopted. The Metropolitan was the only line on which every point and signal was interlocked.

With regard to the reports of Colonel Yolland, of which "the Board of Trade feel it their duty to emphasise the conclusions," they are on many points so fully and minutely in accordance with our own remarks at the time of the occurrence of the accidents, that the only point left in doubt is, how far the recommendations made in our columns have been directly utilised for the public service, or how far different professional men, impartially studying the same facts without any mutual exchange of ideas, have arrived at identically the same conclusions. Which be the case matters but little, but the fact of the accord is one of good omen.

Colonel Yolland has ascertained that on several occasions the North British Railway Company has felt it necessary to complain of the great speed at which some of the North-Eastern Company's trains were run over their line between Edinburgh and Berwick. It appears, however, to the inspector that it is the state of the line which renders the rate of running unsafe. In pointing out those wholly elementary precautions, which were neglected by the North British Company during the operation of repairing their line near Berwick (which neglect, together with the failure to reduce the speed of the trains over the unfinished portion of the line, caused the accident), it is dismaying to find the Government inspector stooping so near the ground as to attach great blame to "the foreman of the platelayers." Is there no engineer to the line? If so, what has the Government inspector to do, directly, with his subordinates? The fact that a Royal Engineer officer, familiar as he must be with the rules of hierarchical subordination, has in such a case to express an opinion as to the conduct of an ordinary workman, seems to betoken a marvellous absence of anything like systematic organisation of the service of the line.

With regard to the Wennington disaster, again we find "the act of the foreman and gang of platelayers" blamed as contributing to the occurrence. The want of cant in the rails, and the absence of a check rail, to which we before called attention, are also mentioned as contributing to the ease with which the engine left the rails. But the public cannot deal with foremen and gangs of platelayers. The public has a right to expect, and does expect, that there shall be, on every railway, an engineering officer of adequate standing directly responsible for the state of the line, for the state of the rolling plant,

and for the relation between the good order of these two integral parts of the great compound machine, and the speed at which it is driven. It is with such an engineer that the Government inspector alone ought to have to reckon. It is the engineer who should be primarily responsible, in the face of the world. And if any of those employed under him, in any grade, have disobeyed his orders, and thus incurred danger or wrought damage, it is for the engineer, in self-justification, to prove the fact, and to ask that the due penalty should be inflicted in the right quarter. In the behalf of the safety of the public we protest against the Inspector of the Board of Trade telling the world that "foremen," or "gangs of workmen," are "greatly to blame." In each of the cases in question we have to choose between attributing what occurred to the unexpected failure of some mechanical appliance, or to a neglect of duty not far—if at all—removed from criminality. It is with the responsible managers of a line that the public has to deal in such cases, and to descend at once to the hand that erred, without taking any notice of the head, is something like Sydney Smith's metaphor of patting the dome of St. Paul's to give pleasure to the Dean and Chapter.

As to the brakes in the Wennington case, it seems that the Westinghouse brake was on the tender, that there was a hand-brake in the guard's van, and that there was no brake on the engine, or on any other of the nine vehicles which composed the train. It is, therefore, evident that the brake power was inadequate, and was far inferior to that which should have been applied to a train running at such speed. But we must be allowed to say that the establishment of this fact throws very little light on the cause of the accident. The driver must have known,—at all events, ought to have known, but in our opinion must practically have known, —what the brake power was. He ought to have been aware whether it would retard the train properly before arriving at the station. There is no doubt that it failed so to retard the train, and the question of interest to the mechanic (and indeed to the public) is, why did it so fail to retard it? It is all very well to say there were only two brakes; but the driver know that. Did both act? or if not, why not? Was the brake on the tender in order? Was it applied? How was it that the engine was driven over the curve at a speed at which it was certain to run off? These are the points which a scientific inquiry ought to elucidate. We fully agree with Colonel Yolland when he says that *if* the train had been fitted with a good continuous brake, and *if* it had been under the control of the driver, and *if* the driver had made use of it, the leading van would not have run 166 yards from the point of crossing. But surely we do not require a Government official to tell us that. That much is perfectly obvious to any one who has read with attention the Report of the Royal Commission on Railway Accidents, published in 1877. If the train was running at thirty miles an hour, it would have been brought up by a good set of brakes in 15 seconds,—that is to say, in 220 yards. But in the absence of this unusual retardatory power a much greater distance was necessary for slackening speed. What we want to know is, when ought the two brakes that were actually on the train to have been applied? When were they applied? and what was the true reason that the speed was unchecked?

It is of the utmost importance that the cardinal points of every disaster should be distinctly brought out. Colonel Yolland calls attention, with great justice, to the noting and registering every fact concerning the permanent way, in any case of accident, before "the removal of those marks which are the surest guides to the elucidation of the causes which led to the accident." But it is possible to take a view of causes which is so narrow as to be of little use. The public naturally says, Who is to blame? But what the engineer wants to know is,—what is to blame? Extra speed, at a given point, was the mechanical cause of the accident. We want to know why, in that particular case, the speed was excessive. It is no reply to be told, if there had been a better brake the train could have been stopped. That we knew before; and it is leaving the track to go off from the inquiry on that scent.

A contemporary, whose information on mechanical points is of an unusually good character, says that the inspectors to the Board of Trade have over and over again pointed out that almost all railway accidents, especially those of a graver character, are due to one of three causes, —the neglect of the block system, the omission properly to interlock points and signals, or the absence of adequate brakes. To a certain extent that is true, although the experience of the last few weeks shows that this list of causes is far from exhaustive. The human machine breaks down, sometimes, under responsibility or fatigue; and it is to this kind of failure that at least two of the latest railway disasters were due. We have with us the weight of the highest authority when we express the opinion that every attempt to throw human responsibility on to automatic machinery has at least its dangerous side. We do not call the interlocking of points and signals automatic. It is a precaution usually of the utmost value. But we do feel convinced that anything which tends to induce the regular use of a violent retardatory power for the sudden stoppage of a train, with the result of allowing the driver habitually to approach a station or crossing at full speed, introduces a new source of danger; and one which, as recent events have shown, may be a more fertile cause of disaster than some of those which we are seeking to avoid. Let us, by all means, have ample brake power, but let it only be relied on, to any great extent, for the prevention of apparent danger, not for the regular working of a line.

THE BRUSSELS EXHIBITION.*

The brilliant representation of her industrial arts that Belgium shows in the Brussels Exhibition is of that peculiar nature that renders almost impossible a hurried epitome. Even after a comparatively lengthy notice of the more salient points, so many important features have been omitted that it would be unjust to pass to the Modern Industrial Arts Section before devoting a few more words to the exceptional show made in the Retrospection Section, which forms the great feature of the Exhibition. Those who remember the Exhibition held at Manchester in 1857, so fitly termed an Exhibition of Art-Treasures, may form some conception of the gathering made here; for the choicest marvels produced from the jealously-guarded and little-known,—too-little-known,—treasure-houses of the churches, the convents, and various ecclesiastical bodies that exist in Belgium, as they have done, untouched for so many centuries, have been contributed, and combine to form, with treasures from the wealthy corporations and educational establishments, a show such as no loan-collection could have gathered together. From sources such as these come forth "gems of purest ray serene," which know not of the ruthless hand of the dealer or the commercial fashion-ruled fluctuation of the auction-room. It is this feature which, as in the case of Manchester, will mark the Brussels Retrospective Section in the annals of Exhibitions, offering a *histoire de travail*, perhaps, even more interesting than that of Paris in 1867, as almost exclusively showing the artistic industry of one country.

There are, however, to be easily detected many marked features of foreign origin, but these only add a zest to the unity of the whole, Italy, Germany, Holland, Spain, England, and the East all contributing to enhance the general effect. Among these stands foremost a feature which would merit, did but our space allow, an article to itself,—the room in which M. Somzee, a Belgian collector, has exhibited a portion of his choice collection of Italian majolica-ware and other rarities. In one large room, in the cases ranged round the walls and in the centre, are gathered together several hundred of the choicest pieces of that sixteenth-century majolica, known as Gubbio-ware, a sight such as is rarely to be seen; and beautiful, indeed, is this array of one of the busiest decorative art industries of the *cinque cento*,—so beautiful, that ten times the space they occupy might be ornamented with the treasures that are here crowded together, gorgeous in their glow of colour, heightened by, in some cases, the delicate *lustro* of age, in others by that of the artist, who, however, was always loth to employ its aid when his own design sufficed to decorate the simple piece of glazed earthenware that he rendered a priceless gem, to be disputed by princes and cardinals. What marvels by Maestro Giorgio and his contemporaries exist in these cases we know not, as no catalogue has been made of this collection, nor has, again, the necessary aid of labels been thought of,—a feature the value of which the Manchester Exhibition of now twenty-three years back did not neglect to understand. But the general character of the works is so familiar that it is easy to distinguish many of the vases and dishes, from Gubbio, from Faenza, from Castel Durata, from Pesaro, and from Forli, and many another pleasant town in Raffaelle's country; the well-known *spezzeria*-pots from Caffagiolo,—the tradition of the ornamentation and use of which is handed down to the druggists' shops of the present day. A rare collection of glazed and painted tiles, also of Urbino ware, fills a space at least three yards square in the centre of the room, the corners of which are crowded with other treasures of the Italian industrial arts, too numerous to mention, but among which let us not pass over the several rare Florentine *cassoni*, or marriage-coffers of the fifteenth century, carved and gilt and painted with all that luxury of decoration that belonged to the early Renaissance. No famous artist has happened to decorate the panels which adorn each of these coffers; but luck might have thus spared the creation of a great painter, for, as is well known to collectors, the artists of the Renaissance did not disdain to paint such *cassoni*.

To one other treasure of M. Somzee's collection we can alone afford to refer,—a choice piece of time-stained, but still perfectly-preserved, Arras tapestry, which has wisely been placed behind glass. Complete with its border, the whole piece scarcely measures 2 ft. 6 in. square. Through the now even-toned mellowness to which exposure has reduced the once brilliant colours, lighted up by the glitter of the gold-thread, it is not difficult to trace the master-design of some contemporary of Memling, if it is not by that patient artist himself. Purchased in Italy, this gem of the looms of Arras has returned to its native country, and now justly forms one of the pearls of the tapestry show.

A feature which it might be expected would have proved, as such gatherings usually do, of more than passing interest,—the collection of national portraits,—has, owing to the manner in which these have been hung, lost much, if not all, of its instructive character. In their valuable aid as decorative "properties" these portraits have been sacrificed, and, scattered about the Exhibition as they are, an examination of them is rendered difficult to a degree; while here, again, the utter want of label or catalogue renders these pieces of painted canvas unmeaning. To be of instructive value, a collection of portraits, whether national or what not, must be hung in some systematic order, and, above all, be carefully catalogued.

Another of the great arts of the past in Belgium is here but very inadequately represented,—the art of the glass-painter. Destruction has sadly lessened the number of master-pieces with which the Belgian painters decorated many a cathedral and church throughout the country. Many fine pieces still exist, but these could not, of course, be exhibited. There are, however, to be seen some good specimens of the art, but which give only a very imperfect idea of the power of the renowned Flemish *verriers* of the Middle Ages and the Renaissance.

To those interested in musical matters, the choice collection of Belgian musical-boxes particularly appeals; here, from the early days when the musical notes find no separate expression beyond a few mere dotted marks placed between the lines of the big-lettered psalter, we trace the beautiful art in which the Belgians were renowned throughout Europe down to our own modern complicated system. As a complement to this collection, there are exhibited a number of musical instruments. These, again, are mostly made in Belgium, which boasts of more than one famous maker, Rucker, of Antwerp, being the Belgian emulator of the fame of Stradivarius and Guarnerius.

A word is due to the Belgian armourers, whose works are here well exhibited; the Belgian knights of old were no less generous patrons of the artist-blacksmiths of their time than were the princes of Italy, of England, of Germany, and of France. Nor are there wanting among the well-chosen collection of arms beautiful specimens of work, on which something more than the ingenuity of the artisan has been bestowed,—marvels of patient decoration, rich with damascened work and engravings; arquebuses and powder-flasks, gems of coloured inlaid work, and

a

* See p. 316, *ante*.

sword-hilts, worthy a place by the side of the goldsmith's most cunning productions. Among the arms, all choice specimens, will be noticed with more than usual interest the sword of Rubens, its hilt a rare piece of damascened gold work, not far from which reposes in another case, picturesquely filled with the collars and badges of a number of St. Sebastian or archery societies, the collar that Rubens wore in his official capacity at the Academy of Fine Arts at Antwerp,—another piece of delicate metal-work.

With a hasty mention of the rare collection of ivories,—to which no reference has as yet been made,—our notice of the Retrospective Section must unwillingly be drawn to a close. Of these peculiarly interesting works, in which have been preserved for us some of the few remains of the art of the mystic commencements of Christianity, the Exhibition shows some rare specimens of several of the periods into which collectors classify these rare and precious works; early Christian diptychs, and quaint book-backs, religious, Romanesque, Renaissance, and purely secular work. In the country of "Il Fiammingo," as François de Quesnoy was called by the Italians, among whom he worked so long, there are naturally here to be found a number of works attributed to that renowned artist; attributed only, as De Quesnoy never signed his work, but fame has not neglected to keep due record of his memory, as it has of many another great artist of the busy past, and long is the list that Belgium has contributed to the history of art. The exhibit of the Minister of Public Instruction, to which casual reference has already been made, is one that deserves more lengthy notice, consisting as it does of a large and carefully-selected series of photographs of all the great works of the Belgian sculptors, from the eleventh century down to the present day, whether existing in Belgium or abroad, where so many Belgian artists have left their works. To quote at length the list of works exhibited would form an interesting epitome of the history of Belgian sculpture. Here each photograph is carefully labelled, and a genuine pleasure it is to be able thus to pass a complete review of one of the great branches of the past art of the country. One is carried in this manner to many a quiet old church in Belgium, and many a gorgeous cathedral in France, in Germany, in Austria, and in Italy. Name after name, too little known, passes before one, and work of rarest merit, reposing undisturbed in out-of-the-world corners and in still busy centres of activity. Exquisite work of the eleventh, twelfth, and thirteenth centuries; work of the succeeding centuries and the Renaissance, among the great artists of which Colin of Mechlin, the artist of the Emperor Maximilian's tomb at Innsbruck, and some less known work at Prague and at Heidelberg, should take a higher rank than is usually accorded him; work of the sixteenth and seventeenth centuries, when the Belgians still held high their reputation; down to the last century, and the present day, when they fall no lower than their brother artists of the rest of the world; the list is a long and suggestive one.

In Belgium the artistic traditions of the past are not yet dead, as the section of the modern industrial arts clearly shows, and to this we must hurry on, regretfully leaving the retrospective section, to pass time in which would be an education in itself. One feels ashamed to have to notice in the haste of a few minutes' survey works that have taken so many patient weeks and months to design and elaborate, and which can never again be produced,—which seem, indeed, almost out of place in the hustle and the crowd, speaking as they do of the quiet and repose of the cloister, the workshop, and the hearth, of centuries ago.

Chelmsford Main Drainage.—On the 30th ult. Mr. F. Chancellor, chairman of the Sanitary Committee of the Local Board of Health, Mr. Charles Pertwee, the Board's surveyor, and Mr. W. J. Botterill, of London, the contractor, met in the King's Head Mead, and raised the "penstock" in the old sewer, and set the sewage in motion in the new outfall sewer, which is of brick and concrete, egg-shaped, and 2 ft. 6 in. high, by 1 ft. 8 in. wide. They afterwards walked to the receiving-tanks at Brook End, a distance of 1¾ mile, and there checked the time of the arrival of the sewage, which worked out exactly as calculated by the Surveyor. Chelmsford, according to Mr. Chancellor, is now in the enviable position of being well drained without having to pump one pint of sewage.

THE PROGRESS OF ELECTRIC LIGHTING.

EYESIGHT AND SAFETY.

The general satisfaction which has hailed the latest effort at electric lighting, that of the Royal Albert Dock at Silvertown, gives an especial appropriateness to the printing, at this moment, by the Institution of Civil Engineers, of the "Notes," by Mr. K. W. Hedges, C.E., "On the Principal Systems of Electric Lighting in Use in England and the United States." Already printed in the convenient pamphlet form in which the Transactions of the Institution are from time to time issued, these Notes will form part of the forthcoming fourth volume of the Proceedings for the Session 1879–1880, which will be volume lxii. of a series which, under the judicious editing of Mr. James Forrest, is growing into a comprehensive and extremely valuable professional library.

The lighting of the Royal Albert Dock is an attempt, on a large scale, to turn night into day. Each of four horizontal steam-engines, of 20 nominal horse-power, drives seven Siemens dynamo machines, which act as light-producers, and one machine of the same kind, which is used as an excitor. These engines are placed at four stations, from each of which it is intended to work twenty-four lights. The number of lights actually produced is twenty-six, each of which is placed on a latticed standard, 80 ft. high. The area of the Dock thus illuminated is about a mile and three-quarters in length.

The three systems which, according to Mr. Hedges, have made the most progress in practice are the Gramme, the Siemens, and the Brush. An adequate account of the rapid extension of the last-named system in the United States does not, unfortunately, come within the survey of the "Notes" in question.

In England, the most important installation of the electric light during the year 1879, was, we are told, the lighting of the Picton Reading-room in Liverpool, which is effected by the Gramme machine, and the Serrin regulator or lamp. The area lighted is not stated by Mr. Hedges. Three Serrin lamps are enclosed in an umbrella-shaped reflector, which throws the light on the ceiling, whence it is a second time reflected on the eye. The glare is thus diminished, and that probably with less loss of light than by transmission through partly transparent screens. A slight hissing noise is observed. The cost of the light is stated at 1s. 9d. per hour, as compared with 7s. 8d. per hour for gas. The horse-power employed is not stated.

The St. Enoch Station, the terminus of the Glasgow and South-Western Railway, is now lighted by Crompton lamps, arranged in lanterns having octagonal mirror reflectors, and slung about 35 ft. above the platform, and 27 ft. from the side walls. The span of the roof is 198 ft., and the height from the platform 80 ft. The length is not stated, nor is the engine-power. Each lamp is worked by a 6,000-candle Gramme machine. The cost of the six lamps is 3s. per hour, independent of the cost of driving power. The gas previously consumed cost 4s. 5d. per hour.

The esplanade of the town of Blackpool is lighted by four lamps, each worked by a separate Siemens generator. The lamps are fixed on the top of pillars, 60 ft. high, and are enclosed in lanterns furnished with reflectors that throw the light for about 150 yards in each direction. Mr. Alexander Siemens states the total cost of lighting six lamps, of 6,000-candle power each, for five hours, at 3l. 6s. 10d. by electricity, as against 7l. 5s. by gas. In comparisons of this kind the local cost of the gas ought always to be stated. It is true that this price is likely to be proportionate to that of the steam-power used for working the dynamo machines. But when information is volunteered on these points it ought to be complete, as it is otherwise of but little value. If we calculate aright, the cost per hour per lamp is 26·7d., as against 21·0d. at the Picton Reading-room. But the candle-power at the latter spot is not stated. In fact, it seems very difficult to get at the exact cost of electric lighting; when we come to inquire into details, some omission or other often becomes obvious.

The lighting of the reading-room of the British Museum is effected by four Siemens lamps, of 6,000-candle power, each worked by a separate dynamo-electric machine. Details of the engine-power are not given. The cost is brought out at 8s. per hour, as against 4s. 9d. for gas, at the price of 3s. 9d. per 1,000 cubic feet. In all these matters it is most desirable that not only results, but details, should be given. The amount of the illuminating power produced at the focus is one thing, that of the quantity and quality of the light that falls on the page of the reader is another. As far as we can form an opinion, we should say that the effect on the eye is highly objectionable in both cases. We are convinced that nothing tends to the rapid deterioration of the sight more certainly than reading, or still worse, drawing, by gaslight. We recommend every student or every one who reads or writes much by artificial light, to use a Queen's reading-lamp, or a candle or pair of candles provided with a shade. We should expect that the degree of pulsation which so often characterises the electric light would render it far more injurious to the working eye than gas itself. Then it has to be borne in mind that the lamp or candle may be at 18 in. or 20 in. from the book; the gas-burner may be at 3 ft. or 4 ft.; the electric-light at 30 ft. or 35 ft., and in each case the proportion of light that falls on a page to that created at the focus of illumination will be inversely as the squares of these numbers. Let us light open spaces, as far as practicable, by electric suns; but we counsel those who care for their eyes to reflect on what we have said. Let them compare the fatigue of the eye after three or four hours' work by the Queen's reading-lamp and by gas.

A statement of the performance of the Brush machine, furnished by Mr. Brush, is printed by Mr. Hedges, but it is of too technical a nature for extract. Mr. Hedges has not so much to say as to Mr. Edison's efforts as will be found in the pages of the *Builder*. The Werdermann lamp, to the light of which we are disposed to give the preference at present over any electric light with which we are acquainted, has been introduced at the South Kensington Museum. Eight of these lamps, Mr. Hedges states, were placed in the Art Library at that institution, and worked off a Gramme machine. The light was steady, and the room kept cool, but the cost was found to be greater than that of lighting by gas. Considering the small size of the apartment, it is difficult to make this statement harmonise with those that precede it. We can conceive no cause for extra cost in the Werdermann lamp. We rather tend, therefore, to the view, that in the care which is given to every matter of detail in the Art Museum, under the direction of the thoughtful and accomplished librarian, photometric observations may have been taken with more direct reference to the visibility of the page brought under the eye of the reader, than to the amount of light produced at each luminous focus. At all events, we trust that what we have said may have the effect—first, of inducing all writers on the subject of electric lamps to bring forward full, clear, and attested details of every instance of illumination as to which they write; and secondly, of directing attention to the great difference between the quantity and the quality of the light which is desirable for the student, and that which is desirable for the nightly illumination of halls and theatres, of stations and dockyards. Nor should it be forgotten that it is in the lighthouse and the steamboat that the chief field for the display of the electric light is at present found; nor that it is yet an untried question how far safety, combined with adequate illumination, can be offered by the electrician to the coal-miner.

WESTMINSTER VESTRY-HALL COMPETITION.

The drawings sent in competition have been open to inspection at the United Westminster Schools during three days of this week.

The design to which the first premium has been awarded we publish in our present number, with some descriptive particulars, and may therefore dispense with any detailed comments upon it, which our readers can make for themselves. We may say that, as far as plan is concerned, we believe we should have come to the same conclusion as the referee,—that it is, on the whole, the best working practical plan of the set, though it has points in detail very much open to question. Some people may like a surveyor's clerk's office with two rather small windows on either side of a fireplace in the outer wall; but we should hardly ourselves recommend such an arrangement. Again, the requirements for two retiring-rooms with lavatories, &c., in connexion with the public hall, would naturally lead to the conclusion that these are intended for gentlemen and ladies respectively, since rate-

payers are to be found in both sexes; and how impossible this use of the rooms would be will be seen at once from the plan. It may be said that in this and some other points the wording of the instructions is not so explicit as it should have been. Judging, however, from some experience in looking at competition drawings, our impression is that not one competing architect in fifty understands the planning of accessory offices of this kind. For the external design of the building we refer the reader to our illustration and description.

Of the remaining designs there are three,—"Portoullis" (second premium), "Black Star" (third premium), and "Unitas,"—which especially deserve attention. We may, moreover, mention that "Sunm Cnique" shows a neat Free Classic elevation, which, however, hardly looks so well in perspective; and "Civis," a good, but rather heavy, elevation, in more orthodox Classic style, but which is obviously too expensive. The plans in both cases are not good.

The main requirements of the building are surveyor's and vestry-clerk's offices, with waiting-rooms, &c.; a rate-collectors' office, with separate entrance from the street, but communicating internally with the general offices, and other usually required offices for the work of a small town-hall establishment; rooms for medical officer, sanitary inspector, gas-meter testing, &c. These come on the ground-floor, and on this floor also, in the rear of the building, is to be a large hall for ratepayers' meetings, with public entrance from Gardener's-lane, on the flank of the building. On the second-floor is to be a vestry-hall, with lavatory and hat and cloak rooms (specified to be in communication with each other and with the lobby), with a strangers' gallery, which is rather ambiguously described as "not to be within the area of the vestry-hall," and yet to be "a more important feature than is usually the case," and with a retiring-room contiguous to it, for use on occasions when strangers may be ordered to withdraw. The rest of this floor is occupied by committee-rooms and a waiting-room for deputations. The only important point in the plan which is left to the discretion of the competitors, therefore, is whether the vestry-hall should form a feature in front of the building, or should be kept in the centre. The latter is, of course, the most economic plan, and has, therefore, been wisely adopted by most of the competitors, though, of course, it destroys the principal opportunity of giving any special architectural character to the front. We proceed to make a few comments on the three designs above-named.

"Portoullis" (Mr. John E. Trollope) is a design of late Elizabethan character, effective in general appearance, but too much is spent on a clock-tower, which runs away with a great deal of masonry, and is out of place where economy was an object. The vestry-hall is brought to the front on the upper floor, and its windows form a feature in the design of the front. The vestry-clerk's offices are fairly planned, to right of the main entrance, and the rate-collectors' office is conveniently arranged, except that the fireplace comes in a very awkward position. Surveyor's rooms well arranged; waiting-room would be better *en suite* with clerk's room. The way round to the Sanitary Inspector's office seems tortuous, and the general arrangement of plan somewhat deficient in simplicity. Approach to the large room good, but lavatories opening into main passage too conspicuously next door to each other. We propose to illustrate this design in our next.

"Black Star" (Messrs. Hunt & Steward), a "Queen Anne" design of not very interesting character. Vestry-clerk's offices conveniently placed and arranged; rate-collectors' room in right place, but cuts off the light from the passage; surveyor's offices satisfactory; retiring-rooms to public hall badly arranged if they are supposed to be for ladies and gentlemen respectively. First floor has vestry-hall in centre, members' cloak-room and lavatory clumsily planned, and room wasted in this and staircases; waiting-room too far off and with bad access to vestry-hall.

"Unitas" (Mr. J. P. Seddon), a Gothic design, certainly the best hit of architecture of the set; the author sends alternative Queen Anne elevations, which are adequate; any one who can design in Gothic can design in Queen Anne; "there's nothing in it." Alternative plans, A the cheaper, with vestry-hall in centre; B with vestry-hall in front, and forming a good feature in front elevation. The waiting-rooms which should be in immediate connexion with the vestry-clerk's and surveyor's offices respectively are not *en suite* with them in either plan, in one case very far off. The public hall is an octagon, with low walls and high roof, much more inexpensive in construction than the others, but the octagon is a bad shape both for speaking in and for seating the audience. The two sets of retiring-rooms are very well planned in themselves and quite separate, but we can hardly imagine it would meet the case to have them opening out of the hall at the furthest point from the entrance; they should be in connexion with the access to the room. The upper floor is very satisfactory in plan B; in plan A the cloak and lavatory rooms are too prominent on either side of the entrance-passage to the vestry-hall, and the waiting-room for deputations is too disconnected and has bad access to the vestry-hall; but this defect exists similarly in the first premiated design. This is the only plan which exactly carries out the instructions as to the strangers' gallery, which is partially screened from the vestry-hall by an arcade of three arches, and has commodious retiring-rooms immediately in the rear.

There is one important point in connexion with the decision in regard to which some explanation is desirable. The instructions state that the cost of the whole building is not to exceed 15,000*l*. The three premiated designs are just over this limit, but in all these cases, according to the referee's report, this is without counting the public hall in the rear. But the instructions have no reservation in regard to the public hall; they state explicitly that the sum above named is to include the whole cost, exclusive of movable furniture. Has there been any subsequent understanding upon this point? And if so, did all the competitors know of it? If not, it appears to us that "Unitas" may have a technical ground of complaint. His plan A is the only one which at all looks as if it might be carried out for 15,000*l*., including the hall of meeting. We do not say his plan is better than that of "Stet,"—in some points it is decidedly inferior, though the architectural design is certainly better; but he has made an effort to comply with the stated conditions of cost, with more apparent success than the others, and this calls for some explanation. We put the question, therefore, but without by any means joining in or favouring the complaints which have been made about anything like unfair play, which we do not credit. On the contrary, we feel very strongly that some of the profession are putting themselves in a very absurd position by clamouring against the decision of a professional referee, immediately after there has been a general declaration on the part of a great number of their body against all competitions in which a professional referee is not employed. This is both foolish and undignified. The profession, by the mouth of their central representative body, have undertaken, or a great number of them have, not to enter into any competition unless there is to be a professional adjudicator. They have no sooner done so, than they seem disposed to fall foul of the first professional adjudicator who decides a competition. They cannot expect infallibility in a professional referee any more than in a committee of non-professional men; all that can be reasonably counted on is that a professional man will understand and go into the details better. People may think the umpire has made a mistake, though this has yet to be proved; but in all games it is considered very bad form to question the decision of the umpire, if he is a properly-constituted authority: and the *lex non scripta* which obtains in this respect in matches at cricket, or boating, or billiards, is just as applicable to architectural competitions.

Purchases for the Indian Museum.—The Science and Art Department lately decided to send an officer to India to make purchases of Indian art objects, to complete the collections exhibited at the Indian Museum, South Kensington, and it has been announced that Mr. Caspar Purdon Clarke has been appointed to this mission, and that he was to leave for India on the 7th inst. A fund of about 8,000*l*. has been placed at his disposal, of which 3,000*l*. has been contributed by the India Office, this sum being the unexpended balance received on account of the exhibition of the Prince of Wales's Indian presents in 1876, and reserved by his Royal Highness for the purpose of promoting the interests of Indian art.

NEW THEATRE AND DISSECTING-ROOM, MIDDLESEX HOSPITAL.

In order to meet the requirements of the increasing number of students attending the medical schools, the Board of Governors at the close of the last session decided upon partially rebuilding the schools. These works have been carried out during the vacation, and were opened on Monday last by Mr. H. A. Ross, M.P., the annual address to the students being delivered and the prizes distributed in the theatre on the same day.

The new buildings comprise a theatre, dissecting-room, demonstrator's, lecturer's, and prosector's rooms, and large cloak-room for students. The form of the theatre is semi-circular, with prolonged sides, the diameter being 34 ft.: it is capable of holding 200 students, all seats being provided with desks for writing, it being intended to use the theatre for examinations. The theatre is warmed by means of air heated by passing through a chamber under the building containing hot-water pipes; the fresh air being drawn in from the garden and delivered warm in a distributed form in different parts of the theatre. It is lighted by a powerful sun-burner supplied by Messrs. Strode & Co., and in connexion with this is a ventilating-shaft for the extraction of vitiated air. Natural ventilation is also provided by means of a large lantern light.

The dissecting-room measures 35 ft. by 30 ft., and is fitted up with every modern appliance. The building, although carefully planned and substantially carried out, is not intended to be a permanent structure, it being contemplated at some future time, when the opportunity of acquiring other land occurs, to remodel the whole of the schools on a larger and more complete scale.

The works have been carried out by Messrs. Longmire & Burge, under the superintendence of Mr. Matthew Wyatt, architect, of Great Russell-street.

JOTTINGS IN EXETER.

Only one or two buildings of any importance are at present in progress in Exeter. The eastern end of the site of the grammar-school, in High-street, is being built upon by the Exeter Arcade Company (Limited), who are erecting an arcade and coffee-tavern, from the designs of Mr. James Crocker, architect, Exeter, the builders being Messrs. Stephens & Son. The western portion of the site has been secured by the Government for new chief post-office buildings for the city. The new grammar-school buildings are being erected at Victoria Park, Mount Radford (about a mile from the city), from designs by Mr. Butterfield. Many of the citizens are greatly dissatisfied with the removal of the school, not only on account of the demolition of the ancient buildings, but because they feel that they are being practically deprived of what was essentially a school for the children of tradesmen and the better class of working men; and the promoters of the change are accused of intending to make the school into a "high-class school," for the children of people higher in the social scale than those for whose children it was originally intended.

For the new church at Newtown, the plans sent in in competition by the architects of Exeter (to whom the competition was limited), are now under consideration.

St. James's Church, at the higher end of Sidwell-street, is being restored, under the direction of Mr. R. Medley Fulford, architect.

More than one interesting specimen of Domestic architecture has lately been demolished to make way for modern "improvements,"—notably a house at the corner of Goldsmith-street.

The Sanitary Exhibition remains open until the end of this week, but adventitious attractions have had to be put forward to draw the multitude. The Militia band plays every evening, and there are other novelties, such as dancing dolls, and "Try your weight, Sir?" In this way the affair has, we hear, become quite popular.

The statue of the Earl of Devon, in Bedford-circus, is to be unveiled this Saturday, the 9th. It is of bronze, on a granite base, and is the work of Mr. J. B. Stephens, A.R.A., who is a native of the "Ever Faithful" City. Statues of Mr. Denham (a local light) and Sir Thomas Acland, on Northernhay, and of Earl Fortescue,

in the Castle Yard,—all in marble, are by the same sculptor; so are the statue of the Prince Consort, in the Albert Memorial Museum, and the group of the "Deerstalker," now removed from Bedford-circus into Northernhay to make way for Lord Devon's statue. It is not often that native talent is so largely appreciated by fellow-citizens.

In the extensive workshops of Mr. Harry Hems, in Paris-street, a number of works in carving and sculpture were in hand at the time of our visit. They included a fine memorial pulpit and prayer-desk for the parish church of St. Michael, Macclesfield, from the designs of Mr. J. Stevens, architect, Manchester. The pulpit is octagonal, and of wainscot oak, the style being Perpendicular. Eight detached columns rest upon the base, from which spring groins, carrying the body of the pulpit. In this, on each cant, is an ogee-headed niche, containing a sculptured figure, the whole being surmounted by an enriched cornice. The prayer-desk and seat partake of the ornate character of the pulpit. We also noted a couple of figures, SS. David and Cecilia, for the Rev. C. J. Ridsdale's well-known church at Folkestone. These are from the designs of Messrs. Morris & Stallwood, of Reading. A fine rood-screen in oak is in progress for Rodmersham Church, near Sittingbourne, Kent. Of the original screen only one or two small fragments are left, and they have afforded the design for, and been incorporated in, the new work. The screen contains a great deal of delicate detail, and will be surmounted by an elaborate cross. Some rich carved work in old English oak is also in hand, from the designs of Mr. John Lessels, architect, Edinburgh; in one of the circular panels an enlarged and sculptured representation of the old seal of the Abbey of St. Bathan's, at Berwick, has been introduced. Stalls are in hand for St. Michael's Church, Honiton, where Mr. Hems has already restored the rood-screen, which is 50 ft. long, and the finest, perhaps, in Devonshire, for it is groined its unbroken length on both sides. The two parclose screens in the same church are now in hand, *in situ*. Mr. Edward Ashworth, of Exeter, is the architect concerned. For the church of the Holy Cross, Standlake, Oxon, Mr. Hems has just completed a series of full-length angels for the hammer-beam roof. Each angel holds an heraldic shield in its hand. These figures, which are of oak, and 5 ft. high, have been executed from the designs of Mr. Clapton C. Rolfe, architect, Reading. Mr. Hems has been commissioned to execute thirty-two figures of saints, martyrs, and virgins for the same church. He has also just commenced a particularly rich font and cover,—in all, 13 ft. high,—for the parish church of Rotherham. It is a memorial to the late Rev. W. Newton, vicar, and has been designed by Mr. J. P. Seddon. The font itself is of red Corsehill stone, and the cover is of oak. In richness this font recalls to mind some of the sumptuous examples to be met with in Norfolk. For the interior decoration of the *Citizen* newspaper office, Glasgow, Mr. Hems has in hand a number of carved panels, of the so-called "Queen Anne" character, from designs by Mr. T. L. Watson, architect, Glasgow. A rather rich reredos is in hand for Cockington Church, near Torquay. It is in oak, and consists of three canopied compartments, each terminating in a profusion of pinnacles and gablets. This has been designed by Mr. James Hine, architect, Plymouth, from whose designs Mr. Hems is also making a font for Delabole Church, Cornwall. This font is in the fine white Beer stone of which Exeter Cathedral is in great part constructed. Among other works in hand in the shops are some full-length figures of St. Patrick, for Upper Reformatory, near Cork, of which Mr. S. Hennessy, of that city, is the architect.

The Classes of Architecture and Construction at University College, London, will be again conducted by Mr. T. Roger Smith. They will commence on Tuesday next, the 12th inst. Mr. Roger Smith will also repeat the course of lectures on professional practice which he delivered for the first time last session at this college. The class for the study of this subject will meet for the first time on Monday, the 25th inst. It may be worth while to state that any gentleman desiring to attend a single lecture in either class as a visitor will be admitted on giving his name to the attendant.

THE PARKES MUSEUM OF HYGIENE.

This Museum was re-opened on Monday last (after the usual vacation) in connexion with the inaugural *conversazione* of the Medical School at University College. There was a large attendance, and much interest was manifested in the collection of sanitary appliances, to which many additions have been made of late, including a model of a new ventilator presented by Messrs. William Tonks & Son, called the "Architrave Ventilator." This ventilator is an adaptation of the Carrall patent, and has been designed by Mr. Mark H. Judge for the purpose of making an architectural feature of the provision for changing the air of rooms—a provision now admitted to be so necessary that without it no apartment can be said to be properly ventilated. As its name indicates, this ventilator is made to form part of the architectrave or frieze over doors and windows, the opening for the inlet and outlet of air being made above the lintel or arch, or between them and the framework, thus rendering unnecessary any cutting or interference with structural arrangements. The architrave ventilator is made of metal, and consists of three parts, which fit together in such a way that it may be adjusted to suit doors and windows of various sizes. Acting both as an inlet and outlet, it is so constructed that while the incoming current of air is turned upwards, the fresh air is very quickly diffused, and is not carried direct to the ceiling, so as to cause a down-draught, but when gas is being burnt, or when from any other cause the air is hot or oppressive, the ventilator immediately acts as an outlet; and in order that its action may be regulated, whether as inlet or outlet, a controlling lever is provided.

ROAD FORMATION AND STREET PAVEMENTS.

There are several volumes descriptive of road-making, out of which some knowledge may be obtained, and yet there may be very little useful information as to the best modern forms of paving for streets over which there is the largest and heaviest traffic. To settle as to the best material and the best form several points require to be considered.

Highways, streets in small towns, and streets in larger towns, over which the traffic is small, may have macadam formations, the foundation being concrete, and the surface hard broken granite; otherwise, the hardest broken stone available. It is of the utmost consequence to obtain and use the hardest stone available, even if the first cost is more, as bad material may be dear if given.

All roads and streets should have well-drained, dry, and sound subsoils; and all roads will wear better, lasting longer, if there is a bed, or foundation, of concrete, from 3 in. to 9 in. in thickness. This concrete to be the true road; the covering, or pavement of any sort, being only a veneering, to be renewed as worn out.

Roads and streets should have smooth surfaces of such a nature as to afford a foothold, and allow wheels to roll with the least jumping. Wheels, in motion over an uneven surface, jump and ram in proportion to the roughness of the road and the velocity of the wheels. A locomotive engine on the best and smoothest steel rails, jumps, and rams in proportion to the velocity. Railway engineers have found out by experience that swift trains punish the rails and roads most, and consequently cause most cost in maintenance and repairs. This is true also as to street surfaces.

Railways use steel rails as offering most endurance under the weight, velocity, and ramming blows of the engines and trains.

The nearest approach to a steel-rail surface, for an ordinary street surface, is asphalte. Tramways are not being considered. The objection to asphalte is its slipperyness in wear, under certain conditions of wet and gradient.

Granite and limestone sets, and hard grit stones, make good pavements; but not the best, as the surfaces are rough, from the dimensions and nature of the materials. Indeed, it is considered necessary to lay such stone pavements with open joints, to give foothold. The rough surface of the stone and the open joints constitute a faulty street pavement. Carriages, carts, wagons, cabs, and, above all, spring-vans, if they move at or above six miles per hour, roll, jump, and ram, destroying the road or street over which they move, in proportion to the number of the vehicles within a given time, the weight moved, and the velocity. If there is a sufficient foundation of cement concrete beneath to prevent mud working through the joints to the surface, the surface-wear will not be sufficient to cause mud, but there will be some wearing of the stone and a considerable wearing of iron from wheel-tires and the shoes of horses. If there is a poor and weak base, and the stones can be rammed into it, and the subsoil can rise, there will be a rough, uneven, and muddy surface.

However good granite paving is in a town,—that is, however smooth and solidly laid,—it is noisy and destructive to carriages, destructive to an extent the general public are very little aware of. Coachbuilders, however, know something about it, as the best portion of their income is derived from repairs and renewals.

Of all the road surfaces for streets of swift and heavy vehicular traffic, broken stone makes the worst; and if the foundation is soft, the dirtiest. A macadam stone street in London is merely a mill on which the stone is crushed and ground to mud in wet weather, and to dust in dry weather. The mud is, however, a disinfectant; and, as such, does serve to cleanse the street from horse-droppings, but the dust, mixed with such filth, is most offensive and in every way injurious to shop goods, to clothing, and to the lungs and throats of the inhabitants. The macadam surfaces at Victoria-street, Whitehall, Great George-street, and Parliament-street, are a national disgrace. These streets and their condition ought to open the eyes of members of Parliament to the crass ignorance and stupidity of vestrymen. Streets over which the combined wisdom of Parliament walks or drives to and from the Houses are the worst made, worst cleansed, and consequently the dirtiest in London.

Of late, wood has come into use for street-paving, if one may speak of "wooden paving stones," as the Irishman spoke of "wooden milestones," or of the fireproof warehouse which was "flagged with cast-iron boards." But to the wood-paving: this, when properly laid, possesses all the properties but one requisite for the best surface of a street of great traffic. The surface is smooth, soft, and consequently noiseless, or nearly so. The lacking property is endurance. Wood need not be expected to endure like granite, but the carriages moving over it will last much longer than when running over granite. The best wood-paving must be laid upon a foundation of Portland cement concrete from 6 in. to 9 in. in thickness, to be finished on the surface to absolute truth. The blocks of wood to be pine, 4 in., 5 in., or 6 in. in depth, according to the traffic, the blocks to be laid on a bed of tarred felt, and jointed with a bed of felt (*close-jointed*). A thin layer of asphalte over the concrete may take the place of the bed of felt, but both will be better. A sound soft wood will make a better surface than the harder woods, as the soft wood will give a little to the horses' shoes and wheels of carriages, and rise by elasticity, producing the least noise. Such a street-surface will be even, smooth, and water-tight; there will be neither grit nor mud. In wet there will be no mud, in dry weather there will be no dust; and such surface may be washed hy hose and jet without injury to the drains and sewers, such as would arise from muddy stone pavements or very muddy macadam.

If all things are considered, such as comfort in riding, freedom from noise, from mud, and from dust, it will be cheaper to renew wood-paving every few years, as the case may be, rather than to retain granite sets or macadam.

One of the items of cost in changing from macadam to wood, is the breaking-up of the old road and the forming the Portland cement concrete foundation. In some cases it will be cheaper to retain the macadam crust, level it over with Portland cement, and on this lay the wooden blocks in the usual manner, raising the footwalks. Of course, there are many cases where this cannot be done, but where the roadway must be broken up.

London is just now under a wood-pavement *furore*, to which all who love comfort and quietness may most heartily wish success.

A thunder-storm ought to teach the vestriss a useful lesson, namely, that footwalks and roadways may be washed by hose and jet. In Paris and in Vienna the streets are regularly washed and watered hy hose and jet. If the water belonged to properly-constituted municipalities in London a similar process might be adopted with great advantage.

Civil Engineer.

TABLE GIVING COST AND PARTICULARS OF VARIOUS PAVEMENTS.

Name of Firm.	Address.	Description of Pavement.	Depth of Concrete.	Depth of Paving.	Total Depth.	Cost per Square Yard.			Total per Yard.	Cost of Repairs Annually.	Estimated Life.	Cost of Cleaning per yard per annum.
						Concrete	Paving.	Labour.				
			Inches	Inches	Inches	£. s. d.	£. s. d.	£. s. d.	£. s. d.			
Asphaltic Wood Pavement Company.	Bond-court House, Walbrook, E.C.	Red or yellow deal in blocks, 3 in. by 6 in. by 9 in., on end, resting on ½-in. layer of mastic asphalte, which rests on a 6-in. bed of lias lime concrete (proportions, 1 lime to 5 ballast). The blocks are spaced ½ in. apart in the direction of the length of the road. Heated asphalte poured into joints to a depth of 2 in.	6	Asphalte ½ Wood 6	12½	...	...	...	0 12 9 to 0 14 0	Free for three years, then about 9d.	Twelve to fifteen years.	2d.
Henson's Street Paving Company.	No. 7, Westminster Chambers, S.W.	Red or yellow deal in blocks, 3 in. by 6 in. by 9 in., each joint being filled with tarred felt. The blocks rest on tarred felt, which forms an elastic and impervious joint between them and the concrete.	6 9	5 6	11 15	0 3 3 0 4 6	0 7 0 0 8 0	0 2 9 0 3 0	About 0 13 0 to 0 15 6	*Nil* for two years, then 1s. per yard.	Wear ⅛ in. to ¼ in. per annum under heavy traffic.	3½d.
Improved Wood Pavement Company.	46, Queen Victoria-street, E.C.	"Baltic Red Deal" is used in blocks, 3 in. by 6 in. by 9 in., resting on a 6-in. bed of concrete. Joints of wood filled to half depth with asphalte.	6	6	12	0 3 3	0 6 0	0 2 9	0 12 0	From 9d. to 1s.	From eight to ten years.	3½d.

Messrs. John Mowlem & Co.	Grosvenor Wharf, Millbank, S.W.	"Blocks" (or "Setts") with concrete.	...	...	...	0 3 3	...	...	0 11 0 to 0 18 0	3d.	...	3d.
		Blocks, without concrete.	...	...	...	...	...	...	0 9 0	3d.	...	3½d.
G. H. Stayton, Esq., C.E., Surveyor, Chelsea Vestry.	King's-road.	Wood blocks, with concrete foundation.	...	...	...	0 3 3	0 6 0	0 3 0	0 12 3	1s.	...	3½d.

N.B.—Some of these Modes of Paving are Patented. When concrete is used there should be an interval of ten or twelve days allowed for the concrete to set, if it is practicable to spare this time. The above prices will, of course, vary from time to time as the cost of materials varies.

WOMAN AS A SANITARY REFORMER.*

I STATE at once that the training required is simple,—beyond simple; that every woman who wills to go through it may go through it, and may become mistress by it of the destinies of the world. Not the Fates themselves were more the mistresses of the destinies of the race than the women of an educated commonwealth, who were conversant with the art of the prevention of disease and premature decay. A woman should master physiology so far as to understand the general construction of the human body. She should be rendered fully conversant with the different changes of food that are required for the digestive process in different periods of life; the extent to which the digestive powers should be taxed in infancy, childhood, adolescence, maturity, first and second decline, and old age. She should be made aware what substances, taken as food, are of real and what of spurious quality. She should be taught the relationship which solid foods hold to liquid foods or drinks. She should be told what drinks are foods, and she should specially understand what are the particular foods required for the young during the periods of active growth. In illustration of the value of this last-named fact, it may be stated that if women only knew what foods were requisite to feed the skeleton or bony framework of the living body while that skeleton is in the course of growth, and if she would act upon her knowledge, as she almost certainly would if she possessed it, there would hardly be one deformed child left in the land in one or two generations. Rickets, with all its attendant miseries of bowed legs, crooked spines, and humped backs, would pass away as if by the spell of an invisible enchantress. After the understanding of the digestive system, the woman should learn the principal facts relating to the circulation of the blood, and the blood itself. Nor should she, in respect to the healthy organisation, be less informed respecting that breath of life which is ever being breathed into the living thing by the Eternal Chemist, whose constructions and resolutions are the motions, visible and invisible, of His eternal universe. The complete structure of those breathing lungs should be as plain before her as the outward form of the things she knows best. Equally clear to her should be the leading facts bearing on that receptive system of the body into which the external universe transports itself, and from which, in reflex response, the acts of life, the expressions, the movements, the thoughts, return in wavelike repetition back again, to become themselves external phenomena, linked, as such, with all the visible universe. To the knowledge of nervous function it would be advisable to add to the store of elementary principles a few facts respecting the great glandular system of the body, and of those night and day labourers of the body, the muscles, the woman should learn sufficient to be made aware of the advantages of so training the muscles to work that they shall be daily exercised, shall not be subjected to over-strain, shall be equally subjected, as far as possible, to healthful labour. And of the bony skeleton, on which the muscular engines are laid, and which act as the passive framework and levers of the engine, she should gather enough information to be conversant with all its outlines of form and chemical construction. Lastly, the woman should attain so much instruction in reference to the great membraneous expanses as to know them also. She should learn the necessity of keeping the functions of the skin in due cleanliness and condition for work; so that the bath should be considered as one of the necessities of the daily life, like a daily meal of cleanly substance. The living house thus generally learned, the sanitarian helpmate for us who can do so little beyond our suggestion would be tempted to study until she completely mastered it, the mysterious construction of that deadly-lively house which, until lately, the architect and builder have pitchforked into street and square with facile and contented wisdom of wigwam descent. She would want to learn how the immaculate house is in every room provided with at least moderate ventilation. She would require to find out how most effectively and economically she can maintain in the varying seasons an even and equable temperature. She would aim to consider in what way she could keep the air of the house free of that most objectionable of mischiefs, dust. She would demand to have marked for her on a map or plan the precise position of every drain-pipe in the establishment, and would insist, with intelligent skill, on having every drain kept as systematically clean as the china in the housemaid's cupboard or the metal covers that make so many bright and effective pictures over the dresser of the well-arranged kitchen. She would see, not trusting to the mere word of any one, that those drains were properly ventilated so that sewer air could never enter the domain except as a burglar might enter, by special skill and violence, against which there is no absolute protection. She would learn enough of the chemistry of water to enable her to determine with as much facility as she could tell whether a looking-glass is clear enough to reflect back without fault the image of her face, whether a water was wholesome and drinkable; and she would have a sufficient amount of skill to direct how an impure water might be purified and made safe for her and hers to drink and use for all domestic requirements. She would see to it that damp had no place in any apartment. She would insist that where any living thing that ought not to be present in a house exists in it, that house is unclean, and in some way uninhabitable for health; since health will not abide with anything that is uncleanly. She would see to the biennial purification of the dwelling, as though a Passover were still a universal belief and practice. She would make the very act of cleaning and cleansing clean; she would make the very best places for cleaning and cleansing—the scullery, the landing, the bath-room, the laundry—the cynosures of the household. In the art of perfection, or towards perfection of health, the educated woman would in her domestic sphere bring her best energies to understand the selection, the purification, the preparation, and the administration of foods and drinks. As she would keep seeds of certain pestilence from her fold, or vulgar poisons that kill outright, and proclaim at once with loud voice, "accident, disease, or murder," so would she do her best to keep out those refined and subtle poisons which, in and under the name of strong drinks, bring silently more accident, disease, and murder into this inscrutable world than all the other poisons put together, unlicensed though they be, and so little liked by the exciseman that he would fly them any distance, the Devil himself in company, rather than so much as touch them with his divining rule. That she would acquire a thorough knowledge of the best art of cookery; that she would acquire a good knowledge in choosing foods in season; that she would become an adept in detecting actual wholesome from actual unwholesome foods; that she would find out what foods are most suitable for persons of different age and constitution; and that she would distribute food with well-balanced hand, neither feeding over indulgently nor parsimoniously, I take for granted. But I expect she would learn to do more than all these things in relation to food. She would be able better than any one to put to the test the experience whether it is good or necessary to go to the living animal creation at all for human food. I am in doubt. It does not seem to me that man is constructed to be a carnivorous animal. It does not seem clear, putting the anatomical argument altogether aside, that it can be good to go to secondary sources of supply for our food when Nature bountifully presents them to us from her prime source. It does not seem reasonable that we should employ millions of living laboratories for our daily food, and take the risks of disease which they in endless forms produce and propagate for us, when we can get all that is necessary without the chance of such production and of such propagation. It does not seem certain, when we know that the vegetable world is the original source of every particle of living food, and that carnivorous animals have to depend on the herbivorous for their supplies—so that carnivorous feeding is an anomaly rather than a basic principle of nature—it does not, I repeat, knowing these things, seem certain that the cost of the support of the living laboratories is justifiable on any ground except the extravagant process of making work that work may be at hand and employment procurable. Still I am not sure whether the secondary supplies of food for man from the animal world are or are not necessary, and that doubt it is in the *rôle* of the educated woman to solve. Her discernment, properly and eagerly directed, would soon settle whether those about her were injured or benefited by an exclusive vegetable and fruit diet. It has been one of the endeavours of my life to show that we living men and women make in our own corporeal structures a refined atmosphere, which I have called a nervous atmosphere, or ether,—an atmosphere which, present in due tension, distinguishes life; which, absorbed or condensed, distinguishes death; an atmosphere through which the external world vibrates and pierces us to the soul; an atmosphere which, pure and clear, brings us peace and power, and judgment and joy; an atmosphere which, impure and clouded, brings us unrest and weakness, and instability and misery. We make it from foods and drinks, and as we make it, it makes us. Go into the wards of a lunatic asylum, and notice amongst the most troubled there the odour of the gases and the vapours they emit by the skin and breath. That odour is from their internal atmosphere, their nervous ethereal emanation. They are mad; mad, we say, up to suicide, or murder, or any criminal folly. Can it be otherwise? They have secreted the madness; they are filled with it; it exhales from them. Catch it, condense it, imbibe it, and in like manner it would madden any one. See, from the study of foods, out of which the radiant or deadly atmosphere is made. What fields of discovery open to the mind. A mother, watching the effect of food on her gloomy, saturnine child, may detect how she can so feed it that the cloud shall pass away. Happy mother of a child! Far, far happier mother, perchance, of science and hope. In some great establishments for the insane so much gloom is secreted in the nervous recesses of human frames, that many times a day, but for excessive vigilance, some terrible hand would raise itself against itself, to kill itself. What if in a wiser day, however far off, the removal of that little cloud from a troubled child should show the way to the removal of those denser, blacker clouds which lower and create storms in human breasts, overpowering altogether the radiant nervous ether! What if from that minor event this greater one should follow! What nobler accomplishment of noble deed could woman perform, save and except when she is the mother of her kind? Women should know the correct names and characters of the more common diseases, and they should know, by sight, the every-day contagions or communicable diseases. All the best-known methods of preventing disease should be at their finger's ends, and the rule of the sick-room should be their faithful care. The woman should know everything about registering the temperature of the sick room and degree of humidity; the mode of ventilation; the different special methods of feeding, washing, and changing the sick; the most efficient means of disinfecting, and of removing or destroying the poisons of the communicable diseases. How, in this way, the woman could help the physician none but the physician can understand.

> "Truth may never be confirm'd enough,
> Though doubt should ever sleep."

I declare it again, that if, in the management and treatment of any of the acute and of many of the chronic diseases, you gave me, in this climate, absolute control of the fire and the window of the sick-room, I could determine the course of the illness. There is no department of practice more neglected, in respect to principles, than the management of offspring in its earliest youth. Love there is plenty of; admiration unbounded; rational systematic training the poorest that can be described. Women, in addition to instruction on all the points above-named, should understand the little appreciative law of temperaments; the nervous, the bilious, the sanguine, and the lymphatic. She should study the combinations of these, and she should observe how temperament influences health, taste, activity, and disease. From this she would learn how different natures would intermix in work or play, and what work, what play would suit the nature. The sanguine child, ruddy and red, with blue eyes, red hair, strong muscle, quick movements, restless limb, she may set to study at books, whilst she curbs exercise with no fear that books will kill, for it will outlive any book. The bilious child, with dark eyes, dark skin, black hair, stolid expression, thoughtful brow, she will not set to the study of books as the work of life; for books may kill; physical exercise may save, but will never be carried voluntarily to injury. The nervous child, with fair skin, light hair, blue eye, quick but feeble movement, timid glance, yet, perhaps, un-

* By Dr. B. W. Richardson. See p. 409, *ante*.

hounded ambition, she will spirit gently; will balance between physical and mental labour; will apportion excess of neither, and will never urge unduly to any effort. The lymphatic child, large of body, pale, with grey or blue eyes, brown hair, shambling step, watery lip, and slow determination, she will rouse to action both physical and mental, with the full assurance that neither effort will do anything but good. Beyond the study of temperaments, and the special dangers connected with them, she should devote her mind to the consideration of what the learned D'Espine has designated the mental contagions. She should study emotional contagion with especial care, and on one emotion, that of fear, she should keep the most watchful observation, because she will discover it to be the most common and disastrous of all contagions. She will never excite it for a moment by story of superstition or dread. Finally, in physical psychological training there would stand out for contemplation, and action founded upon it, one more subject,—that marvel of the marvellous in living phenomena, heredity of type and action, extending to health, and extending, alas! to disease in its deepest foundations. She should stand to resist with her full persuasive might that process which I have elsewhere called the intermarriage of disease. She will tell her sisters what that terrible process means. She will tell that diseased heredity united in marriage means the continuance of the heredity as certainly as that two and two make four; that madness, consumption, cancer, scrofula, yes, and certain of the contagious diseases, too, may be perpetuated from the altar; and that the first responsibilities of parents, towards the offspring they expect, ought to be, not how to provide for wealth and position over which they have no control, but that preliminary healthy parentage which is the foundation of health, and without which position and wealth are shadowy legacies indeed. Delicate ground, you may say. I admit the fact. But in a world in which those who study the living and the dead most carefully rarely see a man or woman hereditarily free from disease, even this ground must be entered on by the enlightened scholar. I touch on it here for the best of all reasons, that the subject it includes, affecting deeply the human heart in its sympathies and affections, is one on which the influence of woman, the arbitress of the natures that are to be, is all potent for good or for evil. To know the first principles of animal physics and life; to learn the house and its perfect management; to learn the simpler problems relating to the fatal diseases; to ordain the training of the young; to grasp the elements of the three psycho-physical problems; the human temperaments, the moral contagions with their preventions, and the heredities of disease with their preventions,—these, in all respect and earnestness, I set before this Congress as the heads of the educational programme for our modern woman in her sphere of life and duty. Let these studies be hers, and once more may he applied to her the promise of that wisest of men, with whose words I opened this discourse: "She shall rejoice in time to come. The heart of her husband doth safely trust in her." And,—sum and sum of all hopes, ambitions, happiness!—"Her children rise up and call her blessed."

CONGRESS OF THE SOCIAL SCIENCE ASSOCIATION.

The Congress of the Social Science Association was opened in Edinburgh on Wednesday last under promising auspices, and we shall, as usual, make our readers acquainted with the pith of such of the papers and discussions as may seem to be the most likely to interest them. The inaugural address of the president of the Association, the Right Hon. Lord Reay, was delivered on Wednesday evening, in the Free Assembly Hall. The Right Hon. John M'Laren gave his address as President of the Jurisprudence Department on Thursday morning; immediately after which the sittings of the various departments in their several rooms were opened.

Lord Reay's address was entirely political. The concluding two paragraphs, which we print, sufficiently show the purport of it:—

"If a Continental statesman asks me whether England does not yield too much to the instinct of isolation, I give him this answer: 'Isolation from your quarrels is absolutely imperative to us, but it is also the best thing we can do for you. England and her colonies will be a refuge to all who are tired of State despotism and of militarism, and who wish to live under another economy. Power, no doubt, has a tendency to lurk in your big guns, but happily, also, in strong brains. In your social condition the army and the bureaucracy absorb the best forces of the country. We prefer to see our strong brains at work, not only in the political and military spheres, but also in solving scientific and social problems, in literary and artistic work, not to mention theology and philosophy. Whether, in the long run, your system will not prove weak as against ours remains to be seen. All we ask is to be left alone. You cannot expect us to put our brains at your disposal, to do the work which your own brains are quite as fit to perform. While you increase the number of your officials and of your soldiers, we open new channels for our trade; we remove all that cripples the advance of education or of prosperity in the nation. You assimilate your citizens to some abstract ideal which you call State. We strengthen our position by adhering to independent, self-developed principles, which constitute the natural links between the English races. Our State is nothing but the result of a living and healthy organism, which does not receive its inspiration from Government offices, but which is left to evolve its own destinies by a number of influences, all of which escape our control. To the adjustment of these self-acting forces we do not apply our legal machinery, as you do. They are left to adjust themselves. We do not attempt to produce a law-made nation, which meets a Government functionary at every turn. The person in England whose absence would probably be more felt than that of any functionary is the boy who sells the penny newspaper. Whether it is a better thing that a nation should be guided by uninspired writers, by leaders of various schools of thought, than by the depositaries of the secret of the State ideal, may well be left to the future to determine." The Anglo-Saxon world is a planetary system in itself. It moves in its own orbit. The voices of Anglo-Saxons all over the world murmur with no uncertain sound what is the duty of English statesmen. Do not seek, they murmur, to adjust the balance of power. Do not attempt to meddle with the internal constitution of other States. Do not pretend to be arbiters of the destinies of the world. Do not enter into engagements which are not imperatively required. Do not fetter in any way our freedom, unless freedom itself is threatened. Prevent any attack being made on the independence of the weaker States of Europe. Promote concert whenever and wherever you can, leaving the responsibility to those States who decline to co-operate for a good object, and to ward off perils. Increase the fund of prosperity to be distributed among her Majesty's subjects in England, in Canada, in Australia, in India, in Africa. Let England and Scotland continue to be,—what they have never ceased to be,—Parent Homes. Increase their attractiveness, that they may always be looked upon with filial affection. Wherever we go, the end and aim is to return to our English home. Guide and control our generous impulses when we might be committed to rash courses. Extinguish old abuses and prevent new ones from cropping up. Invigorate the social system where it shows decay. Remove the obstacles which stand in the way of genius. Give us knowledge for growth, as has been forcibly said. Recognise individual merit wherever it is found. Elevate, not the State, but the individual citizen, who by individual effort strengthens our social system. The respect paid to our scientific men, to our men of letters, to our artists, we consider ennobling to the national life. The great trust we have committed to you is one of constant watchfulness. '*Vigilate, Deo confidentes*,' should be your and our motto. We do not wish to establish a cementing bond of union for Anglo-Saxon greatness other than that which we have inherited from our ancestors: a stanch, brave, and deliberate obedience to the precepts of liberty, which are never antagonistic to cautious progress; and cautious progress alone is uninterrupted progress."

The address of the President of the Health department, Dr. John Beddoe, will be delivered on this Saturday morning (the 9th), and that of the President of the Art Department, Professor Richmond, on Tuesday, the 12th.

THE JOSIAH MASON SCIENCE COLLEGE, BIRMINGHAM.

The opening of this important building was celebrated on Friday, October 1st, when an inaugural address was delivered by Professor Huxley. The first stone was laid on the 23rd of February, 1875, and the building has been erected from the designs and under the personal superintendence of Mr. Jethro A. Cossins. We give a view of the college and plans of the ground-floor. Not long ago we printed some particulars of the structure, but it will probably be thought convenient if we now describe it pretty fully at the risk of repeating what has been said before. Of the admirable founder's remarkable career we spoke in our last number.

The site on which the college stands extends from Edmund-street to Great Charles-street, and comprises about an acre of land, with a frontage of 150 ft. to the former thoroughfare, and a depth of 133 ft.; but only about half the ground is at present covered with buildings. These are arranged around two quadrangles, the main block fronting to Edmund-street, and a range of buildings of about the same bulk standing parallel with it at the rear. The two are connected by east and west wings, and by a covered central corridor and out-offices, which divide the enclosed space into two open courts, each of ample extent for the purposes of light and ventilation. With the exception of the east wing, all the buildings are four stories in height, and in the centre of the principal façade a large museum has been provided, partly in the lofty roof. The whole of the walls are of brick and stone. For the front in Edmund-street an excellent deep-red brick from Kingswinford has been employed, with Portland, Bath, and Bolton Wood stone for the windows and other details. The elevation is symmetrical, having the principal entrance in the centre. It is in the thirteenth-century style, with details of a somewhat French character. The ground-floor is raised 7 ft. above the street level, and a massive plinth of Bramley Fall stone is carried to this height. It is somewhat unfortunate that the space in front of the college is only partially-open ground, so that it is impossible to get a full view of the whole structure. The college is entered by a deeply-recessed arch, with shafts of grey York stone. Their bases stand above the plinth, and thus the mouldings and all details liable to damage are placed above the reach of injury from accident or otherwise. The entrance is closed by handsome wrought-iron gates, sliding into grooves in the jambs. Over the gateway projects a stone balcony, above which is an elaborate oriel window, of two stories in height. The lofty central gable, against which the upper part of the oriel abuts, is terminated by a mermaid,—the crest of the generous founder of the institution, at a height of 122 ft. above the pavement. All the windows,—and there are sixty of them in front of the building, besides the dormers and oriels,—have geometrical tracery within recessed arches, with moulded and shafted jambs, the latter having carved capitals. A stone balcony extends along the whole of the front, at the level of the roof, and is stopped at the angles of the several blocks by octagonal turrets, carried out from the lines of the front on moulded corbels. On the façade at various points are carved the arms of Birmingham, Warwickshire, Worcester, Worcestershire, and of Sir Josiah Mason. The roofs, which are of a very steep pitch, are red-tiled, and are pierced by dormers.

Entering the college by the groined porch, which has moulded ribs, resting on dwarf columns, with carved capitals, the spaces between the wall ribs being filled with geometrical tracery and carved spandrels, the visitor finds a central corridor, about 100 ft. long by 8 ft. 6 in. broad, with transverse corridors branching to the right and the left. The latter conduct to the offices connected with the administration of the college, a room allotted to the Natural History Society, and two professors' rooms. The side corridors turn northwards along the wings of the building. In the eastern wing there are two rooms and a class-room for the use of female students, and in the western two class-rooms and an assistant's room for males. These rooms, which are about 15 ft. square, have windows looking into the quadrangles, and also receive light from the corridors. The corridors end in smaller doors to the apartments in the northern main block, to which, however, the principal approach is by the central corridor. Proceeding along the latter from the entrance, the

visitor first passes on his right the handsome main staircase from basement to top, which opens from the corridor, and is divided from it by an arcade of moulded arches, resting on polished Aberdeen granite columns, with carved capitals. A door opposite leads to cloak-room, lavatory, &c. The windows of the corridors and staircases throughout are of stone, with shafted jambs, carved capitals, and moulded arches. There are also staircases at the extremity of the transverse corridors communicating with every story, and descending into the basement.

At the extreme end of the central corridor are two fine apartments, each 18 ft. by 30 ft. The one on the right is the library and reading-room, and has behind it an ante-room, which can either be used as a place for conversation or as a separate reading-room for ladies. The room on the left is the physics laboratory, fitted with every requisite. It also has an ante-room, which is set apart for apparatus, and a dark room for spectroscope studies. The western corridor is continued past the end of this room along the annexe, which projects further towards Great Charles-street, and in which are provided a workshop and two rooms, at the disposal of the professor of physics.

On reaching the first floor by the principal staircase, a short turn to the left conducts to the rooms facing Edmund-street. The chief and central room is the chemical-lecture theatre, 49 ft. by 33 ft., fitted with seats tier above tier, for the accommodation of 155 students. The male students will occupy the lower half, and the female students the seats above and behind them, a separate entrance being provided for each sex. The arrangements for the convenience of the lecturer or demonstrator are complete. He has a long table fitted with sinks, mercury-bath, down-draught flues (to carry away the noxious fumes that may be evolved in any of the demonstrations), and taps supplying hydrogen gas, oxygen gas, and water, with improved arrangements for regulating the supply. In the wall behind the lecturer is a niche, closed by a shutter, for the purpose of receiving preparations and appliances from his assistant in the ante-room, with which it communicates on the other side. There is also a glazed niche, with stench-flue over, in which any process may be carried on in sight of the students. The theatre is admirably lighted, but can in a few moments be rendered dark by the drawing of opaque blinds, with which the whole of the windows are furnished. Reference has already been made to the ante-room for the lecturer's assistant. This is a large apartment, furnished with slabs, sinks, stench-flues, and everything which could be desired for the preparation of chemical experiments and demonstrations. Behind this there is another room, in which what are called chemical collections may be permanently kept in readiness. Leaving the lecture-theatre by a door at the top of the auditorium, there is a class-room for electricity and another for magnetism, &c. These complete the front rooms on the first floor. In the west corridor are rooms for the biological professor and demonstrator, and adjoining them is a room for models employed in the biological department, which occupies the adjoining end of the north block. The corresponding corridor on the east side is that giving access to three rooms to be used for apparatus and other purposes in connexion with the physics department. The first floor of the north main block is occupied by two other lecture-theatres,—one for biology and mathematics, and the other for physics; the latter 47 ft. by 30 ft., and the former a little smaller, with preparation-rooms at the end of each. The biological department is the one nearest the projecting annexe mentioned in the description of the ground-floor, and in this are provided a biology workroom and museum.

The second-floor, or top story, is principally devoted to the chemical department, for which the arrangements are of the most extensive and complete kind. A large room, 52 ft. by 33 ft., in the front of the building, over the chemical lecture theatre, will be used as a general assembly and examination room. The window of this room is the oriel, which forms such a conspicuous feature in the façade; it is a lofty well-proportioned apartment, and will be available for meetings of scientific societies. Upon one side of it are the private study and private laboratory of the chemistry professor, fitted up with every requisite for research; and on the other side are rooms for the curator of the museum and for class purposes. The laboratories are situated end to end in the north block or back range, and are lighted both by windows and skylights. These measure together about 104 ft. long by 32 ft. wide, and are divided by a screen in the centre. The larger laboratory is for qualitative analysis, and the smaller for quantitative. The arrangements have been the subject of great thought and investigation by the architect, with a view to render them as complete and well-devised as possible. In the qualitative laboratory there are four double operating-tables, fitted with sinks, gas, and water for forty students, and there is a large unencumbered table in the middle of the apartment for long trains of chemical apparatus. The sinks at the tables are drained into depositing-tanks, where valuable deposits are retained. Along the walls are ten niches for operations giving off fumes, each provided with a flue, which rapidly carries off the vapours produced into the outer air. There are slabs at each window for investigations requiring a large amount of daylight, and shelves are arranged along the walls with all the reagents required by the students in their investigations. At the end of the laboratory are slabs and ovens for drying purposes. The laboratory for quantitative analysis is a little shorter than the one just described. In addition to fittings and appliances similar to those in the other laboratory for thirty-two students, there are two large ventilated niches lighted from the back. There is an extra room in the annexe for gas analysis, another for delicate weighing operations, and a room for the demonstrator. The western wing is not carried above the first-floor, but the eastern wing affords accommodation for a chemical reference library and reading-room, a room for combustions and fusions, and a steward's store-room. From the latter the students will be able to obtain all the apparatus they may require, on leaving a receipt with the steward.

In addition to the floors previously described, over the third floor, in the centre of the front block, is a large and lofty room, with open timber roof, and partially lighted from the top, intended for use as a museum. The basement story, extending under the whole of the ground-floor, is lofty and well lighted, and contains store-rooms.

The ventilation and warming of the college are upon an improved and effective plan. Near the centre of the area rises a very large chimney-stack to a height of about 160 ft., and it is divided into three flues by thin partitions. The central flue carries the smoke from the boiler, and heats the air in the adjoining flues, which are used for ventilating the lecture-theatres. The pipes from the fume-niches in the chemical laboratories also communicate with the stack by means of a horizontal flue round the walls. The warming is effected by a coil of pipes, containing 4,475 superficial feet, placed in a vault in the sub-basement. These are warmed by the water from the large boiler, and the air from the courts, passing over the pipes, is conducted by flues to every room in the building. In summer, cold air is admitted into the rooms by the same means. The drains are ventilated into a separate flue, carried up into the main shaft. Another important feature is the lavatory accommodation, which is ample and complete, there being cloak-rooms and lavatories on every floor opposite the central stairs, while the larger number of closets are in the yard beyond, and entirely cut off from the main building. A lift runs through all the floors for taking up stores and other things, and there is also a common shaft carrying the gas and water pipes, the junctions to which are easily accessible upon each floor. There are about one hundred rooms in the college, and 370 windows, while at present about 8,000 ft. of gas-piping have been used.

Sir Josiah Mason has built the college, and has furnished its various departments with the necessary fittings entirely at his own cost, so that the resources of the trustees remain untouched. Mr. J. A. Cossins, as his architect, has devoted himself to the work.

The building has been erected without making a single contract. The architect himself laid out the work, engaged and superintended the workmen, and saw personally to the execution of every detail. Mr. Hodgkiss was his manager; the stonework has been executed by Mr. Prothero; the carving is by Mr. J. Smith: Messrs. Camm, Brothers, have supplied the ornamental glass; the gasfittings are by Messrs. R. W. Winfield & Co.; the wrought-iron entrance-gate is by Messrs. C. Smith & Sons, Deritend; the painting by Mr. Potter; and some of the movable fittings by the Midland Joinery Company; the rest, including the fittings of the lecture-theatre and laboratories, having been made in the college workshops, under the superintendence of the architect. The furniture for the trustees' room and the assembly-room has been made by Messrs. Marris & Norton; and other rooms have been furnished by Messrs. Chamberlain, King, & Jones, and Messrs. Manton & Sons.

The building will probably cost about 60,000*l.*, and the income from the endowment is from 3,000*l.* to 4,000*l.* a year.

The trustees have power, we are glad to say, to make provision for instruction in art as well as in science; and by a supplemental deed they are authorised to include in the course of study certain subjects requisite for the training of medical students.

NEW BUILDINGS AND EXTENSIONS AT PAINTERS' HALL.

Painter-Stainers' Hall, in Little Trinity-lane, is in the hands of the builders. The existing building, which replaced the old hall,—destroyed by the Great Fire of London,—is said to have been erected and first opened in 1669, being thus 210 years old.* The principal frontage of the hall is in Little Trinity-lane, but advantage is being taken of the inclosed open area above the Metropolitan District Railway, on the north side, to put a new face on the ancient structure, visible from Queen Victoria-street. This new elevation is built with red brick, the style of architecture being of the Queen Anne type. The frontage is surmounted by a large central pediment, with the arms of the company carved in red brick. Two lofty arched windows, in three divisions, on the east and west sides of the frontage respectively, are intended to be filled in with stained glass, containing the arms of all the past masters of the company. This new frontage will form the north side of the dining-hall of the company, which is being enlarged in that direction to the extent of about 12 ft., and when completed this apartment will be about one-half larger than its present size, and capable of dining between 300 and 400 guests. The restorations likewise include a new roof, immediately over the Little Trinity-lane frontage.

Mr. Edis is the architect, and the contractors are Messrs. Watson, Brothers, of Charlotte-street, Portland-place. Mr. Thorn is clerk of the works.

THE WIDENING OF COVENTRY-STREET.

The Coventry-street improvement project will now shortly be carried out, when this West-end thoroughfare will be considerably widened on the south side, from Whitcomb-street, near Leicester-square, to its junction with the Haymarket, so as to make it about 60 ft. in width, and bring it into direct line with Piccadilly. A few weeks ago the materials of the whole of the houses and shops which are required to be taken down in order to carry out the improvement were sold, and the site upon which they stood is now almost cleared. The property cleared away comprises nearly thirty houses and shops in Coventry-street, Oxenden-street, Princes-street, Whitcomb-street, and also four large houses and shops and other places of business on the east side of the Haymarket. Of the entire area occupied by the four separate buildings in the Haymarket which have been taken down for the improvement, the site upon which two of them stood, at the angle of Coventry-street and the Haymarket, will form part of the widened thoroughfare, whilst the two houses which joined them, lower down in the Haymarket, will be rebuilt. The improvement will likewise lead to the erection of a superior class of buildings on the south side of Coventry-street, set back in the direction of Oxenden-street, Princes-street, and Whitcomb-street respectively.

An Old Workhouse.—The proposal that the Salisbury City Workhouse should be razed to the ground, and in its place a choir chapel be built by the Dean and Chapter of the cathedral, has met with considerable opposition from the Society for the Preservation of Ancient Buildings. Audley Hall, the building in question, dates back to a period earlier than Henry VII., and is noticeable as a fine example of ancient Domestic architecture.

* Some particulars as to the rebuilding of the Hall, together with some notes of the company's history, will be found in our last volume, p. 673.

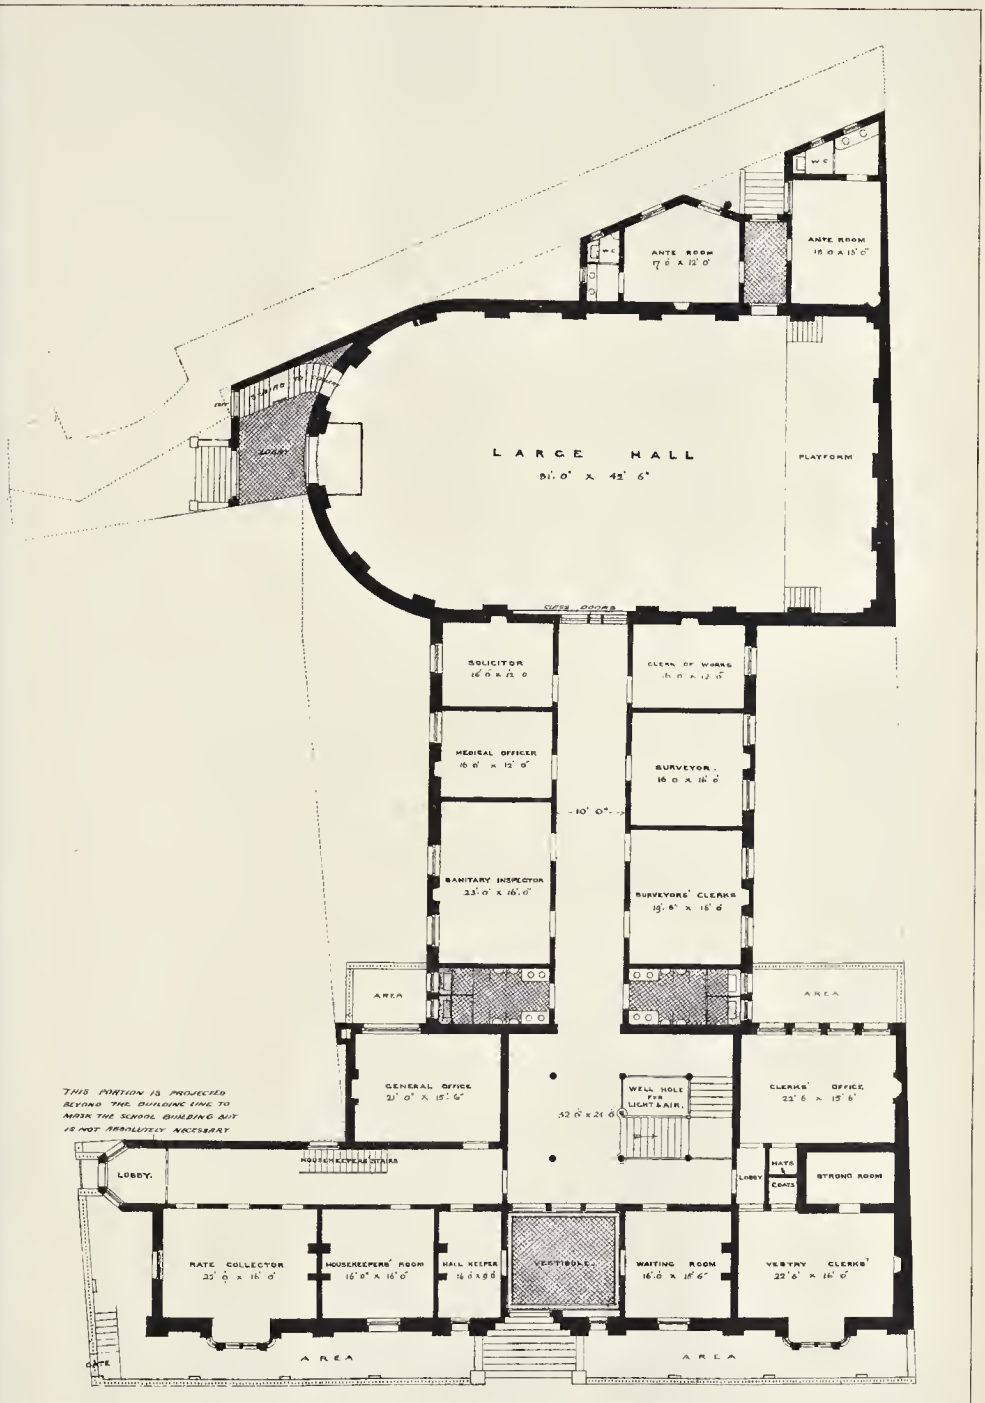
WESTMINSTER PAROCHIAL OFFICES.—Design by Messrs. Lee & Smith, to which First Premium was Awarded.



DESIGN FOR WESTMINSTER PAROCHIAL OFFICES.—*Plan of Principal Floor.*

Whiteman & Bass Photo Litho 256 High Holborn

Wyman & Sons, Printers, 74 Great St.

DESIGN FOR THE WESTMINSTER PAROCHIAL OFFICES.

We illustrate the design for the Westminster Offices, by Messrs. Lee & Smith, architects, to which the first premium was awarded; giving the principal elevation and plan of the ground-floor. We append some of the particulars given by the architects themselves to explain the design. They say they have considered the vestry-hall the most important matter, and have placed it in a position where the deliberations can be carried on in quietude and free from the noise of the streets. It is lighted by windows on three sides, the dimensions of hall being 49 ft. by 41 ft. and 25 ft. high, with a gallery at one end for strangers, and a retiring-room on the same level as the gallery, which is over the hat and coat room. The hall is approached by a staircase with steps 6 ft. 6 in. wide, rising from an inner hall, 32 ft. 6 in. by 21 ft. 6 in., lighted and ventilated by a lantern-light. This staircase also gives access to the committee-room, 42 ft. by 22 ft. 9 in. and 20 ft. high, the two smaller committee-rooms, the library, room for deputations and strangers' gallery, the hat and coat room before referred to, and the lavatories and conveniences.

The library, or members' tea-room, is provided with a serving-room in connexion with the housekeeper's stairs.

The ground-plan shows the chief entrance in the centre of the main front in Little Charles-street, by a vestibule, 16 ft. by 16 ft., on one side of which is the hall-keeper's room, and on the other a waiting-room, so that any person entering comes immediately under the notice of the hall-keeper. Both these rooms communicate with the large inner hall and corridor. Opposite the entrance, and across the inner hall, is a corridor, 10 ft. wide, on either side of which are the offices of the surveying, sanitary, and legal departments. On the left of the main hall is a corridor, 8 ft. wide, in which are the following rooms,—First, the hall-keeper's room, then that of the housekeeper, and opposite these the gas-testing office, and at the further end the rate-collectors' room, with separate entrance and waiting lobby.

It will be seen, by looking at the ground-plan, that the departments are divided into three:—1. The vestry clerk; 2. Surveyor, medical officer, and solicitor; 3. The rates and gas.

The large hall for meetings of the ratepayers is provided at the back, and will in this position afford room for 1,000 persons, this being the number suggested in the instructions.

The principal entrance to the hall will be from the main front, directly down a corridor, 10 ft. wide, with additional entrance in Gardener's-lane, which, in the event of the hall being let on any special occasion, will render it entirely independent of the vestry-hall and offices should it be so desired. The necessary space for accommodating 1,000 persons cannot be obtained without a gallery: this can be formed at one end or by a gallery all round the room. The materials for the exterior would be bricks and terra cotta.

The entrance-hall, staircase, gallery, corridor, large committee-room, and vestry-hall will receive a certain amount of decoration to give them the dignity requisite for a public building.

The roofs of the front are carried up to give height and dignity to the building, surrounded as it is by high structures.

The small scale of drawing for the elevation failed so completely, the designers say, to show the details of the building, that they prepared one on a larger scale; and they further note that they have not made three elevations, as according to their plan only two will be seen: consequently a considerable saving would be effected, by using which the principal fronts could be rendered somewhat more ornamental than could otherwise be the case, having reference to the sum named for the cost.

Sir H. Bessemer and the Freedom of the City.—The Gold Casket, designed and manufactured by Mr. J. W. Benson, of Ludgate-hill, illustrates the process of the conversion from the raw material to the application of the steel. It is of solid English design, surmounted by a modelled figure of Commerce, standing between a stack of pig-iron and the converter. On either side of the rounded cover are vignettes (in *repoussé* work) of a L. & N. W. Railway Locomotive (entirely constructed of this steel, and standing on its steel rails) and of a steel-clad ship.

"THE PRACTICE OF AN ARCHITECT."

We took occasion, some time since, to point out what we conceived to be the errors and injurious tendencies of an article published in the *British Quarterly* and titled "The Profession of an Architect." In the current number of that periodical the editor has allowed a writer, Mr. Roger Smith, also to say something on the other side of the question, and it may be useful to reprint a portion of his article. In the first part of it the writer obviously follows some of our lines:—

A professional man is one who either with his hands or his brain does for the individual who employs him work of more or less consequence or difficulty which the employer cannot perform for himself. A profession seems to have been so called to signify the fact that the person holding it professes or puts himself forward as an expert in some one thing. For example, the profession of law, of arms, of medicine is taken up by men who profess themselves skilled in law, in warfare, or in the healing art. An architect professes to be able to advise about buildings and to represent his employers in conducting the erection of buildings; that is to say, to design, superintend, and direct them. And before we can talk of the fine art of architecture, it is indispensable that all relating to contrivance and construction is first fully provided for. Many buildings, indeed, make no pretension to be called works of art, and in the strictest sense of the term are not architecture; for although all architecture is building, it by no means follows that all building is architecture; but even for such works the experience, the skill, the scientific attainments, and the business tact of the architect are as much required as where there is also an intention to aim at producing artistic work.

In the works which make undoubted claims to be our architecture in the most rigid sense that can be attached to the term, we do not find anything that exempts them from the conditions already laid down. Cathedrals and churches equally require to be planned, drawn out, estimated, contracted for, superintended, and paid for, and there is nothing in their nature which places them in these particulars in a different category from common buildings. When it is complained that architecture has become a profession, the complaint is as unreasonable as though it were directed against the medical or the legal profession. It is a more reasonable ground for both complaint and regret that architecture is sometimes attempted by men who are by no means competent to act as professional advisers. Persons of undoubted ability as draughtsmen, but not otherwise qualified, have sometimes obtained the position of architect to a building, and naturally enough have landed the undertaking in difficulties financial or structural, or both.

The unfortunate facility with which any one may assume the title of "architect," and the chances left open to all comers by the competition system, have together occasionally enabled such men to secure works of considerable importance and prominence. The result has often been severe disappointment and pecuniary loss to the employer, and sometimes complete disaster to the so-called architect, and has unfortunately reflected discredit upon the profession for which he had not fully qualified himself.

It may be assumed, however, as a point which few persons will venture to contravene, that whatever be the artistic excellences of the buildings to which we give the name of Modern Architecture, they must, if they are to be built at the present day, be designed and erected by persons capable of working under such conditions as those just laid down, and not apt to run counter to them. And it is only so far as the profession of the architect is adapted to the conditions under which it has to work that it can fulfil its duty to the public. The nature of that duty, often exceedingly arduous, and never unimportant, may have been to a large extent inferred from the statements already made; but perhaps a slight sketch of the ordinary routine of an architect's usual procedure in connexion with a building may not be out of place.

The first duty of an architect in connexion with a new work is to inform himself exactly as to what is wanted. The variety of the objects for which buildings are required makes very large demands upon the intelligence, the adroitness, and the training of the man to whose lot it falls to design them. An architect has to be quick at seizing the essential idea or ideas upon which his building depends for its success as a contrivance; and he must be sure as well as quick. This kind of insight is only acquired by practice and training, and were there no other reason why an architect must be a man of good special cultivation as well as good natural abilities, this part of his work is in itself sufficiently difficult to require an accomplished specialist.

The design, in its earlier stages, rather implies than sets forth much that will have to be foreseen and provided; but from the first its author ought to be able to see that it is capable of being carried out in all its details, whether of arrangement, construction, artistic design, or cost; and as he advances, he has to grasp all these matters and hold them, so to speak, in a strong grip; for if any one of them escape him, his work is likely to prove unsuccessful.

The design of a building is, moreover, not complete, even if its arrangements are such as to make it fit for its intended use, unless it be thoroughly sound, stable, and well considered as a structure. This requirement—a very wide one—calls for a knowledge of materials, their strength and nature, and the mode of putting them together; of foundations, and the modes of making them secure; and of the forces which are at work sapping the stability of structures, either by way of gradual decay or of a sudden and violent attack; and such knowledge the architect requires to possess, and is called upon to exercise, in a way which varies more or less with every building. It should be remarked, too, that the circumstances of the present day not infrequently call for close economy in the use of materials and the appropriation of space, so that the limit of stability is often unavoidably approached. Now, too, it is more often than formerly necessary to provide for a mode of occupation exceptionally trying to the fabric. Public halls, for example, with their crowded audiences, are, in modern towns, as a rule placed on upper stories, so that the safety of some thousands of people depend upon the provision of ample strength in the construction of their floors. Commercial and manufacturing buildings, again, are often made to support vast loads; the floors of others are crowded with heavy machinery in rapid motion, while such constructions are commonly built with an economy that verges on parsimony, so that it is essential to make them strong and secure without rendering them costly. This is not always, if ever, an easy task.

It has been pointed out that all the appliances and contrivances in use at the present day, and all the building material obtainable in every part of England and many foreign parts, are at the disposal of the architect, and that every portion of the country is open to him as his field. It is consequently necessary for him, if he is to be equal to his opportunities, to know something of the materials, the climatic conditions, and the local building customs of every part of this country; and this alone implies that much varied information has been got together such as is difficult to obtain, and can only be acquired by diligent personal search. The various mechanical and scientific appliances available in buildings also require to be understood. The architect should know which of them will suit his client's purposes, and should be able to secure that those which are selected for employment shall be efficiently and properly introduced. This involves no small knowledge of men as well as inventions; for it is not only necessary to know what contrivances are best, but also what artificers or tradesmen can be relied upon to construct or fix those contrivances in a workmanlike manner, and with a good prospect of their answering the end for which they are to be employed.

The part of the work done by the architect in his own room culminates in the preparation of a complete set of working plans and of a specification descriptive of the materials and labour to be employed. The undertaking then enters on another stage. The architect has to direct the negotiations, measurements, &c., which result ultimately in an arrangement with contractors or tradesmen who shall execute the work, and he then personally and by deputy supervises the carrying of it out to completion. During its progress he has to certify from time to time that such payments on account as are agreed upon have become due; and at its close it is his duty to settle and state the final accounts. Now it is of all things necessary for the successful discharge of these duties that the

architect should be a man of business, and that he should be strong enough not to be afraid of the people with whom he has to negotiate, and over whom he has to exercise control. How far an architectural draughtsman and a superior operative acting together,—the combination recommended in "The Profession," &c.,—would be able to obtain the necessary command over an energetic, unscrupulous, overbearing, and wealthy contractor may be doubted; yet if a man of that class obtains a building contract, it depends almost solely upon the architect's personal influence, straightforwardness, and independence to keep him in his place and to secure the due execution of his contract.

Above all things, the direction of a building operation requires the services of a man of upright, straightforward, independent integrity. The writer of the article under reply has permitted himself to insinuate that it is a common practice with architects to receive bribes, which he dignifies by the name of "sly percentages," from the tradesmen whose work they have to superintend. Either he is not in a position to know, in which case it is unjustifiable to bring such a charge, or he is in such a position, in which case a far more severe term ought to be employed to characterise what he must he well aware is a slander. That there are persons entirely unfit to bear the name, who call themselves architects, has been already admitted, and there can be no doubt that such people take all that they can get by fair means or foul; but men regularly occupying the recognised position of architects of respectability are as honourable as the members of any other profession. To be trusted and trustworthy is the first necessity of professional life. The present writer may, perhaps, be permitted to add that his personal experience confirms him in his belief that the sly percentages spoken of in the article are not offered,* as well as not accepted.

To judge by his language, the author of "The Profession of an Architect" seems to attach something like criminality to the very mode of payment always adopted. The custom has now become universal that under ordinary circumstances, and for the usual services, an architect charges his employers a lump sum equal to five per cent. upon the amount of money spent. For the public this is a very fair mode of making a charge, and the rate is moderate. No building worth attending to at all can well fail to reap advantage to the extent of at least one shilling in the pound from the skilled design and supervision under which it has been carried out. To the architect the payment is, on an average of his works, moderately remunerative. Occasionally it is good pay; often, especially in small intricate buildings, or in the case of buildings in remote situations, it is miserably inadequate; and there can be no doubt that architects would be gainers were this custom abandoned, and the habit of charging for the time actually expended on each work substituted for it. The advantage of payment by a lump sum is that, being known beforehand, there is little room for dissatisfaction or dispute; and rough though the method of assessing the amount undoubtedly is, there is in it substantial fairness. For an architect to reside at one work, and superintend it wholly, as the writer suggests, appears to be in no wise necessary,—at any rate, in this country,—now that railways and good roads have made every part of England easily accessible; nor is it quite certain that the result would answer the expectations of those who tried the experiment. Too much interference might possibly result from the presence of an active-minded man bound to one building every day, and all day long; and nothing so surely mars any undertaking as vexatious interference, however well-intentioned. To the suggestion that this resident architect ought to be an operative, I reply that, at present, so much of supervision as a working-man can give is given, and in a fairly effectual way to the carrying out of work, but not certainly to the design. The superintendence of every building is under the care of a foreman placed by the contractor or builder in charge of the work. He is an operative who has been marked out by his superior knowledge or intelligence, and who can usually understand the plans, and can direct the undertaking so far as materials, the employment of labour, and the putting together of the work are concerned. In most buildings of importance the architect is also represented by a permanent "clerk of works," who is generally a man of much the same sort as the builder's foreman,—that is to say, an intelligent operative. The practical knowledge and experience of one or other of these men,—or both together,—can generally be trusted in all matters that relate to materials and structure, but it is the rarest thing in the world for them to understand the science of construction or the art of architecture. The *meaning* of a moulding, a feature, or an ornament of any sort, seems beyond the grasp even of the operative who executes it; and the best workman rarely proves capable of anything beyond a mechanical adherence to a drawing. With the solitary exception of carvers in stone and wood, much the same may be said of all classes of operatives employed in building,—they seem rarely to possess any kind of artistic feeling in respect of the work they do, and never to be so informed as to be able to act as resident architects in the manner suggested in the article under reply. The most unsatisfactory results, from an art point of view, commonly follow the efforts of any artisan who has had energy enough to establish himself in a small way. The deplorable little structures, known commonly as "weekly property,"* seem to be the limit of the unassisted efforts of the artisan, turned master builder, in most instances; and how far these are from architecture let those say who are most familiar with them.

There appears no sufficient reason why, within fair limits, an architect who is able and skilful should not reap the reward of his abilities in the increasing number of his clients, just as a physician, when he becomes eminent, finds patients flock to his consulting-room. The parallel holds good in another respect; for as the fee of the young physician is not less than that of an established one, so architects of very different professional standing regulate their charge by the same percentage. It is quite true that when very numerous works are entrusted to the same architect much of the preparation of the drawings, and not a little supervision of the work, must be delegated, just as the carrying out of the directions of the physician is necessarily delegated to nurses and other assistants.

In the architect's office the plans which he originates are often, to a large extent, drawn out by assistants. This takes place under the supervision and control of their principal, with the constant addition of his own touches; and the work so done is virtually much the same as he himself would do, did time and opportunity permit.

The amount of personal work in the way of sketching and designing actually done with their own hands by many of those architects whose practice is the most extensive, is, however, enormous. The most busy architect of the present day is, in all probability, the one who has charge of the Palace of Justice now in course of erection in London. Yet it is his boast that all the working and detail drawings of this enormous pile are the work of his own hands, and, in addition, he is pursuing nearly the same course with all his other work. Whatever may be the idea entertained by the writer of "The Profession of an Architect" as to the assistance which he supposes is obtained from clever clerks, he may rest assured that the success of an architect of the present day depends, as a matter of fact, mainly upon his personal skill as a draughtsman. Four abler architectural draughtsmen could not be found in all England than the four gentlemen who, as Academicians and Associates, represent architecture in the Royal Academy,—a position the highest to which any architect can aspire. They are Academicians and Associates, however, not because of the excellence of their drawings, but of their buildings.

That which is most unfavourable to modern architecture is not the perfection of the methods placed at its disposal, but the absence of that universal and spontaneous effort which, during not less than four centuries, made architecture the foremost expression of popular energy, faith, skill, and feeling. Could we once more gather up into this one channel all the force of the most powerful minds in Europe, and leave them without science, and almost without literature, bereft of steam, without the printing-press, without great commercial or philanthropic undertakings, without other paintings or sculptures than works of a decorative character; could we, in short, force back the tide of time that has flowed on for five centuries, and then say to Europe, "Build; throw the best powers of your best men into this channel,"—we should soon find that human activity, administrative, structural, and artistic, concentrated into architecture alone, would infuse a vitality into that art beyond even the vigorous growth which we have witnessed in natural science in our own day. But it is not the part of sensible men to desire the impossible, and there is not the smallest reason to suppose that a return to what it is presumed may have been the methods in which the buildings of the Middle Ages were managed would ever (were it practicable, which it is not) bring us one inch nearer to spontaneous living architecture, unless we could make the whole age move back also.

The idea has been apparently entertained by the author of "The Profession of an Architect" that architects as a rule obtain their practice, or the bulk of it, by competitions; and this unknown, or at least unnamed, critic appears in his hostility to success to be willing to spread this delusion, for no other reason than that some architects who have succeeded in life have also succeeded in competitions. It is quite true that, owing to the prominence given to public competitions, and to the fact that every now and then designs for a really important building are obtained in this way, the subject is associated in the public mind with the practice of architecture. But the truth is that public competitions are resorted to for only a moderate proportion even of public works, and that the designs for all our best buildings, such, for example, as churches, banks, club-houses, and private dwellings, are rarely, if ever, obtained in this way. Men, who as public men, will resort to public competition because it is customary, or because it affords a chance of exercising a little nepotism undetected, or because it affords a convenient escape from the claims of rival architects, are far too shrewd to employ so imperfect and unbusiness-like a method when their own interests are at stake. Still, competitions do take place, and some few architects are frequently competitors, and many occasionally become so. But, we repeat, if it were not for the conspicuousness of competitions, they would not be much taken note of as influencing architectural practice. Even those architects who, having obtained an important building to erect through a competition early in life, have had an opening towards success made for them of which their ability and skill has enabled them to make use, will be found to have really only gained a very small amount of their life's work in competition; in short, nothing can be more untrue than the degrading sketch of an architect's position and mode of procedure given at pp. 335, 336, of the article.

A competition has this great defect, that it forces the architect and employer asunder at the very moment when they ought to be consulting together, and that each is placed at a disadvantage and induced to do his worst rather than his best. The employers make up their own mind among themselves as to what they are going to do at the very moment when they ought to have the opinion of an experienced and responsible adviser to tell them what is really within their reach; they then surround their proceedings with a thin veil of mystery which, on the one hand, makes steps that are in themselves perfectly innocent seem as though they were unfair, and, on the other, offers a ready cloak for any species of unfairness which it may be really desired to perpetrate. Meantime the architects, left to prepare their designs without proper consultation with their clients, are well aware that it is not what they themselves consider best, but what the committee consider best, that is likely to win the day, and are accordingly sorely tempted to launch out into projects far beyond the means really disposable. These evils are more or less mitigated by the employment of a professional adviser, and by some other departures from the stereotyped programmes; but the system has little to recommend it, and is much to be deprecated even at his best; and if it were at all as com-

* Twice, and only twice, in a course of practice extending over twenty-five years, and bringing me into contact with tradesmen of every sort and kind, has any such thing as a percentage been offered or even suggested to me by a tradesman. Were such offers customary, I must have had my share of them. During the last ten or twelve years I have been largely engaged as an arbitrator and a witness in cases arising out of building disputes. These have been varied and not seldom obstinate and angry, and in some cases it would have been to the advantage of one party or the other to disparage the architect; but I have never yet, in any case, heard proof given, or even a charge seriously made, that an architect had received a bribe from any tradesman or contractor, as I must have done were such percentage common.—T. R. S.

* Houses of which the rents are collected weekly, i.e., of the value of about 12s. 6d. per week downwards.

mon as it is conspicuous, might prove more seriously prejudicial to the profession of architecture than it ever has been or will be.

On the other hand, there can be no doubt that in many respects competitions do good to the individuals who engage in them. They offer an opportunity to many a young professional man, little if at all occupied as yet, of preparing designs for real buildings to occupy actual known sites, and to be built for definite purposes and under definite conditions. This is, if taken in moderation, not a bad training for actual practice hereafter, and there is enough of stimulus in the excitement and in the chance of possible success, remote though that chance may be, to induce a young man to do his best. Again, there is a freedom from the restraint of responsibility,—a restraint which often fetters the imagination of an architect sorely,—that sometimes acts like wine to the genius of men of true ability, and induces them to do their best. Competitions thus do actually from time to time become the stepping-stones across which an unknown and obscure artist of real power makes the first stage of his journey in life. In a few rare cases they have called forth the best powers of men of admitted talent and experience, but that has generally been when, as was the case in the competition for the Law Courts, the invitation is restricted to a few well-known names and the prize is a large one.

LARGE SALES OF BUILDING SITES IN THE SUBURBS.

Several sales of building sites on estates laid out for the purpose in different localities around the metropolis have taken place during the past week or two, there being in almost every instance an active demand amongst builders and others for the various sites offered.

On Tuesday evening, the 28th ult., Messrs. Protheroe & Morris submitted for sale, at the Prince of Wales Hotel, Wimbledon, eighty-eight plots of freehold building land, forming a portion of the Woodside Estate at Wimbledon. The several plots offered have frontages of from 20 ft. to 25 ft., with a depth ranging from 109 ft. to 144 ft. There was a good attendance of buyers, and most of the plots were sold, the prices obtained ranging from 5*l.* to 6*l.* per foot frontage. A large corner-plot, having a frontage to Gap-road of 123 ft. in length, with a depth of 90 ft. at one end, and 36 ft. to Alexandra-road, was purchased for 500*l.*, Mr. Shaw, of Tooting, being the buyer. This plot had been reserved by the vendors for an hotel.

On the following Thursday evening Messrs. Protheroe & Morris also offered for sale at the Castle Inn, Tooting, the first portion of an estate now converted into building land, but which has hitherto been known as the Exotic Nursery, at Tooting, situated in Garratt-lane, near the Balham and Tooting railway stations, and about seven miles from the City. The plots offered were thirty-four in number, having frontages to Fountain-road of 20 ft. by a depth of 100 ft. Considering the lateness of the season there was a good attendance, and most of the lots were sold, the prices obtained averaging about 3*l.* 5*s.* per foot frontage.

On the same evening Mr. R. J. Collier held an extensive sale of a similar character in a large marquee, specially erected for the purpose, at the Queen's Head Hotel, Green-lanes. It consisted of the first portion of the freehold building land, known as the Haringay New Park Estate, situated on the high road from London to Southgate, within a short distance of Finshury Park and the Alexandra Palace, and described as advantageously placed within easy distance of four railway stations. The number of plots offered for sale consisted of 145, suited to different classes of purchasers. They varied in dimensions from 18 ft. to 22 ft. frontage, and from 70 ft. to 172 ft. in depth. Several of the plots are appropriated for shop purposes, and others for villas and houses of a moderate class. There was a very large attendance at the sale, and all the lots were sold at prices varying from 80*l.* to 140*l.* each, or at the rate of from 4*l.* to 6*l.* per foot frontage. The total proceeds of the sale amounted to 11,060*l.*

On Saturday evening last, Mr. F. M. Whittingham offered for sale at the Castle Hotel, Woodford-green, the first portion of the Woodford-green estate. The property fronts Woodford-green, and is in the immediate neighbourhood of Epping Forest. The number of plots submitted for sale was 61, having frontages of 20 ft. each, and a depth of from 100 ft. to 173 ft. All the plots fronting the green were sold, realising an average price of 7*l.* per foot frontage, or about 1,900*l.* per acre, and also most of those fronting Higham-road,—a new road made through the estate,—which realised 5*l.* per foot frontage, or 1,600*l.* per acre, the total amount of the sale being 4,059*l.*

DIRT, DISEASE, AND CRIME.

The Recorder of Dublin, in charging the grand jury at the opening of the Quarter Sessions on the 1st inst., referred to the intimate relation which subsists between the presence of unsanitary conditions and the existence of a heavy criminal calendar and a high death-rate. Having quoted particulars of the overcrowding of the city from the report of the Royal Commission which sat last year, he said:—

"We are responsible if we do not,—every one of us publicly or privately connected with this city,—labour to change it. I say deliberately that this state of things,—30,000 people living in the chief city in houses which have been condemned as uninhabitable,—a crime-rate and a death-rate so extravagantly excessive,—are subjects as deserving, far more deserving, imperial consideration than some of the burning questions, the alleged grievances, which are now shaking society through the length and breadth of the land. There are at least four things which must be done. I cannot detain you by stating my reasons here. There must be a revaluation of the city. The incidence of taxation at present is unjust: some property is overtaxed; a considerable portion has escaped taxation, and more still is taxed below its proper value. Secondly, there must be the co-operation of the central Government, at least to the extent of advancing the necessary loans, on exceptionally favourable terms as to the length of time for repayment, for it would be manifestly unjust to charge to the existing generation only the defaults of generations past. In the third place, there must be co-operation of the wealthy suburban townships, for the labouring poor of the city are the labouring poor not only of the city within the bounds, but the whole metropolitan district. In the fourth place, there must be the co-operation of private enterprise, as in Glasgow, where a somewhat similar state of things has been successfully coped with, and where the population displaced by the improvements were provided for by private enterprise, and that without loss. We cannot hope that all this would happen here. We have an Artisans' Dwellings Company, who have done much; but their operations must be necessarily limited, having regard to the work to be done. It may be a little wide of the mark to suggest here the co-operation of private charity; but all have heard of the great work in London for the homes of the poor effected through the beneficence of Mr. Peabody, and it is at least possible that, were the necessity widely known, some one would be led to act in the same direction here. At least, it is unjust and unreasonable for people simply to say, 'the question is one for the corporation, with which we have nothing to do.' No doubt the corporation, as the responsible authority, have the chief burden upon them, and they are already engaged, under the leadership of the Lord Mayor, in carrying out several of the suggestions in this report; but the Lord Mayor himself has stated that this evil of the tenement dwellings,—which is the evil of evils,—is one too gigantic to be dealt with by the Council in the present state of their finances, and those who ask the Corporation to do their duty must be prepared for the self-sacrifice of bearing a portion of the burden of supporting the Corporation in seeking the means by which alone it can be discharged."

AN ANCIENT BARROW IN WALES.

In connexion with the recent meeting of the British Association at Swansea, an excursion was made to an ancient barrow, discovered on Mr. Hussey Vivian's property at Park le Breos, in Gower. It was discovered, says Mr. Vivian, in 1869, under the following circumstances:—Up to that period no road existed in the valley. Finding that its beautiful grassy sward was much destroyed by the haulage of timber, I determined to make a road, and entered into a contract for its construction. Towards the lower end of the valley there was a heap of stones grown over with brambles and shrubs, and surrounded by a few ash trees. The contractor, finding that stones would cost him less from this heap than from the quarry, commenced its removal, and on doing so soon came on human bones. I was at once advised of the discovery, and on examining the place was convinced that it was a cairn. Soon afterwards, in August, 1869, the Cambrian Archæological Society met at Bridgend. I invited its members to come on to Swansea and assist at the opening of the cairn. Sir John Lubbock also kindly responded to my invitation. The cairn presented the appearance of a large heap of stones 60 ft. long and 56 ft. broad, with the top of one large stone protruding from the centre. The small stones were removed, when a carefully-constructed chambered tumulus was revealed, consisting of four lateral compartments leading off from a central passage, two at each side near the end, with a space between. The bearing of the central passage is nearly north and south; it is 18 ft. long by 3 ft. wide. It contained the bones of ten persons. The north-eastern chamber is 6 ft. long by 3 ft. 6 in. wide, and contained the remains of six persons; the north-western chamber is 5 ft. long and of irregular form, 4 ft. broad at the end and 8 ft. at the entrance. It contained the remains of two persons. The south-west chamber is 5 ft. long and 4 ft. wide, and contained the bones of four persons. The south-east chamber is 5 ft. 6 in. long and 3 ft. 6 in. wide, containing two sets of bones. The central passage is approached by a hell-mouth entrance, and roughly walled on each side, 10 ft. in length. The upright stones forming the central passage and lateral chambers vary from 3 ft. to 6 ft. in height above ground, and are irregular, so as to preclude the supposition that covering-stones were used. None such appeared in opening the cairn. The bones were submitted to Dr. D. Morton Douglas for examination, and such portions as appeared to be of scientific value were retained, and the remainder were placed in terra-cotta vessels and re-interred each in its separate compartment. Such bones as are of interest I have now presented to the Oxford Museum through Professor Rolleston. No flint implements were found in the tumulus, but some fragments of rough, unbaked pottery were discovered.

BORING WITH SMALL TUBES.

In the vicinity of Antwerp much difficulty is experienced in obtaining water, owing to the fact of the ground being entirely a deposit of fine sea-sand, of a blowing nature.

Mr. Huger, the agent of the Great Eastern Railway Company at Antwerp, has been trying to ascertain how deep the bed of sand extended, and has made his first attempt on a very small scale, employing an "Abyssinian" tube well, only 1¼ in. diameter, driven by a "monkey" weighing 75 lb. With this little tube he has been able to reach to no less a depth than 152 ft., testing the soil at short intervals the whole way down, and demonstrating that nothing but sand extends to this depth.

It is now very probable the attempt will be followed upon a large scale.

PRESTON.

Health of the Town.—At the last meeting of the Town Council, on the presentation of a report from the Sanitary Committee, containing the recommendation that notice should be given to the owner of two houses requiring that they should be closed as unfit for human habitation, a discussion took place, in the course of which statements were made as to the health of the town which call for immediate attention. Alderman Satterthwaite, for example, said,—Respecting the mortality, they would see that for the past month it had been 37 per 1,000, and for the month preceding it was 32 per 1,000. If they would look at the ages of the persons who died they would find that the mortality had been principally among those under two years of age. From two years and upwards the death-rate had not exceeded the average. For this month 205 out of 316 had been under two years of age. The rate under two years of age was 65 per 1,000 for this month, and 60 per 1,000 for the last. During the past five weeks there had been 145 deaths from infantile diarrhœa among children under two years of age. That was a serious matter, and it was rather humiliating that the exertions of the Sanitary Committee had not had a better result. The report was ultimately adopted—so should fresh measures be.

Floor of the Town-hall.—The council were afterwards occupied for a long time in the consideration of a proposition to take up the particularly firm and solid flooring of the hall constructed under the direction of its architect, the late Sir G. G. Scott, and substitute, at a considerable expense, a yielding or "bending" floor more pleasant to dance on. Alderman Hibbert, in opposing the proposition, wisely expressed a hope that the council would inquire, before passing any motion, whether the town-halls at Manchester, Leeds, Bradford, Hull, Bolton, Rochdale, Halifax, Blackburn, and Chorley, had floors constructed upon a "bending" principle. If they could find such, and could procure testimony that such floors answer in general respects, his opposition would fall to the ground. He succeeded in passing as an amendment,—"That the question of altering the construction of the Guildhall floor be referred back to the committee, with an instruction to inquire and report to the council whether there exist any public hall floors of similar construction to that now proposed."

We learn that the existing floor is constructed as follows:—11 in. by 3 in. single joists, 11 in. apart, with bearings of 13 ft., and resting co-extensively upon the side walls and upon intermediate sleeper walls, which last are carried upon the granite pillars and stone vaulting of the room below. These joists it is proposed to take up and replace to a dancing area extent of 65 ft. by 39 ft., with three beams, 9 in. deep and 1 ft. 1 in. wide, resting upon the walls at each end, having a bearing of 39 ft., and trussed with iron rods; and each beam having under it at two intermediate points of the bearing metal springs or discs, which themselves rest upon the sleeper walls. Upon this yielding basis are to be binding joists, and bridging joists, covered by the present boarding, taken up and replaced. The number of times the hall has been used for balls or dancing assemblies since its erection in 1866 has averaged, we understand, about four or five a year,—the majority private and not public balls. If the council are wise they will let well alone.

PROFESSIONAL REFEREES IN COMPETITIONS.

Sir,—"One who Signed it,"—that is, the memorial to the Institute with reference to Architectural Competitions,—does not treat us quite fairly. He brings forward an instance in which the views of the memorialists were carried out, expresses a very pretty admiration of the successful result, and then proceeds to state that he thinks the memorial will do no good, although he signed it. We are not all of us quite so hopeless. Some of us, and we are glad to have the *Builder* with us, consider the memorial one of the best things done for some time; and are willing to believe that the Institute will not allow the good resolutions to be wasted, but will help every respectable practitioner to be a party to a self-denying ordinance with a view to the general good No reasonable person expects that professional referees will always be perfectly wise, or always able so to deal with conditions conflicting with reason and with each other that no competitor will feel able to grumble if he tries. In the law courts and in arbitrations there are false judgments and glorious uncertainties, but submission to the decisions of unskilled persons has yet to find an advocate. When it becomes the custom to employ the eminent architect who is to act as referee to draw up the conditions, as the memorialists wish that he should, failure of justice will, one hopes, be the rare exception, rather than the rule, as has happened so commonly during the time of haphazard decisions.

If "One who Signed it" has some reasons (beyond a general belief in the awkwardness of human creatures and a despair of things in general) for thinking as he says he does, he will be doing good service by making them known to the signers of the memorial and to the world, in the opinion of

Another who Signed it.

THE EDUCATION OF THE WORKMAN.

Sir,—There is no one who reads the *Builder*,—and who does not?—who will not read "E. G.'s" sensible letter on the above subject with interest. He laments, as others do, the difficulty of getting good general workmen, and yet, if I understand him rightly, he favours specialism, and special schools. Does he not see that this specialisation is one reason why you cannot get the good, old-fashioned, all-round, general workman? "That is not my business," or "That is not my work," is the answer you get from a workman from whom you expect to get general utility. But I fear, sir, there is something lying yet much deeper than this, and "rotten in the state of Denmark." "E. G." almost hits it when he speaks of the want of emulation; but what causes this want of emulation in a nation? It is when *sic vos non vobis* is written on the wall, and men come to believe that if they project any improvement for a master, for a company, for the State, the credit and the reward will be wrested from them either by unscrupulous capital or unscrupulous power. Invent any educational machinery you may, it will not cure this disease; the apathy of the slave sets in, and men will just satisfy the task-master and no more. When a nation has come to this pass of a widespread want of emulation, you may multiply technical institutions as you will without in the slightest degree effecting a cure; the nation that ceases to have the spirit of emulation is a nation on the road to ruin. There are, however, more causes than this highway robbery of men's suggestions, ideas, projects, &c., one of which may be the hard and fast rule that men shall not make a profit of their superior ability; but this, too, when analysed, is simply depriving the individual of his advantage, and of the value of his property. The only remedy for the evil would be the prompt restoration of honest freedom, a fair field and no favour. Then we should again have emulation; men would work with a will; the State would be revivified, and we should never again have to lament the want of a man for any good work: we should find for all departments the good general workman.

W. Cave Thomas.

SUBURBAN BUILDING AND THE BUILDING ACTS.

Permit me to enter a protest against a mode of building to some extent prevalent in the suburban districts,—in my view of the matter a reprehensible and vicious mode of construction,—one, however, not provided against by the Building Act, 1855, viz., the banking up of foundations, on the natural level of the soil, by concrete enclosed by planking. If reference is made to the Act of 1844 we find the following as regards foundations, "Depth below Ground," in reference to the depth below the lowest ground or area adjoining:—"The *top* of the footing of every party fence wall, and of every external and party wall, to be at the least 3 in. *below* such surface." It appears to me trenches cut for walls are an essential element in their stability, and I suggest that, to provide proper foundations, the top course should not be less than 12 in. below the natural surface or level of such ground.

The present Act, 1855, simply enacts that "the foundations shall *rest* on the solid ground or upon concrete, or upon other solid substructure."

Why the salutary provision as regards foundations provided by the Act of 1844 should have been expunged, and the present regulation made, is a "*res difficilis ad explicandum*."

Another defect in building, and one attended with danger, is the late period at which the drains are put in, often when buildings are approaching completion. Before the walls of any building are more than 3 ft. above the ground, it should be compulsory that the drains should be completed.

As regards bad building, on which so much has been written, I cannot conclude without expressing an opinion that no real improvement in these matters will be effected until the legal position of the freeholder or ground landlord is recognised, and he is made jointly responsible with the builder for what is put on the ground through his agency; the legal maxim, *qui facit per alium facit per se*, should be insisted on.

Unscrupulous, careless, or ignorant landlords will always find unscrupulous agents to cover their ground at a minimum of cost. Let the sins of these nefarious proceedings be shared in their due proportions by either delinquent; but for the future the public have only themselves to thank if they allow the real culprit to escape.

R. L. Sibley.

THE GROUPS FOR BLACKFRIARS BRIDGE.

Sir,—Mr. Edmeston's letter is timely, and may be of service to sculptors. That is, supposing the character of the works required and the prizes offered warrant the competition of men of talent. It cannot, however, be disguised that there is a growing disbelief in the honest administration of competitions of the kind proposed. There is a conviction that it is often determined who is to have the commission before the terms of a competition are advertised. If not so flagrant a breach of faith as this, the first appearance of the notice is a signal for the several members of a committee to commence tactical proceedings in favour each of his own *protégé*. The worst work sometimes triumphs. Now, if competitions are really of any advantage to art, they can only be so if carried through with rigorous fairness. The only chance that I see for this would be the appointment of a professional committee of selection, a committee of artists. Painters and sculptors should insist upon this, or refuse to compete.

Observer.

KITCHING'S MEMORIAL READING-ROOMS, MILNTHORPE.

The foundation-stone of this building was laid on the 3rd ult. by Mr. Thompson Bindloss, of Castle Green, near Kendall. The building will be erected as a memorial to the late Mr. John Kitching, M.R.C.S., of Milnthorpe, brother to Mrs. Bindloss. It will be built at the sole expense of Mrs. Bindloss, and will cost over 2,000*l.*, and will be supported, when completed, by that lady.

On the ground-floor there will be a coffee-room, 21 ft. by 15 ft.; reading-room, 16 ft. by 15 ft.; with spacious entrance-hall, &c. On the first floor will be a lecture or concert room, 37 ft. by 21 ft., approached by a pitch-pine staircase. On this same floor will be a library, also retiring-rooms, &c.; above will be rooms for chess, bagatelle, and other amusements. The architect is Mr. Eli Cox, Kendal.

PROVINCIAL NEWS.

Altrincham.—On the 1st inst. temporary premises for a Conservative club were opened at Altrincham. A site for a permanent building has been given by the Earl of Stamford and Warrington. The cost of the premises which it is proposed to erect will be about 3,000*l.*

Derby. — The Derby Tramways Company have now completed the Osmaston-road and Friar-gate lines, which have a total length of about two miles and a half. The lines have been laid by Messrs. Mousley & Co., contractors, under the direction of the company's engineer, Mr. Joseph Kincaid, of Great George-street, Westminster, and under the personal superintendence of Mr. Barlow, resident engineer (on behalf of Mr. Kincaid), Mr. Coultharst, borough surveyor (on behalf of the Corporation), and Mr. A. Johnston, engineer (on behalf of the contractors).

Hull.—At a meeting of the Parks Committee of the Hull Corporation, held on the 1st inst., an informal discussion took place with reference to the desirability of obtaining additional parks for Hull. The chairman said the only property belonging to the Corporation that might be utilised as a park was the Walton-street site. Some time ago they had the offer of the old Botanic Gardens, but it was thought that the position was not suitable, and the cost of the property would be very great. Mr. Downs suggested that the Asylum land might be very well laid out for a park, and it might be made to pay for itself by the building of villa residences around the property. No action was taken.

Lincoln.—On the 1st inst. the new Bishop's "Hostel" at Lincoln,—formerly the old County Hospital,—was opened by the lord bishop of the diocese. The building was purchased of the hospital authorities for 3,800*l.*, and the alterations have cost about 3,000*l.* The old board-room and dispensary have been converted into a chapel, and the large waiting-room into a library and reading-room. The males' ward, on the ground-floor, has been made the dining-hall, the upper end being used as a sitting-room for the students, and what was the operation-room is now the servants' hall, while the kitchen, scullories, &c., remain in almost the same positions as before. There are, on the first floor, a bedroom and sitting-room set apart for the use of the Prebendaries residing out of the city who have preaching turns at the Cathedral. The extreme west wing of the building has been arranged as a private residence for the Vice-Chancellor, Canon Crowfoot. The whole of the floors have been taken out and renewed, likewise the greater part of the ceilings, and the walls have been colour-washed and painted. The alterations have been carried out from plans by Messrs. Goddard & Son, architects; the contract was taken by Messrs. Martin & Sims.

Manchester. — The Manchester meeting of Friends have authorised the committee of the Friends' Hall of Residence to expend a sum of 12,000*l.*,—8,000*l.* of which the meeting itself provides,—in the erection of a permanent and specially-designed hall of residence in place of the temporary premises in Greenheys. The institution was founded in October, 1876, and was mainly due to the presence in lodgings in Manchester of the sons of Friends who had come from distant parts to study at Owens College.——One of the most important improvements which the corporation have recently effected is that which has just been completed at the foot of the approach to London-road railway station. The entrance to

the station from Piccadilly was formerly greatly obstructed by a block of buildings which stood on the east side of that thoroughfare. This has been removed, and the road considerably widened by the construction of a new bridge. The improvement has been carried to Dale-street, where the old bridge has been removed and replaced by one of a much more substantial character, the contract having been carried out by Messrs. R. Neill & Sons, Manchester Together, the improvements will cost about 25,000*l*. The extension of Tib-street from Market-street to Church-street, a work which must (says the *Manchester Courier*) necessarily be protracted in consequence of the terms that have to be arranged with the owners of the property,—is being carried a step farther by the demolition of a portion of the warehouse of Messrs. Rylands & Co. (limited). When the improvement is completed the street will have a uniform width, and the Oldham-street traffic will be much relieved.

Newcastle-on-Tyne.—A meeting has been held here to consider proposals for the formation of a technical college. The Mayor (Mr. R. Cail) presided. Dr. Rutherford read a report, giving information respecting the means adopted for the advancement of technical education by the City and Guilds of London Institute, and said that in connexion with the School of Science and Art, students were found for classes in blowpipe analysis, carriage building, tanning leather, and telegraphy, but no student offered himself for examination in carriage building. The results of the examination were exceedingly satisfactory in regard to the students from the Science and Art School, seven national prizes being awarded to them, thus giving it the first place in the kingdom. The Committee, wishing to do their part, appealed to the public of the Northern counties to extend the area of its teaching, so as to cover the whole of its diverse and important industries, to keep the instruction up to the hour, and to provide for the training of teachers. This could only be efficiently done by the establishment of a technical college. It was resolved, "That the Committee of the Science and Art School be and are hereby appointed the Committee (with power to add to their number) to carry out the scheme."

Ramsgate.—In compliance with a request of the Ramsgate smack-owners, the Local Board have decided to erect a building for the purpose of a fish-market. Plans are now being prepared which will be submitted to the Board of Trade for approval. It is expected the building will cost between 600*l*. and 700*l*. It is to be erected near the clock-house, and will be 100 ft. long and 30 ft. wide.

NORTH OF ENGLAND GAS MANAGERS' ASSOCIATION.

The above Association having selected Sunderland as the *locale* of its seventh half-yearly meeting, the gathering took place on Saturday last in the Board-room of the Sunderland Gas Company, Fawcett-street. Mr. J. H. Cox, of Sunderland, president of the Association, presided, and representatives attended from most of the principal towns in the North of England and in Scotland. The President, in the course of his opening address, mentioned the opening of the new gasworks for the Bishop Auckland District Gas Company, the new retort-house and other considerable extensions at the Hendon station of the Sunderland Gas Company; and last, though not least, the commencement of operations at the Jarrow station of the South Shields Gas Company, where might be seen in full operation the improvements in machinery and apparatus for charging and drawing retorts, the invention of Mr. W. J. Warner. He said that, thanks to the scientific labours of Sugg, Bray, and others, improved methods of street illumination were being extensively adopted in crowded thoroughfares in many large towns, and no doubt the success which had already been attained would cause a rapid development of the system.

Several papers were read, and the works of the Sunderland Gas Company at Hendon were inspected.

The Dublin Town Council on Monday last resolved to invite the Social Science Association to hold their Congress in Dublin in 1881, "as they dealt with a great many subjects most interesting to the Corporation in regard to municipal law and sanitary science."

ART EXHIBITIONS.

Birmingham School of Landscape Art.—The annual exhibition of the works of the present and past members of the Birmingham School of Landscape Art was opened on the 4th inst. in the Young Men's Christian Association Rooms, Needless-alley.

Leek.—An art exhibition, got up for the benefit of the Leek Mechanics' Institute Art Classes, was opened on the 4th inst. at the Union Buildings, by the Right Hon. Lord Norton. The collection of oil paintings includes many famous pictures. Foremost amongst these are Mrs. E. Butler's "Balaclava" and "Quatre Bras." There are also exhibited ninety-two water-colour drawings from the South Kensington Museum, illustrative of the rise and progress of the art in England from 1710.

Edinburgh.—A collection of paintings, &c., illustrative of Scottish art, was opened on Wednesday last, in the Royal Scottish Academy Galleries. The exhibition, which will remain open six or eight weeks, has been made in consequence of the visit to Edinburgh of the Association for the Promotion of Social Science. It includes nearly 600 separate works, the larger number being those of living or recently deceased artists.

Hertfordshire.—On Wednesday last, at the Shire-hall, Hertford, Lord Lytton opened the Herts County Fine Arts Exhibition. The loan collection includes many articles of great beauty and antiquity, some of which were collected in India by Lord Lytton. There are water-colour drawings by eminent masters, ancient needlework, bronzes, Indian, Chinese, and Japanese work in gold, silver, ivory, stone, and wood, and ancient tapestry, &c., exhibited by the Marquis of Salisbury, from Hatfield House; Earl Brownlow, Ashridge House; Earl Cowper, Panshanger; and the Earl of Clarendon. Mr. John Evans and Mr. Robert Hanbury also contribute to the collection. In the art department upwards of 200 drawings are exhibited for competition.

Stray Portraits.—A suggestion for an exhibition of portraits of unknown origin has been submitted to the South Kensington Science and Art Department, and the department has promised to give due consideration to what it terms a "useful suggestion." The number of such works scattered throughout the kingdom is enormous, and it is thought that bringing them under public notice would lead to the identification of many historical celebrities.

ACCIDENTS.

Fall of a Bridge in Lancashire.—On the evening of the 1st inst. a bridge which spanned the East Lancashire Railway at Fernhill, Bury, gave way, and a large portion of it fell on and blocked up the lines for about two hours. The bridge connected the foundry of Mr. Alderman James Park, engineer and paper-machine maker, with Fernhill, Bury, and was a wooden structure of a fragile nature, which had existed many years, but for some time past had been noticed to be in a state of decay, and at the time of the accident it was undergoing repair. At noon on the day of the accident a rag engine, weighing about five tons, was taken over the bridge without accident, and at six o'clock in the evening the workmen in the foundry, to the number of about 100, passed over it on leaving work. Forty minutes afterwards the bridge fell. The supposition is that the weight of the rag engine was the real cause of the accident. A train from Dacie Bridge to Bacup had passed under the bridge only five minutes before it fell.

Fall of a Chapel Floor in Manchester.—An inquest was opened on Monday in Manchester by Mr. Smelt on the body of a widow named Catherine Lynch, aged 70, who lost her life by the falling of the floor of St. Aloysius' Roman Catholic Chapel, Ardwick. The congregation were leaving the room after mass on Sunday, when a beam of the floor snapped in the midst, creating a gap of several yards, through which some scores of people were flung on the benches and desks of a schoolroom beneath. A scene of great distress and tumult followed, and Mrs. Lynch died soon after her removal to a neighbouring surgery. It appeared that a pillar supporting the beam had first fallen from its place, owing, it was stated, to wet-rot. The pillar fell some days before the accident, but it was considered that the beam was sufficient of itself to support the floor in that part. A verdict of "Accidental death" was returned. A mechanic named James Kilty is in a dangerous condition, he being 67 years of age, and having both thighs broken.

Bursting of a Water-tank at the Crystal Palace.—On the 1st inst., at half-past one p.m., while water was being pumped into the two large tanks at the Crystal Palace which supply the fountains, with a view to the firework display in the evening, one of the tanks gave way, and an aperture appeared 16 ft. square, through which the water rushed in a flood. Parts of the tank, weighing several hundredweight, were carried to a distance of 250 ft. One of the servants of the company rushed out to see what was the matter, and was carried away by the water to a distance of 200 yards before he could be rescued. The same thing happened to a man who had just left his cart to take a drink of water at the fountain standing in the centre of the Crystal Palace Parade, but both men were rescued from the water without any serious injury. All the trees and shrubs in the neighbourhood of the water-towers were washed up, some of them being carried away, together with about 60 yards of the fence down the Fountain-road, the water running as far as the Sydenham-hill station, a distance of three-quarters of a mile. The fall of the water left a hole in the ground after the downpour had ceased to a depth of 16 ft. Damage was done also to the grounds of neighbouring residents. The two cisterns supplying the Palace and fountains stand on iron pillars and staging, 80 ft. high, beyond the north-west end of the building, and are attached to each other by communicating pipes. Each tank is constructed of cast-iron plates, about $\frac{3}{4}$ in. in thickness, and each is 48 ft. square, 16 ft. deep, and will contain when full 700 tons of water. The tanks, it is said, had been inspected in due course, and no suspicion seems to have been entertained of their perfect stability until a few minutes before the fracture, when one of the men employed on the spot noticed a perceptible leakage, and hurried off to inform Mr. Carr, the clerk of the works, of the fact. Fortunately for that gentleman he did not happen to be in his office at the moment, or he would in all probability have arrived on the scene just as the tank burst and belched out its entire load of at least 600 tons of water.

St. Gothard Tunnel.—Another accident is reported from the St. Gothard Tunnel. About 150 ft. from the Wattingen, or Göschenen end, upwards of 30 ft. of the roof of masonry, together with an immense mass of loose rock, fell in. Four men, it is believed, were killed.

Fall of a Wall in Dublin.—Dr. Whyte, the Dublin City Coroner, held an inquest on Saturday last on the body of Mrs. Mary Thompson, who was killed by the fall of a wall in Temple-court. The wall formed part of a house which was being demolished by a man named Joseph Lube, who failed, in the opinion of the jury, to take sufficient precautions to protect the lives of passers-by. A verdict of "Accidental Death" was returned.

CHURCH-BUILDING NEWS.

Tywardreath.—The parish church of Tywardreath, near Par Station, Cornwall, was reopened on the 8th ult., after a restoration which, to a great extent, has been a rebuilding, for with the exception of the tower and the arcade, the whole church has now been re-built, a course determined on as necessary in consequence of the dilapidated state of the walls and the dangerous condition of the roofs. The roofs were found to be so defective as to preclude all possibility of restoration, but they have been exactly reproduced. The walls are built of the local stone; the dressings are of Pentewan stone. The tower arch, which has now been opened up, is a good sample of modern masonry, and is of St. Stephen's stone. The masonry in the organ-chamber, and, indeed, most of the internal masonry, is of Pentewan stone. The old oak pulpit has been refixed at the north corner of the chancel step, upon a base of Portland stone. The various avennes are laid with encaustic tiles, supplied by Messrs. Minton, Hollins, & Co. The windows throughout are glazed with tinted and coloured glass, by Messrs. Fonracre & Watson, of Stonehouse. The fine old Perpendicular font has been refixed. It is octagonal in shape, with deep double-membered tracery on every cant. The seating in the nave and aisles is of pitch-pine, open, and with square-headed ends. Eight of the old bench-ends have been preserved, and have been re-used in the transept. They are of massive oak,

traceried, and all hear shields, upon which are curious devices. The stalls are of oak, and of elegant design, richly carved. A new parclose screen divides the chancel from the Rashleigh or south-chancel aisle. This screen is of English oak, about 30 ft. long. Its tracery is very rich, the heads springing between the mullions being ogee and crocketed, and the whole is surmounted by a carved cornice. The carving and tracery-work upon these screens and upon the stalls, including those in the Rashleigh aisle, is by Mr. Harry Hems, of Exeter. The bosses and wall-plates of the roof and the base of the pulpit have been carved by Mr. West, of Plymouth. Mr. Holman, of St. Just, did the ironwork. The church contains several curious monuments, which have been carefully replaced in the walls. The architect under whose superintendence the restoration has been carried out is Mr. Richard Coad, and the contractors were Messrs. Carah & Edwards, of Crowan. The cost has been upwards of 3,000*l.*

Featherstone.—Featherstone church, Pontefract, is now undergoing partial restoration, the south portion of the structure having been in a dangerous state from decay. During the progress of the work, which is entrusted to Mr. Freeman, of Featherstone, many remains of those who fell during the sieges of the castle at Pontefract have been found.

SCHOOL BOARD SCHOOLS.

London.—On the re-assembling of the School Board for London on the 30th ult., after the recess, Sir Charles Reed, the chairman, in the course of a review of the work of the Board during the ten years in which it has now been at work, said,—"At the close of the year 1871, when the voluntary schools had furnished their returns, and our own work had just begun, there was accommodation in all for 262,259 children, or 39·4 per cent. of the estimated population of school age. At Midsummer last the denominational schools had provision for 269,469 children, or 8,000 more than in 1871, while we had provided for 225,236, giving a total accommodation for 494,705 out of a present child-population of 740,577, or 66·8 per cent. Thus, we have now seats for two out of every three children needing elementary education. If we confine our view to the past year, it is seen that the accommodation afforded by the denominational schools has declined 2,884, while ours has increased by 15,008. This latter increase has involved the acceptance of tenders for 24 new schools, accommodating 21,751 children. These schools are planned upon our usual scale, smaller schools being proportionately more expensive. The average cost per head on the tenders of these twenty-four schools last built has been 8*l.* 18s. 5d., which includes the provision of teachers' rooms, schoolkeepers' houses, boundary walls, and, in several cases, extra deep foundations. The buildings, while free from display, are designed to be durable, attractive, and well equipped for their purpose. The Board has now acquired by purchase freehold sites giving a total area of over 151 acres.

Stapleford.—New Board schools at Stapleford, Notts, were opened on the 28th ult. The buildings, which are of red brick with stone dressings, have been erected at a cost of about 3,200*l.*, from the plans of Mr. R. C. Sutton, architect, Nottingham, the contractor being Mr. C. Moult, of Stapleford. The school furniture has been supplied by Messrs. J. Wright & Son, of Nottingham, the desks being of the design known as the "Nottingham desk."

Harborne.—The foundation-stone of new Board schools at the junction of Heath-road and York-street, Harborne, was laid on the 28th ult. by Mr. Thomas Griffiths (chairman of the School Board). The building is being erected to accommodate 500 children,—viz., 266 in the larger school and 234 infants. It will be in the Gothic style, and constructed of red brick, and will comprise a large school measuring 63 ft. 3 in. long by 22 ft. wide for boys and girls, with two class-rooms 20 ft. by 20 ft. each; a committee-room of the same dimensions, and a sewing-room for girls 29 ft. 9 in. by 20 ft. The infants' school will be 47 ft. long by 26 ft. wide, with two class-rooms, each 20 ft. by 16 ft. A master's residence will also be erected fronting the Heath-road. The buildings are being carried out by Messrs. Harley & Son, Smethwick, from designs by Messrs. J. R. Sharp & Co., architects to the Board.

Miscellanea.

A Wooden House.—We mentioned some time ago the changes that were being made at Hollingbury Copse, which was in the past the most unkempt and neglected copse, perhaps, in the neighbourhood of Brighton. The London correspondent of the *Dover Standard* has recently given a graphic description of the Copse, &c., at the present time, from which we extract the following:—"I spent Tuesday in a country residence which, I think, would be very interesting to a great many architects. The owner and occupier has been his own architect, and has had built the kind of place he thought he would like, on a site, which, in itself, is a kind of paradise. Indeed, I was reminded of Morris and his opening stanza: 'Folk say a wizard to a Northern King at Christmas-tide such wondrous things did show, that through one window men beheld the spring, and through another saw the summer glow, and through a third the fruited vines arow, while still unheard, but in its wonted way, piped the drear wind of that December day.' Well, this house I am telling you of (if it can be called a house) stands on a hill. From one window you can see the bleak hills stretching out for miles; from another you look on to the Channel; and from a third you look into the green mazes of a beautiful copse with clear water breaking and brawling over stones, and slipping and singing between ferns and the roots of old trees. But what I started to tell you I have not yet mentioned. This residence is entirely built of wood. The floors are wood; the walls are bare polished wood; and the roofs are bare polished wood. And very rich a picture looks on such a wall, and very bright and dainty is a dinner under such a roof. Let me tell you that this residence is built in compartments, or what would be called chapels, the chapels being connected one with another by corridors. There is a dining-room chapel, and breakfast-room chapel, and a tea-room chapel, and a library chapel, a study chapel, &c., and each has its own particular charm of shape or situation."

Sheffield New Corn Exchange Buildings.—On the 30th ult. the roof-rearing supper to the artificers and *employés* at this building was given at the Pheasant Inn, Broad-street, Park. Mr. Charles Hadfield (of the firm of M. E. Hadfield & Son), presided, and 130 persons sat down. We are informed that a similar entertainment took place at Leeds for the workmen engaged at the extensive establishment of Messrs. Tomlinson & Son, the contractors, where the massive oak roof for the building, and the joiners' work, are being executed. In drinking the health of the Duke of Norfolk, Mr. Hadfield remarked that his Grace had taken a practical interest in all the details of the important work in which they were engaged from its commencement. His Grace was a great builder, and as the most liberal patron of the building trade in the United Kingdom he had additional claims upon them. Mr. Tomlinson, jun., proposed the toast of "The Architects, Messrs. M. E. Hadfield & Son," which was duly acknowledged by the chairman, who proposed "The Contractors," remarking on the loyal interest and good conduct displayed by every man connected with the works from the commencement. Mr. Tomlinson, in replying, gave some interesting details of the quantities of materials in the building, remarking that amongst the rest upwards of two-and-a-half millions of bricks, 150 tons of oak timber, and 200,000 Broseley tiles, had been supplied up to the present time. The clerk of the works (Mr. Payne), the foremen, and the workmen, were duly toasted.

Gas Profits in Manchester.—The annual report of the Gas Committee of the Manchester Corporation was issued on the 1st inst. In spite of the bad trade, and a smaller increase in consumption than usual, the net result of the year's working enables them to place at the disposal of the Improvement Committee the sum of 52,000*l.*, which represents the net profits, except 1,612*l.*, which comes from the reserve fund. The profits of the gas department pay the cost of all the street improvements in Manchester, and several hundred thousand pounds have been received from the Gas Committee for this purpose during recent years.

Art and the State.—The inaugural lecture of the winter session of the Midland Institute, Birmingham, was delivered on Monday evening last by Mrs. Mark Pattison, who took as her subject "The Relations between Art and State created in France by the Policy of Richelieu."

Presentation to an Art-Master.—On the 29th ult. a large number of the students of the Nottingham School of Art and their friends attended at a *soirée* in the institution in Waverley-street, organised for the purpose of presenting to the headmaster, Mr. John S. Rawle, F.S.A. (who, after fourteen years' connexion with the school, is about to leave to take the position of headmaster of the West London School of Art), a testimonial of their appreciation of the ability with which he has conducted the school, and of their personal esteem. The testimonial consisted of two gilt and oxide salvers, with figures and ornaments in bold relief, richly chased and finished, and a vase and stand *en suite*, the whole being fitted into a handsome pollard oak case. These articles were manufactured by Messrs. Elkington, from the designs of Mr. Morel. The testimonial was accompanied by an illuminated and framed address, designed by Mr. G. Staynes, a former student, and executed by various students,—Miss Pitman, Miss Goodyer, and Miss Hopkinson. The four elementary stages of drawing were represented on the address by Mr. Staynes, and Morning, Noon, and Night by Miss Ada E. Fussell. The address spoke in the most cordial terms of Mr. Rawle's fourteen years' labours in Nottingham, and its sentiments were endorsed by Mr. S. Dutton Walker and other gentlemen who spoke on the occasion. The West London School of Art ranks next in size to the central school at South Kensington, having accommodation for 1,000 students.

House Foundations at Hampstead.—At a meeting of the Hampstead Vestry on the 30th ult., upon the consideration of the recommendation of the Works Committee with regard to a road at Kilburn, Mr. Pearse stated that, when the committee went to view the road, he noticed that the floor-joists of some of the houses rested only on four layers of bricks, and there were 6 in. of water in some of the foundations. He considered that this was calculated to produce fever and other illnesses in the houses when inhabited, and he wished to know whether the Vestry had any power to interfere. Mr. C. B. King said that when the drains were put in they would carry off the water. The Chairman said that was a matter for the parish surveyor. Mr. Pearse: That is a myth. The Chairman said he hoped the attention of the parish surveyor would be called to it. To his (Mr. Hawksworth's) own knowledge there were many buildings in the parish that were in a very disgraceful state.

Messrs. Robert Boyle & Son, the well-known ventilating and sanitary engineers, of London and Glasgow, show, at the Ecclesiastical Art Exhibition, Leicester (held in connexion with the Church Congress), a large variety of their air-pump ventilators, specially adapted for the ventilation of churches and schools, to which buildings they have been applied extensively and with much success. Messrs. Boyle have made a speciality of the ventilation of such buildings. The merits of the air-pump ventilators have been too often referred to in our columns, and are too well known, to require any further description here just now.

Worcester Diocesan Architectural and Archæological Society.—A large number of the members of this society paid a visit to Coventry on the 24th ult., and under the guidance of Mr. W. G. Fretton, Mr. M. H. Bloxam, and others, the following places of interest were visited:—Remains of Cheylesmore Manor House, Steeple of the Franciscan or Grey Friars' Monastery, Ford's Hospital, St. Mary's Hall, St. Michael's Church, Holy Trinity Church, Free Library, remains of Benedictine Priory and Cathedral, timber houses in Butcher-row, Hospitium, city walls and gates, St. John's Hospital, timber houses in Well-street, Bond's and Bablake Hospitals, St. John's Church, Peeping Tom at the King's Head Hotel, Palace-yard, Knave's Post, White Friars' or Carmelite Monastery, Carthusian Monastery of St. Ann; south walls of city and Cheylesmore Gate, Martyrs' Field, and Park. In the afternoon the party were entertained at luncheon by Mr. W. Odell, Bishop-street.

A Good Contractor.—The general committee of the cathedral of St. Finn Barr, Cork, have presented to Mr. Delany, who has executed the three towers and spires of the cathedral, under Mr. Burges, an illuminated copy of a resolution unanimously passed, expressing their sense of the skill and ability with which he has carried out the contract entrusted to him.

Slates and other Building Materials, North Wales.—The local correspondent of the *Mining Journal* says:—The shipping of slates to the Baltic ports from Portmadoc is now ceasing for the season. Although not equal to some former years, the summer trade, now closing, has been a decided improvement on last year. An inland trade also has grown up for this district, and large numbers of slates are now forwarded by both the Cambrian and London and North-Western Railways. From the port of Carnarvon a better trade has been done likewise, still the trade will not be what it ought to be until the building trade of Scotland,—on which to a considerable extent this port depends,—recovers itself. Quarry-owners are making sacrifices, in order to get rid of their old stocks of small-sized slates, and only yesterday a large number (10 in. by 6 in.) were sold for 5s. per 1,200. Some of the sett quarries, near Portmadoc, are doing but little, but this is hardly, I think, due to slackness of demand. The Moel-y-Gest Quarry is working vigorously, and the quarry is about to be connected with the railway by a new siding. The brick, tile, and stone trades of the Ruabon district follow the fluctuations in the building trade, and they are, therefore, at the present time not so good as they might be. The trade, too, in common bricks is hardly remunerative at present prices. Mr. Mason, of the Trevor Brickworks, has commenced the manufacture of bricks for the lining of iron furnaces, by mixing with the fire-clays of the coal-measures the sandstones which lie at the base of these, and which correspond to the "gannister" beds of the North. A similar attempt was made some years ago by Mr. Edwards, of Trevor, but for some reason or other the manufacture was discontinued.

A Big Blast of Granite.—The granite quarry of Messrs. William Sim & Co., at Furnace, has been visited by the magistrates and members of the town council of Glasgow for the purpose of witnessing a big blast which it had been arranged should take place immediately on the steamer arriving at a safe position opposite the quarry. The attention of the passengers was directed to a black mark on the eastern side of the quarry face, a considerable height above the quarry floor. This was the mouth of the mine which led to the chambers charged with the gunpowder. The mine penetrated to a distance of 50 ft., where a shaft was sunk to a depth of 50 ft. At the foot of the shaft there were branching mines. One went in a direction towards Loch Fyne to the extent of 16 ft., including the formation of a chamber excavated to contain 5,000 lb. of gunpowder. Another passed in a northerly direction to a considerable distance, at the end of which was a chamber for 3,500 lb. of gunpowder. The chambers were communicated with by means of electric wires, and immediately on the signal to 'fire,"—the blowing of the whistle,—being given from the steamer, there was a tremendous upheaval of a large portion of the mountain side. The lines of displacement were calculated to be equal to about 18,000 cubic yards, or 37,000 tons of material. The blast was entirely successful.

The Stockwell Orphanages.—On the 4th inst., Mr. George Palmer, M.P., laid the foundation-stone of a "Reading House," and the Rev. H. Stowell Brown laid that of a "Liverpool House," as additions to the "Houses" erected on the grounds of the Stockwell Orphanages, in the Clapham-road, founded by the Rev. C. H. Spurgeon and his congregation at the Tabernacle. Mr. James Spurgeon stated that the erection of the buildings would cost 11,000*l.*, of which 7,000*l.* had been subscribed, and 3,000*l.* more promised.

Liverpool Art Club.—In connexion with the above club, it is announced that the opening of the embroidery competition is postponed to the 15th of November. Mr. P. H. Rathbone has promised to deliver an address on the present exhibition of Italian photographs, on Oct. 25th. An exhibition of caricatures will be opened on December 20th, and an exhibition of paintings, drawings, sketches, and designs by amateurs on January 20th.

The Melbourne International Exhibition was opened on the 1st inst. with very promising auguries. We gave a view of the building in our volume for 1878, p. 1305. Messrs. Reed & Barnes are the architects.

Company of Turners' Competition.—The works sent in will be exhibited at the Mansion House, London, on the 12th and 13th inst. The prizes will be presented by the Lord Mayor on the 14th.

The Photographic Society of Great Britain opened their annual exhibition on the 2nd inst., in the Gallery of the Society of Painters in Water-colours, Pall-mall East. It contains a great deal worth seeing. Some landscapes by the School of Military Engineering, and others by Dr. Huggins, Mr. F. A. Bridge, and Mr. E. Gould, all printed in the platinum process, show that this is a method which is gaining ground; it gives the appearance somewhat of a good pencil drawing, besides being quite indestructible. We observe that there is now a Platinotype Company. In the important application of photography to copying famous pictures of large size, the Berlin Photographic Company contribute a silver print of the same size as the picture of the Madonna di San Sisto in the Dresden Gallery. This fine copy was taken in nine separate plates, each about 36 in. by 24 in., and with perfect success. Some landscapes by Mr. W. Harvey Barton, which include water, are very remarkable; Nos. 41 and 42, for examples. No. 201, "In Maiden Meditation Fancy Free," by Mr. H. P. Robinson, has rightly received a medal.

Saving in Parish Work.—At the meeting of the Camberwell Vestry on the 29th ult., the Sanitary committee recommended that they be empowered to negotiate for and purchase, or, if deemed best, to take on lease or otherwise, a depôt for the deposit of the dust. Mr. Lassam, in moving the adoption of the report, said that Mr. Reddin's tender for 1876-77 amounted to 3,400*l.* This was not accepted, the vestry deciding to do the work themselves. The work was done by the vestry at a cost of about 2,400*l.*, making a net saving of 1,000*l.* In 1878-79 the cost was under 2,000*l.*, or about 2s. 6d. per load, as against 5s. 6d. under the old contracting system. In 1879-80, the net cost of collection amounted to 2,060*l.* 16s. 3d., or about 2s. 6d. per load, showing a total saving of 2,000*l.* The motion was carried.

Over Darwen Market House.—The foundation-stone of the above was laid on Saturday, October 2nd, by the Mayor, Mr. Alderman Snape, J.P., in the presence of a numerous company. The stone was of Shap-granite, with an inscription in gilt letters. A chased silver-gilt trowel was presented to the Mayor by the corporation. The works are well in hand, the difficulty attending the diversion and covering in of the river, which runs under the market, having been overcome. The architect is Mr. Charles Bell, of London, and the contractors are Messrs. Orrell & Sons, of Darwen. The Clerk of Works is Mr. Hobson-Haigh.

The Sunday Society.—This organisation intends to be very active during the coming winter. It will be represented at the Social Science Congress, and a paper will be read on its behalf by the Rev. Robert B. Drummond, entitled "Sunday Reform." During the sitting of the congress a public conference will be held in Edinburgh in support of the opening of museums on Sundays; and on October 25th Professor Tyndall will preside over a public meeting in the largest hall in Glasgow in support of the objects of the Society.

Fire at the Louvre, Paris.—On the evening of the 2nd inst. a fire broke out in the Pavillon de Flore, the western extremity of the Louvre buildings, the apartments temporarily occupied by M. Hérold, the Prefect of the Seine. The fire was fortunately confined to the apartment and the story on which it is situated. The event has caused an outcry in Paris against having inhabited dwellings alongside the galleries of the Louvre, where no lights are allowed at all.

Lectures on Architecture.—The directors of the Edinburgh Philosophical Institution have arranged a course of lectures for the ensuing session. The programme includes an exposition of the "Principles of Design in Architecture and Ornament," by Mr. H. H. Statham.

A Statue to Jean Cousin, the painter and sculptor of the sixteenth century, was inaugurated last week, at Sens. M. Turquet, Minister for Fine Arts, presided, and most of the leading artists of France were present.

The Fitzalan Chapel at Arundel.—Complaints are made by visitors that the permission, recently conceded by the Duke of Norfolk, to visit this chapel two days a week, has been withdrawn.

The Princess's Theatre, Oxford-street.—The work of reconstructing this theatre is now so far advanced that it is confidently expected that the house will be ready for opening about the end of the present month.

Christ Church Sunday-school, Cockermouth.—A Sunday-school is about to be erected in connexion with Christ Church, Cockermouth, Cumberland, the Rev. John Green, M.A., vicar. The building will be of white freestone, from Talantire quarry, in the immediate neighbourhood. The roof will be covered with Buttermere slates, with red-tile cresting and terminals. The interior woodwork will be of pitch-pine, varnished, the roof being open-timbered. The architect is Mr. W. C. Jennings, of Cockermouth.

A New Industry.—A new invention has been introduced into the Cleveland district, viz., the manufacture of paint from steel scale for the protection of iron and steel from corrosion.

TENDERS

For three cottages, with cowhouse, stable, &c., at Old Basford. Mr. Herbert Walker, architect. Quantities by the architect:—

Newham, Old Basford	£1,248	11	0
Jew & Hickling, Arnold	1,024	0	0
Cargill, New Basford	1,010	0	0
Hind, Nottingham	995	0	0
Mason, Old Basford	995	0	0
Mason & Pratt, Nottingham	993	0	0
Ellis, Nottingham	958	0	0
Musson, Carrington	940	0	0
Raven, New Basford	927	0	0
Wayte, Arnold	918	0	0
Ingham, Old Basford	891	0	0
Bains & Turton, Old Basford	870	0	0
Scott, Nottingham	868	12	0
Wheatley & Maule, Nottingham	859	0	0
Judd & Cooper, Hyson-green	846	0	0
Stainforth, Bulwell	833	0	0
Price & Hooton, Nottingham	799	10	0
Musson, Hucknall	790	0	0
McCulloch, Bulwell (accepted)	769	0	0

For the erection of a house and sale-shop at Old Basford. Mr. Herbert Walker, architect. Quantities by the architect:—

Richer, Hucknall	£869	10	0
Mason & Pratt, Nottingham	570	0	0
Ellis, Nottingham	515	0	0
Stainforth, Bulwell	514	0	0
Holdsworth, Hucknall	511	0	0
Judd & Cooper, Hyson-green	497	0	0
Cargill, New Basford	495	0	0
Jew & Hickling, Arnold	487	0	0
Musson, Carrington	484	0	0
McCulloch, Bulwell	480	0	0
Mason, Old Basford	471	0	0
Wheatley & Maule, Nottingham	468	0	0

* Accepted.

For the erection of four houses at Bognor, Sussex, for the Bognor Hotel and Residences Company, Limited. Mr. G. Gard Pye, architect. Quantities by Mr. O. Stanger:—

French, Lisson-grove	£5,125	0	0
Nicholls, Brockley, S.E.	4,976	0	0
Lissaman, Leamington	4,813	13	4
Ennor, Julian, & Co., St. George's-road, S.E.	4,677	0	0
Longley & Worth	4,599	0	0
Smith, Bognor	4,540	0	0
Everett & Son, Colchester	4,400	0	0
Huey, Parkstone	4,376	0	0
Garrod, Spitalfields	4,083	0	0
Bull, Chelsea	3,995	0	0
Cooper, Slindon-common	3,659	0	0
Vaughan, Acton	3,488	0	0
Lacy, Westminster	3,300	0	0

For the erection of lodge, stables, and cow-house buildings, Edgware. Mr. James Geo. Buckle, architect. Quantities by Mr. Chas. L. Cadney:—

French	£2,295	0	0
Haines	2,195	0	0
Childs	2,169	0	0
Sawyer	2,136	0	0
Doune	2[illegible]25	0	0
Holloway	2,050	0	0
Parker	2,000	0	0
Hussey	1,958	0	0
Augood	1,890	0	0
R. & E. Evans	1,890	0	0
Beale, Battersea (accepted)	1,650	0	0

For the erection of new infirmary and dispensary, Worthing. Mr. W. Oldham Chambers, architect. Quantities supplied:—

Nurcombe, Hove	£4,031	0	0
Card & Son, Lewes	3,935	0	0
Braid & Co., Chelsea	3,850	0	0
Stevens & Bastow, Bristol	3,799	0	0
Sawyer, London	3,786	0	0

Peters & Redford, Horsham*	2,987	0	0

* Accepted.

For house at Hayes, Bromley, Kent, for Mr. S. A. Day Mr. W. Berriman & Son, architects:—

Croaker	£1,200	0	0
G. & S. Fisher (accepted)	1,125	0	0

For the Wragg Museum, Free Library, and School of Science and Art, with terra-cotta front, for the Corporation of the Borough of Stafford. Mr. J. B. McCallum, borough surveyor. Quantities by Mr. C. R. Dalgleish, of Stafford:—

Espley	£1,945	0	0
Adams & Pemberton	1,894	0	0
Reynolds	1,881	0	0
Whittome	1,838	0	0
Bridgett	1,810	10	0
Tracey	1,797	0	0
Gee (accepted)	1,775	0	0

For house for Mr. W. Booker, of Redhill, Surrey. Mr. H. Booker, architect:—

Bucklands (accepted)	£349	0	0

For two houses, for Messrs. Needham & Jarrett, Redhill, Surrey. Mr. H. Booker, architect:—

Burton (accepted)	£415	0	0

For re-building Nos. 128 and 129, Aldersgate-street, for Messrs. W. H. & L. Collingridge. Mr. John Collier, architect:—

Hall, Beddall, & Co.	£11,553	0	0
Patman & Fotheringham	10,957	0	0
Williams	10,870	0	0
Wall	10,700	0	0
Holland & Hannen	10,297	0	0
Lawrence	9,994	0	0
Brass	9,973	0	0
Morter	9,927	0	0
Crabb (clerical error)	8,990	0	0

For the erection of an infants' school in the parish of St. Peter's-in-Eastgate, Lincoln. Messrs. Watkins & Scorer, architects. Quantities supplied:—

Martin & Sims	£881	0	0
Harrison & Horton	797	0	0
H. & D. Taylor	770	0	0
Chambers	764	0	0
Cox & Horton	761	0	0
Millson	735	0	0
Pykett	730	0	0
Swaby	725	0	0
Close & Co.	724	0	0
Crosby & Sons	699	0	0
Slingsby	690	0	0
Kendall	689	0	0
Cowen & Lansdowne	666	0	0

For district church, New Swindon, Wiltshire. Mr. Ferrey, architect:—

Hill & Higgs, London	£4,740	0	0
Jarrett, Croydon	4,200	0	0
Wall & Hook, Brimscombe	3,950	0	0
Boyce, London	3,853	0	0
Barrett, Swindon	3,646	0	0
Franklin, Deddington, Oxon	3,643	0	0
Wiltshire, Swindon	3,598	0	0
Estcourt, Gloucester	3,564	0	0
Jones, Gloucester (accepted)	3,480	0	0

For new lecture-room and approaches, to Heath-street Chapel, Hampstead. Mr. W. A Dixon, architect:—

Manley	£1,721	0	0
Burford	1,696	4	3
King	1,634	0	0
Stead Bros.	1,629	0	0
Staines & Son	1,570	0	0
Russell & Cowley	1,480	0	0
Allen	1,479	10	0

For additions, &c., to printing-offices, May's-buildings, St. Martin's-lane. Messrs. Chadwick & Son, architects:—

Kirk & Randall	£1,689	0	0
Laing & Son	1,538	0	0
Patrick & Son	1,448	0	0
Rider & Son	1,448	0	0
Lawrence	1,423	0	0
McLachlan & Sons	1,289	0	0

For house and shop, Pond-lane, Clapton Park, for Mr. G. H. Mitchell. Mr. Frederick Wallen, architect. No quantities:—

Dearsley	£700	0	0
Jarvis	698	0	0
Huntley	657	0	0
Steel & Son	649	0	0
Julia	640	0	0
Jones	600	0	0
Parish (accepted)	500	0	0

For alterations at No. 32½, Walworth-road, for Mr. Gabriel. Mr. G. Treacher, architect:—

Kirk	£877	0	0
Gill	877	0	0
Newstead	875	0	0
G. & S. Fisher	859	0	0
Simpson	760	0	0

For altering and adapting premises in Rupert-street, Bristol, for printing and publishing offices, for Messrs. J. Wright & Co. Mr. Herbert J. Jones, architect:—

Saville (accepted)	£516	0	0
For new Concrete Floor.			
Williams (accepted)	£73	0	0

For alterations at No. 17, Small-street, Bristol, for Messrs. R. B. Lavery & Co. Mr. Herbert J. Jones, architect:—

Saville	£434	0	0
Johnson	390	0	0
Krauss (accepted)	380	0	0

For alterations at No. 12, Bridge-street, Bristol, for Messrs. Wm. Summers & Co. Mr. Herbert J. Jones, architect:—

Eastabrook & Sons	£910	0	0
Humphreys	888	0	0
Passco	804	0	0
Cowlin & Son	779	0	0
Heaven	740	0	0
Krauss (accepted)	720	0	0

For alterations and additions to Fern Villa, Anerley-road, for Messrs. Edie Bros. Mr. Joseph S. Moye, architect:—

Saala	£867	0	0
Marr	720	0	0
Fox	695	0	0
Hollidge & Stuart (accepted)	637	0	0

TO CORRESPONDENTS.

Corrwallis (the water companies, as a rule, do not base their charges on *any parochial assessments* It is made on the annual letting value of the house, and the percentage is regulated by their separate Acts of Parliament. In one company within our knowledge 4 per cent. on the rental is the maximum, while in another it is 7 per cent.; and these only provide for water to be used for domestic purposes and on the ground-floor. There is an increased charge for high service. All baths are extra, and so are all water-closets that are more than 10 ft. above the level of the street paving, lavatories, house-maids' sinks, &c. These may be reckoned on the first scale (the 4 per cent.) at from 6s. to 8s. a tap; and the others, of course, in proportion. We know nothing specially of the New River Company.—A. H. (the objection in question to the subway system was raised long ago but is not maintainable).—Vestry (the cistern for drinking water should be disconnected from the water-closet works).—M. F. H. C. (next week).—D. S. (next week).—M. (received).—J. E.—J. S. M.—W. C. J.—M. & S.—W. C. T.—S. & S.—G. & S. F.—H. R.—L. & S.—J. M. J.—S. W. H.—C. W.—D. W.—H. R. & S.—M. W.—E. W.—A. H.—D. & L.—A. L.—G. O. All statements of facts, lists of tenders, &c. must be accompanied by the name and address of the sender, not necessarily for publication.

We are compelled to decline pointing out books and giving addresses.

Note.—The responsibility of signed articles, and papers read at public meetings, rests, of course with the authors.

CHARGES FOR ADVERTISEMENTS.

SITUATIONS VACANT, PARTNERSHIPS, APPRENTICESHIPS TRADE, AND GENERAL ADVERTISEMENTS.

Six lines (about fifty words) or under ..... 4s. 6d.
Each additional line (about ten words) ..... 0s. 6d.

Terms for series of Trade Advertisements, also for Special Advertisements on front page, Competitions, Contracts, Sales by Auction, &c. may be obtained on application to the Publisher.

SITUATIONS WANTED.

FOUR Lines (about THIRTY words) or under ..... 2s. 6d.
Each additional line (about ten words) ..... 0s. 6d.

REPLIES TO ADVERTISEMENTS.

Addressed Box —, Office of "The Builder," Cannot be forwarded, but must in all cases be *called for*, and the Office Receipt produced

PER CHARGE FOR A BOX IS AS UNDER:—
For "Situations Wanted" Advertisements ..... 3d. per Week.
For all other Advertisements ..... 6d. per Week.

PREPAYMENT IS ABSOLUTELY NECESSARY.

*** Stamps *must* not be sent, but all small sums should be remitted by Cash in Registered Letter or by Money Order, payable the Post-office, King-street, Covent-garden, W.C., to

DOUGLAS FOURDRINIER, Publisher,
Addressed to No. 46, Catherine-street, W.C.

Advertisements for the current week's issue must reach the office before THREE o'clock p.m. on THURSDAY.

The Publisher cannot be responsible for DRAWINGS, TESTIMONIALS, &c. lent at the Office in reply to Advertisements, and strongly recommends that of the latter COPIES ONLY should be sent.

TERMS OF SUBSCRIPTION.

"THE BUILDER" is supplied *direct* from the Office to residents in any part of the United Kingdom at the rate of 12s. per annum, *prepaid*. Remittances payable as above.

The Builder.

Vol. XXXIX. No. 1967. Saturday, October 16, 1880.

CONTENTS.

Smokeless London.

HE appearance of fog six weeks before the month of November, the recollection of last winter's experiences, and the fact that all the physical conditions necessary for their recurrence have again presented themselves, afford a gloomy prospect for the millions of men, women, and children who are forced by circumstances to spend the coming winter in London. Persons who have already taken flight, and we know of many, have every reason to congratulate themselves upon the change. An echo of the dismal forebodings of unfortunate journalists who have returned to town after their autumn holiday will reach them on the sunny heights of Italy in time to confirm the wisdom of their early exodus. Their retrospect of London will not be marred by the remembrance of any premature disappearances of the sun at mid-day, nor of breakfasting by gas-light, nor of dangerous gropings in unutterable darkness for the turning into some familiar street. To these fortunate few, London may be only the London of the parks in June, and the story of the fog no more than a subject for kindly commiseration in letters written to their benighted friends from the regions of perpetual summer. But what is to be done for the Londoner by profession or by the decrees of Providence, who, let his wishes or his lungs be what they may, must face this ordeal of an intolerable atmosphere? Some effort ought surely to be made to discover if possible the sources of the evil, and no time should be lost in providing a remedy.

The first part of the problem may already be said to have been successfully solved, for the connexion between yellow fog and smoke, long suspected, has at last been proved. It can be demonstrated experimentally that the ordinary course of nature, in the case of our densely-populated cities, has been arrested. Envelopes of oleaginous tar surrounding the aqueous particles of the mist are discovered to be the medium that retards the dissipating influences of the sun. Dr. Frankland's experiments upon the effects of smoke on the evaporation of water have traced the principal cause of the evil to its source, and the direction in which scientific effort can alone be successful has been pointed out with the certainty of a complete induction. It appears that every inhabitant of a large town is a contributory to the mischief from which the community is suffering; but since the necessities of our civilisation demand the use of coal, it is only natural that the public should turn round upon science and inquire if the supply of these wants is incompatible with the blessings of an uncontaminated atmosphere.

If we suppose the case to be referred to a man of science with a wide experience in this particular field of inquiry, the course he would most probably pursue would be to examine first into all that had already been done to get over the difficulty in the case of fuel used in our great industries. Secondly, he would inquire if any of the apparatus which has been proved to be efficient in these cases can be made applicable to the domestic consumption of coal; and, in the event of his being unable to afford any reasonable hope of their ever becoming generally adopted, he would require to offer some alternative method of getting rid of the evils complained of. We cannot be far wrong in adopting this course, and inquiring, in the first place, if any apparatus is in successful use among our manufacturing processes that could be applied to our domestic hearths.

We will take one or two typical instances, in which the incentives to economy in the use of coal have stimulated efforts that have been crowned with complete success, not only in avoiding waste and saving money, but as regards the purification of the atmosphere, which is the natural consequence. The industry that holds the most prominent position in these respects is the iron trade. For many years the only way to make money in the manufacture of iron has been to save it, or, in other words, to produce it at less expense than one's neighbours. The efforts to attain this object have led to innumerable inventions, many of which are more expressly devoted to the saving of fuel. The escape of smoke is incompatible with this object, and hence the hundreds of appliances that have been introduced for consuming it. Turning to the blast-furnace, which is the most gigantic apparatus in existence for the combustion of coal, and which is fed, not by shovelfuls, as in the case of ordinary furnaces, but by tons, it must be confessed with regret that there is nothing whatever to lead us to hope that what has been done in the past to improve it, or is ever likely to be done in the future, will be applicable to the conditions of a domestic fire.

The first great advance that was made upon the more primitive methods of combustion in the blast furnace was the introduction of the hot-blast. This exceedingly simple appliance consisted of an apparatus made up originally of little more than a fire burning so as to heat a pipe, through which the air required for the consumption of the coal was passed on its way to the furnace. The heated air was a great improvement on the previous method of admitting it at the temperature of the surrounding atmosphere, but though a great economy was effected, the problem of complete combustion was by no means solved by its adoption. The next great improvement has become general only within the last few years, and it is not yet by any means universal. It consists in re-using the waste gases that previously escaped in the form of smoke and flame from the mouth of the furnace, by burning them in the ovens that heat the hot blast. An immense saving of fuel has been attained by the adoption of this improvement, and the blast furnace, instead of being as it once was, one of the most wasteful and offensive appliances in the iron trade, has now become in its more perfect form one of the most economical and the least troublesome as a source of pollution to the atmosphere. Looked upon as a test of what can be done, the improvements referred to are of special interest in their bearing upon the consumption of fuel upon a large scale, but, unfortunately, they are altogether inapplicable when used away from the superintendence of skilled, or at least practised workmen. Here, then, in the case of the most successful apparatus for avoiding the pollution of the atmosphere in the whole range of the iron trade, we find a positive blank as regards the application of these improvements to an ordinary domestic fireplace. The conveyance of the waste gases from the drawing-room fire into a combustion chamber would be as impracticable as making use of them to heat the air that supplied the draught.

In other departments of the iron industry great economies have been effected in the consumption of coal; but there seems to be no more reason to expect them to be applicable to the fireplaces of London than are the improvements of the blast-furnace. But the inference that may be drawn from the apparatus to which we are now about to refer is of wider application. The blast-furnace is an appliance by itself. If we have to turn from its economy and its smokelessness with regret, as not even affording a suggestion as to how these improvements could be applied so as to ameliorate the miseries arising from the prevalence of smoke in our great cities, the disappointment is alleviated by a consideration of the unique character of the apparatus, both as regards its function and its size. But no such consolation is to be found in the case of the recent inventions for saving fuel in other departments of the iron trade, because these really embrace all the conditions that are necessary to the complete combustion of coal in every possible manufacturing process that requires large quantities of heat. The regenerative furnace of Dr. Siemens consists of a practical application of scientific principles that is available for an immense number of purposes besides the conversion of iron. The furnaces of Mr. Spence, which go even further in the direction of theoretical completeness, and which are in daily use at Woolwich arsenal, are also capable of the most various applications; but in neither case is there any likelihood of these ever being practicable upon the miniature scale of a domestic hearth. Not only an intense heat, but a steady heat, is absolutely essential to the success of both, and these conditions are necessarily precarious in the case of a household fire that may at any time be left to go out, or nearly out, at the discretion of those who are the recipients of its warmth.

In the whole range of our national industries

the appliances to which we have referred, more especially the improvements in the blast furnace and the regenerative system of Dr. Siemens, are those which are representative of the progress that has been made, and the inquiry therefore naturally rises, are they applicable in a practical way to the question of the domestic consumption of coal in such a vast community as that of London? We are reluctantly compelled to confess that they have in no way advanced the settlement of this most important problem, and it may even be said with truth that they have not even contributed to its solution. If they have had any influence at all, we are inclined to believe that they have rather retarded our progress than advanced it, because they have held out vague hopes to the great majority of the public that what has been done in the case of the iron trade may one day be applicable to the domestic hearth. If such hopes had even a possible chance of fulfilment, the constant expression of them might contribute to their being ultimately realised, but we confess that they appear to us to be altogether illusory. The reasons upon which this belief is based rest upon the fact that the domestic hearth as used in England differs, not only in degree, but in kind, from every apparatus in the iron trade, or any other industry in which the problem of complete combustion has hitherto been successfully solved.

It is quite true that the fuel is the same, and that the phenomenon of combustion depends in both cases upon an admixture of air with the burning coal. It may even be said with truth that there is nothing to prevent the most perfect system on a large scale being adopted in miniature; but this brings us to what is the real point of departure between the large and the small method of using ordinary coal, and constitutes the difference in kind to which we have already referred. The element of a very high temperature, which is attainable in a large furnace, and which is essential to its economy, is practically impossible in the case of any apparatus on the scale of an ordinary fire-place, and this high temperature is just as essential to complete combustion as a due admixture of the substances that go to produce the phenomenon. Without this element the most perfect reproduction of a large furnace on a small scale, even supposing it to be practicable, would be altogether unavailing as a smoke-consuming domestic hearth.

It is in this absence of high temperature that we discover reasons for the failure of innumerable appliances on a small scale for solving the problem of complete combustion as it occurs in the case of the domestic use of coal. In many of these the quantity of air supplied is in excess of what is necessary, and frequently the mode of applying it is all that could be desired. In others, by ingenious methods of forcing the escaping gases rising from a fresh addition of fuel to pass through the clear heat of a previous charge, from which the smoke has already escaped, an excellent result is obtained. But yet the causes of failure in all these cases is practically the same. Absence of a high temperature in the first set of appliances is just as fatal to success as it is in the second; for in both instances the calculations of the inventor are completely upset by the very common domestic condition of a fire on the point of going out, to which fresh fuel is added in excess. It is then, in spite of every ingenuity, that a state of things occurs which is practically absent in the case of all large furnaces, and the inevitable consequence is an escape of smoke from the chimney.

The point to which we have more especially drawn the attention of our readers is one that has not escaped the notice of men of science, who have made the pollution of the atmosphere their special study. The wonder is that some definite proposals have not yet followed, even from the present state of our knowledge with regard to the combustion of fuel on a small scale. Dr. R. Angus Smith, who has made not only many most important original contributions to the solution of the problems connected with the purification of the atmosphere, but whose special business it has been for many years to digest the labours of others, says, in his work "Air and Rain," when speaking of coal-smoke,—"It is not from want of air, or oxygen, that the black smoke is not burnt, the amount of air here" (referring to certain furnaces and chimneys which he had examined) "is found far in excess of that required. Now, patentees have too much confined themselves to the supply of air, a commodity easily given, but not so easily used. The want is in reality heat." If these remarks are applicable to the case of boiler furnaces on a large scale, they are much more significant in the case of ordinary domestic hearths, where the attainment of a very high temperature, evenly maintained, is practically impossible. If, then, great heat is essential to the complete combustion of ordinary coal, and if it is not possible to obtain it in the domestic consumption of large towns, we are forced to conclude either that the pollution of the atmosphere must go on indefinitely, or that we must fall back upon some modification of the fuel which is at present in use. It must always be borne in mind that conditions of temperature which are quite incapable of coping with the rich carbonaceous products of our coal-mines in their ordinary state, are nevertheless amply sufficient to produce the phenomenon of complete, or at least smokeless, combustion, when a portion of the smoky constituents of the fuel have been removed. It is practically impossible, even in an ordinary open fireplace, to produce smoke from coal out of which gas has been extracted to the extent of from 3,000 to 5,000 cubic feet per ton, and the material resulting from the operation is in every way superior to common coal. It must not be supposed that the removal of one-third, or even one-half, of the total gas contained in coal results in the production of coke. On the contrary, it leaves us with a residue that will produce the cheerful fire so dear to the heart of every Englishman. If the extraction of some proportion of the gas contained in ordinary coal is the only possible way in which a great city like London can be made absolutely smokeless, it would surely be wiser to adopt this alternative at once than subject the community any longer to the continually increasing evil of a contaminated atmosphere.

It is difficult to realise the extraordinary addition that would be made to the amenities of existence within the metropolitan area if such a course were successfully carried to a conclusion. The London of the early morning is full of subjects that attract attention on account of their pictorial charms. The river, the bridges, the great highways, the lofty towers, seem as if witnessed for the first time when first seen in the crystal light of the brightening dawn. But the glory is soon overcast. The toiling millions at their morning meal are the earliest witnesses of the change. The smoke ascending from the humble hearths soon mingles with the denser volumes from the West; and the leisured and professional classes, who rise at a period of the morning when 100,000 homes have contributed their quota of pollution, know nothing of the beauties of London in the early dawn.

In summer a curious spectacle is seen by those who take the trouble to watch the atmospheric changes of the day. In warm weather, as the use of coal is almost entirely confined to the cooking of food, so we find the smoke of the town and the meals of the community are altogether synchronous. The common experience of the wealthier classes is to waken in an atmosphere of smoke or fog. This is the time when London breakfasts. If a gentle wind is blowing up or down the valley of the Thames, the smoke-fog of the morning meal will roll away when the fires that cooked it have gone out, and may be discovered in a murky cloud, as far away as Hampton Court, before the time appointed for rekindling the culinary hearth. It is during this interval,—often about eleven o'clock,—that upon going into the parks, we glory for a few short moments in the simulated freshness of the country air. The mist that rises from the ground is silvery-white, and the sunlight falls on the foliage of the trees unsullied by the dingy haziness which seems at other times to take a refuge among the labyrinth of leaves. Again the workman's meal comes round, and the smoke that rises from the fire that cooks his rasher of bacon is soon seen mingling with the contributions of chimneys connected with the operations of luncheon. Then, except the wind be strong, London is grimy for the rest of the day, and the dinners of the West End keep up the nuisance till the period of the setting sun. But, in winter, no lucid intervals occur. The demand for heat goes on the whole day long, and it only needs the combination of an aqueous atmosphere to produce the horrors of a genuine fog.

If, then, all this can be avoided by the simple expedient of removing a proportion of the gas from the coal, it seems only reasonable that this should be done. The smoke that at present escapes is wasted heat, and only soils our houses and our clothes. If it were first extracted from the coal it would give us light, and the tar, instead of enveloping the particles of mist and rendering them impervious to the action of the sun, would be available for the dyeing of our garments.

We have no wish to disparage the importance of many ingenious and useful inventions for economising fuel in domestic hearths. Many of these, and notably the slow-combustion stoves, in which the important element of time is introduced to allow of the more complete combustion of the fuel with the air, are excellent in their way; but the present deplorable condition of London and all our great cities must be looked upon as a commentary on their inefficiency to bring about a radical improvement. At the best they only economise the fuel, and leave the problem of complete combustion on a small scale, and without skilled attention, unsolved. Meantime, the discomforts and dangers arising from smoke and fog are becoming more pressing every day, and it appears to us that if the removal of a certain proportion of the gas from the fuel used in our great cities is a practicable and economical expedient, and *primâ facie* it appears to be so, then the sooner some such course is adopted the better it will be for the health and the wealth of the whole community.

By cheapening gas, and so leading to its more general use in cooking and heating, the course proposed might, in a secondary way, further assist in producing the desired result.

HEALTH AND THE HOUSE-BUILDER.

Of late years,—truth to tell very much too late,—what may appropriately be called a new school of doctors has been established, the school of "prophylactic" doctors; and a very good school it is. Inasmuch as prophylactic medicine can only give effect to the most radical of its precepts by co-operative alliance with the building trades and the architectural profession, we propose in this article to initiate, not to say a better acquaintance between the two,—for, up to the time being, there has been no acquaintance at all,—but an acquaintance.

We will not hesitate to assume, without offence, that the majority of native builders, and some few native architects, have not learned Greek, and therefore do not know what the word "prophylactic" means. It means *preventive*, and something more; which something we shall acquire a better idea of when we explain that "phylax," or "phulax," is a guard or sentinel, and the prefix of "pro" means that he is stationed well in front in guard over some body or bodies,—some thing, or things,—stationed behind. Prophylactic medicine, then, has for its object the prevention of disease by the adoption of judicious safeguards, instead of the curing of disease when it actually comes. Seeing that English people are not nomads, living in tents,—shifting their tents from spot to spot,—free to the breezes, the breezes free to them, but passing most of their lives,—the whole of their sleeping lives,—in substantial, permanent habitations; seeing that those permanent habitations are mostly constructed without any sort of previous acquaintance or intercourse, much less interchange of view or opinion, between house-constructor and house-occupier; it stands to sense that prophylactic doctors can never have a fair field on which to work with full effect until a good relationship shall have been established between them and the building community.

Unquestionably the most radical point to be kept in view when constructing a house, with regard to permanent sanitation, is the nature of the concrete or foundation upon which it is to be constructed. If the foundation be of festering germ-originating, malarious gas-evolving materials, nothing can go well with the health of those who inhabit that house, until the festering has exhausted itself by lapse of many years,—perhaps many generations.

When, in a neighbourhood where building is going on, we see a board announcing "Rubbish may be shot here!" the public may take it for granted the permission thus liberally accorded will meet with literal fulfilment. Odds and ends will be thrown there,—"rubbish" in its most obnoxious sense. We have had the curiosity, this sometime past, to take stock of metropolitan foundation-building rubbish, and

have got quite accustomed to see the predominance amongst it of preserved meat tin canisters, and old shoe leather. It might have been thought that the manufacturers of prussiate of potash would have had something to say about the old shoes; leather, like horn and hoof, being a factor in their chemical process. This, however, does not appear to have been the case; at any rate, it is not the case to an extent that can satisfy any prophylactic physician. The preservative virtues of tan notwithstanding, leather will rot in time; and whilst rotting will give off injurious emanations. It is the preserved meat-tins to which the most injurious effects of such a foundation as we have described are mostly attributable, and every day those tinned provisions coming more and more into use, the evil is exacerbated.

Coming now to the practical question up to which our remarks have been leading:—What practical means can be adopted for destroying or counteracting the malarious influences due to such a foundation? A mixture with earth would be satisfactory, but real honest earth is not in the majority of cases available to the urban builder. Earth is Nature's own disinfectant for organic decomposable things buried underneath it. We see what earth can accomplish in this way when applied to earth-closets. Well-ordered cemeteries and churchyards, again, supply another example of what earth can do in disposing of organic emanations. In the month of July, 1877, there existed some six-and-thirty thousand graves in Kensal-green Cemetery; and if we assume for present needs that each of these graves held five corpses, the assumption may not be far wrong. This gives 180,000 corpses for the graves alone, without reckoning those in the catacombs. The earth of Kensal-green Cemetery is by no means well adapted for its purposes, being too aluminous,—clayey,—and too wet. Nevertheless, the object proposed to be accomplished is accomplished with tolerable completeness. If, then, urban builders could obtain good honest earth-mould for mixing with their foundation rubbish, injurious emanations would not ascend; this not being available, quicklime is the most practicable, though not the best of substitutes. Lime does not act in the same manner as earth; there being not only difference of degree; the difference is radical. We can only understand in what the variation consists after contemplating the nature of decomposition products that a rubbish foundation such as we have assumed would evolve. Whenever organic matter, of whatever kind, decays, the evolution products resolve themselves into the two classes of inorganic or dead, and organised or living. To the first category belong ammonia, pure and simple; hydrosulphate of ammonia, more popularly known as sulphuretted hydrogen, and more fashionably as sulphide of ammonium; carbonic acid, more fashionably known as carbon-dioxide and carbon-anhydride; marsh gas, together with other products not so important. To the second category belong microscopic organised germs. Whenever animal matter decomposes, nitrogen and sulphur must be evolved in one form or another, seeing that nitrogen and sulphur are invariable constituents of animal bodies. When vegetable bodies decompose, there will be very little sulphur to evolve (most vegetables containing no sulphur), and if we regard the products of vegetable life as a whole, not much nitrogen. Practically every body is cognisant of the truth that decomposing vegetable bodies yield products much less offensive to the sense of smell than animal bodies, the explanation of which is that vegetable bodies contain much less nitrogen proportionately, and very much less sulphur. As for the latter, if such vegetables as garlic, onions, shalot, leeks, and the rest of that tribe, all belonging to the botanical natural order *liliaceæ* be excepted, and mustard, cress, cabbage, together with kindred vegetables comprised in the botanical natural order *cruciferæ* or *apiaceæ*, sulphur may be banished from consideration as an element of vegetable life.

Contemplating now the effects on health of the gaseous products just specified, ammonia,—*i.e.*, ammoniacal gas,—is, sanitarily, the least injurious of the lot; yet such persons as would affirm that ammoniacal gas when diluted by atmospheric air to such a degree that breathing the mixture is not sensibly repugnant to the lungs, and habitual living in the mixture not irritating to the eyes, ceases to be injurious to health, would do well to accompany on his rounds some medical man who has a patient, or patients, living in the small apartments over mews. In these residences the presence of ammonia may always be detected by smell alone; and the injurious consequences of dwelling in such an atmosphere will be seen in the general aspect of the dwellers. With the groom himself things may be moderately well under general circumstances, seeing that he is more out of doors than the others; but even the groom, should he happen to cut himself, will discover an effect of breathing the ammoniacally vitiated atmosphere in the long time it takes for the cut to get well. Ammonia, though about the least injurious of the non-organic emanations from decomposing matter, is assuredly not to be ignored in that respect. As for sulphuretted hydrogen and its combination with ammonia, both are, or can be, deadly poisons. One inspiration of sulphuretted hydrogen, undiluted, would infallibly kill the incautious breather on the spot; nay, even when diluted, rapid if not instaneous death might result, as it has been known to have resulted. Some fifteen years ago the following incident was recorded in the newspapers:—Some individual endowed with more chemical faith than chemical wisdom chanced to live in the vicinity of a street-drainage grating which evolved evil odours; whereupon he, having heard or read that oil of vitriol was a great purifier, threw some oil of vitriol down the grating; then applying his nose and taking a sniff to learn if the purification was complete, fell down dead. So injurious is sulphuretted-hydrogen that, even when much diluted, it may kill by skin absorption, as was proved long ago by some French veterinarians. They put a horse, all but his head, into a caoutchouc bag; then charged the bag with a mixture of atmospheric air and sulphuretted hydrogen, having only sixteen per cent. of the latter. By conditions of the experiment, it must follow that, should the animal be affected by the sulphuretted hydrogen, this could only result from skin absorption. Under this treatment the horse died.

Marsh gas, or light carburetted-hydrogen, already enumerated as being amongst deleterious gaseous emanations, may always be detected in the water of stagnant pools, charged with organic decomposing matter. From the water of such pools it may be collected. Not many years since, indeed, this was the only source from which investigators could obtain light carburetted hydrogen for experiment; no artificial method of preparing it being known. In marshy, fenny situations this gas abounds. These localities are always and everywhere insalubrious, but especially when situate in hot climates. The unhealthiness of localities where rice is grown is proverbial, rice being really an aquatic grass. Habitual inhalation of an atmosphere charged with marsh-gas has been thought by many pathologists to be the immediate cause of ague, or marsh-fever. An equally probable hypothesis is, however, that the disease in question results, not from inhalation of the gas itself, but from inhalation of minute germs or spores, organised, and, by microscopic aid, sometimes, perhaps always, visible, and co-existent with the gas.

The second category of disease-creating, invisible agents,—invisible, that is to say, to the naked eye,—organised germs, have only had their existence visibly demonstrated in quite recent times. Very soon after microscopic inquiry had revealed the existence in nature of an immensity of littleness in counterpart to the long-known and contemplated immensity of greatness, the very probable idea dawned that just as the microscope had rendered visible the existence of certain minute things, which hitherto had not been suspected to exist; so, probably, even microscopic vision had its limits. It was reasonable to suppose the existence of myriad small living things, which not even the microscope could render manifest. Probably this is the case, but, leaving hypothesis for the safer ground of experiment, we will now state how the visible existence of some living germs at least present in the atmosphere was demonstrated. The plan adopted was most ingenious, and when stated will be plain. *Imprimis*, the two points must be apprehended that gun-cotton dissolves in ether, giving a transparent colourless solution; and that gun-cotton wool, like ordinary cotton wool, can be made to act as a filter. Apprehending these facts, a French philosopher tried the following experiment:—Passing a current of atmospheric air for a certain time through a mass of gun-cotton wool, packed tightly in a glass tube, then dissolving the gun-cotton in ether, and examining microscopically the solution, he found abundant germs. Conclusive though this ingenious experiment was up to the stage at which we left it, the truth which it was made to disclose is only half told. The air which had been filtered through the gun-cotton was passed into a glass vessel, into which some broth had been put; and, one time having elapsed, it was found that the broth so circumstanced would not putrefy, though a duplicate sample of broth exposed to unfiltered air for an equal time and at the same temperature putrefied. This beautiful experiment opened a large field of speculation. The fact had been long known to experimentalists that all putrefiable matters, so far as experiments had gone, disclosed to the microscope a crowd of living organisms, in every case of specific kinds according to the species of matter undergoing putrefaction. In this way it was known that putrefying flour-paste was crowded with eel-like animalcules, which, indeed, have acquired the name of "flour-paste eels," from the resemblance. To whatever putrefying thing the microscopist turned his regard, he found specific organised forms. In most cases these organised forms were vegetable, of the fungus or mushroom nature; in other cases, as, for example, in putrefying paste, the specific organisms were animalised, though an abundance of fungoid growths constituting mould were found too. To an inquisitive mind the question immediately presses for solution,—Where do the living things referred to come from? Either they must be spontaneously generated, or else developed from germs, spores, eggs, or whatever else we choose to call those minute initial points of vitality. The belief in spontaneous generation is of great antiquity, but as experimental science advanced, it came to be scouted, only surviving in the minds of tidy housewives, who, one and all, protested, and continued to protest, up to the period of development of the scientific female, that dirt bred (*i.e.*, spontaneously generated) fleas. Of late, however, a school of scientific men, invading the domain of scientific females, pronounced their belief in spontaneous generation too. Many still continue to hold that opinion, but how they can consistently do so in presence of testimony furnished by the gun-cotton experiment repeated again and again up to the time being invariably with the same results, is to the preponderance of thinkers extraordinary. Chemists, when regarding the atmosphere chemically, are doubtless right in defining it to be a mechanical mixture of four volumes nitrogen and one oxygen, together with a comparatively minute but variable portion of carbonic acid. Prophylactic doctors, architects, and builders, however, must form a more extended idea of the atmosphere than this. They must contemplate it as being charged with a multitude of germs all ready to develop into fuller life, on finding resting-ground suitable for their development. If the objection be alleged that the germs are not an integral part of the atmosphere, but extraneous things contained in the atmosphere, the sole result is to import a metaphysical disputation on a practical matter, not altering practical indications of teaching in any degree. It must not be understood that the atmosphere exclusively is concerned in the diffusion of germ life. On the contrary, these little organisms pervade articles of food and drink. Few pathologists would at this time feel justified in denying that Asiatic cholera is alone communicable by the actual ingestion (*i.e.*, swallowing) of specific germs. Asiatic cholera is quite a modern disease, only dating from 1819. Its first victims were individuals who had been eating some rice from a crop on which had been observed a growth of a peculiar mould never previously seen. Not all microscopic germs are prejudicial. Some perform demonstrably useful work in the economy of nature. Without the presence of germ life there could be no fermentation of any kind. We have already seen how, in the absence of germ life, putrefaction (*i.e.*, putrefactive fermentation) could not be established, and the same inability applies to every other variety of fermentation. Hence springs the designation under which certain diseases are classed as being "zymotic" or fermentive. Perhaps the fermentive theory of disease has received more extensive application than is warranted by scientific demonstration. For example, that bane of the English climate,—consumption,—is considered by many pathologists to be refer-

able to the presence and development of specific germs; and on this assumption the hypothesis has been based that the pine-forest cure,—as it has been called,—of consumption, owes its efficacy to the circumstance that patients lodged in the depths of a pine-forest have to breathe, during their sojourn, an atmosphere charged with turpentine; which, like in this respect to carbolic acid, is destructive to minute forms of organic life, whether vegetable or animal. Assuming that we have rendered obvious the intimate connexion which naturally subsists between house-construction and prophylactic medicine, we would ask whether the connexion is not too often violated, and in such a radically important matter as house foundations, whether the violation may not be expected to prove the cause of future disease? If a foundation of chemically objectionable materials there needs must be,—such as the old shoe-leather, sardine-boxes, and meat-cans, to which we have adverted,—ordinary prudence suggests the need of disinfection. It is, unfortunately, too much the custom to go to work empirically in the employment of disinfectants, forgetting that such bodies, though having one common generic name, are endowed each with specific action. It by no means follows that a disinfectant best against a certain class of impurities may not be the very worst against others. Quick-lime, for example, has a sort of popular repute of acting as a disinfectant on every possible offensive thing, and under every possible condition. Its range of efficacy is large, no doubt, but cases may be easily specified in which lime is totally inert,—other cases in which it is injurious. Lime, not being volatile, is not atmospherically diffusive. It cannot, therefore, purify air except the air be forced through it. Quick-lime will be the best available purifier in the case of having to deal with a festering slowly putrefactive mass. It will destroy the germs to the action of which putrefaction is due. It will decompose hydrosulphate of ammonia and fix sulphur. It will rapidly corrode and render unputrefiable all organic materials. These comprise a fair list of advantages to the credit of lime as a disinfectant. On a future occasion we may indicate some of the abuses of lime regarded as a prophylactic agent, and explain the mode of action of certain other disinfectants.

BUILDING AND BUILDING MATERIAL IN CANADA.

Next in interest to the living humanities of a people comes architecture, which, interwoven with all, survives them all,—crystallisation, as it were, of the sum of facts that go to make up a nation's existence. This is what is drawing the attention of new-light students so markedly to the contemplation of old-time monuments, nor can we expect to furnish a less worthy, if less durable, subject for scrutiny to our successors at the far future end of time's vista.

Canada now means an empire covering half a continent, and, rapidly growing homogeneous, must powerfully influence the world at no distant date,—perhaps (such are the mutations of fortune) destined to really become the Greater Britain. Much of our bone and sinew, a good deal of our healthy brain, is being exported to Canada; the workers are building up the country with force and with patience. Of what, then, are built the houses of the workers? Canada is much thought of as a land of snow, but her summers are nearly as characteristic a feature as are her winters; these are hot enough, so that if there are to be found some snug temporary huts composed of snow, there is a wider range of building materials from which to choose. As for these snow huts, however, they are occasionally met with in districts where timber is poorly accessible: mining regions, or the banks of some rivers to which resort the Indians and trappers in winter time. They can only be successfully made after a fresh snow-fall in moderate weather, when the snow is no longer of its usual dry and powdery nature that forbids its being moulded. These huts are, when possible, made over a hollow cone of brushwood, but where this is not possible, they are formed like big ant-hills with a hole in the top through which the smoke of the fire inside may find egress. Over this hole are placed two short columns of packed snow, and upon these a slab of the same material, so that no snow can enter. Doors are extemporised of blanket or bear-skin, the internal fittings of the hut being of very primitive kind; and yet it is comfortable enough.

It is rare, however, that wood is not obtainable in the older provinces, so that the cosy dwellings of the shanty-men are far oftener met with than is the snow-hut. Varying according to the nature of the timber of which they are made, and not intended to last, all agree in being substantial and warm. The shanty-man, or "lumberer," is a man of independent spirit, who, slinging his rifle behind him and shouldering his axe, enters the wilderness with perfect composure, regardless of the lack of milestones and highways. He knows north from south by the "dip" of the trees, and cuts his own road when need be. Being sociable, he prefers company, yet often does his prospecting alone,—his first care, having met with a suitable field of operations, being the erection of his shanty. He carries with him no carpenter's set of tools: his axe is his one weapon. With it he fells trees and cuts them into lengths; how large may be these trees, and in what way he builds his shanty, are points that depend upon whether he have help or not. If alone, he drives two saplings into the ground at each corner of his shanty, and between each pair drops lengths of light timber, slotted close to their points of insertion, so as to receive the cross-bars. These being placed, the roofing is laid on, and the slope made afterwards. One side is modified by the necessity that exists for a door, but the principle remains the same: uprights driven into the earth in pairs, and firmly bound together at the tops, and, sometimes, the centres. Moss or cedar-branch packing does the rest; a chimney is made of four roughly-hewn slabs of wood, a short length or two of timber rolled indoors, when, having spread his couch of fragrant cedar-brush, the shanty-man lies down to enjoy his first pipe. When the lumberer is, as often happens, only one of a large party, his house is more strongly built. Sills having been laid, uprights, grooved on two sides from top to bottom, are tenoned in. Down these grooves are slidden horizontal timbers, squared at the ends, but otherwise "in the rough"; lastly, door, chimney, and windows are provided. Many of these shanties are adapted to withstand a bombardment from all but the heaviest of the old smooth-bore guns. Where timber is valuable, they are taken apart on leaving, and go to make the raft, which is floated over a dangerous course of hundreds of miles, and along the broad breast of St. Lawrence to Quebec. Otherwise they are left standing, to mock the unfortunate explorer who may have lost his way in those wilds with the promise of accommodation that he will not find. Yet, wooden houses do not exclusively belong to the professional lumberman.

So rapid has been the growth of many parts of Canada, that where thriving towns stand to-day, a few years ago was nothing but the unbroken forest. Here, when the settler first came, he staked out his farm and deliberately erected cottages and outhouses of rough timber. These stand to this day to witness to his marvellous upward progress in material prosperity. Toilsome work it was, this felling of trees and drawing of stumps, but here lies his farm smooth as a lawn, except where the plough has left its even furrows, and here still stands the cottage which saw the first "stumping-bee," with its array of immense bon-fires turning night into day. The farmer is proud of his house, and will not have it pulled down; his children may do that, says he, and sure enough they will by and by.

The face of the country in civilised Canada is fast changing. But, if you will enter his house you will admit that the farmer is, not without reason, proud of his dwelling. Neatly wainscoted inside, and well, if roughly, finished, there are no signs visible of the rough exterior. There is an upstairs, too, where the beds are skilfully made to project from the walls, as in the bunks of a ship. Possibly the farmer's first ideas of carpentry were borrowed from the sleeping accommodation of one or other of the badly-arranged sailing-ships that used to be thought fit enough for emigrant ships in the good old days of thirty years ago.

In the infancy of Canada, while towns were thus built of timber, the Government-house was wont to outstrip the rest, both in workmanship and grandeur. Private and public, that those were no contemptible residences may be inferred from the fact that many leading citizens prefer these old structures for their present town residences to any of modern contrivance built of brick or stone. There are, in Canada, still hamlets to be found in which town-hall, school, and churches are all of wood. While such is the case with respect to the older provinces, the same holds good in the prairie regions of the north-west, wherever wood of any dimensions is accessible. There, the half-breeds build with round timbers; from 16 by 16 to 16 by 24 square feet being the usual area of foundations. Sills are laid, as already described, six posts hewn, one for each corner, and two in the middle, lengthwise; grooves of 2 in. are cut in the posts and plates to hold these. Timbers are next cut, tenoned to fit grooves, and slipped in, thus making the sides and ends. The cracks are plastered within and without, and whitewashed. For the roof, poles are laid rafter-fashion, and filled in with clay or mortar, mixed with grass, puddled into the mass at one end, the butts of the grass projecting from and covering the clay. This plan of roofing is recommended to the notice of English farmers, as being cheaper than thatch, and quite as serviceable.

Most people are aware that there is a scarcity of large timber in the north-west, so it may be said that pine is imported to Winnipeg from Minnesota. Poplar and dressed white pine sell at $25 per 1,000 ft. Most of the houses in Manitoba are of frame, but brick is coming into use. It must not be thought, however, that the country is destitute of timber, for spruce, aspen, and stunted oak are found in abundance, and large enough for many purposes. Beyond the Rocky Mountains lies British Columbia, chosen home of giant timber-growths. The Douglas and Menzies firs, and the cedar, reach 250 ft. in height, whilst even the pretty maple attains 150 ft. The birch is thought tall at 70 ft., and is only found at the edges of British Columbian forests. This tree is, however, found beyond the prairies in most of Old Canada, and serves a number of useful ends besides this of house-building. Birch-bark makes the Indian's light canoe, which, when he meets a portage, he carries upon his back to the next length of smooth water, to re-launch it afresh there. Birch-bark is his thrifty squaw's medicine, and is the material of which her husband's leggings are wrought. An inner lining membrane of the birch-tree is used by the Indians as paper, whereon to paint records of prowess in the chase. Birch-bark serves also for the covering of tents, and, twisted into cordage, for fishing-lines. The Old-Country settler, glorying in the sharpness of his axe and the strength of his thews, despises such flimsy material, but the Indian knows better than to do hard work for a sentiment.

Next in order to massive timber for building purposes comes lath and plaster, perhaps at this day the most generally used material. It is a source of wonder to strangers how quickly and cheaply arise neat rows of houses in Canadian suburban districts, but if they watched the process, they would cease to be surprised. Every prosperous labourer hopes to build his house: a feat which he often accomplishes, in spare intervals between working-hours, with his own hands.

This is how he does it. When possible, he makes a good stone foundation, but timber does very well, and then he gets through the heavy work of erecting the frame, as already described, only his corner-posts need no grooves.

When soundly placed and capped, he nails carefully-fitted strips of 1 in. pine between the frame works, top and bottom, so that the edges are presented. Across these vertical pieces he tacks light laths, not too close together, and finally plasters the whole surface with mortar, forcing the plaster between the interstices of the wood work. For the inside, a smooth mortar is used, while for the outside, a coarse kind is thought better; indeed, it is usually thrown, instead of laid on, and often made to take an artificial wavy surface. Occasionally, plastering is altogether omitted outside, and planking substituted, but whichever plan be adopted, the result is a serviceable and comfortable building. The roof is made at a slope sufficient to divert the heavy snow-falls, and upon the rafters, close together, laterally, and overlapping each other, are laid wooden shingles, which take, in Canada, the place of slates.

Only two small nails are needed for the upper corners, and the work is begun at the eaves. It is better to have two rows of shingles. These essentials of a Canadian building are cheap, and, taken altogether, durable, lasting for nine or ten years, but have many disadvantages, among which not the least is their liability to catch fire in the hot months.

Many a street has been burned down by the settling of a stray spark upon the wooden roof of a building adjacent to the one which was burning. So well known is this that no sooner does a fire show itself than householders mount to the roofs and cover them with wet blankets. Shingles also warp beneath the intensity of an August sun, whilst they have a bad habit of absorbing water during unusually protracted rainfalls. In spite of these defects, shingling is a flourishing trade. Numbers of "shingle-mills" exist all over the country, where the hum of circular-saws never ceases during the day. The writer had several months' experience of this craft, and is prepared to state that shingling is, in the late autumn, very cold work, and, owing to the slippery state of the ice-glazed roofs, dangerous. The roofing of houses is possibly a trade in England, as house-painting and window-glazing certainly are, but the writer found it expedient to undertake small contracts in each of these branches, together with a good many more alien to the subject of this paper. Whether slate will ever take the place of the Canadian shingle is uncertain: many public buildings are thus roofed, it is true, but only where expense and weight are of no consideration, and slates have an unpleasant faculty of retaining heat longer than is desirable. Canadian slate, such as is ordinarily used, is not of good quality; that is to say, it cannot be split into thin sections, and is far more absorbent than English or French slate. Where houses are for the most part so light as in Canada, heavy roofing is not desirable, and thus, shingling is, in spite of all to its detriment, likely to hold its own for many a year. But the inventor of a material which, while equally cheap, should be proof against fire and water, would certainly make his mark in the Canadian building world. It may be thought straining a point to bring the ordinary roadway under the head of "building," yet the fact is that in Canada the "side-walks" are usually made of wood. The only exceptions are found in several large cities, where stone has been thought more showy. Bearing upon the matter in hand, attention is drawn to the recent report of the Home Metropolitan surveyor upon pavements: in it, preference is given to wood over both stone and asphalte. This refers to wooden blocks for the carriageway; in Canada such paving is much in favour, but wooden planking for the sideways is not known in England. The only conditions upon which planking can be laid on natural ground are "sleepers" and "piles," as occasion may suggest. When in good repair, nothing could be better than these roads, but sometimes town councils and corporations are forgetful of the public safety, and great holes in the planking beset the unwary.

With the development of the country, timber is in ever-increasing demand, so that, with this home consumption and the large export, no wonder that there are upon the Ottawa river and elsewhere saw-mills by the score, turning out millions of boards each day, while, on approaching the newer districts, the hum of the saw-mill is invariably heard. The immense piles of boards that line the river-banks might seem fabulous to one who had not seen them. Indeed, the rivers are in many instances covered with sawdust so thickly as to conceal the water for miles, while the smaller streams are even apt to be entirely choked. There seems, however, to have been some recent legislation to prevent this growing abuse, so it may be reasonably inferred that the myriad trout-streams which beautify Canadian rural neighbourhoods will not cease to present their seductive promises of healthful recreation to the explorer. If only somebody could utilise this sawdust, what a mine of wealth would be have ready to hand! It has been attempted to mould it into blocks for fuel, but with indifferent results, the cost being too great, and the fuel not burning without being subjected to a constant air-blast. Should, however, a solvent be found which, while ensuring a pasty consistency without changing the material chemically, should permit of its being injected under pressure with air, the result would be a spongy mass that must burn readily. This has not yet been done, but it is quite possible in theory.

Now that Canadian cities are growing in wealth, and have more at stake than formerly in case of fire, an event only too common all over North America, there is a strong feeling in favour of doing away with the wooden streets that court destruction from any chance spark. In all large towns, recent bye-laws provide against the erection of wooden buildings within the town limits. All fresh edifices are being built of stone or brick, usually the former. Whether it be that clay is not plentifully found in some parts of Canada, or whether the cost of brickmaking is greater than that of quarrying stone,—at any rate, brick is commonly regarded more as a curiosity than as the simplification of the architectural executive which it is in England. Such brick buildings as are found are well constructed, although the bricks seem sometimes to have been insufficiently baked in the kiln. Stone of various kinds is plentiful enough in most parts of the Dominion, though large areas of the best arable land are without so much as a pebble. Even here, by digging to a moderate depth, beds of rock are reached which, where they are at their lowest dip, are often found to make natural reservoirs for salt brine or petroleum, both important Canadian industries. In Guelph and its neighbourhood, situated within the fertile peninsula formed by the great lakes, are large beds of magnesian limestone, so that this thriving town,—a city within the past year,—is as substantially built as any place in the world. Taking advantage of this cheapness of building material, the churches and public buildings have been ambitiously conceived. Sandstone and granite are found elsewhere, and upon the Upper Ottawa is an abundance of veined marble.

In the district of Muskoka, one of the free-grant tracts, but poorly adapted for farming, the face of the country is seamed with large, outcropping banks of rock of the sterile Laurentian formation. It is of no use in the neatly-finished applications of modern fashionable architecture, nor, indeed, can it be advantageously wrought at all; if ever utilised, it must be as rough material. Hence it serves only to form the backs of the settlers' rude cabins, or as banks whereon to trail the vines that require a supply of reserved heat during the frosty nights. But when Canada has, in consonance with her hopes, emerged victorious from the peaceful contest of the colonies for supremacy, should she desire to erect a pyramid to hand down her fame to the world's end here is enough stone and to spare. Treated as indicated, these rough boulders could, without much cost for blasting, and for transit, be worked into magnificent faces that should redeem the age from charges often brought against our own—of being puny in conception, in execution feeble. This, however, is of the future, while our subject lies with the present. Meantime, while private building enterprise is not likely to flag, the Dominion Government is not behind the age, its expenditure upon public buildings, for one of the recently-passed years, having reached the amount of 1,360,302 dols., or 272,061*l.* sterling. Large builders in good practice had, of course, better stay in London than go to Canada, but there are many smaller ones who could rely upon plenty of work at the outset, and sure profits. Much is to be done by a judicious combination of building and prospecting. A desirable locality is sure to grow in value, even without buildings upon it.

COUNTING THE COST.

Nothing is more hostile to the true and worthy development of the work of the artist or of the architect than any attempt to surprise people into the payment of a greater sum than they intended to pay for any commission which they put in hand. As far as regards the general prosperity of the tectonic professions, it matters very little whether such surprise is planned or is merely the result of slovenliness and want of due forethought. As regards the character of the professional men concerned, of course the difference is palpable. But this fact ought not to lead us to undervalue the mischief that may arise merely from our ordinary habit of taking things a bit at a time, without a thorough forecast of the whole.

This, we take it, is what is now raising no small amount of wrathful contention in the Court of Common Council. In December last, it appears from the discussion at the meeting of that body on the 7th of October, the Court approved of the project of erecting an architectural memorial on the site of Temple Bar, and the execution appears to have been entrusted to the City Lands Committee. If the Court of Common Council had taken the obvious precaution of naming a sum which they were prepared to sanction, and not to exceed, for the monument in question, all would have gone well. This must not be overlooked. Whatever blame may, rightly or wrongly, be attributed elsewhere, here was the point where due precaution ought to have been taken. It is not for the Common Council to ignore this fact.

The City Lands Committee, it seems, were not more careful in the matter than the Common Council had been. They were content with "a rough estimate," and do not appear, if we may judge from the otherwise conflicting statements of Mr. Bedford, their chairman, and Mr. Horace Jones, the City Architect, to have inquired whether the estimate for the building included the cost of the statues with which it was to be adorned. None of the items seem in themselves to be other than fair and reasonable. The sums of 1,250*l.* each for marble statues of her Majesty and H.R.H. the Prince of Wales are as little as could be offered by the first municipality in the world for such works. A thousand guineas for a griffin (presumably of bronze) is not more than a fair sculptor's charge, supposing the design to be one in all respects commendable. Nor is 300 guineas apiece for four bas-reliefs at all disproportionate. Here, then, we obtain the sum of 4,750*l.* Nor can it be contended that it is an overcharge for the work proposed. It is not quite evident to us how far these items, together with the cost of "about 3,000*l.* or 4,000*l.* for the remainder of the work," make up the sum of "about 10,000 guineas," but it seems tolerably clear, first, that if sculpture is to be introduced, it will not be worth the while of the City of London to pay less for it; and secondly, that it is in this question of the cost of sculpture that the misunderstanding has arisen.

Mr. Phillips gave notice of a motion tending to put a stop to the proceeding with the monument. A somewhat stormy discussion terminated by what we suppose must be taken as the vote of a majority of 75 to 51 in favour of the acceptance of the estimate. The notice of motion, no doubt, still stands, so that the subject cannot be considered as finally closed. Meantime, let us take the lesson to heart, that those who begin to build without fully counting the cost are proverbially likely to come to grief.

The daily press is tolerably accordant in condemning the erection of a monument on the site where such serious obstruction to traffic was so long caused by the old Bar—a survival, as it was, of times when carriages were few and far between. The proposal to form a refuge as a part of the monument is one that ought to receive support from the *Builder*, as the original proposer of these safeguards against the danger of the street. But it can hardly be doubted that the particular site is one where the necessary area of ground can be but ill-spared, whether for monument or for island. The public have not been allowed the opportunity of passing any opinion on the architectural merit of the design, and unless this prove to be in every way suitable, both for the locality and for the purpose of commemoration, it can hardly be doubted that a well-constructed subway would have been far more valued by pedestrians, if not by all frequenters of that great thoroughfare, than an edifice adorned by noble statues, and crested by a prodigious griffin. A dragon, by the bye, not a griffin, is the animal proper to the City arms.

THE SOCIAL SCIENCE CONGRESS IN EDINBURGH.

On other pages we give the substance of some of the papers read in the various sectional meetings of this, the twenty-fourth annual Congress of the National Association for the Promotion of Social Science, which opened on the 6th inst. In point of attendance, at any rate, the Congress appears to have been fairly successful, for by the afternoon of the second day (Thursday, the 7th) nearly 1,000 tickets had been sold, viz., 538 for members, 265 for associates, and 132 for ladies,—in all, 935. This total compares favourably with the 650 recorded at Manchester last year, as well as with the return of the Cheltenham meeting in 1878.

The usual meeting of working men was held, and was largely attended, although a small charge was made for admittance.

We shall give some additional reports hereafter. Dublin is fixed on as the next meeting-place.

THE QUESTION OF MASTER AND PUPILS IN ART.

SOCIAL SCIENCE ASSOCIATION.

In the Art Department, on the 8th inst., Mr. Hubert Herkomer, A.R.A., opened the discussion on the special question, "How far would the revival of the old system of 'master and pupils' be of advantage, and tend to promote the growth of historical art in the country, and the fitting use of painting and sculpture in our public buildings?" He had, he said, modified the title of his paper as follows:—"How far would the revival of the old system of 'master and pupils' be of advantage in the present day, and tend to promote the growth of true art?" Inquiring, first, how far the old system was advantageous, the writer remarked that the imitative faculties of the mind awaken early, and are the first to be exercised; reason and invention follow. It is thus that all art-workers have built their earliest efforts upon what has gone before them. When they have reached the point where originality begins to assert itself, they diverge into other channels—ripening, advancing, or varying the existing art, according to their powers of originality. History is replete with facts showing that all great souls had to shake off, and frequently with an effort, the influences of their masters, before they could do one single touch of that work that has made them immortal. This reflects seriously upon the system of tuition under consideration. Unless the student is led at the very beginning of his education to expect the final appearance of independent "mind-seeing" and interpretation of nature, he will aim little higher than imitating, not nature, but another man's interpretation of her. This individuality is the great mystery and secret of the art-mind. It cannot be transmitted to others, and cannot be stolen, for the best resemblance to another man's originality of style is but an imitation. The highest mental qualities, being originality and loftiness of invention, would appear last. Considering, then, that the qualities which are active at very early stages are the imitative, and hearing in mind that the system of masters and pupils exercises and encourages those qualities almost exclusively at first, it is not strange that those soul-given qualities, which are fixed for later development, should be lamentably impeded in their attempts to come to life. The system retards the growth of those qualities that make the painter renowned; that is one great flaw. Another danger attached to the system is that of the pupil being put under the wrong master, that is, under one antagonistic in all his ideas and aims to the innate but closely-hidden tastes of the student. Imagine the late Frederick Walker put under Maclise. Surely Walker, whose characteristic was to draw out the tenderest passages of nature, would have had the natural bent of his mind irritated and chafed. As it was, he was placed, with but little artificial tuition, under an engraver, and told to draw as much in the style of John Gilbert as possible. Then he had to draw on wood the sketches of Thackeray for his "Philip"—awful drawings—and Walker sorely wanted to try some original illustrations, instead of working out Thackeray's caricatures. He timidly suggested it, tried it, and at once showed, not traces of having imitated John Gilbert, but the originality that was in his mind. Now, this highly nervous, sensitive man, who never showed his work whilst in progress, even to the models who sat for him, and who would have been the last man in the world to have pupils around him, actually but unconsciously formed a school. From his life and works we can gather—first, that this painter would have done nothing greater (perhaps nothing so great) if he had been placed under a master; and secondly, that he would not have exercised a greater influence than he did by his works alone, if his studio had been full of pupils during his lifetime. After further illustrating the effect of a wrong selection of masters, the writer went on to remark that the works of great men have always had a greater influence upon young painters than personal tuition has had. The cleverness of drawing and so-called learnedness of French painters is as much due to the national character of the artists as to their school influences. In England we have certainly no strong school influences, but we have what is nowhere in the world so strongly developed, and that is originality and individuality of style. The French are as unhappy in their selection of subjects as they are certain of their drawing. It is their aim to strike, to startle, to fascinate. English art, however faulty it may be in precision of drawing, seems to take you by the hand and lead you to nature, and bid you love it,—to humanity, and bid you learn its lessons. This is a national characteristic produced spontaneously without any central impetus such as might accrue from the teachings of one man. What more do we want? Do we want more learning? Those who look for "learning" seem to be under an impression that it cannot be found in realism,—that to show any learning you must paint the Classic only. This is entirely erroneous, and is the cause of the word "learning" being misunderstood. Millais's head of Gladstone was full of profound learning, and so was his hastily-painted portrait of Mrs. Jopling. Learning comes with practice; originality never by practice, but it must be awakened by exercise. There is a danger in too early attempts at picture-painting; but this is only dangerous to the weak, and that only in case their first efforts are successful, so as to cause them to get into one groove, and work only for money. On the other hand, it is a significant fact that of those students who draw and paint such admirable studies from the life, and win gold medals, very few ever become eminent painters. Their mistake lies in simply doing what is placed before them, and in not being obliged to exercise originality, so as to make every study a picture. A master either forces the student into imitation of or similarity to his art; for in most cases the master allows the student to work upon his paintings, and the styles must meet. It is as difficult, however, to define the difference between similarity and imitation as it is to find the exact point where borrowing ends and stealing begins. If the pupil is to be a reflection of the master, the master must be unapproachable in his greatness, and there must be but one kind of art, and that his. We have yet to see the work of art that will positively satisfy all intelligent minds, and we have yet to find the master capable of training students of every variety of mind. Some sort of tuition or instruction is, of course, necessary; but its effect is only felt in the art of the time, when the highest grade studentship is paid much attention to. Good schools, with the best masters, might raise a higher level of art, but it is doubtful whether a higher level would produce more great men.

An interesting discussion followed; in the course of which Mr. Robert Herdman, R.S.A., said the subject which Mr. Herkomer had treated had been one of difficulty in all ages, and he suspected it was a question which would still go on undetermined for a very long time. He thought the question involved three points:—First, that of "master and pupil"; second, that of a school of historical art; and third, that relating to buildings. He thought the growth of a school of historical art would be promoted by giving far greater opportunities for artists to develop any faculty which they might possess in that direction. At present our art was mainly of a domestic character. If our municipal buildings and professional halls were more thrown open to the art energies of the country, he was hopeful that a strong effort would be made on the part of the professional artists to meet such a requirement, and art would have far greater influence in the country. Then, when the time arrived there would almost of necessity be a revival to some extent of the "master and pupil" system, because in such circumstances it would be impossible that any single artist could, unaided, carry out such works; and he believed the best thing for many of our younger students would be that, instead of following their own devices,—a course often leading simply to a restricted and rather useless mannerism,—they should be called in to assist in carrying out such important public works, where they could really give useful aid.

Mr. H. C. Boyes, speaking from his experience as an architect, contrasted the English and Continental systems of education in architecture. In England, he said, a young man was apprenticed to an architect, and learned from his master the technique of his profession. This was not the case abroad. On the Continent, the architect was trained, especially in Paris, more in schools and academies, and they saw the results in the architecture of England and France. In Paris they missed that originality observable in English architecture, which, of course, sometimes degenerated into vulgarity, but which always gave an air of picturesqueness and variety to our buildings. He thought the same thing applied to painting. We had in our painting in England very much greater variety and picturesqueness, though we had less of the French academical precision.

Mr. George Barnett, advocate, discussed the education of architects in this country and in France, and said he thought the result of the Continental system was that they had there a living school of architecture, which he did not think we had in this country. He knew of no building in Edinburgh, with, perhaps, one exception, which appeared to him to be designed as a natural result of the feeling of beauty in the artist, working upon the plan which was required by his employer and upon his materials.

The President (Professor Richmond) wound up the discussion. Touching in the outset of his remarks upon the question as to what should be the education of the student before his powers of selection had been formed, he pointed out, in the first place, that the technique of art was enormously difficult. The hand had to be trained to express what the eye saw or the mind conceived. Mr. Herkomer appeared to think that it was rather detrimental than otherwise for a young painter to be placed under a master with whom he did not entirely sympathise. With that he ventured to disagree. A student might have a great turn for form, and in that case the best master for him would probably be one whose strong point lay in colour, so that the student would have prominently brought before him that in which he was most deficient. He did not agree with the idea that learning was not necessary to art. By learning he meant knowledge of construction, and particularly of the construction of the human form. That knowledge could only be got by being taught intimately and in the studio of a man who was conversant with it. Then there were such things as laws relating to drapery, which, if known and understood, were of immense assistance to any painter. He could not see why both anatomy and those laws governing drapery,—simple enough things to learn,—should not be taught by a master to his pupil, and why that sort of teaching should not be of infinite value. In regard to wall-paintings, the art of the world, he remarked, had been done on walls, and he thought that was the sort of education that was necessary in England to enable men to paint on a large scale. Unless they got some system of art which would enable them to paint large subjects upon walls, he thought their art would degenerate into mere *genre* painting. As to the master and pupil question, it is clear that they could not create originality, but they could further it by educating students in such a workmanlike manner that, when it came to them to express themselves, they should be able to do so in clear language. They should know the grammar of their art, and if they possessed any originality it would come out. After alluding to the influence of allegorical painting, Mr. Richmond, reverting to the subject of education, said that what they wanted, after all, was to further the cause of art. They did not care how the education was got; they wanted the education. On the whole, he believed that they were inclined to think that the teaching gained under the direction of a master was better than that gained under the direction of an academy.

A SCHOOL OF DRAMATIC ART.

SOCIAL SCIENCE CONGRESS.

In the Department of Art, on its first day of meeting, Professor Richmond in the chair,

Professor Fleeming Jenkin, Edinburgh, submitted the first special question:—"Ought there to be a School of Dramatic Art, subsidised by private subscription or endowment, or by the State?" He began by apologising for appearing without his paper, which, he said, had been written and sent to London more than a week ago, and had not been returned. When asked to write about this question, he considered it his duty to go to Paris, with the object of ascertaining what was done there in the way of dramatic teaching at the Conservatoire. This he had done, and though he had not succeeded in being present when a lesson was given, inasmuch as the classes were not open, he had had the very great advantage of talking at considerable length on several occasions with two of the most distinguished teachers in the Conservatoire, and also with one of their most distinguished pupils. Proceeding to describe the method of examination, he pointed out that the jury consisted of twelve or thirteen men representing

the Government, letters, acting, and teaching,—a very efficient body to select the students who should attend the Conservatoire, and there receive gratuitous dramatic teaching. The French National Theatres and the Academy of Letters were essential parts of the system by which dramatic art was taught in France. He feared that, without support from analogous institutions in England, a mere Dramatic College would be barren in results. We could not transplant foreign institutions to our very different soil. The dramatic profession might, however, well consider whether it might not benefit by some such organisation as had been found advantageous in other professions. Almost every other profession had its professional society, and why should actors not have a Royal Dramatic Society? He thought that now the profession was in such a state that the public would accept such a proposal. The society might be founded with statutes, based partly on those of the Royal Academy, and partly on those of such professional associations as the Institution of Civil Engineers. It should be incorporated by Royal Charter, and placed under distinguished patronage by an honorary president of the highest rank. There should be two classes of corporate members. The higher class, of fellows, should consist of a fixed number of really distinguished men and women. The number should be so small as to make the distinction of belonging to that body as great as that of being a Royal Academician. In a profession there was nothing which conduced more to the advancement of the members than their directing their ambition into high channels, and there could be no better distinction with this end than that which was conferred by the profession itself. That was a very important point. There was no necessity for looking for patronage outside the profession. A profession itself could always confer its highest honours. So far, then, the society he suggested would be very closely copied from the Royal Academy. The second class, of associates, should be limited in number, but election even to this class should be so conducted as to make sure that to be an associate of the society would be a real distinction. The persons eligible as associates or fellows would be actors, actresses, and dramatic authors and musical composers whose works had been represented on the stage. No one unconnected professionally with the stage should be eligible, though a limited number of honorary members of marked distinction might be admitted. The intention should be that no actor should be admitted even as an associate who did not practise in what might be called the higher branches of the profession. It would be impossible by verbal distinction to secure this, but the following mode of election would effect the desired result. Each candidate should be recommended from personal knowledge by say three fellows and six associates, and a sketch of the qualifications should accompany the paper, stating definitely what parts the candidates had acted. This paper should be submitted to the Council, and unless the Council passed the candidate the election could not be proceeded with,—the election to be by all corporate members, and a certain number of "black balls" to exclude. A life composition should be paid on entry. The vacancies in the list of fellows should be filled up from the associates of a certain standing. Such a constitution would give a very much larger and more popular body than the Royal Academy, approaching more nearly to the Institution of Civil Engineers. What would be the functions of such a society? In the first place, it would be a fountain of honour. It could confer distinction on the most prominent members of the profession. To be president of such a body would be as laudable an ambition as to be president of the Royal Academy. It would encourage the ambitions and promising younger members by admitting them to its ranks. It could give valuable aid to students by holding competitions, awarding prizes, certificates, even scholarships. We should have a body representing the profession, whose decisions would command respect. We should have a substitute for the Société de la Comédie Française in many of their functions. Secondly, this Society would be a nucleus round which would gather many useful minor institutions. Thus it could administer grants and receive bequests. It could institute and manage benefit societies. It could institute reading libraries, portrait galleries, even a theatre itself could follow. It would be impossible for the fellows to avoid occasionally giving representations in which every part would be taken by a fellow, and these would be so successful that the national theatre would *grow*. The society would encourage the association between writer and actor so necessary to the stage, and would hold meetings at which every subject connected with the stage would be discussed. In a word, they should have an organised profession. Once grant the organisation, and the growth was sure to follow. The dramatic profession must teach itself, raise itself, honour itself, and in the present condition of the stage nothing was wanted to these ends except self-organisation, such as other professions had already adopted. He suggested that the Council might name a small, but distinguished, committee to promote the establishment of such a society as was described in the paper, if, after inquiry, they considered it possible and desirable.

Mr. Philip H. Rathbone, of Liverpool, said he had the very highest hopes of an organisation such as that sketched by Professor Jenkin. The principal difficulty would probably lie in the question as to who should be the first members of the association. Directly they had the association started, he agreed with Professor Jenkin nobody but those professionally connected with the stage should have one finger in the pie; but till it was started he was afraid the names of the first members must include a considerable proportion of outsiders. They knew the difficulty of starting any project when wrong men turned up, and had to be rejected. All that sort of invidiousness must be taken from the profession and placed upon outsiders, and the question arose, upon whom should it devolve? He thought it must devolve on some of those who had taken a great non-professional interest in the drama. Some of the very highest in the land had taken such an interest, and would be prepared to make the first list of members. He thought the idea of a Royal charter was an exceedingly happy one, and that Royal charter ought to name the first members. That done, he did not see the slightest difficulty in the members naming the associates. There was one very important class whom he should like to see much more numerous than it was at present,—that of managers who were not actors. There were very great disadvantages in having a manager who was also an actor, and he did not think they could have a good all-round company till they had as manager of that company a man who was precluded from appearing on the stage at all. He thought very great advantages would accrue from closer communication between the actor and the painter. In Germany the greatest mutual benefits had resulted from the actor and the painter working together in the question of grouping. He also alluded to the importance of the provincial theatres serving as preliminary schools for actors.

Mr. Robert Herdman, R.S.A., having referred to the power of the stage as a means of education and cultivation, and to the fact of its not being at present all that it might be, said that, believing something like what Professor Jenkin had put before them was likely to prove of service, he should certainly be very glad if at the present meeting of the Social Science Congress some step were taken by which the experiment might be made. He therefore moved that the Council be asked to appoint a committee to promote the establishment of a Royal Dramatic Society, if on inquiry they should consider this possible and desirable.

The Rev. William Vincent, Norwich, seconded this proposition. He had listened with interest to the very able address which had been given by Professor Fleeming Jenkin, and he thought it would be a great pity were any movement such as this to fall to the ground for want of being definitely taken up. He looked upon the stage as a very important element indeed in the education of the people, as well as in their recreation, and he thought it was a very great pity that any country like ours should be in the position of not being able to recommend the stage as a means of intellectual enjoyment for all classes of the people. It seemed to him that a very great step would have been taken towards their being able to recommend it, and set it forward as an educational and moral educator, when it was put upon some more satisfactory basis than at present. Having seen the great difficulties that there were to any national recognition of the stage, he thought it was desirable that what seemed to him the most practicable way suggested by Professor Jenkin should have a trial.

The resolution was put to the meeting and carried unanimously.

Mr. H. C. Boyes read a paper by Mr. Bogg on "Dramatic Art and the Dramatic Reform Association"; Mr. Rathbone one by Mr. A. G. Symonds on "Dramatic Reform"; and Mr. Archibald Constable a paper by Mr. Charles Rowley, jun., on "Remedies for Staginess."

ON THE RELATION OF ART TO SOCIAL SCIENCE.*

Holding the office of President of the Art Section of this Congress, I feel in a position of some difficulty and responsibility. Difficulty, because this office has been filled with great ability in previous years, and much has been said of useful wisdom by my predecessors in this chair, and little new can be said concerning purely high-art questions. Responsibility, from the natural feeling lest any words of mine should hinder rather than help the cause of art, and the considerations concerning it which are taking place. It would ill become me to delay the important business upon which we are called together by expressions of personal feelings. But I may express my sense of the honour done to the position I hold at Oxford, by my being invited to take the President's chair at this meeting.

After somewhat careful thought, it has appeared to me that more good may be gotten from an address in this Social Science gathering, dealing with art from a social point of view, rather than with art from its very highest standpoint. Further, being called upon to lecture at Oxford upon the "History and Philosophy of the Fine Arts," it will be a rather pleasant change to address you upon matters of great importance (as they appear to me) relating to the existence or non-existence of the chances of art progress in the United Kingdom. And by that progress I do not mean alone the increased power shown in the painting of pictures, in the making of statues, in the building of cathedrals; but rather I would ask whether, taken generally, art, or the love of the beautiful, is getting to have any firmer grip upon the minds and lives of all classes,—that is, whether the necessity for being the possessor of a beautiful object rather than an ugly object is gaining ground? And if not, what are the chief impediments to the growth of refined tastes among the middle and lower classes? The driest philosopher, or the stiffest-necked utilitarian, will no longer now fail to give art an important place among the necessities of civilised existence. We certainly have an advantage in living in an age of reformation; in an age of freedom of speech, of intellectual growth, of courageous attitude against vices, narrowness, and pedantic usages of all kinds. There is a general desire for improvement among all classes, and a growing wish to cultivate taste. All this must be acknowledged, and yet we are far, very far, indeed, from being an artistic nation. South Kensington's vast machinery for art education, together with its beautiful collection of ancient and Mediæval art, has done something, indeed, to civilise design, and to educate designers into something of more reasonable artists than those who, previously to the Exhibition of 1851, exhibited the lowest corruption of taste. Our National Gallery in the great metropolis has, within comparatively few years, become one of the noblest collections of pictures in Europe. The great towns, Manchester and Liverpool, yearly open an exhibition of pictures, and there are signs in both cities of a desire for monumental art, a desire that the bare walls of their buildings should be decorated with mural paintings.

This great city has its Royal Academy of Arts, among whose members may be found not only distinguished painters belonging to its own nationality, but others, foreigners in blood, but brothers in art. The Universities of Oxford, Cambridge, London, and, as I am informed also, Edinburgh, have, within but a few years, recognised the importance of art as a branch of education by accepting bequests to form art professorships. The Grosvenor Gallery, through the noble enterprise of a single gentleman whose name is well known here, whose name can only be heard with respect by every artist, Sir Coutts Lindsay, has given to the public the chance of seeing a class of pictures long denied to it by

* By Professor W. B. Richmond, M.A., read as President of the Art Department at the Social Science Congress, October 11th.

the persistent non-recognition of their value by the Royal Academy of London. All this looks like vitality, and no doubt does prove a growing interest in art. But we must remember that these museums, these exhibitions, and these lecture-rooms, are visited by a comparatively small class of people; that the very heart of the population, standing mostly in need of æsthetic culture, or of its refining influences, is yet untouched by art; and that outside those whose appetite for what is lovely can be satisfied, there is a hungry crowd which would be satisfied too if it had the means, and were not dragged down into the slough of bad taste by daily influences acting unconsciously upon the minds of it. The vast strides of science, the rapid accumulation of wealth, railways, telegraphs, have created needs to be realised quickly. New towns have sprung up like magic. Old towns have been pulled about without regard to the historical or artistic treasures contained in them; the ruthless reign of iron has prevailed, the unfeeling hand of destruction has satisfied its lust, well nigh, let us hope. The reaction has come. But where are we?

Something worse almost than pulling down our churches has taken place. Restoration has caused even more ruin than the progress of railways. Many of the most interesting and beautiful creations in architecture have been swept away, and this done in no spirit of destruction, but with the mistaken idea that it is possible to restore old work at all: with the idea, too, that neatness and mechanical exactness will not only serve in the place of spontaneity of design, but that it is in point of fact superior and more desirable to it. If one-tenth part of that money spent in so-called restoration had been expended in preserving, by the simple means of adding a buttress to a weak wall or tower, or by strong oak timbers, unplaned, where the roof was weak, or by such-like structural repairs, monuments of the love and skill of those in bygone times, whose simplicity of life rendered simple their faith and ideas, would still remain to us, in the place of what may be called pious frauds. It was with a view to check the headlong and heedless rush of the restoration mania that the Society for the Protection of Ancient Buildings was brought into being. Late in the day through this admirable society has come (too late, indeed, to save much beautiful work from destruction), through the energy of its workers and the enthusiasm and courage displayed by its secretary, Mr. Morris, old work has been protected and respected under the advice of the society; and out of our own country, in Italy and France, the influence of the salutary example set by the Ancient Buildings Protection Society has borne fruit. The mother church of Western Europe, St. Mark's, at Venice, was threatened with destruction, — that noble façade, the labour of the twelfth, thirteenth, and fourteenth centuries, was to be pulled down and rebuilt. Through the exertions of the Ancient Buildings Society such a memorial was drawn up, signed, and sent to Italy, and by reason of the number of its signatures, and the importance of them, we cannot but hope and believe that it has brought the lovers of art in Italy to consider again before they withhold their words of expostulation at a project which would rid the world of one of its greatest treasures.

I have ventured to make use of the term "pious fraud." Restoration pretends at best to be what it is not, and never can be; it pretends to restore work to its pristine beauty, it gives new lamps for old ones, and, as in the ancient story, the new lamps are found to have no virtue in them. The magic of old work disappears under the hand of the modern workman, for the conditions under which the eleventh-century carver and the nineteenth-century carver have worked are so totally at variance that their labours cannot for a moment bear comparison, and it is out of all question that the modern work of to-day can have one iota of the spirit of the ancient work. Therefore, restoration has in it the nature of a deception, and must be most misguiding to those very classes whose correct and chaste taste we must be desiring to cultivate.

Architecture is such a generally necessary art to all, it enters into the wants of every-day life, that it should be, and is, one of the chiefest factors in art cultivation, and hence it can be made to retard or advance the progress of general artistic tastes. So that the placing of new and cold workmanship in the place of old, truly artistic and loving work is defrauding a very large class of people indeed, rich and poor, of the refining influences of superior and nobler work.

The very rapid and easy means of communication by railway and telegraph have in great measure broken down those local characteristics, both in architecture and manners, so interesting in older England. A general, very natural, and to be applauded desire towards greater equality among classes, brought about by modern facilities for their coming daily more and more into contact, has acted in making the lower class ape the appearance of wealth and show of the class just above it. So that, instead of being content with real stability, it demands ornament in its dwelling-place, in its furniture, in its costume. Hence vulgarity, bad work, bad building, bad design, and in the end a tumble-down and demoralising appearance of rottenness or flimsy raggedness. Few sights can be said to be more depressing than the ill-built, stuccoed labourer's house now erected in a village street, mean to the last extent, he it understood, having no inch of good work or interest about it. Sad is its cold slate roof, indeed, in contrast to the old thatch, cool in summer and warm in winter. Melancholy the contrast between its bad bricks and the oak timbers, joined and well mortised, which had stood often the wear and tear of centuries in an old cottage. The taste of the inhabitant of the senseless edifice is lowered. Rarely do we find the same sign of care taken over his cottage garden, the same pride in his creepers of roses or grapes, as was visible in his more primitive dwelling. Yes, very naturally the man, though poor, is influenced by the vulgar want of association, and his pride, in his unsympathetic dwelling, of the comeliness of its surroundings, is ground out of him by it; he becomes vulgar, no longer simple, liking his imitation and really comfortless house because it has window-sashes like the squire's house, and he deceives himself into the thought that so he is a bit higher in the social scale. This instance is only at the confines of the general ostentation which is the product of modern civilisation, and can only be checked by the energy of art.

Checked by those who have taste, and who have a right to speak, saying without fear and in perfect faith in their own convictions, that where the heart is not simple, where there exists a grasping for another's social place, there will exist neither beauty nor morals. It is admitted, of course, that the old will not last for ever, that new cottages must be built; but let them, these new ones, at least be built (in an age boasting of its superior science and superior facilities) as well, and as lastingly, as the old were built. It comes to this really in the long run, that those who desire their dwellings, their clothes, or their furniture, to appear more costly than they really are, are the true delinquents. These are they who pervert taste. Solid stone or brick walls, well roofed, the strongest and simplest furniture, without the overlay of cheap and bad ornament, woollen or linen unadorned garments, will never be vulgar. If this fact could only be made clear to the minds of most of us, a better style, both in house building and house furnishing and dressing, would come about. From a clearly practical point of view, it is so evident that although the first outlay may be greater in building, furnishing, dressing in a solid or simple manner, repairs so expensive and constant need be but rare, and, too, that mental demoralisation where repair cannot be afforded, caused by the rapid decay of showy but bad work, will be avoided.

No one will deny the moral influence exercised, even unconsciously, upon the whole human race, and, too, even upon animals, by the nature of their daily and hourly surroundings from earliest years. That this influence may be good or bad, in morals and æsthetics, needs no words from me.

Now, believing this, and being anxious for that large lower class which composes our labourers, agricultural and others, more especially for the sake of those who will exercise themselves in any craft, such as building, carving, carpentering, cabinet-making, what can we do during the few early years of their education which might guide their tastes in a good direction? And further, what agencies are there at work in the general surroundings of our great cities which tend to degrade rather than to elevate the love for what is beautiful and refined?

I take it for granted that those who are here to-day are interested in art, and that there will be found no one who will say that any child will be less fitted in after-life to perform the simple duties of an artisan or labourer who has been led by daily contact with beautiful objects to prefer them to ugly objects. And though I quite think there are none here who believe that dulness is moral, joy immoral, ugliness chaste, beauty unchaste; yet (though chiefly exploded) this theory has not been without its votaries among excellent though misguided moralists. Now, science has provided us with a means in photography, cheap, and by recent discoveries permanent, by which at small cost any quantity of reproductions of noble works of art in all its branches may be obtained.

I have mentioned that there is a very large class which, through various causes, either from want of desire brought about by faulty early education, or want of means, from overwork, or want of holidays, do not make use of the advantages possible to it of visiting museums, galleries of pictures, or attending lectures upon subjects of æsthetic import. This being so, are there no means by which this present failing may be made up to the next generation? I think there may be.

Since the Education Act has been brought into full play in England, a chance offers itself to get at the very class we want to touch and educate to love what is beautiful and refined; and, as I venture to think, this class would be vastly improved, even morally, by early contact with beautiful objects.

No doubt many here have observed in their passages through picture-galleries, as I have, that the very poorest, those in rags and tatters, are often found rapt in admiration before early Italian pictures, and especially before those of a religious character. This fact has been most noticeable to me in the National Gallery of London. And when we come to think of it, it is reasonable that this should be so. The direct simplicity and reverential treatment of the early pictures has a charm to natures ignorant, perhaps idle, perhaps dissolute, concerning which there is no reasoning; but that bright spark of human feeling, wellnigh, perchance, snuffed out by the degradation of surroundings, is rekindled by its contact with the fire of pure love ablaze in early religious art. So that we must admit the possibility of touching the sensibilities and the nobler emotions of those in the lowest scale of life by the elevating influences of art. Photography being the cheapest and most exact means at hand for the purpose, I would suggest that our Board schools, each and every one of them, and our parish and Sunday schools too, should, under wise guidance of a committee of taste, provide themselves with photographs of fine works of art. And these should not be confined to reproductions from pictures only, but should include architectural details, furniture, patterns, and designs of all sorts. And further, I would have casts from fine carvings, which can be purchased at such a moderate rate as few are aware of; these, with the photographs, should be hung in order upon the schoolroom walls. Every child who can learn to write, one would think, could learn to draw, up to a point to be of great service in after life. Think of the numbers and numbers of artisans who in the departments scattered over the country under the supervision of the Art Department at South Kensington, whose rough and hard-worked hands during the day handle the pick-axe, or trowel, or even spade, endeavour in the evenings to train themselves by tracing the delicate curves of a Greek honeysuckle carved on a stele, or by copying the fanciful ornament designed in years gone by by a Gothic workman. No better was he than these present workmen are, only, having lived in a more artistic and vital atmosphere, his art had life and meaning in it.

What difficulties to such as these artisans are would have been overcome, if in early life, while yet supple, as not yet rendered stiff and difficult of command by the daily exercise of rough work in order to exist, their hands had been cultivated, even up to a limited point of control and sensitive delicacy of touch. And if, at the same time that the young hands are learning, the impressionable youthful mind be cultivated through the eye to dwell upon beautiful objects, what a seed of profit and delight is sown. Of course, it is easy enough to see that there would be many failures attendant upon such a scheme, and a pessimist may say, "Ah, yes! but what good would come out of such super-refinements? You are only training a side of the mind which will never be brought into play in after-life; you will only make your people discontented with their lot in life, and

unwilling to fulfil its drudgeries." But the answer to all this is, "You are only presupposing a result upon a scheme not yet tried; you are only begging the question in stating that cultivated instincts towards refinements weaken self-control and the exercise of severer duties." Further, by teaching children of the artisan class to draw, you are furthering them with advantage in the pursuits that may be in store for them in after-life, and by accustoming their young eyes to dwell upon beautiful design, you are stimulating a faculty where it exists, though latent, perhaps. Again, morally, by teaching the elements of drawing, you put amusement within reach by which spare hours may be enriched, time employed otherwise spent in the tavern.

Healthful amusements, occupations for the eye and hand, are enemies of vice, and the strong armour of probity.*

THE HEALTH DEPARTMENT AT THE EDINBURGH CONGRESS.

SOCIAL SCIENCE ASSOCIATION.

On the 7th inst. the special question for discussion was: "What are the best areas for sanitary purposes, and how far should there be a revision of the mode of electing and continuing the services of the officers under the Public Health Acts?"

Several papers bearing upon it were read, and there was a discussion, in which a number of gentlemen took part.† A general opinion was expressed as to the failure of sanitary action in Scotland, and that an amended Health Act was necessary.

Mr. Greig, inspector of the city parish, Edinburgh, quite concurred in the call for extension of areas for local sanitary authorities. He thought that parochial boards were now very much hampered by the narrowness of the localities they had to deal with, and the objections of the ratepayers to incurring any heavy expense. He thought, at the same time, that the constitution of the parochial boards required improvement, and that an extended area was required as much for Poor-law as well as sanitary administration. He would not, however, increase the number of boards. He thought, rather, that local boards should be consolidated.

Mr. H. H. Collins, hon. secretary of the Department, said he had carefully read over the Edinburgh Act, and he could not understand how, if that Act were carried out in its integrity, and it was not obstructed more than it was in human nature to obstruct, it should fail to prove satisfactory. With it the inhabitants of Edinburgh would be protected, in the question of public health, in a way which no other city in the United Kingdom was at the present moment protected. In that book they had the Bible of public health. Their Act, in fact, should serve as a model for them in other parts of the United Kingdom in their efforts to lower the death-rate, and in that way to lower all the other rates to which they were subject.

Mr. G. W. Hastings, M.P., president of the Council, pointed out that the recommendation of the Royal Commissioners in favour of the adoption of the union as the rural sanitary area, on which the last Public Health Act was framed, had been carried only by a majority of one. The minority had been in favour of the county as the sanitary area. Now, the result of adopting the union had been to make it impossible for rural sanitary authorities to pay their medical officers salaries which could, under any circumstances, induce them to give up private practice and devote themselves to sanitary work. In his opinion, it was a fatal error to cause a medical officer of health to engage in private practice; first, because sanitary functions at the present day were such as demanded not only all the time, but also all the thought and energy of the medical officer who undertook them; and, second, because very often his duties as a public officer conflicted with his own private interests in the pursuit of his own private practice. Accordingly, this adoption of the union as the sanitary area was one of the first things which the Legislature should undo. Even if no other thing were done, this alone would be productive of great good. In his own county of Worcester they had ten rural unions, and, between them and the small burghs, from 800*l.* to 1,000*l.* could easily be paid to one skilled and efficient medical officer, who could do the whole sanitary work of the county.

On the 8th, the special question for discussion was, "What is the best mode of amending the present laws with reference to existing buildings, and also of improving their sanitary condition, so as to render them more healthy, having due regard to economical considerations?"

Councillor Gowans, Edinburgh, opened the discussion. There were, he submitted, radical flaws in our present system of regulating the erection of buildings. The Public Health Act of 1867 was a step in the right direction, but it was intended chiefly to apply to small towns, and was largely permissive; therefore, one community might observe proper precautions, while another was permitted totally to neglect them. Hitherto advances in sanitary science had almost invariably been the result, not of precaution, but of the scare from time to time produced by some frightful visitation of contagious disease. Progress, therefore, had necessarily been spasmodic and unsatisfactory. At the present day the conditions of sanitary well-being were becoming better understood; and he submitted that the following reforms should be given effect to:—(1) There should be drawn up a code of public law on the subject of health applicable to the United Kingdom, and compulsory throughout. (2) There should be appointed a Minister of State for Public Health, with a seat in the Cabinet, to whom local authorities should be directly responsible for due administration of the law. And (3) that no person other than an architect, educated, examined, and qualified as a lawyer or a doctor now was, and under a corresponding responsibility, should be permitted to submit plans to a court. Whilst economical considerations must not be overlooked, they must not be, as at present they were, nearly the main consideration; and Parliament ought to step in and enact that no mere money considerations should interfere to prevent proper sanitary appliances for the preservation of the public health.

Professor Fleeming Jenkin, Edinburgh, read a paper giving an account of the Sanitary Protection Association, founded at the suggestion of the writer in the spring of 1878, to effect the objects indicated as desirable in the question before the Congress. In consideration of an annual payment,—usually of a guinea,—the member obtained:—1st, a report on the condition of his house; 2nd, inspection of alterations made; 3rd, an annual experimental test of the condition of the drainage system. The society was a mutual benefit society, closely analogous to steam-boiler associations. The association numbered about 500 members, and had worked smoothly and effectively.

Sir Robert Christison supplemented Professor Fleeming Jenkin's paper by stating, as president of the association, that the inception and successful results of the association were due to the Professor. He had large experience of the great good which the association had already done. His only surprise was that, instead of their now having 500 subscribers in Edinburgh, they should not have 5,000. Referring to the new Edinburgh Municipal Act, he said the proprietors of buildings might erect buildings one-half higher than the width of the street in which they were built. It was a gross error to allow any street to be so constructed. It ought to be the very reverse.

Dr. Wallace, Greenock, stated that in Greenock many of his suggested improvements were defeated by the action of the Dean of Guild Court, which, he was sorry to say, was too largely made up of speculative builders. But he hoped, as the result of recent action in the town, the Local Authority would be enabled to see that the houses to be erected on certain vacant pieces of ground would be built in conformity with proper sanitary requirements.

Dr. Alexander Wood, Edinburgh, thought, with regard to Councillor Gowans's proposal to secure better-educated architects, that was not what was wanted; but what was wanted was a provision that, when an architect, from carelessness, or something worse than carelessness, built unhealthy and dangerous houses, he should be amenable to be punished by law. The question they had to answer was this,—Were they to allow the poorer classes to remain in houses that generate vice? When a house was unsanitary, it should be pulled down and got rid of. But the work of meeting this evil would not be done by Parliament. It must be done through a philanthropic movement among such of the upper classes as were willing to give their money to the removal of the people from these houses.

Mr. H. H. Collins pointed out that in London they had what Councillor Gowans desired in the way of the better education of the architects, in the shape of the Institute of British Architects, whose certificate was necessary to the appointment of district surveyor, which he himself held.

Sir John Rose Cormack, Paris, remarked that sanitary and domestic architecture were in Edinburgh, and in Great Britain generally, very much in advance of their state in Paris. In fact, all that he could say of them in Paris was, that they were deplorably bad from our point of view,—bad for health and bad for morals. They were nevertheless, deserving of study, as they showed the natural outcome of the evils against what sanitarians were in this country raising a warning voice. In all our large towns the increase of value in property had a dangerous tendency to lower the health-standard of the inhabitants. Even in Edinburgh there was reason to fear that buildings were becoming too much crowded together; the back greens in the new town, Sir John believed, were in danger, which was much to be regretted, as they were, as open spaces, invaluable to the public health. Sir John said that in Paris it is not difficult to point to architectural peculiarities, and social arrangements contingent on these peculiarities, which perpetuate *foci* of infection, and disseminate contagious diseases. The stranger admires the Avenue de l'Opéra and other spacious avenues, with their tree-adorned cleanly-swept pavements, the carefully-watered dustless roadways, and the stately houses. But let him take a back view, and he would turn away in disgust. The building plan which has been followed with wearisome sameness prevents the possibility of cross ventilation. Light and air are excluded. The windows at the back are hemmed in by lofty side walls. Then, again, the servants of each family living on the different flats are crammed into the top story, where they form a population by themselves, in constant communication with the worst slums of the town. This is the plague-spot of Paris. Walking one day in one of the superb streets now adverted to, a French friend truly remarked to Sir John that each fifth floor was a *foyer de perdition*—a hotbed of moral and physical pollution. This architectural peculiarity of Paris, Sir John said, was a thousand times more demoralising than the much-reprobated "bothy system" of agricultural Scotland. Sir John went on to show why typhoid fever and diphtheria were becoming more and more endemic in Paris. He also said that the suppression of cesspools now being carried out was fraught with danger, for the house supply of water was inadequate to the flushing, and the plumber work and masonry were imperfect.

Mr. Allan Carter, C.E., pointed out that an architect was expected not only to know all kinds of sciences, but also to be able to charm his clients out of all opposition, whether that were financial or prejudicial. There was, notwithstanding these difficulties, a very large number of architects in Edinburgh who were thoroughly competent both as artists and as practical men.

The President (Dr. Beddoe) in summing up the result of the discussion, said that in England about 64,000*l.* a year was paid to medical officers of health, besides various amounts paid by various districts who did not accept Government aid. That sum, if judiciously divided, should provide the services of a sufficient number of competent medical men, who should give their entire time to the work. It was worthy of notice that in the last few years the mortality in the seven large towns was considerably less than that in the towns next below them.

Professor Fraser moved, and Councillor Gowans seconded the motion,—"That the meeting strongly recommends that the Council shall consider the question of the sanitary rural areas of Scotland, with a view to an amendment of the law by their extension," and it was unanimously adopted.

On the 9th Dr. Beddoe delivered

THE PRESIDENTIAL ADDRESS.

We are compelled to restrict ourselves to a few of the more salient paragraphs:—

"The subject of modern houses for the working classes—how they are built, and how they

* The remainder in our next.

† We recommend those who are interested to see the *Scotsman*, in which journal, day by day, full and careful reports have been given.

ought to be—has frequently been debated in this section, and would furnish material for a dozen addresses such as mine. I will make but two or three remarks on it in passing. Landlords, whether from philanthropy and a sense of duty, or influenced by public opinion, have done much to improve the dwellings on their estates, and speculative builders have, to some extent, been coerced by building Acts and bye-laws; but I do not think the improvement is so great as is usually supposed. If it were, one would expect to see a decided improvement in the death-rate from phthisis, from pulmonary diseases, and from rheumatism; for warmth, dryness, and proper ventilation ought to act favourably upon all these; whereas, in fact, if phthisis has decreased, other pulmonary diseases have quite made up the difference; and there is no improvement in rheumatism. I should say that, as a rule, the requirements of decency are more studied than they used to be, and that, perhaps, dryness of site and foundation is more looked to; moreover, by the persistent action of medical men and sanitarians, including many names well known in this section, so much has been done for water supply and sewerage, and disposal of refuse, that the great scourge of enteric fever is being gradually abated; but thin walls, bad mortar, and flimsy roofing cannot make warm and dry houses. One curious and unexpected result of building improved cottages has been brought to my notice. I am informed that in a certain Highland district where the proprietors have exerted themselves to build decent and air-tight dwellings for their small tenants, crofters, and labourers, instead of any improvement in health following, consumption, formerly uncommon, became very rife and deadly. Similarly, the natives of New Zealand, though their ordinary mode of lodging is about as ill-contrived and unwholesome as can be conceived, are said to suffer in health, and specifically to become more phthisical, when they take to living in houses of the European pattern. In the case of the Highlanders it is probably want of ventilation which is the fault of the new and comfortable houses. On the whole, it would probably be well to adapt to cottage-building the primary rule of British politics, correcting the evils of the local type of dwelling, whatever it may be, rather than seeking to introduce an entirely new one. The present Earl of Derby, in an address delivered to this association several years ago, recommended that the difficulty put in the way of constructing workmen's dwellings in towns by the exorbitant price of sites should be met by increasing the vertical elevation of the buildings. And we see that the elevation of buildings is constantly being increased, though not so much in the case of workmen's dwellings as of upper class houses, hotels, and warehouses. The change is not one to be commended. A street 50 ft. wide, with houses 80 ft. high, is scarcely more pervious to sun and wind than a lane of 20 ft., with houses of 32 ft. The population on the same area will probably be about the same; and Dr. Farr has shown us that, *cæteris paribus*, the rate of mortality increases as the density of population. Lofty staircases tell unfavourably on the health of those who frequently ascend them; hence the anæmia and functional affections of the heart which are the plague of London housemaids. And there are other evils connected with over-lofty houses well known to the citizens of 'Auld Reekie.' . . . . As for dwellings, though the multiplying of enactments is had, and the multiplying of officials is worse, increasing expense and making openings for jobbery, I am disposed to favour a moderate extension of legislation, especially in the direction of prohibition of what is certainly known to be mischievous or unsafe. Thus it seems monstrous that men should be allowed to build new houses within ordinary flood-mark, as has been done in hundreds of cases within my own knowledge of late years. There are other offences against the laws of nature which are so clearly proved to be such that they are almost criminal, such as carrying a soil-pipe under a house, or placing a water-closet in the middle of it, neglecting to trap a main-drain, and so forth. Surely the perpetrator of these things ought to be held responsible in purse or in person. When an overworked or muddle-headed signalman or pointsman commits a blunder which has fatal consequences, he is amenable to the criminal law; much more should the artisan be so who by scamping his work brings death into an unsuspecting household. I cannot agree with those who say that the public, the house-tenants, are generally indifferent to these things, because they avoid putting themselves to an expense they can often but ill afford in investigating their house-drains for the sake of a doubtful benefit. I should say that among the upper and middle classes at least there is a great though vague horror of 'bad drains,' but they have not usually the skill nor the power to protect themselves, the mason's and plumber's work, good or bad, being covered up or concealed. Few principles in building seem to me more valuable than this,—that the whole work connected with the drainage of a house, sinks, soil-pipes, ejects, and so forth, should be so placed as to be readily inspected and investigated. Meanwhile, as the public are incompetent to protect themselves, it seems to me that the liberty of builders and plumbers to do mischief should be closely restricted."

THE WRECK OF THE SCOTCH EXPRESS.

Railway collisions are becoming a stock-entry in the weekly journals,—not to say in the daily papers. The subject is assuming a magnitude that demands special treatment, rather than such space as can be spared from columns like our own. But there is one lesson which, in our opinion, has been loudly proclaimed by disaster after disaster of late; that is, that we have been too much in the habit of looking to mechanical instead of to moral safeguards. So strongly was the danger of this temptation felt by some of our earliest and most experienced engineers, that they set their faces, perhaps with too much prejudice, against anything like automatic appliances on a railway. This, no doubt, is erring in one direction, but it is quite as unsafe to err in the other, and to throw on any real or imagined scheme for the perfecting of mechanical appliances the responsibility which really depends on the human agent.

With regard to the latter, the obvious importance of adequate pay, limited hours of work, provision for old age and illness, and pecuniary interest, to some small extent, in the safety and in the profit of the working of the establishment, is not less than that of perfect discipline, clear regulations, duly apportioned responsibility, and sure punishment for neglect or breach of order. To that the experience of the wreck of the Scotch express near Leicester, on the 9th of October, teaches us to add uniformity of occupation. In such matters as the working of signals, or the driving of an engine, where a man has one thing to do, which he has done, and done well, for a long time, there is a certain danger incurred by setting him to do something else. Thus Hill, the driver of the wrecked train, is a man of good conduct, long experience, and high character. But on the night in question he was driving an engine of a different construction from his own; and to that fact his overlooking the condition of the gear is no doubt primarily to be attributed. This is a very serious warning to railway managers, as to the distribution and employment of even their best men.

Even more serious than the question of personal responsibility is that of volume of traffic. Looking back to the very commencement of the railway system, we find that this subject has occupied the anxious thought of the fathers of the English railways. How much revenue can be earned from a track of rails with safety is a question that has never been duly investigated. Intervals of ten minutes between following trains were at one time thought to be indispensable. But on the Metropolitan Railway, in 1874, 193 trains left the Moorgate Station, on one line of rails, in every day of eighteen hours, so that the succeeding despatches were only five minutes apart. This enormous traffic, which earned in 1878 38,600*l.* per mile per annum, is carried on safely, because the trains all run at one speed. The moment difference of speed for different trains is introduced, a source of danger springs up; the effects of which, on the one hand, reduce earning power, and, on the other hand, render the avoidance of collisions almost impossible. The London and North-Western, the Great Northern, and the Midland Railways together, have twelve tracks of rail for more than twenty miles out of London. With all these twelve, carrying a traffic that varies in speed from twelve to fifty-four miles an hour, they earn a gross revenue per mile of their aggregate course of less than half that earned on the two tracks of the Metropolitan. And carefully managed as these three great lines are, we find that, in 1878, twenty-six reported accidents to passenger-trains occurred upon them, that being the safest year on record. Thus it is incontestable that the introduction of different speeds on the same railway at the same time limits the earning capacity of the line, and increases the liability to collision to an enormous amount. This is the problem we now have to face, and we only wish that we saw any good reason for concluding that we have come to the close of the chapter of disasters for 1880.

CAST-IRON WATER-TANKS.

It is not very creditable to the constructive skill of English engineering that so many cast-iron water-tanks should have been destroyed by failures, the side plates having been ruptured. In all the cases the failure has been attributed to the inner tie-bolts having given way through rusting at the point of connexion, or the cast-iron "snug" has broken, or the tie-nuts have been too few or imperfectly placed, and too weak. A few plain and short rules may probably prevent, or tend to prevent, such failures in future. "Accidental" failures they are not, but constructive blunders. Cast iron is used for railway-station tanks; but these are not, as a rule, very deep, seldom exceeding 6 ft. in depth, 5 ft. of water, and it is in vertical depth that there is danger. Cast iron is used for tanks in preference to wrought iron, because it endures longer under exposure.

As to the rules. The pressure of water against the sides and ends of a tank is in proportion to the vertical depth of the water, and without going into nice calculations, may, for safety, be roughly taken as ½ lb. per square inch for each foot of depth. A tank to hold 10 ft. in depth of water may therefore be assumed to have a pressure against the sides equal to the full pressure at half the depth, or, say, 2½ lb. on the square inch.

For tie-rods.—The best wrought-iron bears a breaking strain equal to 25 tons on the square inch, but it will not be safe to use more than 5 tons of this assumed strength.

The whole of the support to the sides and ends of the tank (in large tanks) should be assumed to be given by the inner stay-rods, the strength of the tank-plates not being noticed.

In a tank to hold 10 ft. in depth of water safely, there should be two tiers of tie-rods. The lower tier, 3 ft. 6 in. from the bottom of the tank; the upper tier, 7 ft. The top of the tank will be tied by the roof-timbers.

The tie-rods must not be allowed to swag, and so strain themselves and the tank, but must be supported by vertical supports inside the tank.

Every tie-rod must go through the tank-plates at right angles, and be secured to a large outside washer, say from 1 ft. 6 in. to 2 ft. square, and the screw-threads at the inner couplings must not weaken the tie-bolt, but be forged, so as to leave the full strength of the tie-rod.

There must be no diagonal ties, but each tie must have a direct pull, not on the tank-plate, or upon inside brackets, or cast snugs, but on the outside washers. A tank so constructed and so stayed will not burst. It is assumed that the bottom of the tank will be securely supported; the pressure on the bottom plates of a 10-ft.-deep tank may be taken as 5 lb. per square inch.

It will not be desirable to construct elevated cast-iron tanks much deeper than 12 ft., as it will be safer to increase the area rather than the depth. Cast-iron will, of course, bear a very much greater strain than 10 ft. head of water; but there would be a complication of tier-above-tier of tie-rods, and in filling and emptying the sides of the tank would expand and contract unless the tie-bolts were cottared or screwed up tight, and maintained tight.

Civil Engineer.

P.S.—2·3 ft. in depth of water equals 1 lb.

Museum of Sanitary Appliances for Edinburgh.—A correspondent suggests the desirability of establishing in Edinburgh an offshoot of the Parkes Museum. That Edinburgh should have a museum of the kind is certain, and this would be a good moment, while the attention of its citizens is awake to the importance of sanitary measures, to attempt the foundation of it.

AN ARCHITECT'S TOMB IN TORONTO.

THE RAILING FROM ST. PAUL'S.

The tomb of which we give a view has been erected on a portion of High Park, Toronto, by Mr. John G. Howard, of that city, architect, in memory of his wife and in readiness for himself. The cairn is constructed with granite boulders. Mrs. Howard was a Scotch lady, which accounts for the cairn. Mr. Howard himself "is a Masonic Knight Templar,—therefore the double pedestal, terminating with the Maltese cross." The consecrated ground on which it stands is inclosed with some of the old iron railing which surrounded St. Paul's Cathedral, London, England, for 160 years. The cost of erecting the tomb, including vault and iron railing, amounted to $3,120. The granite boulders are all bedded in Portland cement against a brick shaft in the centre, which supports the marble pedestal. This weighs over 10 tons, and came from the Rutland Quarries, Vermont, U.S. Engraved on a brass plate, and fixed round one of the gate-posts of the old iron railing, is the following inscription:—"Sacred to the memory of John George Howard and Jemima Frances, his wife. John George, born 27th July, 1803; Jemima Frances, born 18th August, 1802, died 1st September, 1877. Aged 75 years." On a brass plate fixed round the other iron gate-post:—

"St. Paul's Cathedral for 160 years I did inclose.
Oh! stranger, look with reverence.
Man! man! unstable man!
It was thou who caused the severance.
J. G. H.
Nov. 18th, 1875."

The vicissitudes of the railing are curious. After its removal from St. Paul's it was purchased by Mr. Robert Mountcastle, Waverly-place, St. John's-wood, London, of Mr. J. B. Hogarth, iron merchant, London, and shipped by him in good condition, on board the steamship *Delta*, for Toronto, on the 14th of October, 1874. The *Delta* went on shore about five miles below Cape Chat Light, on the 8th of November. A portion of the railing was recovered from the wreck, and sent to Montreal by the salvage men in the spring of 1875, in a very mutilated state, but was brought from Montreal by Mr. Howard, 17th of August, in that year, and arrived in Toronto on the 21st of the same month. It was repaired by Messrs. William Hamilton & Son, at the St. Lawrence Foundry, Toronto, and finally fixed on the stone curb where it now stands, on the 18th of November, 1875.

Mr. Howard has bebaved munificently to Toronto. High Park, which contains 165 acres, was his property, and had cost him $50,000. Having been largely employed as an architect and civil engineer in Toronto and Canada generally, be considered it his duty to return a portion of the property be had accumulated to the Corporation of Toronto, and the land has been conveyed in trust to the citizens for a public park. One hundred and twenty acres they already occupy, and the other forty-five acres, with all the buildings thereon, they will have after his death, with the exception of the consecrated eighth of an acre, on which is erected the tomb we have illustrated.

DECORATIVE SUGGESTIONS FROM NATURAL FORMS.—No. II.

The aloe and cactus tribe of plants are for the most part rather eccentric than beautiful in outline or style, and not sufficiently decisive in design to furnish much suggestion for ornament; but there are some varieties which are exceptional in this respect. Of these, *aloe plicatilis* is remarkably effective and very regular in design. Its leaves, if they can be so called, grow in a radiating arrangement from the end of the stalk, but the lower leaf only actually and visibly springs from the stalk; the next leaf springs from within the folds of the springing of the lowest leaf, in the opposite direction; the third leaf in the same way develops from the springing of the second leaf, and so on to the top. Thus the bases of all the leaves form a considerable mass in prolongation of the line of the stalk, and regularly folded one within the other in alternate directions, hence the specific name *plicatilis* (*plica*, a fold). The leaves generally lie all in one plane, more so for the most part than in the specimen sketched here, which is a little more irregular; the growth has thus a remarkably artificial and contrived appearance, and requires in some respects less conventionalising than is often the case in translating natural objects into ornament. It is here shown adapted for a wrought-iron railing or grille, in which the folding of the leaves one within another can be carried out almost as in the natural plant, and in a manner perfectly in accordance with the character and the working of wrought iron. It may be added that the turn of the sprays in various directions, falling to one side and the other in the general design, is also almost directly borrowed from the natural plant, in which the collections of leaves grow,—some upright and some drooping in graceful curves to one side or the other, the curves being merely made symmetrical in adapting them to the present design. A more conventional treatment of the plant for wood inlay is suggested, such as might form the border of a wainscot.

The *plicatilis* is a tree aloe, with the stalks growing from a central stem, thus differing from the most typical form of aloe, which is only a mass of thick fleshy leaves all springing from one short stump. This typical form of aloe, as was remarked above, is little suitable for decorative use; but a little specimen of *aloe variegata*, which is here sketched (the plant is only 4 in. or 5 in. high), though keeping the general character of the aloe type, is exquisitely graceful and finished in its lines and construction and its varied arrangement of tints (white and green). In plan the plant is triangular, with slightly hollowed sides, and is almost as regularly constructed as a work of art. It is, however, perhaps for that very reason, difficult to treat ornamentally; an attempt is here made in the form of a marble inlay for a border.

PROPOSED POST AND TELEGRAPH OFFICES, WELLINGTON, NEW ZEALAND.

It always gives us pleasure to comply, so far as we may be able, with requests from our distant colonies that we should make known "at home" what they are doing. In our present number we therefore publish, with some other colonial matters of interest, the design by Mr. Thomas Turnbull, which has been selected in competition, for the Post Office and Telegraph Office proposed to be erected in Wellington, New Zealand, and will, we believe, be carried out. The offices will occupy the whole of the block from Grey-street to Panama-street, the frontage to Custom House-quay being 172 ft., while the Grey and Panama street frontages will be 70 ft. each. The building will be Italian in style, and will be 61 ft. in height, a clock-tower rising from the centre of the front 150 ft. in height. The centre block will be accentuated by eight detached columns standing on pedestals, and surmounted with an entablature and balustrade, the angles being also accented by rusticated quoins and pilasters. The first and second stories will have segmental-headed openings, with pilasters between, those of the third story being circular, and the whole will be surmounted with a handsome entablature, and a parapet with balustrade over it. The pediments at each angle will contain the royal arms, and will be ornamented on the Post-office portion of the building with a statue of Mercury, while Jupiter will occupy a similarly commanding altitude at the Telegraph portion. The public entrance will be in the centre of the Custom House-quay frontage, a flight of steps giving access to an open vestibule, 28 ft. by 12 ft. The Post-office portion of the building will be between this entrance and Grey-street, the remaining, or Panama-street portion, being allotted to the Telegraph department. The postal boxes will be in the vestibule, and to the left will be the public room, 40 ft. long by 19 ft. wide, in which money orders, letters, stamps, &c., may be obtained. The private boxes will be in the rear of the mail-room, the entrance being from Grey-street, and the arrangements on this floor also comprise a strong-room, lavatories, and a letter-carriers' room, the dimensions of the latter being 15 ft. by 23 ft. The upstairs portion of the Post Office will be reached by a staircase from an entrance in Grey-street, and also a stair in the tower. Facing Custom House-quay will be a clerks' room, 39 ft. long, by 19 ft. wide, and another room for the chief clerk, 15 ft. by 19 ft. The secretary will have a room, 24 ft. by 19 ft., and the Postmaster-General and Commissioner of Telegraphs another apartment, 19 ft. by 20 ft. The inspector's room will be also on this flat, and will be 19 ft. square, in addition to which there will be a dead-letter office, 37 ft. by 19 ft., a messengers' room, 23 ft. by 12 ft.; a strong-room, 8 ft. by 12 ft.; and a cloak-room, 15 ft. by 13 ft.

The Telegraph Office will have its public entrance also by the vestibule, the public room being on the right, 31 ft. long by 17 ft. wide. This will be divided by a glass screen from the clerks' office, the latter being 32 ft. long by 10 ft. wide, and lighted in the rear from a paved court or area, 36 ft. long by 19 ft. wide. Upstairs, on the first flat, the whole of the frontage to Custom House-quay, will be an instrument-room, its dimensions being 73 ft. by 28 ft., and the rear portion will contain a storekeeper's room, 50 ft. by 18 ft., and another, 27 ft. by 18 ft. The building will be of brick, cemented, and the estimated cost is 17,000*l.*

PROPOSED WESTMINSTER PAROCHIAL OFFICES.

SECOND PREMIATED DESIGN.

In our present number will be found illustrations of the design by Mr. John E. Trollope, architect, to which the second premium was awarded. As in the case of the design selected for the first premium,* we condense some portions of the architect's own description. It was proposed that the whole of the basement-walls, including the footings, should be constructed in concrete; the external walls above the basement to have an external facing of stone, a lining of brick, and a core of concrete; the principal stair to be of stone, and all the main corridors of concrete, covered with mosaic pavement; the roof to be covered with Broseley tiles.

On the ground-floor the rate-collector has his separate apartment, with entrance from Gardener's-lane, and also internal communication with general offices. The other officers of the Vestry have the accommodation required, each being provided with a separate lavatory.

As to the elevations, the designer says,—"It will be seen that I have kept all the rooms on two floors, and avoided attics. I had two reasons for this; first, I felt that to produce a satisfactory effect, the vestry-hall ought to have an open roof. This at once precluded the idea of having rooms above it; and, secondly, that it appeared to me that any new building so much higher than its surroundings would have a most disastrous effect, and look obtrusive."

The tower is covered with a wooden roof, provided with a bell stage; below, a clock is placed, and again below is the great water-tank.

The cost of carrying out the design for the offices is estimated at 15,000*l.*

At the back of the general offices, with a separate entrance, is placed the assembly-room, provided with a stage or raised dais, gallery, ante-rooms for performers, ante-rooms for visitors, a porter's lodge, and a room for refreshments and the storing of chairs. The assembly-room, it was estimated, would accommodate 500 persons, and could be used for meetings of ratepayers, theatrical representations, concerts, lectures, balls, &c., and could be made self-supporting. The cost of this building could not be included in the sum of 15,000*l.* allowed by the Vestry, and was estimated at 3,800*l.* The assembly-hall, being entirely separate from the vestry-hall and offices, might be built at any future time. The architect has purposely kept the hall as plain in design as possible, retaining flat walls for colour decoration. The ventilation, he considers, would be perfect, and the acoustic properties good.

THE EQUESTRIAN STATUE OF CHARLEMAGNE, PARIS.

Visitors to the Paris Exhibition of 1878 will perhaps remember, among the many features of that great show, the colossal equestrian statue of Charlemagne, of which in our present number we give a view. As a portion of the exhibit of the well-known bronze-caster, Thiebaut, the group attracted, notwithstanding that its position was far from calculated to show to advantage the merits of its design, no small share of attention. At the time when the statue was placed in the Champ de Mars, no site had been decided on, and only recently, after much discussion, has its destination been

* See pp. 449, 453, *ante*.

settled. The remarkable design of the two brothers Rochet.—one of whom, Louis, died, it may fairly be said, in harness,—will at length find a worthy resting-place in the square of the Parvis Notre Dame in Paris,—a spot thrice hallowed by ecclesiastical, secular, and romantic recollections, and additionally interesting as being the original nucleus of this great capital, the island in which the primitive city for many centuries was concentrated. No spot, indeed, could have been chosen which would have been more in accord with the wishes, not alone of the authors of the statue,—both no mean archæologists,—but of the designer of the simple pedestal, the late M. Viollet-le-Duc, whose name is indissolubly connected with Notre Dame.

The brothers Rochet are, as perhaps may be remembered, the authors of the remarkable colossal equestrian statue of William the Conqueror at Falaise, as also of the Don Pedro (another equestrian and colossal statue), which stands in Rio de Janeiro. For France, a peculiar interest is connected with the memory of the Great Charles, whose reign shone so brilliantly in the Dark Ages over his vast empire, and particularly over Gaul, then but recently, to speak comparatively, freed from Roman rule. It was not the intention of the brothers Rochet, in creating this statue, to claim for their country the honour of having given birth to Charlemagne, whose name stands so prominently in the pages of French history. Germany, as is well known, has long set up her claim as the fatherland of Charlemagne, but the Rochets, after patient research, have satisfactorily proved, to Frenchmen at least, that the grandson of Charles Martel was born, not at Salzburg, but on the banks of the Oise, where resided, at the moment of his birth, Pepin and his family.

In the composition of their group the sculptors have, it will be seen by the illustration, most skilfully avoided the difficulty met with so often in equestrian statues, where the principal figure is not in violent action. The days have passed, apparently, when a Colleone, or indeed a Charles I., can be successfully designed by a new Verrocchio, a Donatello, or a Le Sœur, as quietly seated in calm repose; but the brothers Rochet, earnest as they have been in their literary and archæological pursuits, cannot, we suppose, be expected to study with the minute care of a Leonardo da Vinci the pose of an equestrian statue. The difficulty of the single equestrian figure has therefore been overcome by flanking the Emperor with the two famous and almost legendary figures of Roland and Oliver, sung of by Ariosto and the troubadours of old. The paladins leading the horse of Charlemagne, his hands are free for action; the left is firmly planted on the hip, the right grasps proudly the sceptre which the wise and good monarch wielded over the vast empire he had gathered under his rule.

The group is to be erected, as we have already mentioned, in the great square before Notre Dame, which has only recently been opened up by the demolition of the old Hôtel Dieu, to which reference was made not long ago in these columns. Here the statue will, in course of time, stand; but as yet no visible preparations have been made on the spot. The group, which is of bronze, and no less than 25 ft. high, will be placed on a granite pedestal,—designed, as above stated by the late Viollet-le-Duc,—and itself 16 ft. 6 in. high.

For France, a peculiar feature connected with this colossal group consists in its having been purely the work of private initiative, undertaken entirely at the risk and cost of two worthy artists, unassisted by the usual support of a Government subsidy. It is but a fitting recompense to their united labours that they should receive the reward of having their work at length erected in Paris, where their reputation stands high in the esteem of the world of art and of letters.

The Exhibition of Gas Apparatus, Glasgow.—On the 8th inst. Professor A. Vernon Harcourt, of Oxford, delivered, in the Barnhank Drill Hall, the first of a course of special lectures under the auspices of the Philosophical Society of Glasgow, on subjects illustrated by the exhibition of apparatus for the utilisation of gas, electricity, &c. Dr. A. Fergus, the president of the society, occupied the chair. The Professor gave an interesting address on "Domestic Gas-lighting," for which he received a hearty vote of thanks.

RHIND LECTURES IN ARCHÆOLOGY.

The second of the Rhind Lectures in Archæology was delivered last week in the Freemasons' Hall, Edinburgh. Sir Walter Elliot occupied the chair, and there was a large attendance.

Mr. Joseph Anderson, the lecturer, said he meant that day to deal with "Decorative Stonework." The St. Vigeans group first occupied his attention. In the course, he said, of repeated alterations, and latterly of a very extensive re-construction of the fabric of the church, it was found that the twelfth-century builders had utilised a large number of fragments of sculptured monuments as building material. After describing in detail the features of the various remains, the lecturer said he would group the points of interest of one of these remarkable monuments. It bore the cross on the obverse side, symbols and figure-subjects pictorially treated on the reverse. The cross was long-shafted, and the full-length of the stone. It was also peculiarly formed. The long-shafted cross was often called the Latin cross in contra-distinction to the cross with four arms of equal length, which was the common Eastern or Greek cross. But the lines of the Latin cross always made angles at the intersections of the arms. The cross he spoke of was not of the usual form of the Latin cross. It had semicircular hollows at the intersections of the arms with the shaft and summit. This was a peculiarity specially Celtic. The stone also bore an inscription in the Celtic language, written in the alphabet used in the Celtic manuscripts. It presented pictorial representations, which included the human figure, and a variety of animal forms, some of which were true to nature, while others were only imaginary. It presented pictorial representations of objects such as the mirror and the comb, which were true to the reality; and also of objects such as the double disc or crescent, which were found frequently recurring with a remarkable persistency of form on other monuments, although it was utterly impossible to give them names or tell their significance. Apart from the ornamental work on this monument, there are two distinct phases of art—a pictorial, which followed nature and reality, and a conventional, which followed arbitrary and unknown rules. After considering briefly what mode should be followed in the inductions from these rules, the lecturer said that from these features and these considerations to which they gave rise it was evident that, in contemplating the monument as a whole, we stood in the presence of a work of art which did not link itself on with any custom or usage existing in the locality at the present time. The Celtic language still survived in a small proportion of the place-names of the parish, but not one in a hundred of those to whom these names were familiar had any suspicion of their Celtic origin, and this inscription was now the only surviving witness of the fact that the Celtic alphabet as well as the Celtic speech was once known in the lowlands of Angus. The characteristic ornamentation of the monument was unfamiliar to modern eyes, and perplexing to modern ideas. Its symbolism was even less familiar than cuneiform inscriptions and Egyptian hieroglyphs. The stone remained, but the ideas which its art embodied have passed away with the culture which produced them. It had outlived that culture so long that the language it was intended to speak was now unintelligible. Yet that it once spoke eloquently to all eyes, who could doubt? Men did not make monuments without a meaning, unless when their poverty of invention obliged them to have recourse to obsolete forms, and to appropriate the symbols of a dead faith. In St. Vigeans they had a very remarkable group of monuments, remarkable alike as regarded their number and their character, for thirty such monuments was a very large number as compared with all the others existing. If they pictured this group of thirty such monuments clustered round the pre-Norman church on its isolated mound, if they considered the quality of the art, the interest of the one fragmentary inscription that remained, and the mystery of the symbolical representations that occur among them, they could not but regret that a group of memorials so singularly interesting, impressive, and instructive, should thus have suffered irretrievable destruction. They could judge of what had been lost by what remained of these mutilated products of a national school of sculpture, to which the special culture of the present day did not disdain to turn for instruction and for inspiration. He could only draw their attention to the fact that these memorials were neither poor in design nor feeble in execution,—that they were, on the contrary, the productions of able minds and practised hands. Mr. Anderson then went on to speak of the form and characteristics of the Aberlemno group, and their relation to that of St. Vigeans, passing on to describe the Meigle group, and the general features common to the three groups. Special attention was directed to the intense Celticism of their decoration. The transition from the purity of Celtic art to twelfth-century types was then sketched, followed by a consideration of the special features of the pure Celtic type, the area of the type (which is extremely limited), the ruder type which became associated with it, leading on to the period of incised symbol stones. The relative sequence of the two types, and their association with a third, brought the lecturer to deal with the two varieties,—earlier and later,—of free-standing crosses. Speaking of one of the specimens at Iona, Mr. Anderson said it presented no figure-subjects, but was decorated in the purest style of Celtic art with such inimitable beauty, intricacy, and harmony of design, that he was safe in saying of it that no finer specimen of art-workmanship in stone exists in Scotland. Somewhat similar in style, and not inferior in workmanship, was the beautiful cross at Kildalton in Islay. The special feature of its ornamentation was the intense Celticism of its art. No other specimen exhibited this in such a striking manner. Its two panels were filled with divergent spirals and trumpet patterns, and mingled with circles enclosing groups of spirals, and wherever they might be found, and in whatever material they might be executed, would be certainly recognised as products of Celtic art. Nothing like them could be instanced among the art products of any other people or any other time. It might appear to some that he made such remarks as these with what might be regarded as needless iteration. But he did so because he wished to set clearly in the broad light of the present culture the important fact that many of these little-regarded relics of the earlier culture of our country were worthy of attention, for this reason, if for no other, that when they were gone there would be no more like them in the world,—the species would be extinct. It did not seem as if they yet realised the fact that as a nation we were the sole possessors of a series of art products unique in their character, and possessed of such merit as works of arts that the great world of culture would not willingly see them perish.

ELECTION OF TWO DISTRICT SURVEYORS.

At the meeting of the Metropolitan Board of Works on the 8th inst., the first business was to receive the following report from the Superintending Architect on a letter from Mr. R. L. Sibley, District Surveyor for Clerkenwell, requesting the Board to determine the amount to be paid to him, as *interim* surveyor of the late district of West Islington, by the incoming surveyors of the two districts into which the greater part of the district has been divided by the Board:—

"Mr. Sibley, in offering his thanks and acknowledgments to the Board for the recent addition made to his district,* also requests that the Board will determine the amount to be paid to him for his services as *interim* surveyor of West Islington. Mr. Sibley has been acting as *interim* surveyor for a period of ten weeks, and as comparatively few building works have been commenced and completed during that period, he will obtain no adequate return for his services unless the Board order the surveyors who may be elected to pay such a sum to him as the Board may consider equitable.

The fees received in the district during the year 1879 amounted to 1,084*l*. Assuming that the portion of the late district of West Islington, to which Mr. Sibley has been appointed, will produce 8*l*. per annum, and that the remaining portion is of the value of 1,000*l*. per annum, the proportionate value of the latter for a period of ten weeks would be 192*l*. Should the Board see fit to accede to Mr. Sibley's request, I think that the surveyor to be elected for the North-west Islington District might fairly be asked to pay Mr. Sibley 10*l*., and the surveyor for the South-west District 90*l*., in consideration of Mr. Sibley surrendering to them all fees to which he may have become entitled for work within the respective districts."

(Signed) George Vulliamy.

After some discussion, the Board resolved to accede to Mr. Sibley's request, and to adopt the recommendations contained in the Superintending Architect's report.

The Board then proceeded to the election for the two vacant surveyorships, taking that for

* See *Builder*, p. 246, *ante*.

North-west Islington first. There were thirty-three candidates for each appointment. The usual practice was followed of first voting for all the candidates in alphabetical order, and then selecting the six candidates who obtained the highest number of votes from whom to make the ultimate selection. For convenience sake, we give side by side the names of the candidates, together with the number of votes received by them in the preliminary voting for each appointment, viz.:—

	North-West Islington.	South-West Islington.
Ashbridge, A.	19	12
Bridgman, H. H.	22	18
Brooks, C. W.	15	10
Burton, W. J.	1	2
Carritt, E.	18	22
Conder, A.	14	14
Dale, D. R.	20	22
Edmeston, J. S.	8	11
Elkington, G., jun.	12	13
Ferguson, J. M.	9	6
Grellier, W.	3	2
Hammond, F.	29	0*
Hanbury, C.	0	0
Hewitt, E. R.	12	13
Hunter, P.	13	14
James, J. W.	13	10
Karslake, L.	8	7
Large, W. A.	20	19
Lees, W. H.	10	13
McDonell, G.	24	22
McLachlan, H.	12	13
Mundy, T. E.	7	5
Notley, F. C.	12	10
Pownall, R. E.	4	1
Quilter, J. S.	11	14
Seymgour, W. H.	15	12
Smallpeice, W.	7	6
Stenning, A. R.	21	17
Stone, T.	3	5
Street, E.	22	18
Taylor, A. T.	4	6
Todd, F.	17	15
Waine, W.	1	2

North-West Islington.

The five candidates who received the highest number of votes for North-West Islington were therefore Messrs. Bridgman, Hammond, McDonell, Stenning, and Street. There being a tie between Messrs. Dale and Large, a vote was taken as to which gentleman should be included in the six for subsequent voting, with the result that Mr. Dale received 19 votes and Mr. Large 12. Mr. Large was therefore out of this contest. The subsequent voting was as follows:—

	Second Vote.	Third Vote.	Fourth Vote.	Fifth Vote.	Sixth Vote.
Bridgman	9	—	—	—	—
Dale	16	16	16	16	—
Hammond	28	29	24	29	22
McDonell	24	20	20	23	12
Stenning	18	17	16	—	—
Street	19	12	—	—	—

Mr. Hammond was therefore declared to be the successful candidate.

South-West Islington.

The six candidates who received the highest number of votes in the preliminary voting for the South-West Islington surveyorship were Messrs. Bridgman, Carritt, Dale, Large, McDonell, and Street. The subsequent voting was as follows:—

	Second Vote.	Third Vote.	Fourth Vote.	Fifth Vote.	Sixth Vote.
Bridgman	10	—	—	—	—
Carritt	18	11	—	—	—
Dale	20	19	23	17†	14
Large	17	14	14	17†	—
McDonell	21	21	23	21	20
Street	15	17	13	—	—

The result, therefore, was that Mr. McDonell was the successful candidate.

Both the successful candidates thanked the Board for their election, and promised to fulfil the duties of their offices subject to the usual conditions imposed by the Board. They also agreed to conform to the Board's order as to the payments to be made by Mr. Sibley, the *interim* surveyor.

ROAD FORMATION AND STREET PAVEMENTS.

Sir,—I have read "Civil Engineer's" letter on the above subject with great interest and pleasure. Taking a great interest in macadamised roads, I agree with him it is of the utmost importance that the granite should be of the hardest description, especially in this time of steam rollers.

Could not "Civil Engineer," or other of your numerous readers, give some particulars as to the crushing strength of the principal granites now in use, for I am sure this information would be of great service to many of the readers of the *Builder*.

One Interested.

* Previously elected for North-West Islington.

† There being a tie here, the Board voted as to which name should be retained; Dale 20, Large 15. Mr. Large was therefore out of it.

THE SUNDAY SOCIETY IN EDINBURGH.

A largely and influentially attended conference under the auspices of the Sunday Society was held on Monday afternoon at the Royal Hotel, in Edinburgh, convened to consider the desirability of extending the Society's organisation in Scotland, particularly as regards Edinburgh.

The Rev. John Glasse, of Old Greyfriars (Church of Scotland), presided, and, in the course of an able defence of the objects of the Society, he ridiculed the idea that the friends of the Society were endeavouring to secularise the Sunday,—a fear engendered by ignorance and prejudice. The Sunday Society simply asked these people, since they could not interest the "lapsed masses," to allow the Society to try to do so by elevating their tastes and engaging their attention in loftier pursuits than those usually indulged in.

Dr. Andrew Wilson, Edinburgh, in a well-considered speech, which was much applauded, proposed the first resolution, approving the objects of the Sunday Society. This was seconded by the Rev. Alexander Webster (Church of Scotland). He said the question of opening museums and galleries on Sunday had made great progress in Scotland. Those who took part in it were now no longer talked of as irreligious. It was simply said that the change was not expedient.

Major-General Forlong seconded this resolution, and it was supported by Mr. Mark H. Judge (London), and carried. Petitions to Parliament were settled, and after several other speakers had addressed the Conference, it was agreed to establish a branch of the Sunday Society in Edinburgh. The meeting was very enthusiastic, and was one of the best of its kind ever held north of the Tweed.

COMPETITIONS.

Liverpool Conservative Club.—The Committee of the Liverpool Conservative Club some time ago offered three premiums for the best designs for a new Conservative Club to be erected on the site in Dale-street. The competition was limited to Liverpool Conservative architects, and twenty-seven competed, sending in twenty-nine designs, comprising 300 drawings. These have been hung in two large rooms in the Stock Exchange Buildings, and inspected by Mr. Waterhouse, who has awarded the premiums as follow:—First premium (100*l*.), Messrs. F. & G. Holme; second premium (50*l*), Mr. C. O. Ellison; third premium (25*l*.), Mr. George Bradbury. The committee of the club have endorsed these awards. A feature of the competition was that the motto system was discarded, each design bearing the name of its author. The site of the proposed building has an area of 1,100 square yards. The cost of carrying out the plans to which the first premium has been awarded is estimated by their authors to be 28,000*l*. They represent a building whose cubic contents are 710,000 ft. The front elevation (according to the *Liverpool Daily Post*) exhibits a rather striking façade to the main thoroughfare, with the chief entrance near Cumberland-street. The club will contain four stories, and the whole of the building is to be devoted to club purposes, with the exception of the basement, in which the offices of the Constitutional Association will be placed. The design is Classic in style. The plans of Mr. Ellison represent a building having cubic contents of 645,000 ft., the estimated cost being 26,855*l*. Mr. Bradbury's plans are estimated to cost 31,000*l*., representing a building having cubical contents of over 776,500 ft.

The Rowland Hill Memorial.—On the 8th inst. a meeting of the Committee of the Rowland Hill Memorial Fund was held at the Mansion House, the Lord Mayor presiding. There were present Mr. Alderman Nottage, Mr. Alderman Staples, Sir Francis Lycett, Sir John Bennett, Mr. S. Hope Morley, Mr. Charles Barry, Mr. Deputy M'George, Mr. Rokeby Price, Mr. James Whitehead, and others. The fund, including interest, amounted to 17,065*l*., most of which was invested. The sub-committee, with reference to the erection of a statue of Sir Rowland Hill in the City, and the provision of a bust of Sir Rowland in Westminster Abbey, recommended that they should be empowered to spend a sum of about 2,000*l*. on those objects. The City Commissioners of Sewers had granted a site for the statue at the south-east corner of the Royal Exchange, facing Cornhill, and the sub-committee recommended that from the twelve sculptors whom they had selected one should be chosen by competition under conditions which they detailed. The report was received. The sculptors who were stated to have consented to compete were Mr. Birch, A.R.A., Mr. Eli Johnson, Mr. J. Bell, Mr. E. R. Mullins, Mr. J. H. Thomas, Mr. Charles Bacon Mr. Adams-Acton, Mr. Keyworth, Mr. Williamson, Mr. E. O. Ford, Mr. Bruce-Joy, and Mr. Forsyth. Mr. Bell, however, writes contradicting the statement that he had consented to compete, and enclosing a copy of the letter which he sent in reply to the invitation to do so. In that reply he wrote,—"Although not unready, under certain circumstances, to contribute to a competition for a subject of two or three figures, presenting the opportunity for variety of design, I do not take part in unpaid competitions for a portrait statue by itself, not being able to afford to give thought and time for only the chance of employment." In reply to Mr. Bell's disclaimer, the secretary of the committee writes to say that Mr. Bell's letter "was only taken as declining to enter into an 'unpaid' competition. As the committee have decided to remunerate competitors for their designs and models, it was thought fair to Mr. Bell to give him an opportunity to compete under this very different aspect of the case. Of course the committee are quite indifferent as to whether the competition is to be without or with Mr. Bell." This epistle is not only impertinent, but, unless each of the competitors is to be remunerated for the design he sends in, somewhat disingenuous. If the writer has authority for the statement that the committee are "quite indifferent" as to the sculptors who compete, it is to be hoped that the subscribers to the memorial will not tolerate such indifference, likely as it would be to eventuate in a very indifferent statue to a man who has rendered the world a great service. [Mr. Bruce-Joy also writes to say that he did not accept the invitation to compete.]

St. Matthew's Church and Vicarage, Bayswater.—In a limited competition for rebuilding St. Matthew's Church and Vicarage, Bayswater, the committee unanimously selected the design submitted under the motto "Columns avoided," the author being Mr. John Johnson, of Queen Victoria-street, City. It is proposed to proceed with the church as soon as possible, the estimated cost of which, with tower and spire, is 16,000*l*., and the vicarage 3,000*l*. Messrs. Dove Brothers, builders, of Islington, will carry out the works under the superintendence of the architect.

MONUMENTAL.

Major Whyte Melville.—A memorial of the late Major Whyte Melville, the gifted novelist, whose untimely death a year or two ago was so widely lamented, has just been completed at St. Andrew's, N.B. It takes the form of a drinking-fountain, on which the sum of 700*l*. or 800*l*. has been expended. Occupying a well-chosen site in the long and wide thoroughfare of Market-street, it will form one of the most conspicuous objects in the town, being of sufficient height to engage attention from a distance. The stone used in the structure is (according to the *Scotsman*) principally Dumfries red sandstone, the columns and copings being of polished Dalbeattie granite. The lower basin of the fountain, which, like the two higher ones, is of red sandstone, but has a granite coping, and is approached by a step of the same material, measures 14 ft. in diameter, and rises 3 ft. 4 in. above the ground. From the centre of this basin there rises a cluster of five granite columns, surmounted by carved capitals of sandstone, which, in turn, support the second basin. On this basin, which is quatrefoil in plan, a great deal of work has been bestowed, the stone being elaborately carved in designs representing water-plants. On each face of the quatrefoil there is placed a medallion in white marble,—one showing a bust in bas-relief of the late Major Whyte Melville, by Mr. J. E. Boehm, A.R.A., the second and third bearing respectively the family arms and the shield of the Coldstream Guards, in which the deceased was an officer, and the fourth being occupied with an inscription. The third stage of the fountain is a reproduction of the second on a smaller scale, the arrangement of a basin supported by granite columns being repeated,

with the variation that the columns in this case are octagonal. Above this there rises a moulded finial of red sandstone, carrying the fountain to the height of about 14 ft. from the ground. Water will be discharged from gurgoyles, four of which are disposed round the second and four round the third basin, as well as from five jets, four of which are on the second stage, while the fifth is concealed within the finial. The design for this monument, and those for the tomb-stone at Tethury and for a mosaic tablet in the Guards' Chapel at Wellington Barracks, were prepared by Mr. Edis, F.S.A., London; the carving was executed by Mr. Earp, of London; and the work of erecting the St. Andrew's fountain was entrusted to Mr. G. Wallis, London.

Mr. Charles Larkin.—The memorial erected by public subscription to the memory of Mr. Charles Larkin (an orator of more than local renown) in Elswick Cemetery, Newcastle-on-Tyne, was unveiled on the 30th ult. by Mr. Joseph Cowen, M.P. The memorial is Classic in style. It consists of a broad base arranged in step form, upon which is placed a square pedestal, panelled on all four sides, and finished with carved ogee pediments and a dentil course. Above this is the bust of the late orator, surmounted by a pedimented canopy carried on four groups of clustered columns with Ionic caps. The canopy is domed internally, and externally finished with a richly-carved and moulded monumental urn. The whole has been executed in Denwick stone, by Mr. G. Burn. Messrs. Oliver & Leeson were the architects.

Archdeacon Thorp.—A memorial of the late Archdeacon Thorp has just been placed in Kemerton Church. When the chancel was rebuilt by Cambridge friends of the archdeacon, about thirty-five years ago, an arched recess was constructed in the north wall of the sacrarium, destined to receive a monument to his memory as the re-builder of the church. The back of this recess has been filled with diaper work, copied from an example in Canterbury Cathedral. On the floor of the recess, and raised a few inches above it, is the recumbent figure of the late archdeacon, vested in surplice, stole, and hood, and bearing between his hands a chalice resting on his breast. On either side of the head are shields bearing the family arms, and the same impaled with the arms of the Archdeaconry of Bristol. In a slab of Red Emperor marble, of a soft dove colour, the figure is incised in bold lines. These are filled in with black mastic, the larger spaces, such as the stole and shoes, being of black marble. Round the figure is a diaper in yellow Sienna and black marble, while the head reposes on a diapered cushion. The whole surface, which is perfectly flat, bears a high polish. The monument has been erected under the direction of Mr. R. Herbert Carpenter, architect, son of the architect who restored the church. Messrs. Clayton & Bell designed the incised slab, and the whole work has been carried out by Mr. George Hill, of Chelsea.

Mr. James Cassie, R.S.A.—The monument to the late Mr. James Cassie, R.S.A., erected by private subscription over his grave in the Dean Cemetery, Edinburgh, was placed in position on the 5th inst. Designed by Mr. George Reid, R.S.A., and executed in red granite by Mr. Alexander Macdonald (of Macdonald, Field, & Co., Aberdeen), the memorial resembles in form one of the picturesque crosses so frequently met with in the West Highlands, and rises to a height of 11 ft. from the ground. The cross, however, in itself only measures 8 ft., as it rests upon a base about 3 ft. high. The span of the arms of the cross measures 3 ft. 9 in., and the diameter of the wheel connecting these with the upright is 2 ft. 3 in. A bold boss marks the centre of the intersection. A small panel just above the base is reserved for the inscription recording the name, together with the dates of birth and death, of the deceased painter.

Lieut. Hearsey.—On the 2nd inst., the memorial erected by his old schoolfellows at Ockbrook School to the late Lieut. C. J. R. Hearsey, of the 9th Lancers, who fell in the charge against the Afghans in the Chardeh Valley, on December 11th, 1879, was unveiled. It is situated in the entrance to the school-house, and consists of a mural tablet of Caen stone, with statuary marble slab, and Sienna marble columns, the Gothic moulding being ornamented with ivy leaves and berries. The memorial was executed by Messrs. H. & T. Green, masons, Nottingham, from the design of Mr. John S. Henson, architect, Nottingham.

THE DUKE OF CONNAUGHT'S CONSERVATORY AT BAGSHOT.

THE DUKE OF CONNAUGHT'S CONSERVATORY AT BAGSHOT.

The conservatory of his Royal Highness the Duke of Connaught forms an agreeable contrast to the usual run of conservatories, in so far it is not the conventional square usually considered indispensable in conservatory buildings. It is built on to an angle of the wall, and thereby enables an entrance to be obtained from the boudoir at one end facing the garden entrance. At the far end, on entering from the boudoir, a pleasing surprise is obtained as the visitor advances, the angle of the house doubling the width, and producing an effect scarcely expected from the narrow approach as viewed from the boudoir. In the centre of this wall is the dining-room; to the right and left of this, taking advantage of the angle in the wall at the left side, a piece of rockwork has been built with waterfalls, streams, and fish-ponds,—at all times agreeable features in conservatory decoration. The view from the dining-room is charming, disclosing one of the most extensive scenes across the park. To preserve this the decoration has of necessity been kept low; a fountain in the centre is the chief object of attraction seen from the dining-room, and it is only on entering from this door that the main features of the decoration are disclosed. Considering the short space of time allowed, the gardener (Mr. Barden) is to be congratulated on the effective appearance of his plants. The dwarf brickwork is charmingly covered with growing ferns, lycopods, mosses, &c., by a very simple and effective arrangement in tufa, the material of which the whole of the rockwork is constructed, and which enables the walls to become a mass of living foliage, forming a lively and permanent background, and giving effect to the show-plants from time to time arranged in the borders in front. The rockwork and internal decoration have been carried out by Messrs. Dick Radclyffe & Co., of High Holborn, who make such work a special feature, seeking to imitate nature in the display of floral treasures. The illustration is taken from the angle of the wall entering from the boudoir-door.

The conservatory illustrated is designed to accord with the dwelling-house (of which we have given a view).

The materials used in the construction were oak and yellow deal, and especial attention was paid to making provisions for the internal condensation, an item of recognised importance. This was effected by providing water-grooves to each sash-bar, connected with the main gutter, with successful results. In the coldest nights hitherto there have been no signs of drip.

The arrangements for ventilation consist of French casements to the sills, and lifting sashes in the roof, arranged to open simultaneously by an arrangement worked from below.

The floor is laid with Minton's tiles of special design, with ornamental fountain in the centre.

The house being much exposed to the sun's rays, it has been found necessary to protect every part by means of spring-roller outside blinds, arranged to be raised and lowered from the inside. The warming is effected by means of hot-water pipes connected with the boiler serving the dwelling-house. These pipes are placed under the floor and covered with gratings, with valves for regulating the heat.

Hot and cold water is laid on to the conservatory. The decorations are of a quiet description, so as to show the plants to the best advantage, in accordance with instructions from the duke.

The contractors for this work were Messrs. Rosser & Russell, of Charing-cross, who have also fitted up the hot and cold water supply, cooking apparatus, &c., throughout the dwelling-house.

The water supplied to the house is brought from a reservoir three miles distant, and is pumped into three large tanks provided in the tower. The motive-power is obtained from a small stream running through the grounds. The overflow from these tanks is utilised to work a water-engine placed in the basement to pump up the rain-water from an underground reservoir to a fourth tank in the tower. This is automatic in action and requires no supervision.

The architect of the mansion was Mr. Ferrey, under whose superintendence the works have been carried out.

TRURO.

Service was held for the last time in St. Mary's Church, Truro, on Sunday, and the next day the building was handed over to Mr. Jas. Bubb, the clerk of works, for demolition. All will be pulled down save the south chancel aisle, and the eastern end of the southern arcade, which, from the interesting and ornate character of its architecture, is to be incorporated bodily into Mr. Pearson's design for the new cathedral. The spire and part of the tower had already been taken down. They were of grey granite, built some 120 years ago. The mortar in which the stones were bedded was of the poorest quality, being simply earth; and the granite itself was much disintegrated by atmospheric influences. The foundation of the tower, instead of being planted upon the solid rock, was placed a few feet underground, upon a mixture of clay and stones, which appeared at

one time to have been the old bed of the neighbouring river. There are many interesting old monuments in the church; these, together with the bells, the bulb-shaped inlaid pulpit, of Dutch-like type, and all else of historical or architectural value, are to be carefully preserved on the spot, until required again. The church was reseated with open oak benches a few years ago, and these are to be at once removed into the temporary wooden church that has been erected on the north-east end of where the cathedral is to stand. This place, designed by Mr. Henderson, C.E., has been built at a cost of 430*l.* by Mr. Trethowan, and will be used until the choir is built.

TESTIMONIAL TO PROFESSOR DONALDSON.

At a quarterly court of the Scottish Corporation, held in their new hall, Crane-court, Fleet-street, on the 6th inst., Mr. Webster proposed that the best thanks of the Corporation were due, and were thereby tendered, to Professor Donaldson for the excellent manner in which as architect he supervised the erection of the new hall, and the splendid accommodation he had provided for the discharge of the functions of the institution. Mr. Gooden seconded, and suggested that the vote should be inscribed on vellum; and it was eventually left to the secretary to present the testimonial in a suitable manner. In acknowledgment of the resolution, Professor Donaldson remarked that it was above half a century since he had become a member of the court, and his father had been connected with it before him. The interests of the Corporation had always been very near his heart, and he was proud of having been allowed to undertake the erection of the new hall.

GLASGOW ARCHITECTURAL ASSOCIATION.

At the usual monthly meeting of the above association, held on the 5th inst., the secretary, Mr. Russell, read a letter from Mr. Honeyman, honorary president, announcing that he had succeeded in getting the names of six gentlemen for the series of lectures on practical subjects to be commenced this winter. The following is a list of the subjects, with dates of lectures and names of lecturers:—

Nov. 16th, 1880.—Mr. Jas. Thomson,—"Foundations."
Dec. 21st.—Mr. John Honeyman,—"The Building of Walls."
Jan. 18th, 1881.—Mr. Jas. Salmon,—"Drainage and Ventilation."
Feb. 15th.—Mr. John Baird,—"Roofs."
March 15th.—Mr. John Burnet,—"Floors and Partitions."
April 19th.—Mr. David Thomson,—"Interior Arrangements."

All the lecturers are Fellows of the Royal Institute of British Architects.

GREAT DESTRUCTION OF BRICKS.

Correspondents in a position to know, write:—The unparalleled floods of the last ten days have destroyed one-eighth of the season's make of bricks, and at a time when it is utterly impossible to make up for the loss. The total make would probably have been about 900,000,000 if the weather had continued favourable. After a careful comparison with the makers generally, it is computed that the loss is greater than the excess of manufacture over that of last year. Unless the low state of the market should alter, many of the smaller manufacturers will have to cease making after such a disaster.

In the districts of Rochester, Rainham, and Sittinghourne, some of the low-lying fields have been absolutely under water, and the drainage so choked as to be utterly unable to carry off the flood-water. In consequence of this, many millions of bricks in the backs have been washed down, and a large portion washed away irretrievably. The deluge came so unexpectedly that in most instances the makers were totally unprepared for it. In some cases we hear that the actual loss of bricks has been quite one-third of the quantity in backs.

The Proposed Opera-House on the Embankment.—It is stated that the project for the erection of the new Opera-house upon the Victoria Embankment has been finally abandoned.

A BLACK SPOT IN DARLINGTON.

Within the last ten years the Corporation has erected a large Fever Hospital, purchased land and formed a sewage-farm, and bought a site for new corporation offices. During the last five years, from private subscriptions and bequests, have been erected an educational training college for women, and a new grammar-school. 10,000*l.* have just been bequeathed by the late Mr. Edward Pease for a free library, and at this moment, after only a few days' notice, and in spite of the bad times, local subscriptions are pouring in for the purpose of purchasing a second-hand Baptist chapel to form a new parish church. While all this has been done, indeed for ten years before it, there has existed, and still exists, a cottage hospital, which is little better than a plague-spot,—badly designed, badly planned, and badly ventilated, and standing cheek-by-jowl with a tallow-factory! One medical officer after another has been disheartened in his labours in such a hole, and has not hesitated to speak his mind to the powers that be. The poor ironworkers and others continue to subscribe to it, the "kind ladies and gentlemen," some of them enjoying the best social positions in the town and neighbourhood, attend the committee meetings, and visit the patients; but by them not a hand is lifted, or a voice raised, to alter this miserable state of things in this "good old Quaker town of Darlington." A. B.

CASES UNDER METROPOLITAN BUILDING ACT.

PENALTY FOR NOT GIVING NOTICE.

At the Marylebone Police Court, John Allen, 24, Kilburn Park-road, was summoned by Mr. Alexander Peebles, district surveyor, for neglecting to give notice of certain building works, and executing them before giving such notice.

Mr. Peebles said that on the 30th of September in Abbey-road Chapel, St. John's Wood, he found the defendant, a builder, carrying out some alterations. An apse or alcove was being formed, and the wall of the gallery had been considerably reduced in thickness. No notice of the work had been given.

Mr. Sampson, for the defendant, said a new organ was being put in, and they were going to add externally the strength they had taken away internally. The defendant had been away, and left it to his people to give the proper notices.

Mr. De Rutzen said it was absolutely necessary that these preliminaries should be complied with. The defendant would be fined 3*l.* and 12*s.* 6*d.* costs.

WESTMINSTER VESTRY-HALL COMPETITION.

Sir,—In your exceedingly just article on this subject, with almost every word of which I agree, you say, "In all games it is considered very bad form to question the decision of the umpire." In such cases, however, the umpire has been known beforehand and accepted by the players, but not so in this.

You note that "the instructions have no reservation with regard to the public hall"; and you ask, "Has there been any subsequent understanding on this point? and, if so, did all the competitors know of it?" To this, as regards the competitors, I answer, No!

You continue, "If not, it appears to us that 'Unitas' [myself] may have a technical ground of complaint."

Such being the case, I have raised the same question as you have, but a majority of the Vestry have voted that my letter upon it *be not read*.

Now, I am painfully aware that the question, as to which you say some explanation is desirable, is an unfortunate one to be raised at this time, when it is being urged that all competitions should be settled by professional referees.

Mr. Barry, however (not I), is responsible for this misfortune. If professional men are to be judges they cannot be irresponsible ones. To whom, then, are they to be responsable? At least to the profession, in cases such as this. I look, therefore, to my professional brethren and to the professional press for support in my effort to prosecute this inquiry. John P. Seddon.

SIGNBOARDS.

Sir,—There has been going the round of the papers recently the history of hotel and public-house signboards. Will you allow me to point out one of a peculiar nature? In Sobam, Lincolnshire, there is, or was, an inn called the Steam Fire Engine, with a lively oil-painting of that valuable invention. The house was kept by one George Hills, for many years head carman in the firm of Messrs. Merryweather & Sons. The painting was executed by the heraldic painter of the firm, and was presented by his fellow *employés* on his entering into a new sphere of business. M.

VARNISHING OLD FLOORS.

Sir,—I shall be glad to hear from any of your many readers a useful way to varnish or wax floors of a large public hospital. The floors have for fifty years been scrubbed, and this seems to make the varnishing more difficult. G. H. S.

Institute of Art.—The Winter Exhibition of this Society, 9, Conduit-street, W., will open on Monday, Nov. 1.

Miscellanea.

Colonel Beaumont's Hot-air Engine, on which we commented at length some time ago (*Builder*, p. 36, *ante*), was, on the 6th inst., tried on a more extended scale, with such success as to afford hope that before long humanity and economy may be promoted by the abolition of tramway horses, and that the sufferings of travellers by the underground railways may be mitigated by the substitution of atmospherical power for sulphurous locomotives propelled by steam. The engine, which has been designed by Major Beaumont, Royal Engineers, has been for some time running on the short lines of the Royal Arsenal, Woolwich, and although weighing but 10 tons, it has proved capable of hauling a burden of 16 tons up a fair incline. On the 6th inst. arrangements were made to try its powers in a more extended run, such as engines of the kind would have to encounter on London tramways and rails. The air reservoir, which contains only 100 cubic feet of air, was charged at the torpedo pumping-house in the Royal Arsenal, Woolwich, up to a pressure of 1,000 lb. to the square inch, and with this store of energy it was proposed to run to and from Dartford, about 16 miles. Major Beaumont explained the methods which he had adopted in his invention, the chief feature of which was the introduction of an almost imperceptible supply of steam, by which the air, as it is admitted to the cylinder from the reservoir, is largely heated, and, as a matter of course, greatly increased in force. The engine is driven by six cylinders and a double set of machinery at one end, and, having no smoke-stack, resembles in appearance a locomotive tender rather than a locomotive. It runs on four wheels, and in size is less than an ordinary omnibus. It left the Royal Arsenal Station at 12·22 p.m. with a full charge of 1,000 lb. to the inch, passed Abbey Wood Station at 12·27 p.m. with 940 lb. on the gauge; Belvedere, at 12·33, with 860 lb.; and Erith, at 12·36, with 760 lb., arriving at Dartford at 12·50 with a remaining energy of 540 lb. on the square inch. Shunting at the station reduced this pressure somewhat, and at 1·35 the return journey commenced with a store of 510 lb. Although the minimum for effective working is considered to be a pressure of 200 lb., Plumstead Station was reached again at 2·10, but the engine was nearly pumped out, having a pressure of barely 80 lb. remaining. It was stated that another engine is under construction, much more powerful, capable, in fact, of travelling double the distance with a single charge. The operation of pumping the compressed air occupies about fifteen minutes, and it is calculated that an air-engine on this principle, as large as the usual steam locomotive of 50 tons weight, would be considerably more powerful than any locomotive yet made.

River Pollution.—At the Berkshire Petty Sessions, on the 25th ult., the Corporation of Windsor, as the Urban Sanitary Authority, were charged by the Thames Conservancy with polluting the river by causing offensive matter to flow into the stream near the sewage works of Old Windsor, on June 14th. The magistrates fined the Corporation 5*l.*, with 5*l.* 5*s.* towards the costs.——At the Blackburn County Court, on the 11th inst., Mr. W. A. Hulton, the judge, gave his decision in a case brought before him under the Rivers Pollution Act, 1876. The plaintiffs were the Mayor, &c., of Over Darwen, and the defendants were Messrs. Shorrock, iron-founders. It was admitted that the defendants had caused certain rubbish and cinders to be put into the river, so as to interfere with its due flow, but these practices, it was urged, had been openly and as a right carried on for more than twenty years. The Judge, however, decided that the defendants had committed an offence against the Act, and issued an order that they should abstain from further commission of the offence.——The Severn Fisheries Conservators threaten to take proceedings against the Corporation of Worcester, and other public bodies, as well as private persons, on account of the discharge of sewage matter into the Severn.

Burns's Cottage.—"The Auld Clay Biggin" in which Robert Burns was born, hitherto occupied as a public-house, is about to be transferred to the trustees of the Ayr Burns Monument and converted into a sort of Burns Museum. There is a considerable area of ground attached, and this is to be attractively laid out. The price of the whole was 4,000*l.*

The Fall of a Church Floor in Manchester.—Another death (that of a man named James Kilty, aged 67) has resulted from this catastrophe, mentioned in our last. A verdict of "Accidental Death" was returned by the coroner's jury on Monday last. At the inquest held on the body of the first victim, the Rev. Bartholomew Flynn deposed that two weeks before the accident occurred he had noticed that one of the iron columns supporting the floor had moved. The schoolmaster called his attention to it. The pillar was about an inch out of the perpendicular. Mr. Walsh, the schoolmaster, tried, he believed, to put it right by placing a wedge in. Witness saw the pillar again on Tuesday before the accident. It had "gone" a good deal more. He put his hand on it and found that it was loose. He called the schoolmaster's attention to it and went out. In a few minutes after he found that the pillar had fallen. He saw that the pillar had been resting on a log. The log was not sound. Did not think that the falling of the pillar materially weakened the floor. Mr. William Nicholson, architect and surveyor, testified that about twelve months ago, at the instance of Father O'Callagan, he made an inspection of this building. Father O'Callaghan seemed to have no fear of the building, but he was going to have a mission. Witness, as the result of his inspection, told Father O'Callaghan that the floor was quite capable, provided the material was sound, to bear any weight he could put on it in the way of people,—and without the columns. Witness did not think there was any dry-rot about at that time. Was not at that time told of any cracking or giving way. He had seen the building since the accident, and he came to the conclusion that the accident was the result of dry-rot. Was with Mr. Allison, the city surveyor, there on Tuesday, and he believed that that was his opinion. The iron pillar was an element of destruction to the beam. The fungus from the foundation would go up to the beam.

St. Alban's Abbey.—Mr. Henry J. Toulmin, the hon. sec. to the St. Alban's Abbey Restoration, writes:—I hear from good authority that Sir Edmund Beckett has now given orders under a faculty lately granted to him to destroy Abbot Wheathampstead's west window (of the date of Henry VI.), and to replace it with a window of his own composition, which may be exceedingly effective to those who admire the high art of the nineteenth century, but extremely distasteful to those who respect bygone times and the historical associations of this ancient abbey. If the Society for the Protection of Ancient Monuments, aided by a small public subscription, would now proceed against and obtain an injunction, they would prevent this iniquitous proceeding, as Sir Edmund's faculty was to repair the west front, and not to destroy any portion of it. Sir Edmund is carrying out his own wilful way against the remonstrance of his bishop and the wish of the arch-deacon, rector, churchwardens, and sidesmen of the abbey church; and a petition, signed by the Lord-Lieutenant and many of the leading inhabitants of the city of St. Alban's and its neighbourhood, has lately been sent to the bishop of the diocese, requesting him to interfere. Even a lavish expenditure of money from ample resources in this pseudo-restoration will hardly recompense the men of Hertfordshire for the injury done to their great county church. A sum of 400*l.* to 500*l.* would be, I believe, sufficient to repair the window to make it last for a great many years to come. I may say Mr. John Scott, whom Sir Edmund promised to consult (but on such terms as no leading architect could submit to), deprecates and deplores this iconoclasm as much as we do."

Cemetery Chapels and the Burials Act. On the 30th ult. the Hove Town Commissioners, Brighton, held a special meeting to discuss a question which has arisen under the new Burials Act. In November last a resolution was passed for the laying-out of a new cemetery, with two chapels. As the Burials Act now permits Nonconformists to officiate in consecrated chapels, and Church of England clergymen in unconsecrated chapels, it is held that two chapels have become unnecessary. Mr. W. Olding proposed that the resolution of November should be rescinded, and that only one chapel should be erected in the new cemetery, such chapel to be consecrated. On a division 17 voted for the motion and 14 against, but as it requires a clear majority of the entire Board, — namely, 22 votes,—to rescind a resolution, the motion fell to the ground.

The Turnery Exhibition.—The tenth annual exhibition of specimens of hand-turning, under the auspices of the Turners' Company, was opened on Tuesday last at the Mansion House. The collection was a very good one. On Thursday morning the Lord Mayor distributed the prizes. The following were the judges:—In Wood—Mr. J. J. Holtzapffel; Mr. C. H. Gregory, Past Pres. Inst. C.E.; Mr. H. Law, and Mr. E. R. Robson. In Ivory—Mr. A. P. Bower, Mr. J. Jaques, Mr. T. B. Winser, Mr. Morgan Yeatman. In Precious Stones—Mr. Herbert Grueber, British Museum; Mr. J. N. Hunt, Mr. J. Jones, Mr. L. Keller, and Professor Tennant. The judges in their report say that the majority of the exhibits displayed much excellence of workmanship, in many cases novelty of design, and in several considerable appreciation of form and design. The first prize for work in wood, — a silver medal and the freedom of the Company,—was awarded to Mr. F. Nickolay, of Rupert-street, Haymarket, for a pair of vases in wood; and the second,—a bronze medal and four volumes of Holtzapffel on Turning,"—to Mr. John S. Conlson, of Thirsk, for two vases and a card-dish, also in wood. In each class a medal was to have been given provided the specimens entered were considered worthy, and under this regulation the judges have withheld the first prize for ivory turning, awarding the second, which is the same as for wood-turning, to Mr. John Hegley, of Ivy-lane, Hoxton. The silver medal and freedom of the Company, for skill in manipulating precious stones, was taken by Mr. Louis Islar, of Oval-road, Regent's Park; and the bronze medal and 5*l.* by Messrs. Reuter & Warner, of Wardour-street.

The Vyrnwy Water Scheme, Liverpool. At the meeting of the Liverpool City Council on the 6th inst., the report of the Water Committee contained the following recommendations:—That the joint tender of Messrs. Laidlaw & Sons and Messrs. Robert Maclaren & Co., to supply 500 tons of 12-in. and 500 tons of 7-in. iron pipes for the sum of 4*l.* 11s. per ton, be accepted. Also that the council accept the tender of Messrs. Coobrane, Woodside Ironworks, Dudley, for 8,000 tons or thereabouts of iron pipes for the first section of the works between the Vyrnwy Reservoir and Parc Uchaf. Mr. Wilson moved the adoption of the recommendations. Alderman Bennett objected to the contract for the 8,000 tons of iron pipes being passed that day. Iron was coming down in price, and if they waited a little longer it might come down much lower. Mr. Picton thought the council ought to be furnished with some distinct information as to the exact relation of Mr. Hawksley to the scheme. Mr. Wilson said that as soon as the draft agreement with Mr. Hawksley was made up it would be submitted to the council, and all the necessary information given. The Mayor explained that if they employed Mr. Hawksley to carry out these works his charge would be 2½ per cent. commission on the cost of them. If he was not to be the engineer, then they would have to pay Mr. Hawksley some fair amount of money for the work he had already done. The motion was carried.

The New Cattle Market at Kettering was opened on the 1st inst. It has an area of about an acre and a half. The cattle-pens, which are of wrought and cast iron, and paved in granite, afford accommodation for about 800 beasts, and the sheep-pens, which are of similar construction, will hold about 1,400 sheep. In the south-eastern corner there is a public weighing-machine by Kitchener, of Warmington. The whole of the works were designed by Mr. R. W. Johnson, architect, Melton Mowbray, and Mr. George V. Henson had the contract for the general works. The contract for the iron-work was commenced by Mr. F. B. Wallis, and finished by Messrs. Keay, of Birmingham. Mr. Coleman was clerk of the works. The total cost of the market has been 8,000*l.*

Sanitary Legislation.—Mr. William White, F.S.A., in a letter to the *Times*, says,—The reform most urgently required at the present moment is the extension of the Act which is designed to allow tenants and sanitary authorities, even in the absence of agreement, to compel landlords to amend defects in the drainage of rented houses. The Act is almost inoperative on account of the difficulties, or supposed difficulties, of exercising the coercive power without expensive litigation; but apart from this it contains no adequate provisions for the correction of defective soil-pipes and water-service.

Payment of Architects, Birmingham School Board.—At the meeting of the Birmingham School Board, on the 7th inst., the Rev. H. W. Crosskey read the report of the Sites, Buildings, and Repairs Committee. They reported that the resolution passed at the adjourned meeting of the Board on the 8th of July respecting the salary to be paid to the architects, was referred to Messrs. Martin & Chamberlain, and the decision of the Board had been accepted. For some time the work of the building surveyor, which includes the preparation of the quantities for the contractor, and the final measuring up of additional works or variations from the original contract, and the preparation of accounts, was performed by a firm of building surveyors; but considerable delay and difficulty being found to result therefrom, it has for some years past been undertaken by the Board's architects. It was, however, altogether apart from the architects' ordinary duties, and the committee considered it advisable that the work should still remain in the architects' hands, and they recommended that they should be allowed the usual professional charges for taking out and furnishing quantities, viz., 1¼ per cent. and 2½ per cent. for the final measuring up of additional works and preparing the accounts. The report was approved.

Appointments.—Mr. Alfred Horne has been appointed town surveyor by the Worthing Local Board.——At the meeting of the Metropolitan Board of Works, on the 8th inst., the Works and General Purposes Committee reported as to the arrangements for filling up the vacancy caused in the engineer's department by the death of Mr. James McCleary, and recommending that Mr. H. T. Wakefield, who has for some time past been temporarily engaged in the department at a salary of 3*l.* 3s. per week, be appointed during the pleasure of the Board to fill the vacancy, and that he be placed in the third class of officers, at a commencing salary of 130*l.* per annum. This was agreed to.——The Liverpool City Council, on the recommendation of the Finance Committee, on the 6th inst., resolved that Mr. Frederick Holford be appointed a junior architectural draughtsman in the surveyor's department, at a salary of 90*l.* per annum.

The late Mr. Asahy.—The will and codicil of Mr. Richard Ashby, formerly one of the members of the Court of Common Council, late of Manor-road, Stamford-hill, who died on the 3rd ult., was proved on the 22nd ult. by Miss Ann Breakspear Ashby, the daughter, and sole executrix, the personal estate being sworn under 30,000*l.* According to the *City Press*, the testator gives a sum of upwards of 10,000*l.* due to him from his late partnership business (as builders, in Bishopsgate-street) and a policy of insurance on his life in the National Provident Institution, as to one-half thereof to his son, Richard Vaughan Ashby, and as to the other half upon trust for the widow and children of his deceased son, George Scarlett Ashby. All his real estate and the residue of the personalty he leaves to his said daughter.

Bad Building at Brixton.—At the meeting of the Lambeth Vestry, on the 7th inst., the Sewers and Sanitary Committee reported that they had visited some buildings in course of erection on the Elm Park Estate, Brixton Hill, and they requested that the Vestry would call the attention of the Metropolitan Board of Works to the quality of the bricks used in the inside walls of the buildings upon the estate, contrary to the Act of 1878. They further requested that the Board might make the necessary inquiry into the matter. Mr. Fowler said the material used was extremely bad, and it appeared that the builders had not been interfered with in consequence of the district surveyor (a bed-ridden old gentleman) being unable to attend to his duties. The recommendation was agreed to.

Lecturee on Sanitary Mattere. — On Monday evening last Dr. A. Maxwell delivered the second of a series of "Medical Talks" at the Young Men's Christian Association, Aldersgate-street, the subject being "Dangers to Health; or, Unhealthy Houses." A number of pipes and other utensils were lent by Messrs. Doulton & Co., of Lambeth, and Messrs. J. Tylor & Sons, of Warwick-lane, for the purpose of illustrating the lecture.

Burning of Arbroath Guildhall.—Between two and three o'clock on Sunday morning a fire broke out in the Guildhall of Arbroath. The building was completely destroyed, with documents of local and antiquarian value. The cause of the fire is unknown.

Building Societies and the Parkes Museum.—At a meeting of the directors of the Nineteenth-Century Building Society, Mr. George Palmer, M.P., chairman, held on the 6th of October, the following resolution was passed unanimously, on the motion of Miss Richardson, and seconded by Mr. Henry Rntt:—"That as, in the opinion of this meeting, a course of Lectures at the Parkes Museum of Hygiene, on House Sanitation, would be most valuable to the members of building societies (who to a very large extent own the houses they live in), the secretary of this society he requested to ask the Committee of the Museum whether such a course of lectures could not be given gratuitously during the ensuing winter."

A Roman Amphitheatre at Buda.—The Pestb newspapers describe the finding of a Roman amphitheatre at Altofen during excavations carried on there by Karl Torma. The first traces were met with on the 20th of September. That the remains are really those of an amphitheatre was fully established by the 26th. It is a striking fact that the axes of the ellipse, in which form the building was constructed, were directed with mathematical accuracy to the four points of the compass, the large axis from east to west, the small from north to south. It was also interesting to find that the size of the amphitheatre considerably exceeds that of the famous amphbithеatre of Pompeii.

Llanrwst, North Wales.—New premises for the Nortb and South Wales Bank have lately been erected by Mr. Samuel Parry, builder, Llanrwst, at the north-west corner of tbe Market-place. Ahove the Bank are arranged suites of offices, and a large public hall, devoted to the nse of the county court, magistrates' meetings, and also for public entertainments. The style of the building is English Domestic Gothic; the materials used were local stone for the walling stones, and Runcorn stone for tbe dressings. Half-timber framiog bas been employed in the upper stories. The architect is Mr. Edmund Kirby, of Liverpool.

Sewer and Closet Ventilation.—The little Cornish town of Padstow furnishes evidence of the value of the ventilation of sewers. Acting on the recommendation of tbe Local Government inspector, the Local Board have, during tbe last eighteen months, ventilated the sewers so as to permit sewage gas to escape into the atmosphere as soon as it is generated, and before it becomes dangerous to the public health. As a result, it is reported that the town has, during the last twelve months, enjoyed complete immunity from zymotic diseases.

Topography.—The Committee of the Topographical Society of London, which has heeu formed for the purpose of collecting and publishing maps, views, and other materials for the history of London, have made arrangements for the holding of the inaugural meeting of the Society on Thursday, the 28th inst., at four o'clock. Tbe Lord Mayor has granted the use of the Long Parlour at the Mansion House, and will preside on the occasion. Cards for the meeting may be obtained from Mr. Henry B. Wheatley, F.S.A., 18, John-street, Adelphi.

Sewer Fatality in Birkenhead.—Ahout nine o'clock on Wednesday morning, a sbocking sewer fatality occurred at Birkenhead. Five men in the employ of the Corporation were overcome by the fumes of sewer-gas while opening a sewer in Cleveland-street. One (named Michael Donnaney) was killed, and great difficulty was experienced in restoring the others.

The New City of London School.—The foundation-stone of the new buildings for this school were laid on Thursday last, the 14th inst., by Mr. J. E. Walford, the chairman of the school committee. Messrs. Davis & Emanuel are the architects of tbe buildings, of which we published a view and plans in our last volume. pp. 602-5.

Builders' Benevolent Institution.—The tbirty-third annual dinner in aid of the funds of this Institution is fixed for Thursday, the 11th prox., when we trust that a large number of the friends of the Institution (which has recently increased tbe amounts of the pensions granted to annuitants) will rally round the president, Mr. Thomas F. Rider.

The Exhibition of Wood-Carving and Kindred Arts, at the Albert Hall, South Kensington (opened last March), has closed, and tbe various objects are being removed. The collection, as we have pointed out, was largely representative, and has been visited and enjoyed by a large number of persons.

Mr. and Mrs. German Reed's Entertainment.—On Wednesday evening, October 20th, a new first part will be produced, entitled "A Turquoise Ring," from the pen of Messrs. W. E. Godfrey and E. W. Craigie; the music supplied by Mr. Lionel Benson. Mr. Corney Grain has also a new musical sketch, "The Haunted Room," which he will give for the first time on the same evening.

TENDERS

For the erection of two shops at Turnham-green, for Mr. O. Davies. Mr. E. Monson, jun., architect:—

The Completion of Cologne Cathedral.

ON Friday, October 15, with Emperor's weather slightly threatening, and amidst the joyous clang of bells, the flatter of innumerable flags, and the thunder of cannon, the crowning stone of Cologne Cathedral was laid on the southern tower, at a height of 157 mètres. On the summits of the two spires of Cologne Cathedral rest therefore the loftiest stones that human ingenuity and patience have succeeded in raising in the world.* Sir Christopher Wren, the immortal architect of St. Paul's, who remembered the quaint old cathedral of the English metropolis,—which Hollar has so carefully shown us,—saw the first stone laid of the new building, and lived to see his great conception completely carried out. But six hundred years and more have passed away since the first stone of the Cologne *Dom* was laid with the ceremonial customary on such solemn occasions.

Little can Meister Gerhard, who began, and Meister Johann afterwards, the architects who so long ago planned and devised the edifice,—the glory of which they must, like all creators, have foreseen,—little can they have conceived that it would be for an Emperor William, living at the end of the nineteenth century, to witness and vouch for the completion of their noble conceptions.

Friday's *Te Deum* in the cathedral gained its chief brilliancy from the military element which, as may be imagined, with such a company as was gathered together in Cologne, was of no ordinary nature. The Emperor and his queen, his son, the Crown Prince, and his wife, our own beloved Princess Royal, and their children, the grandchildren of our Queen, added for every Englishman present a further point to a ceremony already of the highest solemnity. We confess that, apart from the interest connected with the completion of the cathedral, the greatest emotion by which, on the whole, we were moved was caused by the sound of our own national anthem, the air of the German Emperor's hymn, "*Heil dir im Siegerskranz*," as we stood within but a few yards of the cathedral itself, and under the fluttering shadow of the English flag, the peculiar significance and poetry of which can be fully understood and felt only when one is far from home.

For a long time past the Cologne folks have been preparing for the solemn moment of the completion of their cathedral,—in reality, for 600 years and more,—but, as is well known, the works have remained during the greater part of that long period sadly stationary; it is only within the present century that any activity had been impressed on the progress of the great design.

At the Wallraff Museum in Cologne, a not ill-executed fresco represents the ceremony of the laying, in 1842, by the reigning Emperor's father, of the first stone of the works which have now completed the cathedral, and there, standing by the late Emperor's side, is well portrayed the Kaiser William, as Crown Prince, as might be seen near him on Friday last *his* son, the popular husband of our own Princess Royal. During those thirty-eight years various ceremonies have marked the progress of the works, till at length the last stone was on the 15th inst. lowered into its final resting-place on the summit, as we have before remarked, of the southern tower. There, as we gazed up, under an architecturally-designed canopy of scaffolding tastefully covered with fir branches, the coping-stone was seen poised, ready at the proper signal to be let slowly down into its destined resting-place.

To solemnise this final act, so long awaited, Cologne was *en fête*, the streets be-garlanded with a traditional beauty that reminded one for all the world of the pictures of the Early Italian Renaissance masters, Crivelli, Mantegna, or Squarcione, and their decorative school; while the flags and heraldic devices which so plentifully adorned the passage of the Emperor showed that the traditions of Hans Burgkmeir and the familiar triumphant procession he designed with his brother artists for the Emperor Maximilian are far from dead in the fatherland of Albert Dürer. The flags and heraldic devices, indeed, added a great beauty to the scene, for whatever may be said of the danger of the picturesque element in architecture, the heralds in their best days did not disdain the aid and even the control of the painter and the architect.

On Thursday,—the day, by the way, erroneously announced by two of our leading journals as the day of the great ceremony,—Cologne was feverishly preparing for the morrow's momentous occasion, but all was ready to receive at nine o'clock next morning the Emperor and the other distinguished guests, a mere enumeration of whose names would read very much like the interesting pages of the now sadly diminished *Almanach de Gotha*.

After a rapid and what is called brilliant drive through the town, service in the Protestant church, and a simple *Te Deum* in the cathedral, the actual ceremony commenced in the great piazza in front of the cathedral, where the remarkable company was assembled. The address read and duly signed by the Emperor was, in the midst of a cantata specially composed for the occasion, hoisted to the summit of the southern spire, eagerly watched in its slow ascent by innumerable opera-glasses, and then laid under the last stone. The speeches that followed were lengthy, from the Emperor and President of the Cathedral Completion Fund Society; indeed, to those out of ear-shot, the delay at this point seemed long. But nothing, in these hasty days, more reconciled the impatient and the thoughtful to the tedium of this portion of the ceremony than the recollection of the six hundred years and more that it had taken to raise the stone to its present position and the events that had occurred in Germany during that time.

Carefully guided by the workmen, who could be spied with difficulty by the opera-glass at their immense height, the massive stone could be seen, at the proper moment, slowly descending; and when at length it was finally settled down, and the pulley and its tackle removed, the Imperial standard was hoisted, as had been announced,—unfortunately, the breeze was too feeble to shake out its folds,—the bells commenced their merry clang, the cannon roared, and Cologne Cathedral was completed. It was, as may be imagined, an anxious moment for the many thousands gathered in the Dom-platz, at every available window, and in many a narrow street throughout the town, when the stone which had so long been watched by thousands of upturned eyes began to quiver; but the moment of excitement was a short one, and soon the crowd dispersed. The Emperor and the other guests returned to the railway station in the royal carriages (none of which would have been a credit to Long Acre, though they had been sent from Berlin), and the whole party were invited to the palace at Brühl.

In Cologne itself the rejoicings were continued longer, Saturday being marked by an historical procession such as the Germans know so well how to get up. But the chief ceremony was over, and many hundreds who had travelled far to be present on the occasion of the completion of the cathedral hurried home, the picture of the still scaffold-hidden spires and the crowded streets of the resting-place of the relics of the three famous kings never to be effaced from their minds.

WE have availed ourselves of the skill of German artists to place before our readers views of the finished cathedral from several points, the west front, the east end, and a more general view from the south-east. The engraving includes, too, records of the aspect presented by the structure in the year 1500, when the works came to a standstill, and in 1878 when the spires were being fast proceeded with. It shows, too, the Emperor Bell and the ancient and still magnificent Shrine of the Three Kings who came from the East with presents to the infant Saviour.* In an early number we shall give a few details of the architecture on an enlarged scale. Some erroneous statements have been printed touching the discovery of the original design of the architect, and we may as well tell what we believe to be the correct story. The designs for the principal front, which, it seems,

* The spire of Rouen Cathedral is 151 mètres high; the Nicholas Church, in Hamburg, 144; St. Peter's, Rome, 138; the Pyramids of Cheops, 137; St. Paul's, 111; and Notre Dame, Paris, 68.

* See p. 500.

were formerly kept, one with the archives of the cathedral, and the other in the Masons' lodge, were lost when the French occupied the city in 1794. In 1814, one of the drawings, namely, that which represents the north tower, was accidentally discovered in a corn-loft at Darmstadt by a decorative painter who was about to occupy the loft as a studio. Being drawn on parchment, it had been used for many years as the bottom of a sort of tray in which to dry beans; but with the exception of the marks left by the nails which fastened it to the wooden rim, and a fracture in the lower part of it, was little injured. It fortunately came into the possession of Dr. Möller, the distinguished architect, of Darmstadt, who published a facsimile of it in 1818, and from whose lips we had the story. At the time of the discovery of this drawing, M. Willemin was publishing his work "Monumenta Français inédits," and Dr. Möller was struck by the analogy which appeared between the style of a large window represented in the twelfth number of that work, and that of the details of the tower at Cologne. He mentioned the circumstance to M. Boisserée, who was then occupied on his large work on the Cathedral of Cologne; inquiries were made of M. Willemin, and it was learnt that the window in question formed part of a very large drawing of a church on parchment, and then in the possession of M. Imbart, an architect in Paris, who had obtained it from M. Fourcroy. M. Fourcroy, it seems, had found it in Belgium. M. Boisserée contrived to purchase the drawing, and it was at once recognised as representing a part of the façade of Cologne Cathedral.* It was afterwards sold to the King of Prussia, and his Majesty presented it to the city of Cologne. United with the drawing discovered at Darmstadt, it represents the whole of the principal front. The size of the drawings together is about 6 ft. 6 in. wide and 13 ft. long.

This statement the Director of this journal published in very early days after a pleasant visit to Darmstadt, and at the time when the King of Prussia was giving an impetus to the movement in favour of the completion of the cathedral.† At that time, as we wrote, the choir, with its side aisles and chapel, was the only part of the cathedral which was complete, the towers and nave remaining in an unfinished state,—a splendid promise only, an outline of a magnificent intention, which yet remained to be filled up and made perfect. Fired by the successful restoration of the ancient works, and anxious to realise the original idea in all its integrity and unity, the inhabitants of Cologne determined on continuing the works vigorously. On the 16th of February, 1842, a society was organised for that purpose, and the day was set apart for religious intercession and rejoicings. The enthusiasm displayed on this occasion was extraordinary; a procession of more than 5,000 persons took part in the ceremonies of the day. Protestants and Roman Catholics, Liberals and Conservatives, joined on one common ground, and outvied each other in generous efforts to ensure the completion of the monument.

The outburst of feeling on the part of the inhabitants of Cologne was responded to, not merely throughout Germany, but in the neighbouring countries. Branch societies were formed for the purpose; literary men and artists associated to publish magazines, the profits of which were to be devoted to the cathedral; a committee to receive subscriptions was organised in France, and another in Rome. The King of Prussia made himself responsible for 8,000*l.* per annum, and further suggested that each of his provinces should defray the cost of one of the flying buttresses. The King of Bavaria was not behindhand in the good work. In Germany all classes of society, all professions, all faiths, spontaneously united in favour of the work, not merely, as M. César Daly wrote at the time, under the influence of a lively interest in the welfare of the arts and for their sublime creations, or even from a sentiment of piety, but from a new-born feeling of the re-establishment of moral unity in Germany, and a desire to retrieve its ancient grandeur. Piety, art, and patriotism,—love of God, love of the beautiful, love of country,—united in favour of the completion of a building in which modern Germany gives her hand to the Germany of the Middle Ages, across three centuries of discord.

Cologne has just now celebrated the glorious result of these well-conceived and well-continued efforts.

* It is supposed that the drawing had been carried from Cologne about the middle of the fifteenth century, to serve as a model for some of the numerous churches which were then built in the Low Countries.

† "On the Present State of Cologne Cathedral, and its Proposed Completion." By Geo. Godwin, jun.—*Civil Engineer and Architect's Journal*, vol. v., p. 201.

ART AT THE SOCIAL SCIENCE CONGRESS.

The address of the President of the Art Section, which we have been enabled to give in this and our last number, is one of the best addresses which have been delivered since that section was inaugurated. It dealt with art from a "social" point of view, and was broad in its views, without being vague or unpractical. The only point in regard to which we may call Professor Richmond a trifle unpractical is in reference to that much-vexed and much misunderstood question of architectural restoration. He adopts the general views of the Society for the Preservation of Ancient Buildings, lauding the "enthusiasm and courage" with which its views have been urged, and the carrying out of its main objects entered upon; an enthusiasm and courage certainly remarkable, inasmuch as they have not unfrequently been exercised in equal disregard of accuracy as to the statement of facts or courtesy in the manner of making such statements. Artists are naturally very strongly on the side of artistic sentiment in these matters (though not more so than ourselves, and many other architects); but like painters and sculptors in general, Mr. Richmond has no accurate perception of the practical effect which his proposed mode of dealing with buildings would have. He wishes that one-tenth of the money spent in restoration had been expended in such structural repairs as "adding a buttress to a weak wall or tower, or by strong oak timbers, unplaned, where the roof was weak." We should really like Mr. Richmond to see in reality, as we can pretty clearly see in our mind's eye, what some of our cathedrals and churches would look like if they had been subjected, since the first period when their state of decay began to be recognised, to a regimen such as this. The spectacle would possibly open the eyes of some of the fanatical anti-restorationists a good deal as to what their recommendations really amount to. In fact, an able and well-known architect did offer us a very clever and amusing drawing of the results of the treatment recommended by the Society on a supposed old church, and we only declined it, not from any want of sympathy with it, but because those among our readers who did not know how exceedingly unpractical were the demands of the Society might have misunderstood it, and have supposed that the *Builder*, which has always been against any destruction of an old building when it can possibly be avoided, had changed its tactics and principles.

Enough of that, however, for the present. One or two other points in Professor Richmond's address we should like to take the opportunity of supplementing and supporting. Nothing could be more true or more practical than the suggestions as to the importance (as urged, too, in these pages) of bringing good specimens of art before the notice of the children in our primary schools, by the aid of photography. And we are glad to notice that Professor Richmond does not confine this recommendation to exhibiting reproductions of pictures only; he wishes to have photographs of good architectural decoration, carving, ironwork, &c., brought before the eyes of our young and learning population. This might be of the greatest value. The mere early habit of looking at good work is an immense training to the eye and taste, even without a word being spoken about it. What we constantly see has more silent influence on our ways of feeling and thinking about art than many persons would readily believe; without even knowing anything about principles or schools, the man or child (even) who is in the habit of seeing high-class design becomes insensibly tutored by its spirit, and feels intuitively the difference between that and vulgar or inferior design. In the case of those who are to be artisans, especially in connexion with building, how valuable it would be, not only to themselves, but to the architect, for them to have an early habitude of seeing good work and understanding that it was good. As it is, you may find an excellent workman in stone or wood, or iron, who will execute with equal conscientiousness, as far as is in him, a design which is thoughtful or refined, or one which is vulgar and unmeaning; and no attempt to explain the essential difference between them will reach his comprehension, which has never been prepared for such considerations. No doubt, the case will be still bettered if we can secure that some good general training as to the meaning and the principles of art could be given by our Board School teachers; this, however, would be much more difficult to attain, as there will probably be the threefold labour of first persuading the authorities that there is any good in art-teaching at all; secondly, deciding what is to be taught; and, thirdly (and, perhaps, most difficult of all), finding any persons applying for Board School masterships who would have the requisite knowledge of the subject or judgment in treating it. But even without this, the mere turning loose, as it were, representations of good art in our schools would have a beneficial effect on the mental training of the pupils.

Another point on which we are very glad to see Professor Richmond taking up the cudgels is in regard to the abominable and all-pervading vulgarity of our illustrated street-posters. These are a standing and, in large towns, a nearly universal influence in degrading public taste, and putting vulgarity (and sometimes indecency) on a pedestal for the public gaze. One or two instances in which able artists were induced to design things of this kind where the figure was introduced, attracted so much attention that we have wondered that the idea of seeking for higher artistic aid in such things was not recognised as one that might pay commercially. Not only does the present style of wall-pictures vulgarise the taste of the public, but even where comparatively harmless in this respect, it familiarises the eye with bad drawing and misrepresentation. Recently, for example, the Metropolitan District Railway Company have endeavoured to call special attention to the fact that they have opened a direct railway to Putney Bridge, by hanging up in all the stations a map of London and the suburbs, upon which is engraved a huge ill-drawn black hand, pointing with a fore-finger abnormally long to the situation of the new station. Nothing could be more hideous than the appearance of this sprawling black claw, rather than hand, on the paper; whereas an outline of a hand truthfully represented would be a beautiful thing, and would answer the practical purpose just as well. We have gazed on this portentous hand frequently, with the feeling that in no country where there was any public knowledge of, or feeling for, art, could such a thing have been put forth on the walls,—such a libel on

> "Flesh and bone and nerve that make
> The poorest, coarsest human hand
> An object worthy to be scann'd
> A whole life long for their sole sake."*

There surely might very well be an official oversight over what is painted on our walls, to ensure that it shall come up to a certain standard; but here, again, the difficulty will be to persuade any among our rulers that such a subject is a *dignus vindice nodus*. The vulgarity of these posters appears perhaps more flagrantly odious when we come across one, as one sometimes does, stuck on a gate-post or on an old barn far out in the country, to be seen from the turnpike road, and we are suddenly recalled from the innocence and freshness of nature to what may truly be called, in Ben Jonson's words, "the adulteries of art." If artists were employed to draw these, the sight of an advertisement in a country spot would be rather pleasing than otherwise, recalling to us amid the charms of nature, the equal, though widely different, charms of art and culture. The assistance of competent artists in such matters would not be financially so difficult to procure as might be supposed, for the artists are convinced of the vulgarising effect of the present style of advertising pictures, and there is chivalry enough in the artist world to induce many, probably, to think more of the good they would be doing than of the remuneration to be gained in the first instance. And if it became established in public opinion that a higher style of art for advertisements was the right thing, the artists would reap benefit from the movement in the end, even if they were to sacrifice themselves a little, commercially, in initiating it.

The question of "the nude," as it is called, came up again at the Congress, chiefly *apropos* of a paper by Dr. Phené, in which the author laid unnecessary stress on the vicious use of the figure which had been made in some periods of

* Browning.

art, or we might rather say of the corruption of art, and it was argued that nude statuary and classical subjects were out of place in modern countries. This we entirely dissent from, as our readers would expect. In regard to subject, although it is quite true that we do not want to have the well-worn types of Greek Venuses and Apollos and nymphs reproduced to us (the rock on which Gibson wrecked himself), it is true that sculpture remains still, as much as ever, the finest medium for representing ideal thoughts in a plastic form, and that idealising means getting rid of the conventional. On this point we beg to quote the judgment we heard one day from a very young lady, a dear little girl of seven or eight, greatly interested in her small way about the Academy pictures, and who betrayed especial admiration of Mr. Poynter's "Visit to Æsculapius." An older relative was inclined to check her admiration of it, as a picture not entirely "proper" for little girls to look at, but she answered, "Oh, but you know, when you see a picture like that, you must *think*." The child had evidently got into her small mind the notion that this was ideal art, and not to be considered in a more realistic way, though she could only express it in that vague manner. It is a pity that some of the older children who range round our picture-galleries, and profess to have their sensibilities shocked by the nude pictures, cannot have it got into their heads that when they look at some pictures "they must think." Professor Richmond, it is true, in his reply on the discussion of Dr. Phené's paper, very rightly drew a contrast between the healthy and the unhealthy nude picture, speaking strongly in regard to the character and feeling of some French paintings of the class, more strongly and explicitly, in fact, than we generally hear a painter speak. In the course of the discussion, Mr. Rathbone said that the conflict which was raised in Liverpool in regard to Tadema's "Venus" a year or two ago had led to an advance in perception on the part of the public, as they had three nude figures in the present exhibition, of which no one complained. We always considered, as we before said, that Mr. Tadema's picture was a bad one to base a controversy on the subject on, because it is open to the objection of being too much of a mere artist's study, certainly not an ideal picture, or one before which "we must think." Still, the fact mentioned by Mr. Rathbone illustrates what we have often said, that the public must become habituated to the free display of the figure in art, and that the more they are so the less they will have any feeling of impropriety about it, and the more they will come to understand its unequalled beauty and its value as a means of the highest expression in art. As in many other cases, propriety in this is mainly a matter of habit or convention. At all events, people who do not innately feel how much nobler a thing is the human figure *per se*, when shown in a fine and healthy state of development, than when treated as a mere clothes-peg on which to hang a mass of often unhealthy, cramping, and ill-designed garments, had better let art alone altogether.

THE PAINTINGS IN THE GREAT ROOM OF THE SOCIETY OF ARTS.

The paintings by James Barry, R.A., which for close on 100 years have adorned the upper portion of the walls of the Society of Arts' Great Room in John-street, Adelphi, have just been carefully and successfully cleaned of the film of dirt which has latterly obscured much of the drawing and colour of these large works. Their refreshed appearance will be hailed with pleasure by the admirers of Barry's style of art. It opens up a new life, as it were, for the works, and affords a favourable opportunity for new studies to be made of these hitherto almost obliterated paintings.

Whilst for rich glow of colour, although there are unquestionably some bright and luminous passages, one might not propose to draw a comparison between these works and some of the great paintings in the Ducal Palace, at Venice, and whilst for composition and draughtsmanship one would not, either, propose to put them into the lists with the Sistine Chapel frescoes, they are nevertheless important as works of art, and, at the time at which they were done, when an affectation of Classicism pervaded a large section of the productions in fine art and literature, they were probably as able expressions of a curious bent of imagination, as any that then evolved themselves in colours on canvas.

From his early days Barry seems to have shown a predilection for Classical mythology, the influence of which was inherited in these times from the painters of the Renaissance. He painted a signboard for his father's public-house, with a figure of Neptune, and, much later, after his visit to Italy, where he became still more strongly imbued with Classic idealism, he, like many others of his contemporaries, dressed passing events in the guise of antique episodes. For instance, his "Death of General Wolfe at the Battle of Quebec," was a Classic composition of nude figures. In a spirit counter to such mannerism, as its opponents held it, Benjamin West treated the same subject realistically, and, when criticised for so doing, he maintained that the battle of Quebec took place in a locality of which the Greeks and Romans never heard, and that in 1759 there were no warriors clad in Grecian and Roman costumes. This blow at Classical affectation served to foster the feeling for realism, and was not without influence even upon Sir Joshua Reynolds.

We might glance at the difference between the classicism of fine art under the presidency of Sir Joshua Reynolds, and that under the presidency of Sir Frederick Leighton, were it not that the question is a large one, and would require more space for discussion than is at our disposal. At the same time, we may, for the sake of illustrating our allusion to this question in a cogent way, recall to our readers' remembrance Mr. Poynter's painting of "Nausicaa," which was exhibited at the Royal Academy in 1879. In this we had Mrs. Langtry's face appearing upon the shoulders of a Grecian maiden playing tennis with Nausicaa; but this adaptation of a modern face to an ancient costume does not savour of the solecism and anachronism perceptible by probably every one who looks at Barry's Alfred the Great leaning upon the shoulder of William Penn, who is showing his code of equal laws to Lycurgus; or at Sir Francis Drake and Captain Cook as Tritons swimming attendance upon Father Thames.

When James Barry generously offered to paint the walls of the Society of Arts' Great Hall, the opinions of Montesquieu and Winckelman were working an effect in teaching people to observe their own particular capabilities and capacities. Thus it was said that English people were devoid of imagination, taste, and sensibility; that they failed in works in which genius was necessary. These and other assertions, which might now be held to have become obsolete,—if they were ever more than ambiguous and loose,—seem to have stung men like Barry to the quick; and Barry, almost foremost in the movement of refuting them, wrote and painted to disprove the unpleasant dicta of the foreign philosophers and critics. In a letter to the Dilettanti Society, published some time after the completion of his Society of Arts pictures, he stated that his intention had been of endeavouring to effect a union between the Grecian style and character of design and "all those lesser accomplishments which the moderns have so happily achieved."
