The use of *fire-arms* appears to have been of great antiquity in India. They are prohibited by the code of Gentoos laws, which is certainly of a very ancient date. The phrase by which they are denominated is *agneester*, or weapons of fire; and there is mention made of *shet agnee*, or the weapon that kills an hundred men at once. It is impossible to guess at the time when those weapons were invented among the Hindoos; but we are certain, that in many places of the east, which have neither been frequented by Mohammedans nor Europeans, rockets are almost universally made use of as weapons of war. The Hindoo books themselves ascribe the invention of fire-arms to *Baeshkookerma*, who formed all the weapons made use of in a war betwixt the good and evil spirits. Fire-balls, or blue lights, employed in besieged places in the night-time, to observe the motions of the besiegers, are met with every where through Hindoostan, and are constructed in full as great perfection as in Europe. Fire-works also are met with in great perfection; and, from the earliest ages, have constituted a principal article of amusement among the Hindoos. Gun-powder, or a composition somewhat resembling it, has been found in many other places of the east, particularly China, Pegu, and Siam; but there is reason to believe that the invention came originally from Hindoostan. Poisoned weapons of all kinds are forbidden in this country.

The Hindoos are remarkable for their *ingenuity* in all kinds of handicraft; but their utensils are simple, and in many respects inconvenient, so that incredible labour and patience are necessary for the accomplishment of any piece of work; and for this the Hindoos are very remarkable. Lacquering and gilding are used all over the country, and must have been used in very early ages; though in some places the lacquering is brought to much greater perfection than in others.

The principal article of *food* throughout all Hindoostan is rice, and of consequence the cultivation of it forms the principal object of agriculture. In this the most important requisite is plenty of water; and when there happens to be a scarcity in this respect, a famine must be the consequence. To prevent this as far as possible, a vast number of tanks and water-courses are to be met with throughout the country, though in some places these are too much neglected, and gradually going to decay. After the rice is grown to a certain length, it is pulled up, and transplanted into fields of about 100 yards square, separated from each other by ridges of earth; which are daily supplied with water let in upon them from the neigh-

bouring tanks. When the water happens to fall below the level of the channels made to receive it, it is raised by a simple machine named *picoti*, the construction of which is as follows. A piece of timber is fixed upright in the ground, and forked so as to admit another piece to move transversely in it by means of a strong pin. The transverse timber is flat on one side, and has pieces of wood across it in the manner of steps. At one end of this timber there is a large bucket, at the other a weight. A man walking down the steps throws the bucket into the well or tank; by going up, and by means of the weight, he raises it; and another person standing below empties it into a channel made to convey the water into the fields. The man who moves the machine may support himself by long bamboos that are fixed in the way of a railing from the top of the piece of upright timber towards the wall.

A number of other kinds of grain are to be met with in Hindoostan, but wheat is not cultivated farther south than 18° latitude. It is imported, however, to every part of the country by the *Banjaries*. These are a set of people belonging to no particular cast, who live in tents, and travel in separate bodies, each of which is governed by its own particular regulations. They frequently visit towns on the sea-coast, with bullocks loaded with wheat and other articles; carrying away, in exchange, spices, cloths, but especially salt, which they carry into the inland parts of the country. Some of their parties have several thousand of oxen belonging to them. They are rarely molested, even in time of war, otherwise than by being sometimes pressed into the service of an army to carry baggage or provisions; but for this they are paid, and dismissed as soon as the service is over. The Hindoos themselves are prohibited from going out of the country, under the severest of all penalties, that of losing their cast. Notwithstanding this, however, it is certain that they do settle in foreign parts in the character of merchants and bankers. Perhaps these may have a toleration from the principal bramin, or there may be an exemption for people of their profession; but this is not known. At any rate, wherever they go, they appear inviolably attached to their religious ceremonies, and refuse to eat what is prohibited to them in their own country. The *Ryots*, or people who cultivate the ground, are in many places in the most miserable situation; their only food being some coarse rice and pepper, for which they are obliged to endure all the inclemencies of a burning sun, and the inconveniences which attend alternately wading in water and walking with their bare feet on the ground heated intensely by the solar rays; by which they are frequently blistered in a miserable manner. All this, however, they submit to with the utmost patience, and without making any complaint, expecting to be released from their sufferings by death; though even then their religion teaches them to hope for nothing more than what they call *absorption into the essence of the Deity*; a state almost synonymous with what we call *annihilation*.

HINDOOSTAN, a celebrated and extensive country of Asia, bounded on the north by the Great and Little Thibet; on the south, by the hither peninsula of India, part of the Indian Sea, and Bay of Bengal; on the west, by Persia; and on the east, by Thibet and the farther peninsula. It is situated between 84° and 102° of east longitude, and between 21° and 36° of north latitude; being in length about 1204 miles, and in breadth 960; though in some places much less. This country was in early times distinguished among the Greeks by the name of *India*, the most probable derivation of which is from *Hind* the Persian name. We are assured by Mr. Wilkins, that no such words as *Hindoo* or *Hindoostan* exist in the Sanscrit or learned language of the country; in which it is named *bharata*, a word totally unknown to Europeans. The vast country of Hindoostan is at present divided among the following powers.

1. *Timur Shah*, son of *Ahmed Shah*, or *Abdallah*, possesses

an extent of territory to the north westward before we come to the river Indus. This country, extending all the way betwixt India and Persia, is known by the name of *Duran*, or *Turan*; and was possessed by the Afghans, of whom *Abdallah* became the sovereign. He was descended from an illustrious family; and having the misfortune of being taken prisoner by *Hussien Khan*, then chief of *Kandahar*, along with his brother *Zulfecur Khan*, they were released by the celebrated *Nadir Shah* in his passage through that country to *Hindoostan*; but as that conqueror still looked upon them with a jealous eye on account of their great influence with their countrymen, both were sent to *Mazandaran* in Persia. Here *Zulfecur Khan*, the brother of *Ahmed*, died; and, some time after, we find the latter promoted to the command of a body of Afghan cavalry in the Persian army. He continued attached to the interests of *Nadir* while that conqueror lived; and even attempted, though ineffectually, to revenge his death. Proving unsuccessful in this attempt, he returned to his own country; and, arriving at *Kandahar*, was saluted chief of the Afghans. In the course of a few months he became master of all the countries which the Mogul had been obliged to cede to *Nadir Shah*; and, encouraged by the distracted state of the affairs of *Hindoostan* at that time, he crossed the *Indus*, and plundered the country to the south-east. An indecisive battle fought with the Indian army under the command of the prince royal and vizier, in which the latter was killed, obliged *Ahmed* to return to his own territories; but he soon undertook another expedition, in which he conquered the province of *Lahore*. In 1755 he returned; and after staying some time at *Lahore*, marched to *Delhi* the capital, having been invited thither, as was supposed, by the Mogul himself, in order to get rid of the tyranny of his vizier. The latter was accordingly deserted in a battle by order of the emperor, and obliged to surrender himself prisoner; but instead of being put to death, he had the address to ingratiate himself with the conqueror; and the unfortunate *Allumghire*, the Mogul, was obliged to submit to be ruled by him as before. *Ahmed* took care to indemnify himself for his trouble, by laying the city of *Delhi* under a heavy contribution: and having staid for about a month, during which time he concluded a marriage betwixt his son *Timur* and the emperor's niece, he marched against a tribe of Hindoos named the *Jauts*, and conquered the greatest part of the province of *Agra*. In this expedition he surprised the city of *Matra*, famous for being the birth-place of *Krishna*, the Apollo of the Hindoos; and sacrificed to the *Gopia*, the muses of the country. He failed in his attempt to surprise *Agra* through the resolution of *Fazil Cawn* the governor; after which he led back his troops to *Delhi*, where he married the daughter of *Mohammed Shah* the late emperor, whom *Allumghire* had in vain solicited for himself.

Having settled his son *Timur* in the government of *Lahore*, *Ahmed* quitted *Hindoostan*, and returned to his dominions, where he found every thing in confusion. *Timur*, who during his father's absence had been frequently disturbed by the *Seiks*, a tribe of Hindoos who profess deism, was in 1760 driven out by a vast army of *Mahrattas* commanded by *Roganaut Row* the *Paishwa's* brother, of whom so much mention is made in history. Next year, however, *Ahmed* crossed the *Indus*, and easily recovered his former territories; soon after which he became head of a league formed among some of the Indian princes, in order to oppose the overgrown power of the *Mahrattas*. In this enterprise he proved successful; and overthrew the *Mahrattas* in a decisive and very bloody battle, in which more than 50,000 of them were killed on the spot. The pursuit lasted several days, and their vast army was totally dispersed; *Ahmed* being every where received with acclamations as the deliverer of the faithful. In 1762 he again crossed the *Indus*, with a view to conquer, or rather to exterminate, the *Seiks*, whose incursions

had become very troublesome, and even dangerous, to his kingdom. Having defeated their army, and forced them to take refuge in the woods and strong holds, he set a price on the heads of all those who professed their tenets; and that with such success, that heaps of them are said to have been piled up in all the principal towns in these parts. At last, hearing that they had assembled in great numbers to celebrate an annual festival, he marched with an army to surprise them. The Seiks, however, were well provided for his reception, and an obstinate battle ensued. During the time of the engagement an eclipse of the sun happened, which, though disregarded by the Seiks, greatly dismayed the superstitious Mohammedans. Ahmed was therefore defeated; and though he frequently returned, was never able thoroughly to subdue that people. At last, having been long afflicted with an ulcer in his face, he died on the 15th of July 1773, at a place named *Kobtoba*, among the mountains of Kandahar, to which he had retired for the sake of coolness, and was succeeded by his son Timur, who still continues to enjoy the sovereignty. The dominions of this prince extend a very considerable way to the northward of the Indus, but he possesses nothing in Hindoostan besides the province of Kashmir.

2. The *Seiks* inhabit a country on the other side of the Indus, and making part of Hindoostan properly so called. They derive their origin from a Hindoo named *Nanuck* of the cast of *Khatri*. His father, named *Baba Caloo*, possessed a small district in the province of Lahore named *Telvandi*, where *Nanuck* was born in the year 1470. Like other founders of new sects or nations, he is said during his infancy to have given many indications of his future superiority to the rest of mankind. He seems, however, to have received no farther education than what was common to young men of his cast: *viz.* reading, writing, and arithmetic, and hearing the *sastras* or commentaries on the sacred books. In his early youth he was married to a woman of his own cast, by whom he had two sons. Being a convert to the worship of the Invisible, or deism, he accustomed himself to declaim against the folly of worshipping idols, and the impiety of paying adoration to any but the Supreme Being. At the age of 25 he left his family to visit Bengal and the eastern parts of Hindoostan; in a second journey he visited the south, and in a third he went as far as Persia and Arabia. On his return from this last journey, he expressed a desire of remaining in his native country; and was furnished, according to his wish, with a piece of ground on the banks of the river *Bavy*, about 80 miles north-eastward from the city of Lahore. Here he took up his residence for the rest of his days; and choosing to be free from the cares of this world, he dwelt at a distance from his wife and children, who came occasionally to visit him. Having acquired great reputation for his piety, wisdom, and learning, he died at the age of 70; and since his death the place of his abode has obtained the name of *Dibra Daira*, or "the place of worship." His eldest son founded a sect of devotees named *Nanuck Sboiy*; but his second employed himself in the usual occupations of mankind. On account of the oppression of the Mohammedan governors, however, he removed from *Telvandi*, the estate of his ancestors, and settled at *Kartarpour*, which his descendants still possess. They are respected by the Seiks on account of their being the posterity of *Nanuck*, but are not held in any veneration on a religious account.

The doctrines of *Nanuck* were taught by a favourite disciple of his named *Lbina*, but on whom he bestowed on his death-bed the appellation of *Angud*. By him the doctrines of the sect were collected in a work named *Potby*, or "the book;" and an history of the life of *Nanuck* himself was given in another named *Jenum Sakky*. Both these were written in a particular kind of character called *Gour Mouekty*, and said to have

been invented by *Nanuck* himself. *Angud* named for his successor another disciple called *Amerdofs*; and this method of continuing the succession seems to have been practised as long as the disciples continued to own one supreme chief.

For many years the Seiks lived in peace, and gained the goodwill of the Mohammedan governors by their quiet and inoffensive behaviour. By degrees their numbers and their power greatly increased, but in proportion to their good fortune, they seem to have lost their virtue; so that their gourous, or chiefs, who had hitherto borne the character of apostles, at last stood forth as military leaders. The first of these was named *Tuigh*, whose successor, named *Govind Sing*, was the tenth and last of the gourous. He engaged in a rebellion against the government; but was at last obliged to submit, and even attended the emperor *Bahader Shah* in person. At last he was assassinated by a *Petan* soldier, not without a suspicion of the emperor himself being concerned. As he did not name a successor, his followers chose a chief for themselves named *Banda*, who soon began to make depredations on his neighbours; but being at last taken prisoner, and sent to Delhi with his family and many of his countrymen, they were all put to an ignominious death. By this execution the Seiks were so much exasperated, that they swore eternal vengeance against the Mohammedans, and have ever since manifested a most implacable hatred against them. Taking advantage of the distraction of the Mogul empire by the invasion of *Nadir Shah*, they conquered several provinces. Wherever they came they threw down the mosques, and obliged every one to quit the country who refused to embrace their tenets. Their war with *Ahmed Shah* has been already mentioned. Since his death they have recovered all the territories they lost during their contest with him; and now possess the greatest part of *Moulton*, as well as several districts in the province of *Delhi*; including in their territories the whole of that rich country named the *Panjab*, on account of five rivers which descend from the northern mountains, and inclose or intersect it, running afterwards into the *Indus*.

The Seiks, as has already been mentioned, worship one God; but without image, or believing in any mediator. They eat all kinds of meat except beef; sparing the black cattle, in all probability, on account of their utility. Pork is very generally eaten, probably on account of its being forbidden by the Mohammedans. They are commonly dressed in blue, a colour reckoned unlucky by the other Hindoos. Their dress consists of blue trowsers of cotton, a sort of plaid generally chequered with blue and thrown over the right shoulder, with a blue turban. Their government is lodged in an assembly of different chiefs; but who, as individuals, are independent of one another, and have separate territories. They meet annually, or oftener if occasion requires, at a place called *Antberfer*, which is held in a kind of religious veneration; where there is a large tank lined with granite, and surrounded with buildings, and beautifully ornamented. Their force is very considerable, amounting to no fewer than 200,000 cavalry. However, they can seldom be brought to act in concert, unless the whole nation be threatened with some imminent danger. They are a strong hardy race of men, and capable of bearing much fatigue; and so expert in war, that of late almost all the neighbouring countries have been laid under contribution by them, several petty chiefs having consented to pay them a small annual tribute in order to avoid their incursions. When in the field, none but the principal officers have tents, and those extremely small, so that they may be struck and transported with the greater quickness and facility. In cold weather the soldiers wrap themselves during the night in a coarse blanket, which in the time of marching is folded and carried on their horse. Their country is well cultivated, populous, and abounding in cattle, particularly horses, which are reckoned the best in all Hindoostan. This may pro-

bably be owing to the studs which were formerly established in different places of the province of Lahore on account of the Mogul himself. Stallions were sent thither from Persia and Arabia, and there was a fixed order to send to the studs in Lahore all such Arabian and Persian horses as by any accident should be rendered unfit for mounting. Notwithstanding their deism, the Seiks are said to have a superstitious veneration for their sword; inasmuch, that before one of them will eat with a person of another religion, he draws his sword, and passing it over the victuals, repeats some words of prayer, after which he will freely partake of them. Contrary to the practice of all the other Hindoos, they dislike the smoking of tobacco; but many of them smoke and chew bang, which sometimes produces a degree of intoxication.

3. The provinces of Delhi have, in the course of a few years, frequently changed their masters, but have scarce at any period during that time been under the authority of the sovereign. Their last governor was named *Nadjiff Khan*, under the title of generalissimo of the emperor. He was involved in the ruin of Mohammed Kouly Khan, cousin to Soujah ul Dowlah; after which he went to *Casim Aly Khan* nabob of Bengal; after whose expulsion he retired with a party of horse to Bundelcund into the service of *Rajah Coman Sing*. He next joined the English; and at last became the general of *Shah Allum*. With a body of English sepoy who had been put under his command, and some other troops whom he had taken into his service, he subdued the countries near Delhi, conquered almost all the territories of the *Jauts*, reducing the cities of *Agra*, *Diag*, and other principal towns. These conquests were indeed effected in the name of the Mogul, but he derived little benefit from them; *Nadjiff* being the real master, and keeping possession of them till his death, which happened in 1782: and since that time the countries we speak of have been involved in a scene of continual anarchy and bloodshed.

4. Next to the provinces of Delhi are the dominions of the independent *rajabs*, whose dominions lie contiguous to one another. The principal are those of *Joinagar* or *Jaypour*, *Joadpour* or *Marwar*, *Oudiapour* or *Chitore*, and *Jesalmire*. These countries are under a kind of feudal constitution, and every village is obliged to furnish a certain number of horsemen at the shortest warning. The people are brave, hardy, and very much attached to their respective chiefs; and their army is very formidable, amounting when collected to about 150,000 horsemen.

5. The *Jauts* were a tribe who followed the occupation of agriculture in the northern parts of Hindoostan. About 40 years ago they were formed into a nation by *Tackou Souragemul*, proprietor of an inconsiderable district. After making himself master of all the countries dependent on *Agra*, of the town itself, and many other important places, he was killed in battle with *Nadjib ul Dowlah*, the *Rohilla* chief, in 1763. Since that time the power of this people has been so much reduced by domestic contentions and foreign wars, that the present *rajah* possesses only a strong town named *Bartpour*, with a small district around it. The *Jauts*, however, it is said, are now manifesting a martial disposition, and thus may possibly be soon in a condition to recover their former extent of territory.

6. The most considerable of all the Hindoo powers are the *Mahrattas*, with whom the Europeans first became acquainted in their original territories of *Malabar*. The first of their chiefs was named *Seeva*, or *Seeva-jee*; who is said to have been descended from the ancient Hindoo emperors, and whose father was lord of a small district, for which he paid tribute to the Mohammedan king of *Vizia-pour*. For some reason, unknown to us, he was at last arrested by order of that king, and died in confinement; but his son *Seeva-jee* took up arms in defence

of his country, and made himself master of several important places, with a considerable tract of territory, which were afterwards ceded to him by the queen-regent, the king of *Vizia-pour* having died soon after the commencement of the war.

Seeva-jee having thus established himself, soon became formidable to his neighbours. Many of the Hindoo princes put themselves under his protection, and he at length ventured to make war upon the emperor *Aurengzebe*. In this he proved unsuccessful, was taken prisoner, and carried to *Delhi*. Having found means, however, to make his escape, he quickly recommenced hostilities; and the emperor, who was now far advanced in life, thought proper to come to an accommodation with so troublesome an enemy. On this occasion the *Mahrattas* pretend that their prince obtained a grant of 10 per cent. on all the revenues of the *Deccan*; which has often served as a pretence to invade that country, and levy contributions on the southern nabobs. Since that time the *Mahrattas* have become so powerful, that all the princes of *Hindoostan* are alarmed when they put themselves in motion. Their territories extend about 1000 miles in length and 700 in breadth; and they are governed by a number of separate chiefs, all of whom acknowledge the *Ram Rajah* as their sovereign, and all except *Moodajee Booflah* acknowledge the *Paishwa* as his vicegerent. The capital of the sovereign was *Sattarah*; but the *Paishwa* generally resides at *Poonah*, one degree to the southward, and about 100 miles distant from *Bombay*. The country extends along the coast nearly from *Goa* to *Cambay*. On the south it borders on the territories of *Tippoo Saib*; on the east it has those of the *Nizam* and the *rajah* of *Berar*; and on the north those of the *Mahratta* chiefs *Sindia* and *Holkar*.

7. The *rajah* of *Berar*, besides that country, has the greatest part of *Orixa*. His dominions extend about 600 miles in length from east to west, and 250 from north to south. The eastern part of the *Orixa* extends along the sea-coast for about 150 English miles, and divides the British possessions in *Bengal* from those commonly called the *Northern Circars*. On the west his territories border upon those of the *Paishwa*; on the south, upon those of the *Nizam*, *Mahomet Hyat* a *Patan* chief, *Nizam Shah*, and *Ajid Sing*. The *rajah* himself resides at *Nagarpour*, about midway betwixt *Calcutta* and *Bombay*.

8. *Madajee Sindia* has the greatest part of the government of *Malva*, together with the province of *Cardeish*. The remainder is under the government of *Holkar*; who, as well as *Sindia*, pretends to be descended from the ancient kings of *Malva*. The principal residence of *Sindia* is at *Ugein* near the city of *Mundu*, which was once the capital of these kings. *Holkar* resides at *Indoor*, a town little more than 30 miles to the westward of the former. The dominions of these, and some other princes of smaller note, extend as far as the river *Jumma*.

The two last-mentioned princes, though properly *Mahrattas*, owe no allegiance to the *Ram Rajah* or great chief to whom the main body are nominally subject. Some time ago the *Mahrattas* aimed at the conquest of all *Hindoostan*, and even avowed a design of expelling all the Mohammedan princes; but their power was effectually checked by the British, and their dissensions among themselves put an end to all schemes of that kind. Still, however, they were ready to watch every opportunity of invading the territories of their neighbours; and their resources being so considerable, they were deservedly accounted a very formidable enemy. The strength of their army consists chiefly in cavalry; and both men and horse are capable of enduring a great deal of fatigue. Bodies of 50 or 60,000 cavalry have been known to travel 50 miles a day for many days together; which, considering the excessive heat of the country, must certainly appear very surprising. The country abounds very much in horses, and there is one kind named the *Bremerteddy* horse, which is greatly esteemed, and sold at a very high price. The

common horse of these parts is lean and looks ill, but is abundantly fit for the purposes of war. The only weapon used by the horsemen is a sabre; in the use of which they are so dexterous, that it is supposed the best European hussar would not be more than a match for a Mahratta horseman. There are considerable studs in every province belonging to the Paishwa and different chiefs; and there are likewise many *jundis* or great herds of horses belonging to particular persons, who turn those they have no occasion for loose in the open plains.

The Mahratta horsemen are dressed in a quilted jacket of cotton, which is supposed to be one of the best defences against a sword that can easily be contrived of equal lightness; but the heat of the climate frequently renders it necessary to be taken off. The rest of their dress consists of a pair of trowsers, and a kind of broad turban which descends low enough to cover the neck and shoulders. In cases of emergency the horsemen carry provisions both for themselves and their horses in a small bag tied upon the saddles: the food of the rider consists only of a few small cakes with a little flour or rice, and some salt and spices; the horse is fed with a kind of peas named *gram*, or with balls made of the flour of these peas mixed with butter, prepared after a certain manner, and named *ghee*, together with some garlic and hot spices. These balls are given by way of cordial, and have the property of invigorating the animal after extraordinary fatigue. Sometimes it is said that they add a small quantity of *bang*; a kind of drug which possesses an exhilarating virtue, and produces some degree of intoxication. The Mahratta cavalry seldom make any use of tents: even the officers frequently have no other accommodation than a small carpet to sit and lie on; and a single camel is able to carry the whole baggage of the general. The officers, however, are generally well mounted, and have spare horses in the field.

All the subjects and vassals of the Mahratta princes are generally ready to follow them into the field; and in any case in which the honour or interest of the nation appears to be concerned, they generally unite in the common cause. Before they invade any country, the general is at great pains to inform himself of the nature and situation of it; and they have now made incursions into so many different parts of Hindoostan, that there are but few countries there with which they are not very well acquainted. Their great sobriety, and the fatigue they are capable of undergoing, render them very dangerous enemies. In all their expeditions the soldier first provides for his horse, and then goes to his own meal; after which he lies down contented by the side of the animal, and is ready to mount him at the first sound of the *nagar* or great drum. They have their horses under the most excellent management; and by perpetually caressing and conversing with them, the animals acquire a degree of docility and sagacity unknown in other countries. When on an expedition, the horses are accustomed to eat grass pulled up by the roots, which is said to be very nutritive, and to be destitute of that purgative quality which belongs to the blade alone. When they make an invasion, the devastation is terrible; the cattle are driven off, the harvest destroyed, the villages burned, and every human creature destroyed who comes in their way. Notwithstanding this barbarity in time of war, however, they are very humane in time of peace, living in great harmony among themselves, and being always ready to entertain and assist strangers. Many of the cruelties they commit may be justly reckoned the effects of retaliation for other cruelties exercised upon them by their adversaries. Thus in 1771, after having given Hyder Ally a great defeat, they cut off the ears and noses of a whole regiment of prisoners, and in that condition sent them back to their commander, in return for his having done the same to a few prisoners he had taken some time before.

The revenue of the Paishwa is very considerable; being not less than ten millions sterling; but after deducting the expence of collection, and the expence of troops kept in readiness for the service of the state, it is supposed that he cannot receive more than four millions. From this again we must deduct the expences of the troops immediately belonging to the Paishwa himself, and which may amount to about three millions sterling; so that there remains a surplus only of one million after paying all the necessary expences of government. This nevertheless has been managed with such economy, that though long and expensive wars were carried on after the death of Narrain Row, the state was not only clear of debt, but there was a surplus of two millions in the treasury, which Rogobah dissipated.

9. The *Deccan*, as left in 1748 by Nizam al Mulek, was by far the most important and extensive foubadary or viceroyship in the empire. It then surpassed in size the largest kingdom in Europe; but since that time many provinces have been conquered by the Mahrattas, and the northern Circars, by the British. The possessions of the Nizam are also diminished by the cession of the Carnatic to the nabob of Arcot; great part of the territories of Tippoo Saib; and many other provinces of less note. Still, however, the Nizam possesses very considerable territories; but his finances are in such a wretched condition, and his provinces so ill governed, that he is accounted a prince of no consequence, though otherwise he might be reckoned one of the most considerable powers of Hindoostan.

10. The *dominions of Tippoo Saib*, the son and successor of Hyder Ally, are bounded on the north by the territories of the Paishwa: on the south by Travancore, the territory of an independent Hindoo prince; on the west by the sea; and on the east by a great ridge of mountains, which separate them from the territories of the nabob of Arcot. The country lying to the eastward of these mountains is called the Carnatic *Payen Ghat*, and to the westward the Carnatic *Bhalla Ghat*. The latter belongs to Tippoo Saib; and the two together make up the country formerly called the *Carnatic*, though the name is now restricted to the *Payen Ghat*. The situation of the Bhalla Ghat is considerably more elevated than the other; by which means the temperature of the air is much cooler. On the coast of Coromandel there is a pile of ruins called by the natives *Malavipatam*, and by the British *the seven pagodas*. Concerning this there is a tradition, that it once stood at a considerable distance from the sea; though most of the ruins are now covered with water: and there is likewise a tradition, that the mountains we speak of once formed the boundary of the ocean. The revenue and strength of Hyder Ally are said to have been greatly exaggerated; the former amounting to no more than four millions annually, though by his economy and good management he made it answer every purpose both in time of war and peace. He was at great pains to introduce the European discipline among his troops; but notwithstanding all his endeavours, he was far from being able to make them cope with the British. The advantages he gained were owing to his vast superiority in cavalry, and the celerity of his marches; which would have been counteracted had his adversaries been possessed of a good body of cavalry; and it is probable that the event of the war would have been decided in a single campaign. His son Tippoo Saib is said to be a man of less abilities than his father, though more violent in his disposition. Against this prince hostilities were some time ago commenced by the British in conjunction with the Mahrattas, between whom an alliance had been formed. The peace since concluded has been attended with consequences highly advantageous to England.

With regard to the present government of Hindoostan, our limits will not allow us to enter particularly upon it, nor indeed is it perhaps of any importance, as the country is divided into so many different kingdoms; the sovereigns of which,

however they may differ in other respects, seem all to agree in despotism and oppression of their subjects.

The British territories in the East Indies were originally under the jurisdiction of a governor and 13 members; but this number has fluctuated occasionally from 14 to 4, at which it was fixed by act of parliament. In this council, all matters, whether relating to peace or war, government or commerce, were debated, the governor having no other superiority than that of giving the casting vote. In other respects the whole executive power was lodged in his hands, and all the correspondence with the native princes of India was carried on by his means, the dispatches to them being signed by him singly; and all the princes and great men who visited the presidency were first received by him, and then introduced to the counsellors. He was military governor of Fort William, and commander in chief of the presidency; whence, as by his office he was invested with a considerable degree of power, he became an object of some envy and jealousy to the members of the council and other considerable people in that part of the world. This circumstance occasioned the government to be divided into two parties, one siding with the governor, and the other opposing him; in consequence of which, the debates were frequently carried on with an indecent degree of heat and violence. This indeed may be looked upon as one of the principal causes by which the reputation of the British government in the eastern parts of the world has suffered; for, as there were very frequently opinions diametrically opposite to one another recorded upon the same subject, the contending parties in the British parliament had always sufficient authority for what they said, let them take which side they would; and thus the characters of all concerned in the East India government were, with great appearance of justice, set forth in the most opprobrious light. Another source of just reproach was, that the court of directors in England became infected with the same spirit of party which pervaded all other departments of the state; and hence arose innumerable disputes and contentions highly disgraceful to those concerned.

With regard to the administration of British affairs in the East Indies, it must indeed be remarked, that the company now act in a very different capacity from what they originally did. From a society of merchants, they are now become sovereigns of the country to which they trade. The latter character was quite foreign to them; and they have accordingly looked upon that of merchants as the principal one, while that of sovereigns was to be only a kind of appendage to it. Thus, instead of acting for the interest of the country they govern, and which as sovereigns they naturally ought to do, they have acted in many cases directly opposite to it, which, as merchants, is also their natural interest. Hence also, when the administration in India did any thing in obedience to the orders of the directors, which orders being dictated by merchants were prejudicial to the interests of the country, that injury has been sometimes unjustly attributed to their servants, who acted merely in obedience to the orders they received. On the other hand, when the India administration acted with the generous spirit of sovereigns, they were sometimes blamed by the directors, who judged as merchants, and sometimes by the ministry, who were always ready, upon the smallest pretence, to interfere in their affairs.

At the time when the British administration first commenced in Hindoostan, the Hindoo governors were universally named *Rajabs*; but though many of the Hindoo families yet bear that title, it does not appear to resemble, in any manner of way, our titles of nobility, or to be a dignity which can be conferred by any of the princes, or even by the Mogul himself. Hence, in that part of the world there are no ancient nobility, the titles being conferred merely by usurpers, who have neither right nor title derived from any thing but violence.

In this country we find the title of *Zemindar* very common;
VOL. IV.

a word compounded of two others, signifying, in the Persian language, a *landholder*. It appears to have been introduced by the Mohammedans, and to have been a kind of temporary office, prescribing the performance of certain duties, and requiring security for the personal appearance of the *Zemindar*. He is obliged to attend the exchequer of the king's chief collector, at the commencement of every new year, to settle his revenues; and he is not allowed to enter upon the duties of his office for the year without a special order for that purpose. On the death of a *Zemindar*, the candidate for succession must petition the sovereign, engaging himself to perform all the stipulated duties and to pay the customary fees; nor can he enter upon his office without a special investiture. As the *Zemindars* were by virtue of their office invested with considerable power, they soon became not only very despotic in their own dominions, but by degrees began to encroach on the power of the sovereign himself. After the irruption of Nadir Shah every thing was thrown into confusion; the viceroys threw off obedience to the emperor, the nabobs threw off all obedience to them, and usurped their power; at which time it is probable that the *Zemindars* likewise assumed powers to which they were by no means entitled from their office. Notwithstanding this, however, they were sometimes treated by the Mohammedan governors as mere revenue-officers, and used very harshly. At some times there were a set of people bound to the *Zemindars* under the title of *Woodedars*; and these had either a joint power with the former, or were superior to them in the collection of the revenues; and sometimes they were superseded by officers appointed immediately by government itself, under the various names of *Aumils*, *Tabfielders*, or *Sezawruls*. The *Zemindaries* are not limited in extent or value; there being some in Bengal which yield a revenue as high as 350,000l. sterling, while others scarcely amount to 350l.; but all the great *Zemindars*, and many of those in middling circumstances, having procured for themselves the title of *Rajab*, affect much pomp and state in their different districts, and keep their inferiors in as great subjection as the Mohammedan governors keep them. Some of them also have their power augmented by being of the bramin cast. By the reverence supposed to be due to religion on that account, joined with the power conferred upon them by the sovereign, they are in general rendered exceedingly despotic, with an almost unlimited authority to plunder their tenants; in which they were indulged by the nabobs from the motive of plundering them again. From the consultations of the select committee in 1769, we are informed that the *Zemindars* have a power of levying fines at pleasure; that they raise large sums from duties collected in the market; and that they frequently oblige the ryots or husbandmen to work for nothing. In short, the same claims made by the European barons on their vassals in the times of the feudal system, are now made by the *Zemindars* on the common people of Hindoostan. If one of them is to be married, if he has a child born, if honours are to be conferred upon him; nay, if he is even to be fined for his own misconduct, the poor ryot must always contribute his share. Mr. Scrafton, in his history of Hindoostan, sets forth the situation of the inhabitants in the following words:—"Unhappily for the Gentoos, themselves are made the ministers of oppression over each other: the Moor men, haughty, lazy, and voluptuous, make them, of whom they have no jealousy, the ministers of their oppression, which further answers the end of dividing them, and prevents their uniting to sling off the yoke; and by the strange intoxication of power, they are found still more rapacious and cruel than their foreign masters: and what is more extraordinary, the bramins still exceed the rest in every abuse of power, and seem to think, if they bribe God by bestowing a part of their plunder on cows and saquirs, their iniquities will be pardoned."

From this account of the situation of the people of Hindoostan

under their native rulers, it is by no means probable that they could make a worse exchange by falling under the jurisdiction either of the Mohammedans or Europeans. A notion indeed hath been indutritiously propagated, that the British government has behaved with the greatest cruelty in collecting the revenues, and that they have even invented tortures to make the rich people discover their treasures; but on examining the matter impartially, the reverse of this is found to be true. At the time that the British government interfered in the affairs of Hindoostan, the provinces were found to be in a ruinous state, in consequence of the wars which had taken place in the country. Even in the most settled state, and when the administration was most regular, the government was altogether despotic, and the mode of collecting its revenues extremely arbitrary; the punishments inflicted very cruel; and the whole system of government such as would be reckoned quite shocking in Europe. It is only within these few years that the British could effectually interpose in behalf of the natives; and in that short time it has produced a very considerable reformation. It is certain, that the British government has discouraged oppressive measures as much as possible; abolished the cruel modes of punishment used by the Mohammedans; and by instituting a more regular plan of justice, has procured ease and security to the natives, and preserved them in a state of tranquillity altogether unknown to them before its commencement.

One great objection, however, to the India government is, that the English law, which undoubtedly is better calculated than any other for securing the liberties of the people, has not yet been adopted in India; whence it is thought that the company's servants have still showed a disposition to oppress, rather than to relieve, the oppressed inhabitants of Hindoostan. But in answer to this it is said, that the difference betwixt the two countries is so great, that there can be no comparison betwixt the one and the other, nor can the constitution of England be in any degree adapted to that of the other. The religion, laws, manners, and customs, of both Hindoos and Mohammedans, are so essentially different from those of this country, that it is impossible to assimilate them, should ever any thing of the kind be attempted. The only true method therefore of judging whether the present state of Hindoostan is preferable to what it formerly was, is to compare it with what it was under the best Mogul emperors; and in this comparison it must certainly appear that the preference is greatly in favour of the British administration. In Major Rennel's work we are informed, that during the reign of Ackbar, whom he styles "the glory of the house of Timur," the country had never enjoyed so much tranquillity; "but this tranquillity would hardly be deemed such in any other quarter of the world, and must therefore be understood to mean a state short of actual rebellion, or at least commotion." The same author, speaking of the state of the British empire there, uses the following words: "The Bengal provinces, which have been in our actual possession near 23 years, have, during that whole period, enjoyed a greater share of tranquillity than any other part of India, or indeed than those provinces had ever experienced since the days of Aurengzebe." To this we may add, that the provinces have not only experienced a perfect freedom from external invasions, but likewise enjoy a degree of internal tranquillity altogether unknown before, by the subjection and civilization of a set of banditti who inhabited the hills of Rajemahl, and infested the travellers who passed that way; a wandering tribe of religious mendicants, who were wont to commit the greatest enormities.

Another advantage the inhabitants of this country reap from the British government, is the security from violence and oppression either by their Mohammedan superiors or by one another. Under the article HINDOO we have already mentioned the particular circumstance that these people are liable to the

punishment of losing their cast from a variety of causes, and that this is looked upon by them to be the most grievous calamity they can suffer. The Mohammedan governors frequently took advantage of their superstition in this respect to oppress them; and this circumstance alone frequently produced the most horrid confusion. In the instructions given to the supervisors, Mr. Verelst informs them, that "it is difficult to determine whether the original customs, or the degenerate manners of the Mussulmen, have most contributed to confound the principles of right and wrong in these provinces. Certain it is (adds he), that almost every decision of theirs is a corrupt bargain with the highest bidder. Compensation was frequently accepted of even for capital crimes, and fines became at last an intolerable grievance; nay, so venal were the judges at that time, that it became at last a settled rule to allow each of them a fourth part of any property in dispute as a compensation for his trouble. It is impossible to suppose that such monstrous abuses continue under the British government: on the contrary, we must readily believe, what the governors themselves assert, that immediately after the provinces fell under British jurisdiction, both Hindoos and Mohammedans have been left to the free exercise of their religion, laws, and customs. The Hindoos themselves acknowledge this, and are as well pleased with the mildness of the British government, as they are displeased with the superstition and cruelty of the Mohammedans. Under the British government we cannot suppose but that commerce, to which the inhabitants of this country are so much addicted, will be much more encouraged than by the avaricious and barbarous Mohammedans. The latter had imposed so many restraints upon trade of all kinds, by the multitude of taxes collected at the landing-places, watch-houses, markets, &c. that it was almost impossible to carry it on with any advantage. Among other salutary regulations, however, enacted by the British government in 1772, many of those taxes upon commerce were abolished, and a plan laid for effectually liberating the inhabitants from those shackles by which their commerce had been so long fettered. regard has also been paid to the instruction of the people in useful knowledge; and the seminary established at Calcutta by Sir William Jones, certainly does much honour to the founder. Some regard had indeed been paid to this by the Mohammedan emperors; but at the time that the British government commenced, these had been entirely neglected, their endowments resumed by government, and even the buildings fallen into ruin.

From a comparison of any government to which the Hindoos have hitherto been subject, with that of Britain, indeed, it is evident that the preference must be given greatly in favour of the latter. At the time when the British first visited that country, they were not under the jurisdiction of their native sovereigns, nor had they been so for a long time before. The Moguls were not only foreigners, but a most cruel and detestable race of men; and it was by usurpations of their own rebellious subjects that the anarchy and confusion was introduced, in which the country was involved for so long a time. The British are foreigners as well as the Moguls; but the latter, who profess the intolerant superstition of Mohammed, suffer their conduct to be influenced by it in such a manner as to treat the natives with the utmost cruelty. The greatest evil perhaps which results from the British government is, the exportation of great sums of money to a foreign country; but this evil, with respect to the provinces possessed by the British, existed also under the Mohammedan government. The Mogul emperors resided at Delhi, which is far distant from the provinces of Bengal, Bahar, and Orissa, the territories now possessed by Britain; so that the greatest part of the treasure sent to that capital was totally lost to them. In the time of Aurengzebe, the emperor's tribute amounted to three millions sterling; and of this a considerable part was specie; but since that time the tribute was fixed at

only 1,250,000l. and even this was a vast sum; to which if we add that carried out of the country by commanders of mercenary troops who were all foreigners, it is not unreasonable to suppose that under the Mogul government matters were still worse, even in this respect, than under that of Britain.

With regard to the *geography* of this country, Mr. Rennel observes, that though, by the modern Europeans, Hindoostan has been understood to mean the tract situated between the rivers Indus and Ganges on the east and west, the mountains of Thibet and Tartary on the north, and the ocean on the south, the extent of Hindoostan, properly so called, is much more circumscribed; and the name ought only to be applied to that part which lies to the northward of 21° or 22° latitude. The reputed southern boundary of Hindoostan is the Nerbudda river as far as it goes, and the northern frontiers of Bengal and Bahar compose the remainder. The countries to the south of this line are called *Deccan* by the Indian geographers, and comprehend about one half of the territory generally known by the name of the *Mogul Empire*. Our author therefore chooses to distinguish the northern part by the name of *Hindoostan Proper*; which has indeed the Indus and mountains of Thibet and Tartary for its western and northern boundaries; but the Burrampooter river is rather to be considered as the eastern boundary than the Ganges; the latter intersecting some of the richest provinces in the empire. According to this supposition, Hindoostan Proper will equal in size the countries of France, Germany, Bohemia, Hungary, Switzerland, Italy, and the Low Countries; the Deccan and peninsula being about equal to the British islands, Spain, and Turkey in Europe.

Towards the north, Hindoostan is very cold and barren; but towards the south, very hot, and fertile in corn, rice, fruits, and other vegetables. The northern provinces are very mountainous and sandy; while the southern are for the most part level, and well watered with several rivers.

The most remarkable *mountains* are those which surround it on three sides. Those on the west, separating it from Persia, called, in general, *Solcyman Kay*, or *the mountains of Soleyman*, are of a vast height as well as breadth, and are only passable in certain places, through which roads have been made for the sake of commerce. The chief are those which lead to Kabul, Gazna, and Kandahar. This great chain of mountains is inhabited by different nations, the principal of which are the Afghans, or Patans, and the Baluches, who have extended themselves on the side of India, as well as Persia. The mountains on the north are called *Nagrakut*, *Hima*, or *Mûs Tâg*, which has an affinity with *Imaüs*, and by other names, which are given also in common to the mountains on each side, separating Hindoostan from Thibet. The very prospect of these mountains is frightful, being nothing but hideous precipices, perpetually covered with snow, and not to be crossed without the greatest danger and difficulty.

The most remarkable *rivers* of Hindoostan are the Indus and Ganges. The former is called by the orientals, *Send*, *Sind*, or *Sindi*. It rises in the mountains to the north or north-east of Hindoostan; whence, after a long course, first to the south and then to the south-west, it falls into the Persian sea, below Lower Bander, by several mouths. In its course it receives several other large rivers, as the Nilâh, Jamal, Behat, and Lakka. The *Ganges*, called in the Indies *Ganga*, rises in the kingdom of Thibet; entering Hindoostan about the 30th degree of latitude, it runs first south-eastward by the cities of Bikaner, Minapor, Halabas, Banâres, and Patna, to Rajah Mahl, where it divides into two branches. The eastern having passed by Dâkka, the capital of Bengal, enters the gulph of that name about Chatigan. The western, descending by Kossim-Bazar and Hughly, falls into the gulph below Shandernagor, towards Pipeli. Many of the Jews and ancient Christians believed this river to be the

Pison, one of the four mentioned in scripture as the boundaries of the terrestrial paradise. The Indians retain the greatest reverence for its waters, going in crowds from the remotest parts of the country to wash in them, from a persuasion that they wholly obliterate the spots of sin. The reason of this is, because they imagine this river does not take its source from the bosom of the earth, but descends from heaven into the paradise of Devendre, and from thence into Hindoostan. Nothing is more childish than the fables of the Bramins on this subject, yet the people swallow them all. The Mogul and prince of Golconda drink no other water than that of the Ganges: foreigners, on the contrary, allege that it is very unwholesome, and that it cannot be safely drunk till it is first boiled. There are a great number of superb pagodas on the banks of the Ganges, which are immensely rich. At certain festivals, there has been sometimes a concourse of 100,000 people who came to bathe in it. But what principally distinguishes this river, besides its greatness and rapidity, is the gold it brings down in its sands, and throws on its banks; and the precious stones and pearls it produces, not only in itself, but in the gulph of Bengal, into which it discharges its waters, and which abound therewith. The-Chun or Jemma, the Guderasu, the Perfilis, Lakia, and several other rivers, discharge themselves into it during its course.

The *weather* and *seasons* are, for the most part, very regular in this spacious country: the winds blowing constantly for six months from the south, and six from the north, with very little variation. The months of April, May, and the beginning of June, till the rains fall, are so extremely hot, that the reflexion from the ground is apt to blister the face; and but for the breeze or small gale of wind which blows every day, there would be no living in that country for people bred in northern climates; for, excepting in the rainy season, the coldest day is hotter there at noon than the hottest day in England. However, very surprising changes of heat and cold sometimes happen within a few hours; so that a stifling hot day is succeeded by a night cold enough to produce a thin ice on the water, and that night by a noon as scorching as the preceding. Sometimes, in the dry season, before the rains, the winds blow with such extreme violence, that they carry vast quantities of dust and sand into the air, which appear black, like clouds charged with rain; but fall down in dry showers, filling the eyes, ears, and nostrils of those among whom they descend, and entering every chest, cabinet, or cupboard, in the houses or tents, by the key-hole or crevices.

From Surat to Agra, and beyond, it seldom or never rains, excepting in one season of the year; that is, from the middle of June to the middle of September. These rains generally begin and end with most furious storms of thunder and lightning. During these three months it rains usually every day, and sometimes for a week together without intermission: by this means the land is enriched, like Egypt by the Nile. Although the land look before like the barren sands of the Arabian deserts; yet, in a few days after those showers begin to fall, the surface appears covered with verdure. When the rainy season is over, the sky becomes perfectly serene again, and scarce one cloud appears all the other nine months: however, a refreshing dew falls every night during that dry interval, which cools the air, and cherishes the earth.

The *produce* of Hindoostan is very rich in every kind, whether it be fossil, vegetable, or animal. Besides other precious stones found in it, there is a diamond-mine at the town of Soumelpûr in Beugal. Quarries of Theban stone are so plentiful in the Mogul's empire, that there are both mosques and pagods built entirely of it. Some travellers tell us, there are mines of lead, iron, and copper, and even silver; but those of the last if there be any, need not be opened, since the bullion of all na-

tions is sunk in this empire, which will take nothing else in exchange for her commodities, and prohibits the exporting it again. They till the ground with oxen and foot-ploughs, sowing in May and the beginning of June, that all may be over before the rains, and reaping in November and December, which with them are the most temperate months in the year. The land is no where inclosed, excepting a little near towns and villages. The grass is never mowed to make hay, but cut off the ground, either green or withered, as they have occasion to use it. Wheat, rice, barley, and other grain, grow here in plenty, and are very good. The country abounds no less in fruits, as pomegranates, citrons, dates, grapes, almonds, and cocoa-nuts; plums, those especially called *mirabolans*; plantanes, which in shape resemble a slender cucumber, and in taste exceed a Norwich pear; mangos, an excellent fruit, resembling an apricot, but larger; ananas, or pine-apples; lemons and oranges, but not so good as in other countries; variety of pears and apples in the northern parts; and the tamarind-tree, the fruit of which is contained in a pod resembling those of beans. There are many other kinds of fruit-trees peculiar to the country. But the valuable trees are the cotton and mulberry, on account of the wealth they bring the natives from the manufacture of calicoes and silks. They plant abundance of sugar-canes here, as well as tobacco; but the latter is not so rich and strong as that of America, for want of knowing how to cure and order it.

Hindoostan affords also plenty of ginger, together with carrots, potatoes, onions, garlic, and other roots known to us, besides small roots and herbs for sallads; but their flowers, though beautiful to look at, have no scent, excepting roses, and some few other kinds.

There are great variety of *animals* in this country, both wild and tame; of the former are elephants, rhinoceroses, lions, tigers, leopards, wolves, jackals, and the like. The jackals dig up and eat dead bodies, and make a hideous noise in the night. The rhinoceros is not common in the Mogul's empire; but elephants are very numerous, some 12, 14, or 15 feet high. There is plenty of venison, and game of several kinds; as red deer, fallow-deer, elks, antelopes, kids, hares, and such like. None of these are imparked, but all in common, and may be any body's who will be at the pains to take them. Among the wild animals also may be reckoned the musk-animal, apes, and monkeys.

Hindoostan affords variety of beasts for carriage, as camels, dromedaries, mules, asses, horses, oxen, and buffaloes. Most of the horses are white, and many curiously dappled, pied, and spotted all over. The flesh of the oxen is very sweet and tender. Being very tame, many use them as they do horses to ride on. Instead of a bit, they put one or two small strings through the gristle of the nostrils, and fastening the ends to a rope, use it instead of a bridle, which is held up by a bunch of gristly flesh which he has on the fore-part of his back. They saddle him as they do a horse; and, if spurred a little, he will go as fast. These are generally made use of all over the Indies; and with them only are drawn waggons, coaches, and chariots. Some of these oxen will travel 15 leagues in a day. They are of two sorts; one six feet high, which are rare; another called *dwarfs*, which are only three. In some places, where the roads are stony, they shoe their oxen when they are to travel far. The buffalo's skin makes excellent buff, and the female yields very good milk; but their flesh is neither so palatable nor wholesome as beef. The sheep of Hindoostan have large heavy tails, and their flesh is very good, but their wool coarse.

This country is much infested with *reptiles* and *insects*; some of a noxious kind, as scorpions, snakes, and rats; but the lizards, which are of a green colour, are not hurtful. Snakes

and serpents, we are told, are sometimes employed to dispatch criminals, especially such as have been guilty of very atrocious crimes, that kind of death being attended with the most grievous torture. The most troublesome insects in this hot country are flies, musketoes, and chinchies or bugs, the first by day, and the others in the night; when they offend no less by their stench than their bite.

HINE, or HIND, a husbandman's servant. Thus the person who oversees the rest, is called the master's hine.

HINGHAM, a town of Norfolk, with a market on Saturday. It is 12 miles S. W. of Norwich, and 97 N. E. of London. E. lon. 1. 4. N. lat. 52. 43.

HINNOM, or *the Valley of HINNOM*, in ancient geography, a place that lay to the south of Jerusalem. It was also called *the Valley of Tophet*, and was remarkable for the cruel and barbarous worship of the god Moloch, where parents made their children pass through the fire in honour of that idol.

HINZUAN, or JOANNA, one of the Comora Islands, between the north end of Madagascar and the continent of Africa. It has been governed, about two centuries, by a colony of Arabs, and exhibits a curious instance of the slow approaches towards civilization, which are made by a small community, with many natural advantages. Of this African island, in which we hear the language and see the manners of Arabia, an account has been written by sir William Jones, for the Society for the Promotion of Oriental Knowledge, of which he was president. He visited this island, on board the Crocodile frigate, in July 1783. On anchoring in the bay, the frigate was soon surrounded by canoes, and the deck crowded with natives of all ranks, from the high-born chief who washed linen, to the half-naked slave who only paddled. Most of them had letters of recommendation from Englishmen, which none of them were able to read, though they spoke English intelligibly; and some appeared vain of titles which our countrymen had given them in play, according to their supposed stations. "We had," says Sir William Jones, "lords, dukes, and princes, on board, soliciting our custom, and importuning us for presents. In fact, they are too sensible to be proud of empty sounds, but justly imagined that those ridiculous titles would serve as marks of distinction, and, by attracting notice, procure for them something substantial." The appearance of the island from the bay of Hinzuan is thus described by the same writer: "We were at anchor in a bay, and before us was a vast amphitheatre, of which you may form a general notion by picturing in your minds a multitude of hills, infinitely varied in size and figure, and then supposing them to be thrown together, with a kind of artless symmetry, in all imaginable positions. The back ground was a series of mountains, one of which is pointed, near half a mile perpendicularly high from the level of the sea, and little more than three miles from the shore; all of them richly clothed with wood, chiefly fruit-trees, of an exquisite verdure. I had seen many mountains of a stupendous height in Wales and Switzerland, but never saw one before, round the bosom of which the clouds were almost continually rolling, while its green summit rose flourishing above them, and received from them an additional brightness. Next to this distant range of hills was another tier, part of which appeared charmingly verdant, and part rather barren; but the contrast of colours changed even this nakedness into a beauty: nearer still were innumerable mountains, or rather cliffs, which brought down their verdure and fertility quite to the beach; so that every shade of green, the sweetest of colours, was displayed at one view, by land and by water. But nothing conduced more to the variety of this enchanting prospect than the many rows of palm-trees, especially the tall and graceful Arcas, on the shores, in the

valleys, and on the ridges of hills, where one might almost suppose them to have been planted regularly by design. A more beautiful appearance can scarce be conceived, than such a number of elegant palms in such a situation, with luxuriant tops, like verdant plumes, placed at just intervals, and showing between them part of the remoter landscape, while they left the rest to be supplied by the beholder's imagination. Neither the territory of Nice, with its olives, date trees, and cypresses, nor the isles of Hieres, with their delightful orange-groves, appeared so charming to me as the view from the road of Hinzuau." This island has likewise been described by major Rooke, who observes, that it is a proper place of refreshment for the India ships, whose crews, when ill of the scurvy, soon recover by the use of limes, lemons, and oranges, and from the air of the land. The town where the king resides is at the E. side of the island; and though it is three quarters of a mile in length, it does not contain above 200 houses. This town is close to the sea, at the foot of a very high hill. The houses are inclosed either by high stone walls or pailings made with a kind of reed; and the streets are little narrow alleys, extremely intricate, and forming a perfect labyrinth. The better kind of houses are built of stone, within a court-yard, have a portico to shield them from the sun, and one long lofty room where they receive guests; the other apartments being sacred to the women. The sides of their rooms are covered with a number of small mirrors, bits of China ware, and other little ornaments that they procure from the ships: the most superb of them are furnished with cane sofas, covered with chintz and satin matrases. The horned cattle are a kind of buffaloes, having a large hump on their shoulders, which is very delicious eating; but there is not one horse, mule, or ass, in all the island. The original natives, in number about 7000, occupy the hills, and are generally at war with the Arabian interlopers, who established themselves on the sea-coast by conquest, and are about 3000 in number. Though Joanna is not the largest, it may be reckoned the principal of the Comora islands. It claims sovereignty over, and exacts tribute from, all the others: these pretensions it is, however, sometimes obliged to assert by the sword; and, when major Rooke was here, they were meditating an expedition against Mayotta, which was in a state of rebellion. The natives, on being asked the cause of their war with that people, answered, "Mayotta like America." They get their supplies of arms and ammunition from ships that touch here; and it is customary for all to make presents of arms and powder to the prince when he pays a visit on board, which he does to every one. They have a regular form of government, and exercise the Mahometan religion; both being introduced by the Arabians. The colour of these two races of men is very different: the Arabs have not so deep a tinge as the others, being of a copper complexion, with better features and a more animated countenance. They consider a black streak under the eyes as ornamental; and this they make every day, at their toilettes, with a painting-brush dipped in a kind of ointment. The custom of chewing the betel-nut prevails greatly here, as in most of the eastern countries; and answers to the fashion of smoking tobacco or taking snuff with us, except that with them it is more general. No one is without a purse or bag of betel; and it is looked on as a piece of civility to offer it to your friend when you meet him, or take leave. Their religion licenses a plurality of wives, and likewise concubines. They are extremely jealous of them, and never allow any man to see the women: but female strangers are admitted into the haram; and some English ladies, whose curiosity has led them there, make favourable reports of their beauty, and richness of apparel, displayed in a profusion of ornaments of gold, silver, and beads, in form of necklaces, bracelets, and earrings: they wear half a dozen or more in each, through holes bored along the outer rim of the ear. The men seem not to

look with indifference on our fair countrywomen, notwithstanding they are of such a different complexion. One of the first rank among them being much smitten with a young English lady, wished to make a purchase of her at the price of 5000 dollars; but on being informed that the lady would fetch at least 20 times that sum in India, he lamented that her value was so far superior to what he could afford to give. They are very temperate and abstemious, wine being forbidden them by the law of Mahomet. They are frequent in prayer, attending their mosques three or four times a day. Strangers are allowed to enter them, on condition of taking off their shoes. In prayer the people prostrate themselves on the ground, frequently kissing it, and expressing very fervent devotion. Most of the people speak a little English; they profess a particular regard for our nation, and are very fond of repeating to you, that "Joanna-man and English-man all brothers;" and never fail to ask "how king George do?" In general, they appear to be a courteous and well disposed people, and very fair and honest in their dealings, though there are among them, as in all other nations, some viciously inclined; and theft is much practised by the lower class, notwithstanding the punishment of it is very exemplary, being amputation of both hands of the delinquent. The inhabitants, like those of most hot and tropical countries, are indolent, and do not improve by their labour the richness of that soil with which nature has blessed them. "Climate here," says major Rooke, "promotes vegetation to such a degree as requires little toil in the husbandman; but that little is denied; so that beyond oranges, bananas, pine-apples, cocoa-nuts, yams, and purslain (all growing spontaneously), few vegetables are met with. Nor are the natural beauties of the island inferior to its other advantages of plenty and fertility. The face of the country is very picturesque and pleasing, its scenes being drawn by the bold strokes of Nature's masterly pencil. Lofty mountains clothed to their very summits, deep and rugged valleys adorned by frequent cataracts, cascades, woods, rocks, and rivulets, intermixed in "gay theatric pride," form the landscape. Groves are seen extending over the plains to the very edge of the sea, formed principally by the cocoa-nut trees, whose long and naked stems leave a clear and uninterrupted passage beneath; while their tufted and over-spreading tops form a thick shade above, and keep off the scorching rays of the sun. In the interior part of the island, surrounded by mountains of a prodigious height, and about 15 miles from this town, is situated a sacred lake, half a mile in circumference. The adjacent hills, covered with lofty trees, and the unfrequented solitude of the place, seem more calculated to inspire religious awe in those who visit this sequestered spot, than any sanctity that is to be discovered in a parcel of wild ducks inhabiting it, which are deified and worshipped by the original natives, who consult them as their oracles on all important affairs, and sacrifice to them. Being extremely averse to conduct strangers there, they stipulate that all guns shall be left at a place five miles from the lake. The worship paid to these birds ensures their safety and tranquillity; and rendering them of course perfectly tame, they fearlessly approach any one who goes there. The Arabian part of the islanders hold this barbarous superstition in the utmost detestation; but dare not forbid the practice of it, so bigoted to it are the others. E. lon. 44. 15. S. lat. 12. 30. E.

HIO, a town of Sweden, in W. Gothland, seated on the Lake Wetter, 14.5 miles S. W. of Stockholm. E. long. 14. 0. N. lat. 57. 53.

HIP, in the materia medica, the fruit of the dog-rose or wild brier. See ROSA. They contain an acidulous, yet sweetish pulp; with a rough prickly matter inclosing the seeds, from which the pulp ought to be carefully separated before it be taken internally. The Wirtemberg college observes, that from a neglect of this caution, the pulp of hips sometimes occasions a

pruritus and uneasiness about the anus; and the conserve of it has been known to excite violent vomiting. The conserve is the only officinal preparation of this fruit, which does not possess any medical virtues, but is merely used by the apothecaries as a vehicle for other remedies.

HIPPARCHUS, a great astronomer, born at Nice in Bithynia, flourished between the 154th and 163d Olympiads. His Commentary upon Aratus's Phenomena is still extant. Rohault was very much mistaken when he asserted, that this astronomer was not acquainted with the particular motion of the fixed stars from west to east, by which their longitude changes. By foretelling eclipses, he taught mankind not to be frightened at them, and that even the gods were bound by laws. Pliny, who tells this, admires him for making a review of all the stars; by which his descendants would be enabled to discover whether they are born and die, whether they change their place, and whether they increase and decrease.

HIPPJA, in botany; a genus of the polygamia necessaria order, belonging to the syngenesia class of plants. The receptacle is naked; there is no pappus; the seeds are naked, with very broad margins; the calyx is hemispheric, and subimbricated; the radius consists of ten corollulæ, obscure, and rather cleft into three.

HIPPOBOSCA, or **HORSE-FLY**, in zoology; a genus of insects, belonging to the order of diptera. The beak consists of two valves, is cylindrical, obtuse, and hanging; and the feet have several claws. There are four species, distinguished by their wings, &c. The most remarkable is the equina, the pest of horses and cows. This insect is broad, flat, shining, and as it were scaly. Its head, thorax, and abdomen, are yellow, undulated with brown; and the legs are intersected with yellow and brown. The wings, crossed one over the other, exceed the length of the body by above one half; they are transparent, tinged with a little yellow towards their outward edge, and have a spot near that edge of a brown colour. These insects are very difficult to be killed on account of the hard crustaceous shell which covers them; and they fix so close and fast to the poor animals with their claws, that they cannot rub or bite them off without wounding themselves. See Plate 3.

HIPPOCAMPUS, in ichthyology. See **SYNGNATHUS**.

HIPPOCASTANUM, or common horse-chestnut. See **ÆSCULUS**. It may be here added, that from several experiments in the French *Memoires d'Agriculture*, it appears that the fruit of the horse-chestnut affords a wholesome nourishment for cattle, and may even be employed with success for fattening them. It is said to render the tallow of those fattened with it particularly firm. The milk yielded by cows fed upon it, is also said to be thicker and richer than that produced from any other kind of food. The fruit of this tree has been likewise used as food for sheep and poultry, and as soap for washing. It was much employed in powder as a sternutatory by an itinerant oculist, and has been recommended by some others in certain states of ophthalmia, headach, &c. in which errhines are indicated. Its effects as a sternutatory may also be obtained by using it under the form of infusion or decoction drawn up into the nostrils. It is entirely with a view to its errhine power that it has a place in the Pharmacopœia of the Edinburgh college. The bark has indeed been recommended by some as a cure for intermittent fevers; and it is probably with this intention that this part of the hippocastanum is introduced as an officinal article in the Pharmacopœia Rossica. During the late scarcity of grain, some attempts were made to obtain starch from the horse-chestnut, and not without success.

HIPPOCENTAUR, formed of ἵππος "horse," κεντεω *pingo*, "I spur," and ταύρος "bull," in antiquity, a fabulous monster, supposed to be half horse and half man. What gave occasion to the fable was, that a people of Thessaly, inhabiting near

mount Pelion, became thus denominated, because they were the first that taught the art of mounting on horseback; which occasioned some of their neighbours to imagine, that the horse and man made but one animal. The hippocentaurs should seem to have differed from the centaurs, in this, that the latter only rode on bullocks, and the former on horses, as the names themselves intimate.

HIPPOCRAS, a medicinal drink, composed of wine, with spices and other ingredients; much used among the French by way of a cordial dram after meals. There are various kinds of hippocras, according to the kind of wine and the other additional ingredients made use of; as white hippocras, red hippocras, claret hippocras, strawberry hippocras, hippocras without wine, cyder hippocras, &c.

That directed in the late London Dispensatory, is made of cloves, ginger, cinnamon, and nutmegs, grossly powdered and infused in canary with sugar; to the infusion, milk, a lemon, and some slips of rosemary, are put, and the whole strained through a flannel. It is recommended as a cordial, and proper in paralytic and nervous cases.

HIPPOCRATIA, in botany; a genus of the monogynia order, belonging to the triandria class of plants; and in the natural method ranking with those of which the order is doubtful. The calyx is quinquepartite; the petals five, the capsules three in number, and the latter of an obcordate shape.

HIPPOCRATES, the greatest physician of antiquity, was born in the island of Cos in the 80th Olympiad, and flourished at the time of the Peloponnesian war. He was the first that we know of who laid down precepts concerning physic; and, if we may believe the author of his Life, who goes under the name of *Soranus*, drew his original from Hercules and Æsculapius. He was first a pupil of his own father Heraclides, then of Herodicus, then of Gorgias of Leontium the orator, and, according to some, of Democritus of Abdera. After being instructed in physic, and in the liberal arts, and losing his parents, he left his own country, and practised physic all over Greece; where he was so much admired for his skill, that he was publicly sent for with Euryphon, a man superior to him in years, to Perdicas king of Macedonia, who was then thought to be consumptive. But Hippocrates, as soon as he arrived, pronounced the disease to be entirely mental, as in truth it was. For upon the death of his father Alexander, Perdicas fell in love with Philas, his father's mistress: and this Hippocrates discerning by the great change her presence always wrought upon him, a cure was soon effected.

Being entreated by the people of Abdera to come and cure Democritus of a supposed madness, he went; but, upon his arrival, instead of finding Democritus mad, he found all his fellow citizens so, and Democritus the only wise man among them. He heard many lectures, and learned much philosophy from him; which has made Cornelius Celsus and some others imagine, that Hippocrates was the disciple of Democritus, though it is probable they never saw each other till this interview which was occasioned by the Abderites. Hippocrates had also public invitations to other countries. Thus, when a plague invaded the Illyrians and Pæonians, the kings of those countries begged him to come to their relief: he did not go; but learning from the messengers the course of the winds there, he concluded that the distemper would come to Athens; and, foretelling what would happen, applied himself to take care of the city and the students. He was indeed such a lover of Greece, that when his fame had reached as far as Persia, and upon that account Artaxerxes had entreated him by his governor of the Hellespont, with a promise of great rewards, to come to him, he refused to go. He also delivered his own country from a war with the Athenians, that was just ready to break out, by prevailing with the Thessalians to come to their assistance, for

which he received very great honours from the Coans. The Athenians also conferred great honours upon him: they admitted him next to Hercules in the Eleusinian ceremonies; gave him the freedom of the city; and voted a public maintenance for him and his family in the prytanæum or council-house at Athens, where none were maintained at the public charge but such as had done signal service to the state. He died among the Larissæans, some say in his 80th year, some in his 85th, others in his 104th, and some in his 109th. The best edition of his works is that of Foesius, in Greek and Latin. Hippocrates wrote in the Ionian dialect. His aphorisms, prognostics, and all that he has written on the symptoms of diseases, justly pass for masterpieces.

HIPPOCRENE, in ancient geography, a fountain of mount Helicon, on the borders of Bœotia, sacred to the Muses. Some, as Ovid, make Hippocrene and Aganippe the same. See **AGANIPPE**.

HIPPOPHAGI, in ancient geography, a people of Scythia, so called from their living on horse-flesh; the same at this day of the Tartars their descendants. Also a people of Persia (Ptolemy).

HIPPOCREPIS, COMMON HORSE-SHOE VETCH, in botany; a genus of the decandria order, belonging to the diadelphia class of plants; and in the natural method ranking under the 32d order, *Papilionacæ*. The legumen is compressed and crooked, with many incisions on the interior suture. There are three species, two natives of the warm parts of Europe, and one of Britain. They are all low herbaceous trailing plants, with yellow flowers. They are propagated by seeds; but having no great beauty are seldom kept in gardens.

HIPPODROME, **HIPPODROMUS** (composed of ἵππος "horse," and δρόμος "course," of the verb δρέω *curro*, "I run"), in antiquity, a list or course wherein chariot and horses races were performed, and horses exercised. The Olympian hippodrome or horse-course was a space of ground of 600 paces long, surrounded with a wall, near the city of Elis, and on the banks of the river Alpheus. It was uneven, and in some degree irregular, on account of the situation; in one part was a hill of a moderate height, and the circuit was adorned with temples, altars, and other embellishments. See **STADIUM**. There is a very famous hippodrome at Constantinople, which was begun by Alexander Severus, and finished by Constantine. This circus, called by the Turks *atmeican*, is 400 paces long, and above 100 paces wide. At the entrance of the hippodrome there is a pyramidal obelisk of granite in one piece, about 50 feet high, terminating in a point, and charged with hieroglyphics. The Greek and Latin inscriptions on its base show, that it was erected by Theodosius; the machines that were employed to raise it are represented upon it in basso-relievo. We have some vestiges in England of the hippodromus, in which the ancient inhabitants of this country performed their races; the most remarkable is that near Stonehenge, which is a long tract of ground, about 350 feet, or 200 druid cubits wide, and more than a mile and three quarters, or 6000 druid cubits, in length, inclosed quite round with a bank of earth, extending directly east and west. The goal and career are at the east end. The goal is a high bank of earth, raised with a slope inwards, on which the judges are supposed to have sat. The metæ are two tumuli, or small barrows, at the west end of the course. These hippodromes were called in the language of the country *rbedagua*, the racer *rbedagur*, and the carriage *rbeda*, from the British word *rbedeg* "to run." One of these hippodromes, about half a mile to the southward of Leicester, retains evident traces of the old name *rbedagua*, in the corrupted one of *rawdikes*. There is another of these, says Dr. Stukely, near Dorchester; another on the banks of the river Lowther, near Penrith in Cumberland; and another in the valley, just without the town of Royston.

HIPPOGLOSSUS, in ichthyology; a species of **PLEURO-NECTES**.

HIPPOLYTUS, a son of Theseus and Hippolyte, famous in fabulous history for his virtue and his misfortunes. His step-mother Phædra fell in love with him, and when he refused to pollute his father's bed, she accused him to Theseus of offering violence to her person. Her accusation was readily believed, and Theseus entreated Neptune to punish the incontinence of his son. Hippolytus fled from the resentment of his father; and as he pursued his way along the sea shores, his horses were so frightened at the noise of sea calves which Neptune had purposefully sent there, that they ran among the rocks till his chariot was broken and his body torn to pieces. Temples were raised to his memory, particularly at Trœzene, where he received divine honours. According to some accounts, Diana restored him to life.

HIPPOMANE, the **MANCHINEEL-TREE**, a genus of the monadelphia order belonging to the monœcia class of plants; and in the natural method ranking under the 38th order, *Tricoccæ*. The male has an amentum and bifid perianthium, without any corolla; the female perianthium is trifid; there is no corolla; the stigma is tripartite; and the plum or capsule tricoccus. See Plate 10. The *Species* are, 1. The *mancinella*, with oval sawed leaves, is a native of all the West India islands. It hath a smooth brownish bark; the trunk divides upward into many branches, garnished with oblong leaves about three inches long. The flowers come out in short spikes at the end of the branches, but make no great appearance, and are succeeded by fruit of the same shape and size with a golden pippin. The tree grows to the size of a large oak. 2. The *biglandulosa*, with oblong bay-leaves, is a native of South-America; and grows to as large a size as the first, from which it differs mostly in the shape of its leaves. 3. The *spinosa*, with holly-leaves, is a native of Campeachy, and seldom rises above 20 feet high; the leaves greatly resemble those of the common holly, and are set with sharp prickles at the end of each indenture. They are of a lucid green, and continue all the year.

These plants being natives of very warm climates, cannot be preserved in this country without a stove; nor can they by any means be made to rise above five or six feet high even with that assistance. They are propagated by seeds; but must have very little moisture, or they will certainly be killed by it.

These trees have a very poisonous quality, abounding with an acrid milky juice of a highly caustic nature. Strangers are often tempted to eat the fruit of the first species; the consequences of which are, a inflammation of the mouth and throat, pains in the stomach, &c. which are very dangerous unless remedies are speedily applied. The wood is much esteemed for making cabinets, book-cases, &c. being very durable, taking a fine polish, and not being liable to become worn-eaten: but as the trees abound with a milky caustic juice already mentioned, fires are made round their trunks, to burn out this juice; otherwise those who fell the trees would be in danger of losing their sight by the juice flying in their eyes. This juice raises blisters on the skin wherever it falls, turns linen black, and makes it fall out in holes. It is also dangerous to work the wood alter it is sawn out; for if any of the saw-dust happens to get into the eyes of the workmen, it causes inflammation; to prevent which, they generally cover their faces with fine lawn during the time of working the wood. It is with the juice of this tree that the Indians used to poison their arrows.

HIPPOMANES, a sort of poison famous among the ancients as an ingredient in amorous philters or love-charms. The word is Greek, ἵππομανης, composed of ἵππος; "a horse," and *μανια* "fury or madness!" Authors are not agreed about the nature of the hippomanes. Pliny describes it as a blackist caruncle found on the head of a new-born colt; which the dam

bites off and eats as soon as she is delivered. He adds, that if she be prevented herein by any one's cutting it off before, she will not take to nor bring up the young. Virgil, and after him Servius and Columella, describe it as a poisonous matter trickling from the pudendum of a mare when proud, or longing for the horse. At the end of Mr. Bayle's Dictionary is a very learned dissertation on the hippomanes, and all its virtues both real and pretended.

HIPPONAX, a Greek poet, born at Ephesus 540 years before the Christian era. He cultivated the same satirical poetry as Archilochus, and was not inferior to him in the beauty or vigour of his lines. His satirical raillery obliged him to fly from Ephesus. As he was naturally deformed, two brothers, Buphalus and Anthermus, made a statue of him; which, by the ugliness of its features, exposed the poet to universal ridicule. Hipponax resolved to revenge the injury; and he wrote such bitter invectives and satirical lampoons against them, that they hanged themselves in despair. *Cic. ad Famil. vii. ep. 24.*

HIPPOPHAE, SEA-BUCKTHORN; a genus of the tetrandria order, belonging to the diœcia class of plants; and in the natural method ranking under the 16th order, *Calycifloræ*. The male calyx is bipartite; there is no corolla: the female calyx is blind; there is no corolla; there is one style, and a monospermous berry. The *Species* are 1. The *rbamnoïdes*, with a shrubby stem, branching irregularly eight or ten feet high, having a dark brown bark. It is armed with a few thorns, hath spear-shaped, narrow, sessile leaves, of a dark green above, and hoary underneath. 2. The *canadensis* hath a shrubby brown stem, branching eight or ten feet high, with oval leaves, and male and female flowers on different plants. Both these species are very hardy, and may be propagated in abundance by suckers from the roots, by layers, and by cuttings of their young shoots. They are retained in gardens on account of their two-coloured leaves in summer; and in winter, on account of the appearance of the young shoots, which are covered with turgid, irregular, scaly buds. Goats, sheep, and horses, eat the first species; cows refuse it.

HIPPOPODES, HIPPOPEDES, or *Hippopodæ*, composed of *ἵππος* horse, and *πῦς* foot, in the ancient geography, an appellation given to a certain people situated on the banks of the Scythian sea, as being supposed to have had horses' feet. The hippopodes are mentioned by Dionysius, *Geogr. v. 310.* Mela, *lib. iii. cap. 6.* Pliny, *lib. iv. cap. 13.* and St. Augustine, *De Civit. lib. xvi. cap. 8.* But it is conjectured, that they had this appellation given them on account of their swiftness or lightness of foot. Mr. Pennant supposes them to have been the inhabitants of the Bothnian Gulph, and that they were the same sort of people as the *Finni Lignipedes* of Olaus. They wore snow shoes; which he thinks might fairly give the idea of their being, like horses, hooped and shod.

HIPPOPOTAMUS, the RIVER-HORSE; a genus of quadrupeds belonging to the order of belluæ, the characters of which are these: It has four fore-teeth in the upper jaw, disposed in pairs at a distance from each other; and four prominent fore-teeth in the under jaw, the intermediate ones being longest. There are two tusks in each jaw, those of the under one very long and obliquely truncated; in both they stand solitary, and are recurvated. The feet are hooped on the edges.

There is but one known species, *viz.* the amphibius, or river-horse. See plate 4. The head of this animal is of an enormous size, and the mouth vastly wide. The ears are small and pointed, and lined within very thickly with short fine hairs. The eyes and nostrils are small in proportion to the bulk of the animal. On the lips are some strong hairs scattered in patches here and there. The hair on the body is very thin, of a whitish colour, and scarce discernible at first sight. There is no mane on the neck, as some writers assert, only the hairs on that part

are rather thicker. The skin is very thick and strong, and of a dusky colour. The tail is about a foot long, taper, compressed, and naked. The hoofs are divided into four parts. The legs are short and thick. In bulk it is second only to the elephant. The length of a male has been found to be 17 feet, the circumference of the body 15, the height near 7, the legs near 3, the head above 3½, and the girth near 9. The mouth, when open, is above two feet wide; and furnished with 44 teeth of different figures (including the cutting teeth and the canine). The cutting, and particularly the canine teeth of the lower jaw, are very long, and so hard and strong that they strike fire with steel. This circumstance, it is probable, gave rise to the fable of the ancients, that the hippopotamus vomited fire from his mouth. The substance of the canine teeth is so white, so fine, and so hard, that it is preferable to ivory for making artificial teeth. The cutting teeth, especially those of the under jaw, are very long, cylindrical, and chamfered. The canine teeth are also long, crooked, prismatic, and sharp, like the tusks of the wild boar. The grinders are square or oblong, like those of man, and so large that a single tooth sometimes weighs three pounds. The tusks, according to Dr. Sparman, are 27 inches long. With such powerful arms, and such a prodigious strength of body, the hippopotamus might render himself formidable to every other animal. But he is naturally of a mild disposition, and is only formidable when provoked. His bulk is so great, that twelve oxen have been found necessary to draw one ashore which had been shot in a river above the Cape; and Hasselquist says, its hide is a load for a camel. Tho' he delights in the water, and lives in it as freely as upon land; yet he has not, like the beaver or otter, membranes between his toes. The great size of his belly renders his specific gravity nearly equal to that of water, and makes him swim with ease.

These animals inhabit the rivers of Africa, from the Niger to Berg River, many miles north of the Cape of Good Hope. They formerly abounded in the rivers nearer the Cape, but are now almost extirpated; and to preserve the few which are left in Berg River, the governor has absolutely prohibited the shooting them without particular permission. They are not found in any of the African rivers which run into the Mediterranean except the Nile, and even there only in Upper Egypt, and in the fens and lakes of Ethiopia which that river passes through. From the unwieldiness of his body and the shortness of his legs, the hippopotamus is not able to move fast upon land, and is then extremely timid. When pursued, he takes to the water, plunges in, sinks to the bottom, and is seen walking there at full ease; he cannot, however, continue there long without often rising towards the surface; and in the daytime is so fearful of being discovered, that when he takes in fresh air, the place is hardly perceptible, for he does not venture even to put his nose out of the water. In rivers unfrequented by mankind, he is less cautious, and puts his whole head out of the water. If wounded, he will rise and attack boats or canoes with great fury, and often sink them by biting large pieces out of the sides: and frequently people are drowned by these animals; for they are as bold in the water as they are timid on land. It is reported that they will at once bite a man in two. In shallow rivers the hippopotamus makes deep holes in the bottom, in order to conceal his great bulk. When he quits the water, he usually puts out half his body at once, and smells and looks around; but sometimes rushes out with great impetuosity, and tramples down every thing in his way. During the night he leaves the rivers in order to pasture; when he eats sugar-canes, rushes, millet, rice, &c. consuming great quantities, and doing much damage in the cultivated fields. But as he is so timid on land, it is not difficult to drive him off.—The Egyptians (Mr. Hasselquist informs us) "have a curious manner of freeing

themselves in some measure from this destructive animal. They remark the places he frequents most, and there lay a great quantity of pease: when the beast comes on shore hungry and voracious, he falls to eating what is nearest him; and filling his belly with the pease, they occasion an unsupportable thirst: he then returns immediately into the river, and drinks upon these dry pease large draughts of water, which suddenly causes his death; for the pease soon begin to swell with the water, and not long after the Egyptians find him dead on the shore, blown up, as if killed with the strongest poison." The river-horse also feeds on the roots of trees, which he loosens with his great teeth; but never eats fish, as is asserted by Dampier. It was reported to M. Hasselquist, that the river-horse is an inveterate enemy to the crocodile; and kills it whenever he meets it, and that this, with some other causes, contributes much to the extirpation of the crocodile; which otherwise, considering the many eggs they would lay, would utterly destroy Egypt. But Mr. Pennant treats the alleged enmity of the hippopotamus and crocodile as a vulgar error; an eye-witness, he tells us, declaring he had seen them swimming together without any disagreement.—The hippopotami sleep in the reedy-islands in the middle of the stream, and on which they bring forth their young. A herd of females has but a single male: they bring one young at a time, and that on the land, but suckle it in the water.—They are capable of being tamed. Belon says, he has seen one so gentle as to be let loose out of a stable and fed by its keeper without attempting to injure any one. They are generally taken in pitfalls, and the poor people eat the flesh. In some parts the natives place boards full of sharp irons in the corn-grounds; which these beasts strike into their feet, and so become an easy prey. Sometimes they are struck in the water with harpoons fastened to cords, and 10 or 12 canoes are employed in the chase.

The hippopotamus was known to the Romans. Scaurus treated the people with the sight of five crocodiles and one hippopotamus during his ædileship, and exhibited them in a temporary lake. Augustus produced one at his triumph over Cleopatra.

This animal is the behemoth of Job; who admirably describes its manners, its food, and its haunts. "1. Behold now behemoth, which I made near thee: he eateth grass as an ox. 2. Lo! now his strength is in his loins, and his force is in the navel of his belly. 3. His bones are as strong pieces of brass; his bones are like bars of iron. 4. He lieth under the shady trees, in the covert of the reed and fens. 5. Behold! he drinketh up a river: he trusteth he can draw up Jordan into his mouth." The first, the learned Bochart observes, implies the locality of its situation; being an inhabitant of the Nile, in the neighbourhood of Uz, the land of Job. The second describes its great strength; and the third, the peculiar hardness of its bones. The fourth indicates its residence amidst the vast reeds of the river of Egypt, and other African rivers overshadowed with thick forests. The fifth, the characteristic wideness of its mouth; which is hyperbolically described as large enough to exhaust such a stream as Jordan.

An entertaining account of the hippopotamus is given in Sparman's Voyage to the Cape of Good Hope, where these animals are called *sea-cows*. We shall here introduce a few particulars relative to the Hippopotamus Calf, which Mr. Sparman and his Hottentots had the good fortune to take.

"While the calf was yet alive (says he), I made a drawing of it, a copy of which may be seen in the Swedish Transactions for 1778. After this it was killed, dissected, and eaten up in less than three hours time. The reason of this quick dispatch was partly the warmth of the weather, and partly our being in absolute want of any other fresh provisions. We found the flesh and fat of this calf as flabby as one might have

expected from its want of age, and consequently not near so good as that of the old sea-cows; of which I found the flesh tender, and the fat of a taste like marrow, or at least not so greasy and strong as other fat. It is for this reason likewise that the colonists look upon the flesh and fat of the sea-cow as the wholesomest meat that can be eaten; the gelatinous part of the feet in particular, when properly dressed, being accounted a great delicacy. The dried tongues of these animals are also considered, even at the Cape, as a rare and savoury dish. On my return to Sweden, I had the honour to furnish his majesty's table with a dried sea-cow's tongue, two feet and eight inches long. With respect to form, the tongue of a full-grown hippopotamus is very blunt at the tip, and is in fact broadest at that part; if at the same time it is slanted off towards one side, and marked with lobes, as I was informed it is, this circumstance may, perhaps, proceed from the friction it suffers against the teeth, towards the side on which the animal chiefly chews; at least some traces of this oblique form were discoverable on the dried tongue I am speaking of.

"The hide of the adult hippopotamus bears a great resemblance to that of the rhinoceros, but is rather thicker. Whips likewise made of this hide are stronger, and, after being used some time, are more pliable than those made of the hide of the rhinoceros usually are, though they are not so transparent as these latter are when new.

"The food of the hippopotamus consists entirely of herbs and grass, a circumstance of which we are informed by Father Lobo; and which may partly be inferred from what I have already said on the subject, as well as from the figure of the stomach belonging to the fœtus of a hippopotamus given in Messrs de Buffon and Daubenton's elegant work. I therefore do not look upon it as very probable, that these animals, agreeably to the assertions of M. de Buffon, p. 93. or of Dampier in his Voyage, should hunt after fish by way of preying upon them; especially as in some of the rivers of the southern part of Africa, where the sea-cows are seen daily and in great abundance, there is not a fish to be seen; and in others only a few bastard springers, as they are called (*Cyprinus gonorynchus*), which are scarcely as big as a common herring. It is said, that a small species of carp is still more rarely to be met with here. It is true, that the sea-cows sometimes frequent the mouths of the rivers here, which are full of sea-fish, and even sometimes the sea itself: we know, however, that these huge quadrupeds are notwithstanding this obliged to go from thence upon dry land in quest of food. Neither is it probable that they can drink the sea-water; as an instance was related to me of the contrary in a hippopotamus, which, having been disturbed in the rivers, had taken refuge in the sea, and yet was obliged to go ashore every night and drink fresh water from a well in the neighbourhood, till at last it was shot by some people that lay in wait for it there. That the hippopotamuses actually lived in salt-water, I have seen evident proofs at the mouths both of *Kromme* and *Cantour* rivers, particularly in the latter, on my journey homewards; where many of these animals blowed themselves in broad day light, and thrust their heads up above the water; and one of them in particular, which had been wounded by an ill directed shot on the nose, neighed from anger and resentment. In Krakemanma I saw on the beach manifest traces of a hippopotamus which had come out of the sea, but had retired thither again directly. That very attentive navigator Captain Burtz informed me, that he had frequently seen on the eastern coast of Africa sea-horses (meaning probably the hippopotamus) raise their heads above the surface of the water in order to blow themselves and neigh. I have been induced to be rather circumstantial on this subject, as M. Adanson had taken it into his head, in his *Voyage au Senegal*, to limit the

abode of the hippopotamus to the fresh water rivers only in Africa; and M. de Buffon has taken upon him to support this opinion, and to render Kolbe's testimony to the contrary liable to suspicion.

"An old experienced huntsman told me, that he had once seen two hippopotamuses copulate, which they did in the same manner as common cattle. On this occasion the beasts stood in a shallow part of the river, where the water reached up to their knees.

"The method of catching the hippopotamus consists (besides shooting it) in making pits for it in those parts which the animal passes in his way to and from the river: but this method is peculiar to the Hottentots; and is only practised by them in the rainy season, as the ground in summer is too hard for that purpose. It is said that they have never succeeded in killing this huge aquatic animal with poisoned darts, though this way of killing game is practised with advantage by the Hottentots for the destruction both of the elephant and rhinoceros. The colonists likewise were not entirely unacquainted with the method mentioned by M. Hasselquist, as being common in Egypt, viz. to strew on the ground as many peas or beans as the animal can possibly eat, by which means it bursts its belly and dies. But as this method is very expensive, and they can generally have this animal for a single charge of powder and a tin ball, shot in a proper direction, they chiefly and almost solely have recourse to this cheaper expedient.

"The hippopotamus is not so quick in its pace on land as the generality of the larger quadrupeds, though perhaps it is not so slow and heavy as M. de Buffon describes it to be; for both the Hottentots and Colonists look upon it as dangerous to meet a hippopotamus out of the water, especially as, according to report, they had had a recent instance of one of these animals, which, from certain circumstances, was supposed to be in rut, having for several hours pursued a Hottentot, who found it very difficult to make his escape. The people of this country did not entertain that opinion of the medicinal virtues of the hippopotamus, as they did of certain parts of the elephant and rhinoceros; excepting one colonist, who imagined he had found the *os petrosum* of this animal, reduced to powder and taken in the quantity that would lie on the point of a knife, excellent for convulsions (*Stuypen*) in children. That the flesh is reckoned very wholesome food, I have already mentioned.

"Having already exceeded the limits I had prescribed to myself, I do not intend to dwell here on the anatomy of the hippopotamus we caught, particularly as the internal conformation of the calves is somewhat different from that of the adult animal. I shall therefore only briefly mention the following particulars: the stomachs were four in number, and consequently one more than in the *sætus* examined by M. Daubenton, which was kept in spirits. Compare Buffon, tom. xii. tab. iv. fig. 2. The two first stomachs were each of them about seven inches long and three inches in diameter; the third was nine inches in length, and a little wider than the two former; the fourth was seven inches long, and at the upper part five inches broad, but decreased by degrees on one side till it terminated in the *pylorus*, which had an aperture an inch in width, being about half as wide again as the *cardia*. I did not observe any such valves as M. Daubenton has delineated. The first stomach we found mostly empty, it containing only a few lumps of cheese or curd; it likewise differed from the rest by the superior fineness of its internal coat. The internal membrane of the second stomach was rather coarser, and had many small holes in it; it likewise contained several clods of caseous matter, together with a great quantity of sand and mud. The third stomach had very visible folds, both longitudinal and

transversal, on the inside of it, and contained caseous lumps of a yellow colour and harder consistence than the others, together with several leaves quite whole and fresh, and at the same time some dirt. The interior membrane of the fourth stomach was very smooth, though it was not without folds; in the stomach itself there was a good deal of dirt, with a small quantity of curds, which were whiter than they were in any of the other stomachs. This fourth stomach in a great measure covered the rest, being situated on the right side of the animal, and was found to have the upper part of the melt adhering to its superior and interior edge. This latter viscus, which was one foot long and three inches broad, diverged from it downwards on the left side. The intestinal canal was 109 feet long; the liver measured 14 inches from right to left, and 7 or 8 from the hind part to the fore part. On its anterior edges it had a large notch, being in other respects undivided and entire; it was of an oblique form, being broadest towards the left side, where I discovered a gall-bladder five inches in length. In the uterus there was nothing particularly worthy of observation. I found two teats, and the heart surrounded with much fat; the length of this muscle was five inches, and the breadth about four inches and a half. The communication between the anricles, called the *foramen ovale*, was above an inch in diameter. Each lung was eleven inches long, and undivided: but at the superior and exterior parts of the right lung, there were two globules or processes, elevated half an inch above the surface; and on the side corresponding to it, in the left lung, and in the upper part of it, there was a little excrescence, terminating in a point: somewhat below this, yet more forwards, there was found likewise a process half an inch in height. Directly over the lower part of the communication formed between the right and left lung, there was a kind of crest or comb, measuring an inch from the top to the basis.

"One of my brother sportsmen said, he had once observed a peculiar kind of vermin on the body of one of these amphibious animals; but on the calf we had caught we found nothing but a species of leech, which kept only about the anus, and likewise a good way up in the strait gut, where, by a timely abstraction of the blood, they may be of use to these large amphibious animals; and particularly may act as preservatives against the piles, repaying themselves for their trouble in kind. Most of them were very small; but on the other hand there was a considerable number of them. The only large one I saw of this species, being somewhat more than an inch in length, I described and made a drawing of: this is inserted by the name of the *Hirudo Capensis, corpore supra nigricante, medio longitudinaliter sub-brunneo, subtus pallide fusco*, in the elegant Treatise on Worms, which M. Adolphus Nodaer, first secretary of the Patriotic Society, is preparing for the press. Instead of the lighter coloured streak upon the back, there was discoverable in some of these leeches one and sometimes two longitudinal brownish lines, which grew fainter and fainter towards the extremities.

"The huge animal of which we have been speaking, has doubtless obtained its present name of hippopotamus, which signifies river-horse, merely in consequence of the neighing sound it makes; as otherwise in its form it bears not the least resemblance to a horse, but rather to a hog. Neither does it in the least resemble the ox; so it could be only the different stomachs of this animal which could occasion it to be called *sea-cow* at the Cape; and perhaps it is for the same reason that the Hottentots call it the *t'gao*, which nearly approaches to *t'kau*, the name by which the buffalo is known among these people.

"From the account given by Bellonius of a tame hippopotamus, which he describes as a beast of a very mild and gentle nature, as well as from the disposition of the calf we had just caught, it follows, that this animal might be easily brought

over to Europe, where it has been formerly exhibited at two different times in the public spectacles at Rome. For this purpose, the capture might easiest be made at Konaps-river, where these animals, according to the accounts given me by the Caffres, reside in great abundance; and milch cows might be kept ready at hand, in order to rear the calf in case it was a suckling. Indeed I am apt to suppose, that one a little older than this would not be very nice in its food; as that which we caught was induced by hunger, as soon as it was let loose near the waggon, to put up with something not extremely delicate, which had been just dropped from one of our oxen. This perhaps may appear very extraordinary in an animal with four stomachs; but there have been instances of this kind known in common cattle, which in Herjedal are partly fed with horse-dung. Vide A. A. Hulpfers's *Beskrifning om Norrland*, 3: je. Saml. om Herjedalen (*Hulpfers's Description of Norway*), p. 27—87. I have been likewise assured, that this method of feeding cattle has been practised with great advantage in Uplandia, when there has been a scarcity of fodder; and that afterwards these same cattle, even when they have not been in want of proper fodder, have taken to this food of their own accord, and eaten it without any thing else being mixed with it."

HIPPURIS, MARE'S-TAIL; a genus of the monogynia order, belonging to the monandria class of plants; and in the natural method ranking under the 15th order, *Inundata*. There is no calyx, nor any petals; the stigma is simple; and there is one seed. There is only one species, a native of Britain, and which grows in ditches and stagnant waters. The flower of this plant is found at the base of each leaf, and is as simple as can be conceived; there being neither empalement nor blossom; and only one chive, one pointal, and one seed. It is a very weak astringent. Goats eat it; cows, sheep, horses, and swine, refuse it.

HIRÆA, in botany; a genus of the trigynia order, belonging to the decandria class of plants. The calyx is pentaphyllous; the petals roundish and unguiculated; there are three bilabiate seeds.

HIRAM, a king of Tyre, contemporary with Solomon, whom he supplied with cedar, gold, silver, and other materials for building the temple. He died 1000 years B. C.

HIRAM of Tyre, an artist who assisted in the construction of Solomon's temple, and other public buildings at Jerusalem, flourished 1015 B. C.

HIRCANIA, in ancient geography. See **HYRCANIA**.

HIRCH-HORN, a town of Germany, in the circle of the Lower Rhine, with a strong castle. It is seated on the side of a hill on the river Neckar, and belongs to the elector palatine. E. long. 9. 0. N. lat. 49. 28.

HIRE (Philip de la), an eminent French mathematician and astronomer, born at Paris in 1640. His father, who was painter in ordinary to the king, designed him for the same profession: but he devoted himself to mathematical studies, and was nominated together with M. Picard to make the necessary observations for a new map of France, by the directions of M. Colbert. In 1683, he was employed in continuing the famous meridian line begun by M. Picard; and was next engaged in constructing those grand aqueducts which were projected by Louis XIV. He died in 1718, after having written a great number of works, besides several occasional papers dispersed in Journals, and in Memoirs of the Academy of Sciences.

HIRING, in law. See **BORROWING AND HIRING**.

HIRPINI, in ancient geography, a people of Italy, next to the Samnites, to the south-east, and descendants from them; situated to the north of the Picentini, and to the west of the Apuli, having on the north the Apennin and a part of Samnium. The name is from *Hirpus*, a term denoting a wolf in

their language; either because under the conduct of this animal the colony was led and settled, according to Strabo; or because, like that prowling animal, they lived on plunder, according to Servius.

HIRSBERG, a town of Silesia, famous for its mineral baths. It is seated on the river Bosar, 44 miles S. W. of Breslaw.

HIRSCHFELD, a town of Germany, in the circle of the Upper Rhine, capital of a principality of the same name, depending on a famous abbey, which was secularized in favour of the house of Hesse Cassel. It is seated on the river Fulde, 16 miles N. E. of the town of Fulde, and 32 S. E. of Cassel. E. lon. 9. 50. N. lat. 50. 56.

HIRTELLA, in botany; a genus of the monogynia order, belonging to the pentandria class of plants; and in the natural method ranking with those of which the order is doubtful. There are five petals; the filaments are very long, persisting, and spiral; the berry is mono-permious; the style lateral.

HIRUDO, the **LEECH**; a genus of insects belonging to the order of vermes intestina. The body moves either forward or backward. There are several species, principally distinguished by their colour. See plate 3. The most remarkable are the following:

1. The *medicinalis*, or medicinal leech, the form of which is well known, grows to the length of two or three inches. The body is of a blackish-brown colour, marked on the back with six yellow spots, and edged with a yellow line on each side; but both the spots and the lines grow faint, and almost disappear, at some seasons. The head is smaller than the tail, which fixes itself very firmly to any thing the creature pleases. It is viviparous, and produces but one young one at a time, which is in the month of July. It is an inhabitant of clear running waters, and is well known for its use in bleeding.
2. The *sanguisuga*, or horse-leech, is larger than the former. Its skin is smooth and glossy; the body is depressed, the back is dusky; and the belly is of a yellowish green, having a yellow lateral margin. It inhabits stagnant waters.
3. The *geometra*, or geometrical leech, grows to an inch and a half in length; and has a smooth and glossy skin of a dusky-brown colour, but in some seasons greenish spotted with white. When in motion, its back is elevated into a kind of ridge: and it then appears as if measuring the space it passed over like a compass, whence its name. Its tail is remarkably broad; and it holds as firmly by it as by the head. It is common on stones in shallow running waters; and is often found on trout and other fish after the spawning season.
4. The *muricata*, or muricated leech, has a taper body, rounded at the greater extremity, and furnished with two small tentacula, or horns, strongly annulated and rugged upon the rings, the tail dilated. It inhabits the Atlantic Ocean, and is by the fishermen called the *sea-leech*. It adheres to fish, and generally leaves a black mark on the spot.

The organs of generation in leeches are formed like those of the sea and land snails. See **HELIX**. The leech's head is armed with a sharp instrument that makes three wounds at once. They are three sharp tubercles, strong enough to cut through the skin of a man, or even of an ox or horse. The mouth is as it were the body of the pump, and the tongue or fleshy nipple the sucker; by the working of this piece of mechanism, the blood is made to rise up to the conduit which conveys it to the animal's stomach, which is a membranaceous skin divided into 24 small cells. The blood which is sucked out is there preserved for several months almost without coagulating, and proves a store of provision to the animal. The nutritious parts, pure and already digested by animals, have no call to be disengaged from the heterogeneous substances: nor indeed is there an anus discoverable in the leech; mere transpiration seems to be all that it performs, the matter fixing on the surface of its body, and afterwards coming off in small threads. Of this an experi-

ment may be tried by putting a leech into oil, where it keeps alive for several days; upon being taken out and put into water, there appears to loosen from its body a kind of slough shaped like the creature's body. The organ of respiration, though unascertained, seems to be situated in the mouth; for if, like an insect, it drew its breath through vent holes, it would not subsist in oil, as by it they would be stopped up. *Barbul's Genera Vermium*, p. 21.

It is only the first species that is used in medicine; being applied to the skin in order to draw off blood. With this view they are employed to phlebotomize young children. If the leech does not fasten, a drop of sugared milk is put on the spot it is wished to fix on, or a little blood is drawn by means of a slight puncture, after which it immediately settles. The leech when fixed should be watched, lest it should find its way into the anus when used for the hemorrhoids, or penetrate into the œsophagus if employed to draw the gums; otherwise it would make great havoc in the stomach or intestines. In such a case, the best and quickest remedy is to swallow some salt; which is the method practised to make it loose its hold when it sucks longer than was intended. Salt of tartar, volatile alkali, pepper, and acids, make it also leave the part on which it was applied. Cows and horses have been known to receive them, in drinking, into the throat. The usual remedy is to force down some salt, which makes them fall off. If, on the contrary, it is intended that the leech should draw a larger quantity of blood, the end of its tail is cut off; and it then sucks continually to make up the loss it sustains. The discharge occasioned by the puncture of a leech is usually of more service than the process itself. When too abundant, it is easily stopped with brandy, vinegar, or other styptics, or with a compress of dry linen rag bound strongly on the bleeding orifice.

At Ceylon, travellers who walk bare-legged are molested by the great numbers of leeches concealed under the grass. All leeches vary in their colours at some seasons, but they are generally of a dusky greenish brown or yellow, and often variegated. They are said to be very restless before a change of weather, if confined in glasses.

HIRUNDO, in ornithology, a genus of birds of the order of passerines. See plate 10. There are 37 species, chiefly distinguished by their colour. The most remarkable are,

1. The *ruffica*, common or chimney-swallow, is distinguished from all the other species by the superior forkiness of its tail, and by the red spot on the forehead and under the chin. The crown of the head, the whole upper part of the body, and the coverts of the wings, are black, glossed with a rich purplish blue, most resplendent in the male: the breast and belly white, and in the male tinged with red: the tail is black; the two middle feathers are plain, the others marked transversely near their ends with a white spot: the exterior feathers of the tail are much longer in the male than in the female. The food of this swallow is the same with the others of its kind, viz. insects. For the taking of these, in their swiftest flight, nature has admirably contrived their several parts: their mouths are very wide to take in flies, &c. in their quickest motions; their wings are long, and adapted for distant and continual flight; and their tails are forked, to enable them to turn the readier in pursuit of their prey. This species is the first comer of all the British hirundines; and appears in general on or about the 13th of April, though now and then a straggler is seen much earlier. This hirundo, though called the chimney-swallow, by no means builds altogether in chimneys, but often within barns and out-houses against the rafters; and so she did in Virgil's time:

Ante
Garrula quàm tignis nidus suspendat hirundo.

In Sweden she builds in barns, and is called *ladu swala*, the barn swallow. Besides, in the warmer parts of Europe, there are no chimneys to houses except they are English built: in these countries she constructs her nest in porches, and gateways, and galleries, and open halls. Here and there a bird may affect some odd peculiar place: but in general, with us, this species breeds in chimneys; and loves to haunt those stacks where there is a constant fire, no doubt for the sake of warmth. Not that it can subsist in the immediate shaft where there is a fire; but prefers one adjoining to that of the kitchen, and disregards the perpetual smoke of that funnel. Five or six or more feet down the chimney does this little bird begin to form her nest about the middle of May, which consists, like that of the house-martin, of a crust or shell composed of dirt or mud, mixed with short pieces of straw to render it tough and permanent; with this difference, that, whereas the shell of the martin is nearly hemispheric, that of the swallow is open at the top, and like half a deep dish: this nest is lined with fine grasses, and feathers which are often collected as they float in the air. Wonderful is the address (Mr. White observes) which this adroit bird shows all day long in ascending and descending with security through so narrow a pass. When hovering over the mouth of the funnel, the vibrations of her wings acting on the confined air occasion a rumbling like thunder. It is not improbable that the dam submits to this inconvenient situation, so low in the shaft, in order to secure her brood from rapacious birds, and particularly from owls, which frequently fall down chimneys, perhaps in attempting to get at these nestlings.

This bird lays from four to six white eggs, dotted with red specks; and brings out her first brood about the last week in June, or the first week in July. The progressive method by which the young are introduced into life is very curious: First, they emerge from the shaft with difficulty enough, and often fall down into the rooms below: for a day or so they are fed on the chimney-top, and then are conducted to the dead leafless bough of some tree, where, sitting in a row, they are attended with great assiduity, and may then be called *perchers*. In a day or two more they become flyers, but are still unable to take their own food: therefore they play about near the place where the dams are hawking for flies; and, when a mouthful is collected, at a certain signal given, the dam and the nestling advance, rising towards each other, and meeting at an angle; the young one all the while uttering such a little quick note of gratitude and complacency, that a person must have paid very little regard to the wonders of Nature that has not often remarked this feat. The dam betakes herself immediately to the business of a second brood as soon as she is disengaged from her first; which she at once associates with the first broods of house-martins; and with them congregates, clustering on sunny roofs, towers, and trees. This hirundo brings out her second brood towards the middle and end of August. All the summer long is the swallow a most instructive pattern of unwearied industry and affection; for from morning to night, while there is a family to be supported, she spends the whole day in skimming close to the ground, and exerting the most sudden turns and quick evolutions. Avenues, and long walks under hedges, and pasture-fields, and mown meadows where cattle graze, are her delight, especially if there are trees interspersed; because in such spots insects most abound. When a fly is taken, a smart snap from her bill is heard, resembling the noise at the shutting of a watch case; but the motion of the mandibles is too quick for the eye.

The swallow, probably the male bird, is the excubitor to house-martins and other little birds, announcing the approach of birds of prey. For as soon as an hawk appears, with a

will alarm him; he calls all the swallows and martins about him; who pursue in a body, and buffet and strike their enemy till they have driven him from the village, darting down from above on his back, and rising in a perpendicular line in perfect security. This bird also will sound the alarm, and strike at cats when they climb on the roofs of houses or otherwise approach the nests. Each species of *hirundo* drinks as it flies along, sipping the surface of the water; but the swallow alone, in general, washes on the wing, by dropping into a pool for many times together: in very hot weather house-martins and bank-martins dip and wash a little. The swallow is a delicate songster, and in soft sunny weather sings both perching and flying; on trees in a kind of concert, and on chimney tops: it is also a bold flyer, ranging to distant towns and commons even in windy weather, which the other species seem much to dislike; nay, even frequenting exposed sea-port towns, and making little excursions over the salt-water. Horsemen on wide downs are often closely attended by a little party of swallows for miles together, which plays before and behind them, sweeping around, and collecting all the sculking insects that are roused by the trampling of the horses' feet: when the wind blows hard, without this expedient, they are often forced to fettle to pick up their lurking prey.

This species feeds much on little coleoptera, as well as on gnats and flies; and often fettles on dug ground, or paths, for gravel to grind and digest its food. Mr. White informs us, that before they depart, for some weeks, to a bird, they forsake houses and chimneys, and roost in trees; and usually withdraw about the beginning of October; though some few stragglers may be seen at times till the first week in November. Mr. Pennant says, that, for a few days previous to their departure, they assemble in vast flocks on house-tops, churches, and trees, from whence they take their flight. See the articles MIGRATION and SWALLOW. They are supposed to take up their winter-quarters in Senegal and parts adjacent; and seem to possess in turn the whole of the old continent, being known from Norway to the Cape of Good Hope on the one hand, and from Kanttschatka to India and Japan on the other. They are also found in all parts of North America, migrating north and south, as with us. Kalm says, that in America they build in houses and under the out-sides of the roofs; also on the mountains, in such parts of them as project beyond the bottom, as well as under the corners of perpendicular rocks.

2. The *tabitica*, or Otaheite swallow, is five inches in length; its body is of a brown-black colour with a shining blueish gloss, the breast of a fulvous purple, the abdomen of a sooty brown; the bill, tail, and legs are black. It inhabits the mountainous parts of Otaheite. See fig. 1. in the plate.

3. The *esculenta*, or edible swallow, according to Buffon, is less than the wren, and only two inches and a quarter in length. The bill is black; the upper parts of the body are brown, the under whitish; the tail is forked, and each feather of it tipped with white: the legs are brown. See fig. 2.

Mr. Latham thinks, that the size as above described is by much too small, as Mr. Marsden says that the bird "appears to be the common martin;"—"and (says Mr. Latham) we are much inclined to think that it is at least of that size, from the eggs which accompany the nest now in the British Museum, which are as big as those of the martin, and of the same colour. However, we cannot dispute the point." The most curious part of the natural history of this bird consists in the nest, which is composed of such materials as render it not only edible, but one of the greatest dainties of the Asiatic epicures.

These nests (see the article BIRDS-Nests) are found in vast numbers in certain caverns, in various isles in the Soolo Archi-

pelago, situated between longitude 117 and 120, latitude 5 and 7; particularly in three small isles, or rather rocks; in the caverns of which the nests are found fixed to the sides in astonishing numbers. They are also found in amazing quantities on a small island called *Toc*, in the straits of Sunda; the caverns of which are lined with the nests: but nowhere in greater abundance than about Croee, near the south end of Sumatra, four miles up a river of that name. But they are not peculiar to the above places: for they are likewise common from Java to CochinChina on the north, and from the point of Sumatra west, to New Guinea on the east; where the sea is said to be covered with a viscous substance like half-melted glue, which the bird is supposed either to take up from the surface with its bill during flight, or to pick it from the rocks when left there by the waves. Of these nests, it is said, the Dutch alone export from Batavia 1000 pickles, upwards of 1300lb. English weight, every year, which are brought from the isles of CochinChina, and those lying to the east of them. It is much to be wondered, that, among other luxuries imported by us from the east, the use of these nests should not have found a way to our tables; as being yet so scarce in England as to be kept as rarities in the cabinets of collectors. The bird itself at Sumatra is known by the name of *Layonglayong*.

4. The *borbonica*, or wheat-swallow, is about the size of the swift: the plumage above is blackish-brown; beneath grey, marked with longitudinal brown spots: the tail is even at the end: the bill and legs are black. This species inhabits the Isle of France; frequenting places sown with wheat, and glades of woods; affecting elevated situations, and frequently seen perched on trees and stones. It follows herds of cattle for the sake of the flies which surround them; and is frequently seen in the wake of ships in great numbers, in the road near the isle, no doubt for the same purpose. It is often observed of evenings about the clefts in the mountains, where it is said to pass the night; and where it makes its nest, which is composed of straw and feathers. It lays two eggs, of a grey colour dotted with brown.

5. The *francica*, or grey-rumped swallow, is in length four inches and a quarter; having the upper parts of the body blackish, the rump and under parts whitish or grey. This species also inhabits the Isle of France, but not in great numbers; and is found chiefly in the neighbourhood of fresh waters. It flies swift; and is seldom observed to perch. It is supposed to rest in the woods at night, being seen about the skirts of them towards evening. It is generally very lean, and not good food.

6. The *urbica*, or martin, is inferior in size to the chimney-swallow, and its tail much less forked. The head and upper part of the body, except the rump, are black glossed with blue: the breast, belly, and rump, are white: the feet are covered with a short white down. This is the second of the swallow-kind that appears in our country; and of its manners and economy we have the following curious account in the Rev. Mr. White's Natural History of Selborne. "They begin to appear about the 16th of April; and for some time they in general pay no attention to the business of nidification: they play and sport about, either to recruit from the fatigue of their journey, if they do migrate at all; or else that their blood may recover its true tone and texture after it has been so long benumbed by the severities of winter. About the middle of May, if the weather be fine, the martin begins to think in earnest of providing a mansion for its family. The crust or shell of this nest seems to be formed of such dirt or loam as comes most readily to hand, and is tempered and wrought together with little bits of broken straws to render it tough and tenacious. As this bird often builds against a perpendicular

wall without any projecting ledge under, it requires its utmost efforts to get the first foundation firmly fixed, so that it may safely carry the superstructure. On this occasion the bird not only clings with its claws, but partly supports itself by strongly inclining its tail against the wall, making that a fulcrum; and thus steadied, it works and plasters the materials into the face of the brick or stone. But then, that this work may not, while it is soft and green, pull itself down by its own weight, the provident architect has prudence and forbearance enough not to advance her work too fast; but by building only in the morning, and by dedicating the rest of the day to food and amusement, gives it sufficient time to dry and harden. About half an inch seems to be a sufficient layer for a day. Thus careful workmen, when they build mud-walls (informed at first perhaps by this little bird) raise but a moderate layer at a time, and then desist; lest the work should become top-heavy, and so be ruined by its own weight. By this method in about 10 or 12 days is formed an hemispheric nest, with a small aperture towards the top, strong, compact, and warm; and perfectly fitted for all the purposes for which it was intended. But then nothing is more common than for the house-sparrow, as soon as the shell is finished, to seize on it as its own, to eject the owner, and to line it after its own manner. After so much labour is bestowed in erecting a mansion, as nature seldom works in vain, martins will breed on for several years together in the same nest, where it happens to be well sheltered and secure from the injuries of the weather. The shell or crust of the nest is a sort of rustic-work, full of knobs and protuberances on the outside: nor is the inside of those that I have examined smoothed with any exactness at all; but is rendered soft and warm, and fit for incubation, by a lining of small straws, grasses, and feathers; and sometimes by a bed of moss interwoven with wool. In this nest they tread or engender, frequently during the time of building; and the hen lays from three to five white eggs. At first, when the young are hatched, and are in a naked and helpless condition, the parent birds, with tender assiduity, carry out what comes away from their young. Were it not for this affectionate cleanliness, the nestlings would soon be burnt up and destroyed in so deep and hollow a nest by their own caustic excrement. In the quadruped creation the same neat precaution is made use of, particularly among dogs and cats, where the dams lick away what proceeds from their young. But in birds there seems to be a particular provision, that the dung of nestlings is enveloped in a tough kind of jelly, and therefore is the easier conveyed off without soiling or daubing. Yet, as nature is cleanly in all her ways, the young perform this office for themselves in a little time, by thrusting their tails out at the aperture of their nest. As the young of small birds presently arrive at their *γλυσια*, or full growth, they soon become impatient of confinement, and sit all day with their heads out at the orifice, where the dams, by clinging to the nest, supply them with food from morning to night. For a time the young are fed on the wing by their parents; but the feat is done by so quick and almost imperceptible a flight, that a person must have attended very exactly to their motions, before he would be able to perceive it. As soon as the young are able to shift for themselves, the dams immediately turn their thoughts to the business of a second brood: while the first flight, shaken off and rejected by their nurses, congregate in great flocks, and are the birds that are seen clustering and hovering on sunny mornings and evenings round towers and steeples, and on the roofs of churches and houses. These congregations usually begin to take place about the first week in August; and therefore we may conclude that by that time the first flight is pretty well over. The young of this species do not quit their abodes all together; but the more forward birds get abroad some days before the

rest. These approaching the eaves of buildings, and playing about before them, make people think that several old ones attend one nest. They are often capricious in fixing on a nesting-place, beginning many edifices, and leaving them unfinished; but when once a nest is completed in a sheltered place, it serves for several seasons. Those which breed in a ready-finished house, get the start in hatching of those that build new by 10 days or a fortnight. These industrious artificers are at their labours in the long days before four in the morning: when they fix their materials, they plaster them on with their chins, moving their heads with a quick vibratory motion. They dip and wash as they fly sometimes in very hot weather, but not so frequently as swallows. Martins love to frequent towns, especially if there are great lakes and rivers at hand. They are by far the least agile of the British hirundines: their wings and tails are short, and therefore they are not capable of such surprising turns, and quick and glancing evolutions as the swallow. Accordingly, they make use of a placid easy motion, in a middle region of the air, seldom mounting to any great height, and never sweeping long together over the surface of the ground or water. They do not wander far for food; but affect sheltered districts, over some lake, or under some hanging wood, or in some hollow vale, especially in windy weather. They breed the latest of all the swallow kind; in 1772 they had nestlings on to October the 21st, and are never without unfledged young as late as Michaelmas. As the summer declines, the congregating flocks increase in numbers daily, by the constant accession of the second broods; till at last they swarm in myriads upon myriads round the villages on the Thames, darkening the face of the sky as they frequent the aits of that river, where they roost. They retire, the bulk of them I mean, in vast flocks together about the beginning of October: but have appeared of late years in a considerable flight in this neighbourhood, for one day or two, as late as November the 3d and 6th, after they were supposed to have been gone for more than a fortnight. They therefore withdraw with us the latest of any species. Unless these birds are very short-lived indeed, or unless they do not return to the district where they are bred, they must undergo vast devastations some how, and some where; for the birds that return yearly bear no manner of proportion to the birds that retire."

7. The *rissa*, or rufous-bellied swallow, is of the same size with the former; and has the upper parts of the body of a glossy black; the under rufous, growing paler towards the vent: the forehead is whitish; and the bill and legs are dusky. These are found at Cayenne, and not unfrequently as far north as New-York. They build in houses, without any mixture of mud; fabricating the nest with moss, dried plants, and short bits of sticks, all united with a sort of gum, so as scarce to be broken, and lined with feathers, suspending it from the beams and rafters, sides of walls, and eaves of houses. It is sometimes a foot and a half in length; and is fixed by one of its sides, the opening being made near the bottom. The female lays four or five eggs; and the young go out as soon as their wings will support them.

8. The *riparia*, sand-martin, or shore-bird, is $4\frac{3}{4}$ inches in length, with the whole upper parts of the body of a mouse-colour, the throat and under parts white, the bill and legs blackish. It is common about the banks of rivers and sand-pits, where it terebrates a round and regular hole in the sand or earth, which is serpentine, horizontal, and about two feet deep. At the inner end of this burrow does the bird deposit, in a good degree of safety, her rude nest, consisting of fine grasses and feathers, usually goose-feathers, very inartificially laid together. "Though at first (says Mr. White) one would be disinclined to believe that this weak bird, with her soft and tender bill and claws, should ever be able to bore the stubborn sand-bank.

without entirely disabling herself; yet with these feeble instruments have I seen a pair of them make great dispatch; and could remark how much they had scooped that day by the fresh sand which ran down the bank, and was of a different colour from that which lay loose and bleached in the sun. In what space of time these little artists are able to mine and finish these cavities, I have never been able to discover; but it would be a matter worthy of observation, where it falls in the way of any naturalist to make his remarks. This I have often taken notice of, that several holes of different depths are left unfinished at the end of summer. To imagine that these beginnings were intentionally made in order to be in the greater forwardness for next spring, is allowing perhaps too much foresight and *rerum prudentia* to a simple bird. May not the cause of these *latebræ* being left unfinished arise from their meeting in those places with strata too harsh, hard, and solid, for their purpose, which they relinquish, and go to a fresh spot that works more freely? Or may they not in other places fall in with a soil as much too loose and mouldering, liable to flounder, and threatening to overwhelm them and their labours? One thing is remarkable—that, after some years, the old holes are forsaken and new ones bored; perhaps because the old habitations grow foul and fetid from long use, or because they may so abound with fleas as to become untenable. This species of swallow moreover is strangely annoyed with fleas: and we have seen fleas, bed fleas (*pulex irritans*), swarming at the mouths of these holes, like bees on the stools of their hives.

The sand-martin arrives much about the same time with the swallow; and lays, as she does, from four to six white eggs. But as this species is *cryptegane*, carrying on the business of nidification, incubation, and the support of its young in the dark, it would not be easy to ascertain the time of breeding, were it not for the coming forth of the broods, which appear much about the time, or rather somewhat earlier than those of the swallow. The nestlings are supported in common, like those of their congeners, with gnats and other small insects; and sometimes they are fed with *libellule* (dragon flies) almost as long as themselves. This *hirundo* is said to lay only once in a year, and to produce its young more early than the rest of its tribe: though from this last circumstance it would seem probable that they breed at least a second time, like the house-martin and swallow. It does not always take pains to make an hole for a nest; frequently laying in cavities of quarries, and in hollows of trees, where it is convenient. When they happen to breed near hedges and inclosures, they are often dispossessed of their breeding-holes by the house-sparrow, which is on the same account a fell adversary to house-martins. These *hirundines* are no songsters, but rather mute, making only a little harsh noise when a person approaches their nests. They seem not to be of a sociable turn, never with us congregating with their congeners in the autumn. They have a peculiar manner of flying; sitting about with odd jerks and vacillations, not unlike the motions of a butterfly. Doubtless the flight of all *hirundines* is influenced by and adapted to the peculiar sort of insects which furnish their food. Hence (says Mr. White) it would be worth inquiry to examine what particular genus of insects affords the principal food of each respective species of swallow.

9. The *montana*, or crag-swallow, is about the size of the martin, and in its upper plumage like the sand-martin: the under part of the body is rufous; the tail is scarcely forked; the legs are covered with grey down mixed with brown; the bill and the claws are black. These birds inhabit the rocks and crags about Savoy; arriving there the middle of April, and departing the 15th of August, for the most part; now and then some stragglers remain to the 10th of October.

This species is also found in the mountains of Auvergne and Dauphiné; and specimens have been received from Gibraltar.

10. The *purpurea*, or purple swallow, is in length seven inches, and the whole body is of a deep violet, very glossy: the quills and tail are of the same colour, but still deeper, and the last forked: the legs and claws are blackish; and the bill is black. The colour of the female is dusky brown, with a slight tinge of violet. This species is found in summer in Carolina and Virginia; coming in May, and retiring at the approach of winter. The common people are very fond of them; and make little conveniences of boards on the outsides of their houses for the birds to build in, like as is done for sparrows in England; being desirous to keep them near, as they are of much use in alarming the poultry of the approach of the hawk and other birds of prey; not only shrieking violently on the appearance of these enemies, but attacking them with all the efforts of our martins in Europe. See fig. 4.

11. The *apus*, or swift, is a large species, being near eight inches long, with an extent of wing near eighteen inches, though the weight of the bird is only one ounce. Their feet are so small, that the action of walking and rising from the ground is extremely difficult; so that nature has made it full amends, by furnishing it with ample means for an easy and continual flight. It is more on the wing than any other swallow; its flight is more rapid, and that attended with a shrill scream. It rests by clinging against some wall, or other apt body; from whence Klein styles this species *hirundo muraria*. It breeds under the eaves of houses, in steeples, and other lofty buildings; and makes its nest of grasses and feathers. The feet of this species are of a particular structure, all the toes standing forward: the least consists of only one bone; the others of an equal number, viz. two each; in which they differ from those of all other birds: a construction, however, nicely adapted to the purposes in which their feet are employed.

The swift is a summer inhabitant of these kingdoms. It comes the latest, and departs the soonest, of any of the tribe; not always staying to the middle of August, and often not arriving before the beginning of May. A pair of these birds were found adhering by their claws, and in a torpid state, in Feb. 1766, under the roof of Longnor-chapel, in Shropshire; on being brought to a fire, they revived, and moved about the room.

The fabulous history of the *manucodiata*, or bird of paradise (says Mr. Pennant), is, in the history of this species, in a great measure verified. It was believed to have no feet; to live upon the celestial dew; to float perpetually on the atmosphere; and to perform all its functions in that element. The swift actually performs what has been in these enlightened times disproved of the former, except the small time it takes in sleeping, and what it devotes to incubation; every other action is done on wing. The materials of its nest it collects either as they are carried about by the winds, or picks them up from the surface in its sweeping flight. Its food is undeniably the insects that fill the air. Its drink is taken in transient sips from the water's surface. Even its amorous rites are performed on high. Few persons who have attended to them in a fine summer's morning, but must have seen them make their aerial courses at a great height, encircling a certain space with an easy steady motion. On a sudden they fall into each others embraces, then drop precipitate with a loud shriek for numbers of yards. This is the critical conjuncture; and to be no more wondered at, than that insects (a familiar instance) should discharge the same duty in the same element.

The swift is a most alert bird, rising very early, and retiring

to roost very late; and is on the wing in the height of summer at least sixteen hours. In the longest days it does not withdraw to rest till a quarter before nine in the evening, being the latest of all day birds. Just before they retire, whole groups of them assemble high in the air, and squeak, and shoot about with wonderful rapidity. But this bird is never so much alive as in sultry thundery weather, when it expresses great alacrity, and calls forth all its powers. In hot mornings several, getting together in little parties, dash round the steeples and churches, squeaking as they go in a very clamorous manner: these, by nice observers, are supposed to be males serenading their sitting hens; and not without reason, since they seldom squeak till they come close to the walls or eaves, and since those within utter at the same time a little inward note of complacency. When the hen has sitten hard all day, she rushes forth just as it is almost dark, and stretches and relieves her weary limbs, and snatches a scanty meal for a few minutes, and then returns to her duty of incubation. Swifts, when wantonly and cruelly shot while they have young, discover a little lump of insects in their mouths, which they pouch and hold under their tongue. In general, as already observed, they feed in a much higher district than the other species; they also range to vast distances; since locomotion is no labour to them, who are endowed with such wonderful powers of wing. At some certain times in the summer, however, they have been observed hawking very low for hours together over pools and streams; and upon inquiring into the object of their pursuit that induced them to descend so much below their usual range, it has been found that they were taking *phryganeæ*, *ephemeræ*, and *libellulæ* (cadew-flies, may-flies, and dragon-flies), that were just emerged out of their aurelia state. It appeared then no longer a wonder that they should be so willing to stoop for a prey that afforded them such plentiful and succulent nourishment. Swifts sometimes pursue and strike at hawks that come in their way; but not with that vehemence and fury that swallows express on the same occasion. They are out all day long in wet days, feeding about and disregarding still rain: from whence two things may be gathered; first, that many insects abide high in the air, even in rain; and next, that the feathers of these birds must be well preened to resist so much wet. Windy weather, and particularly with heavy showers, they dislike; and on such days withdraw, and are scarcely ever seen. There is a circumstance respecting the colour of swifts (Mr. White remarks), which seems not to be unworthy our attention. When they arrive in the spring, they are all over of a glossy dark foot-colour, except their chins, which are white; but, by being all day long in the sun and air, they become quite weather-beaten and bleached before they depart, and yet they return glossy again in the spring. Now, if they pursue the sun into lower latitudes, as some suppose, in order to enjoy a perpetual summer, why do they not return bleached? Do they not rather perhaps retire to rest for a season, and at that juncture moult and change their feathers, since all other birds are known to moult soon after the season of breeding?

“ Swifts (continues our author) are very anomalous in many particulars, dissenting from all their congeners not only in the number of their young, but in breeding once in a summer; whereas all the other British hirundines breed invariably twice. It is past all doubt that swifts can breed but once, since they withdraw in a short time after the flight of their young, and some time before their congeners bring out their second broods. We may here remark, that, as swifts breed but once in a summer, and only two at a time, and the other hirundines twice, the latter, who lay from four to six eggs, increase at an average five times as fast as the former. But in nothing are swifts more singular than in their early retreat. They retire, as to the main body of them, by the tenth of August, and

sometimes a few days sooner: and every straggler invariably withdraws by the twentieth, while their congeners, all of them, stay till the beginning of October; many through all that month, and some occasionally to the beginning of November. This early retreat is mysterious and wonderful, since that time is often the sweetest season in the year. But, what is more extraordinary, they begin to retire still earlier in the most southerly parts of Andalusia, where they can be no way influenced by any defect of heat; or, as one might suppose, defect of food. Are they regulated in their motions with us by a failure of food, or by a propensity to moulting, or by a disposition to rest after so rapid a life, or by what? This is one of those incidents in natural history that not only baffles our searches, but almost eludes our guesses!”

Swifts never perch on trees or roofs, and so never congregate with their congeners. They are fearless while haunting their nesting-places, and are not to be scared with a gun; and are often beaten down with poles and cudgels as they stoop to go under the eaves. Mr. White informs us, that having untiled part of a roof over the nest of a swift, the dam notwithstanding sat in the nest: so strongly was she affected by natural *στολν* for her brood, which she supposed to be in danger, that, regardless of her own safety, she would not stir, but lay fullenly by them, permitting herself to be taken in hand. Swifts are much infested with those pests to the genus called *bippoboscæ hirundinis*; and often wriggle and scratch themselves, in their flight, to get rid of that clinging annoyance. And young ones, over-run with these insects, are sometimes found under their nests, fallen to the ground; the number of vermin rendering their abode insupportable.

Swifts are no songsters, and have only one harsh screaming note; yet there are ears to which it is not displeasing, from an agreeable association of ideas, since that note never occurs but in the most lovely summer weather. They never settle on the ground but through accident; neither can they walk, but only crawl; but they have a strong grasp with their feet, by which they cling to walls, as already noticed. Their bodies being flat, they can enter a very narrow crevice; and where they cannot pass on their bellies, they will turn up edgewise. In London a party of swifts frequents the Tower, playing and feeding over the river just below the bridge: others haunt some of the churches of the Borough next the fields; but do not venture, like the house-martin, into the close crowded part of the town. The Swedes have bestowed a very pertinent name on this swallow, calling it *ring-swala*, from the perpetual rings or circles that it takes round the scene of its nidification. As these birds are apt to catch at every thing on the wing, many have taken them by a bait of a cockchafer tied to a thread, which they have swallowed as freely as a fish theirs. In the Isle of Zant, the boys are said to get on an elevated place, and merely with a hook baited with a feather, have caught five or six dozen of them in a day. Besides our island, the swift is known to inhabit the whole of the European continent; and has also been noticed at the Cape of Good Hope, and Carolina in North America. Hence, most likely, a general inhabitant of both the old and new continent.

12. The *ambrosiaca*, or ambergris swallow, is about the size of a wren, with a grey plumage and a very forked tail; the bill is blackish, and the legs are brown. It inhabits Senegal, and is said to smell very strong of ambergris.

13. The *pelasgia*, or aculeated swallow, is somewhat less than our chimney-swallow: its plumage is brown, but at the throat whitish, and all the tail-feathers are terminated by a bare pointed shaft. It inhabits Carolina and Virginia in the summer time, and builds in dry situations in the chimneys of houses and cottages.

14. The *melba*, or white-bellied swift, is in length $8\frac{1}{2}$ inches,

and weighs two ounces five drams; the bill is half an inch, somewhat bent, and black: the upper parts of the body are of a grey brown; the wings and tail deepest, with a gloss of red and green in some lights: the throat, breast, and belly, are white; on the neck is a collar of grey brown, mixed with black: the sides are dusky, and white mixed; lower part of the belly, and under tail-coverts, the same as the back: the legs are flesh-coloured, and covered with feathers on the fore-part and inside: all the toes are placed forward, as in our swift. This bird inhabits the mountainous parts of Spain; building in the holes of rocks. It is found also on the borders of the Rhone, in Savoy, the isle of Malta, Alps of Switzerland, and rock of Gibraltar. It comes into Savoy the beginning of April, and frequents the ponds and marshes for 15 or 20 days; after which it retires to the mountainous parts to breed. It flies higher than our swift; but feeds on the same food, and its flesh is accounted a delicate morsel. This species is not numerous. Scopoli says it builds on the summit of the mountains of Tyrol.

15. The *cayennensis*, or white-coloured swallow, is about the size of the martin: the head and bill are black; the chin and throat white, passing from the last in a narrow collar round the neck: between the bill and eye is a streak of white, which forks off into two; one passing a little above and the other a little way beneath the eye: the rest of the plumage is black, with a gloss of violet; but the greater coverts, nearest the body, are brown, edged with white: the quills and tail are black; the last forked: the legs are black; and all the four toes placed before as in our swift, and covered with feathers to the claws. This bird makes its nest in the houses at Cayenne. It is of a large size, in shape of a truncated cone; five inches one way by three the other, and nine inches in length. It is composed of the down of dog's-bane, well woven together; the cavity divided obliquely about the middle, lengthways, by a partition, which spreads itself over that part of the nest where the eggs lie, which is pretty near the base: a small parcel of the same soft down, forming a kind of plug, is placed over the top, serving to keep the young brood from the impression of the air; from which we may suppose them to be very tender.

16. The *erythrocephala*, or red-headed swallow, has a red head, with a short flat dusky bill: the back is dusky, the feathers edged with white: the under parts of the body are white, the tail-coverts pale brown: the wings are both dusky; as is also the tail, which is a little forked. It inhabits India; and is only the size of a small humming-bird.

17. The *nigra*, or black swallow, measures near six inches in length: the colour of the bird is wholly black, and the tail is forked. It inhabits St. Domingo and Cayenne; but is not numerous. It is often seen to perch on dead trees; and only inhabits dry savannas inland. It scoops out a hole in the earth, half a foot in length, with the mouth very small, so as just to permit entrance: in this cavity it constructs the nest and rears its young.

18. The *dominicensis*, or St. Domingo swallow, is 7 inches in length, and wholly black, with the gloss of polished steel, except the belly and under tail coverts, which are white: the tail is very little forked: the legs, bill, and claws are brown. It inhabits St. Domingo, and other of the West India islands, in May, June, and July; and is said to imitate a lark in its song. See fig. 3.

To this article we may not improperly subjoin the following paper (from the Gentleman's Magazine) on the utility of encouraging the breed of swallows, swifts, and martins. "The advantages that accrue to man, from the docility with which the domesticated animals accommodate themselves to his uses, are obvious. But there are others, who attend on him of their

own accord, whose beneficial exertions are little known or observed. Among these I shall at present only notice the family of swallows (*hirundines*); of the four kinds of which bird found in our island three attach themselves to his dwelling, as if peculiarly solicitous for his welfare. This connection seems so reciprocal, that where men do not inhabit, few swallows can find proper conveniencies for their summer-residence; and as their food consists wholly of insects, the most diligent inquirer hath not been able to discover that they injure in the slightest degree the productions of the field or garden; a circumstance nearly peculiar to these birds. The charge which Virgil, copying the Grecian writers, brings against them, of killing bees, is in this country groundless, and I apprehend it to be so in every other:

" Absint———

———Meropesque aliæque volucres,
Et manibus Procne pectus signata cruentis;
Omnia nam late vastant, ipsasque volantes
Ore ferunt, dulcem nidis immitibus escam."

Georg. l. 4. v. 23.

For the mouths of the swallow tribe are by no means adapted to catch stinging insects with impunity. The birds who prey on bees have a long extended bill constructed for that purpose, very different from that of the swallow.

"By the myriads of insects which every single brood of swallows destroys in the course of a summer, they defend us in a great measure from the personal and domestic annoyance of flies and gnats; and, what is of infinitely more consequence, they keep down the numbers of our minute enemies, who, either in the grub or winged state, would otherwise render the labours of the husbandman fruitless. Since then swallows are guardians of our corn, they should every where be protected by the same popular veneration which in Egypt defends the Ibis and the stork in Holland. We more frequently hear of unproductive harvests on the Continent than in this country; and it is well known that swallows are caught and sold as food in the markets of Spain, France, and Italy. When this practice has been very general and successful, I have little doubt that it hath at times contributed to the scarcity of corn. In England we are not driven to such resources to furnish our tables. But what apology can be made for those, and many there are, whose education and rank should have taught them more innocent amusements, who wantonly murder swallows, under the idle pretence of improving their skill in shooting game? Setting aside the cruelty of starving whole nests of young by killing the dam; they who follow this barbarous diversion would do well to reflect, that by every swallow they kill, they assist blasts, mildews, and vermin, in causing a scarcity of bread. Every lord of a manor should restrain his game-keeper from this execrable practice; nor should he permit any person to sport on his lands who does not refrain from it. For my part, I am not ashamed to own that I have tempted martins to build around my house, by fixing scallop shells, in places convenient for their pendent beds and procreant cradles; and have been pleased to observe with what caution the little architect raised a buttress under each shell before he ventured to form his nest on it.

"What has induced me to send you these strictures at this time, are the accounts of the ravages committed on the cultivation of corn in the United States of North America, by an insect called the *Hessian-Fly*. (See the article *HESSIAN-Fly*.) How far there is danger of this desolating scourge being imported into this country by the admission of American wheat, I must leave to abler entomologists to decide. But that this destructive insect should, as hath lately been asserted, totally disappear in one season, after having for a number of years

ſucceſſively laid waſte wide extended diſtricts, is a phænomenon hardly to be aliented to by thoſe who have turned their minds to inquiries of this ſort.

“ Might I not here enlarge on the importance of reſearches into the works of the creation, when we ſee ſtateſmen, as in the preſent inſtance, making ſolemn applications to thoſe who are ſtudious of nature, requeſting their direſtion how to avoid the calamity apprehended from a fly? And may we not then add, that the minuteſt obſervations of this kind are only deemed trivial by the indolent and uninformed?”

“ I recolleſt but a ſingle complaint againſt the ſwallow, and that is made by Anacreon, Od. 12. who bitterly reproaches this bird for diſturbſing him by its twittering while he was dozing away the intoxication of the preceding night. Yet, had the poet been temperate, like Milton, he would with pleaſure have ariſen from his bed at the charm of earlieſt birds.

“ With what joy the Grecians welcomed the return of the ſwallow, appears by the very ancient carol preſerved by Athenæus; of which the following is a tranſlation:—

The ſwallow! the ſwallow! ſhe does with her bring
Soft ſeaſons and all the delights of the ſpring:
The ſwallow! the ſwallow! we're ſure we are right,
For her back is all black, and her belly all white.
From your ſtores, ye good houſewives, produce, if you pleaſe,
Lumps of figs, jugs of wine, and ſome wheat and ſome cheeſe,
With ſome hen eggs the ſwallow will well be content.
Muſt we go then, or ſhall we have any thing ſent?

We will not allow you to do as you chooſe,
To give or give not, to comply or reſuſe;
But will certainly take from its hinges the door,
Or bear off the good dame as ſhe ſits on the floor;
She is little and light, we can manage her ſure. }
Open, open the door to the ſwallow—for we
Are playful young children, not men—you may ſee.

HISPA, in zoology; a genus of inſects belonging to the coleoptera order, the characters of which are theſe: The antennæ are fuſiform, growing gradually larger from each extremity towards the middle; and are ſituated between the eyes: the thorax and elytra are covered with protuberances or ſpines. The larva of this inſect ſeems to be yet wholly unknown. There are but two ſpecies of the perfect animal met with in Europe; one of which, the atra, is found in Britain, and is all over of a deep unpoliſhed black, and has the upper part of its body entirely covered with long and ſtrong ſpines, which render it brittly like the ſhell of a cheſnut. There is even a ſpine at the caſe of the antennæ; the thorax has a row ſet tranſverſely, which are forked; and the elytra are furniſhed with a very great number that are ſingle. Its being thus covered with ſpines, makes it reſemble a hedge hog in miniature. It is rather hard to catch, letting itſelf fall down on the ground as ſoon as approached. It bears its antennæ upright before it. See Pl. 10.

HISPALIS, in ancient geography, a town of Bætica, in the Farther Spain; an ancient mart or trading town on the Bætis, navigable quite up to it for ſhips of burthen, and thence to Corduba for river barges. Called *Colonia Romulentiſis*. It has alſo a conventus juridicus, a court of juſtice or aſſizes, (Pliny). Now called *Seville*. W. lon. 6°. N. lat. 37°.

HISPANIA, in ancient geography, called *Hesperia Ultima*, (Horace), becauſe the weſtmoſt part of Europe; alſo *Iberia*, from the river Iberus. Its name *Hiſpania*, or *Spania*, (Greek), is of Phœnician original, from its great number of rabbits: the Phœnicians, who ſettled ſeveral colonies on the coaſt, calling it *Spanjah*, from theſe animals. It has the ſea on every ſide, except on that next to Gaul, from which it is ſeparated by the Pyrenées. The Romans at firſt divided it into the Farther and Hither Spain, under two prætors. In that ſtate it continued down

to Auguſtus; who divided the Farther Spain into Bætica, which he left to the people to be governed by a pro-conſul; and into Luſitania, which he added to his own provinces; calling the Hither Spain *Tarraconenſis*. Hiſpania was a country celebrated for its fertility, of which it has greatly fallen ſhort in modern times. The people were of a warlike turn, (Strabo); and their bodies being formed for hardſhips and labour, they ever preferred war to peace, and were remarkably prodigal of life (Juſtin, Sil. Italicus). Spain produced ſeveral great men, both in a literary and a political capacity. See SPAIN.

HISPANIOLA, called alſo St. DOMINGO, the largeſt of the Antilles or Caribbee iſlands, extending about 420 miles from eaſt to weſt, and 120 in breadth from north to ſouth; lying between 17° 37' and 20° of N. lat. and between 67° 35' and 74° 15' W. lon. The climate is hot, but not reckoned unwholeſome; and ſome of the inhabitants are ſaid to arrive at the age of 120. It is ſometimes reſreſhed by breezes and rains; and its ſalubrity is likewiſe in a great meaſure owing to the beautiful variety of hills and valleys, woods and rivers, which every where preſent themſelves. It is indeed reckoned by far the fineſt and moſt pleaſant iſland of the Antilles, as being the beſt accommodated to all the purpoſes of life when duly cultivated.

This iſland, famous for being the earlieſt ſettlement of the Spaniards in the new world, was at firſt in high eſtimation for the quantity of gold it ſupplied: this wealth diminiſhed with the inhabitants of the country, whom they obliged to dig it out of the bowels of the earth; and the ſource of it was entirely dried up, when they were exterminated, which was quickly done, by a ſeries of the moſt ſhocking barbarities that ever diſgraced the hiſtory of any nation. Benzoni relates, that of two millions of inhabitants, contained in the iſland when diſcovered by Columbus in 1492, ſcarce 153 were alive in 1545. A vehement deſire of opening again this ſource of wealth inſpired the thought of getting ſlaves from Africa; but, beſides that theſe were found unfit for the labours they were deſtined to, the multitude of mines, which then began to be wrought on the continent, made thoſe of Hiſpaniola no longer of any importance. An idea now ſuggeſted itſelf, that their negroes, which were healthy, ſtrong, and patient, might be uſefully employed in huſbandry; and they adopted, through neceſſity, a wiſe reſolution, which, had they known their own intereſt, they would have embraced by choice.

The produce of their induſtry was at firſt extremely ſmall, becauſe the labourers were few. Charles V. who, like moſt ſovereigns, preferred his favourites to every thing, had granted an excluſive right of the ſlave-trade to a Flemiſh nobleman, who made over his privilege to the Genoefe. Thoſe avaricious republicans conducted this infamous commerce as all monopolies are conducted; they reſolved to ſell dear, and they ſold but few. When time and competition had fixed the natural and neceſſary price of ſlaves, the number of them increaſed. It may eaſily be imagined, that the Spaniards, who had been accuſtomed to treat the Indians as beaſts, did not entertain a higher opinion of theſe negro Africans, whom they ſubſtituted in their place. Degraded ſtill farther in their eyes by the price they had paid for them, even religion could not reſtrain them from aggravating the weight of their ſervitude. It became intolerable, and theſe wretched ſlaves made an effort to recover the uſual enable rights of mankind. Their attempt proved unſucceſſful, but they reaped this benefit from their deſpair, that they were afterwards treated with leſs inhumanity.

This moderation (if tyranny cramped by the apprehenſion of revolt can deſerve that name) was attended with good conſequences. Cultivation was purſued with ſome degree of ſucceſs. Soon after the middle of the 16th century, the mother count drew annually from this colony ten millions weight of ſugar,

large quantity of wood for dyeing; tobacco, cocoa, cassia, ginger, cotton, and peltry in abundance. One might imagine, that such favourable beginnings would give both the desire and the means of carrying them further; but a train of events, more fatal each than the other, ruined these hopes.

The first misfortune arose from the depopulation of the island. The Spanish conquests on the continent should naturally have contributed to promote the success of an island, which nature seemed to have formed to be the centre of that vast dominion arising around it, to be the staple of the different colonies. But it fell out quite otherwise: on a view of the immense fortunes raising in Mexico, and other parts, the richest inhabitants of Hispaniola began to despise their settlements, and quitted the true source of riches, which is on the surface of the earth, to go and ransack the bowels of it for veins of gold, which are quickly exhausted. The government endeavoured in vain to put a stop to this emigration; the laws were always either artfully eluded, or openly violated.

The weakness, which was a necessary consequence of such a conduct, leaving the coasts without defence, encouraged the enemies of Spain to ravage them. Even the capital of this island was taken and pillaged by that celebrated English sailor, Sir Francis Drake. The cruizers of less consequence contented themselves with intercepting vessels in their passage through those latitudes, the best known at that time of any in the new world. To complete these misfortunes, the Castilians themselves commenced pirates. They attacked no ships but those of their own nation; which were more rich, worse provided, and worse defended, than any others. The custom they had of fitting out ships clandestinely, in order to procure slaves, prevented them from being known; and the assistance they purchased from the ships of war, commissioned to protect the trade, insured to them impunity.

The foreign trade of the colony was its only resource in this distress; and that was illicit: but as it continued to be carried on, notwithstanding the vigilance of the governors, or, perhaps, by their connivance, the policy of an exasperated and short-sighted court exerted itself in demolishing most of the sea-ports, and driving the miserable inhabitants into the inland country. This act of violence threw them into a state of dejection; which the incursions and settlement of the French on the island afterwards carried to the utmost pitch. The latter, after having made some unsuccessful attempts to settle on the island, had part of it yielded to them in 1697, and in 1795, the whole was ceded to them by the Spaniards.

Spain, totally taken up with that vast empire which she had formed on the continent, used no pains to dissipate this lethargy. She even refused to listen to the solicitations of her Flemish subjects, who earnestly pressed that they might have permission to clear those fertile lands. Rather than run the risk of seeing them carry on a contraband trade on the coasts, she chose

to bury in oblivion a settlement which had been of consequence, and was likely to become so again.

This colony, which had no longer any intercourse with the mother country but by a single ship, of no great burthen, that arrived from thence every third year, consisted, in 1717, of 18,410 inhabitants, including Spaniards, Mestees, Negroes, or Mulattoes. The complexion and character of these people differed according to the different proportions of American, European, and African blood they had received from that natural and transient union which restores all races and conditions to the same level. These demi-savages, plunged in the extreme of sloth, lived upon fruits and roots, dwelt in cottages without furniture, and most of them without clothes. The few among them, in whom indolence had not totally suppressed the sense of decency and taste for the conveniences of life, purchased clothes of their neighbours the French in return for their cattle, and the money sent to them for the maintenance of two hundred soldiers, the priests, and the government. It does not appear that the company, formed at Barcelona in 1757, with exclusive privileges for the re-establishment of St. Domingo, ever, in fact, made any considerable progress. They sent out only two small vessels annually, which were freighted back with six thousand hides, and some other commodities of little value. See DOMINGO.

HISTER, in zoology; a genus of the coleoptera order of insects. See Plate 10. The first articulation of the antennæ is compressed and curved; the last is considerably larger than the others, and appears to be a solid knob: the head is drawn within the body; the mouth is forcipated: the elytra are shorter than the body; and the fore-legs are dentated. The body of these creatures is polished and very shining, and their form almost square; the thorax large, and highly polished: anteriorly it is made with a slope, in the cavity of which is lodged the head, the position of which is often only discovered by the projection of the maxillæ; for the head, for the most part, is so withdrawn under the thorax, that the insect looks as if it had none. The elytra are as it were cut off towards the extremity, and do not cover the whole of the abdomen. They are extremely smooth, and only have a few striæ, scarce perceptible, situated chiefly towards their outward side. Lastly, the hinder part of the abdomen, which projects beyond the elytra, is round and blunt. These insects are sometimes found in cow-dung, and often on sand. They vary prodigiously in size; but differ very little either in form or colour, they being all very dark. The larvæ, as well as the perfect insects, are frequently met with in the dung of horses, cows, &c.

HISTORIOGRAPHER, a professed historian, or writer of history. See the next article. The historiographer to his majesty is an officer under the lord chamberlain; his salary 200*l. per annum*. There is an office of the same kind in Scotland, with the same salary.

H I S T O R Y.

HISTORY, in general, signifies an account of certain remarkable facts which have happened in the world, arranged in the true order in which they actually took place, together with the causes to which they were owing, and the different effects they produced, as far as could be discovered. The word is Greek, *ἱστορία*; and literally denotes a search for curious things, or a desire of knowing, or even a rehearsal of things we have seen; being formed from the verb *ἵστωρ*, which properly signifies to know a thing by having seen it. But the

idea is now much more extensive, and is applied to the knowledge of things taken from the report of others. The origin is from the verb *ἵστωμι*, "I know;" and hence it is, that among the ancients, several of their great men were called *polyhistoris*, i. e. persons of various and general knowledge.

Sometimes, however, the word history is used to signify a description of things, as well as an account of facts. Thus Theophrastus calls his work, in which he has treated of the nature and properties of plants, an *history of plants*; and we have

a treatise of Aristotle, intitled an *history of animals*; and to this day the description of plants, animals, and minerals, are called by the general name of *natural history*.

But what chiefly merits the name of history, and what is here considered as such, is an account of the principal transactions of mankind since the beginning of the world; and which naturally divides itself into two parts, namely, *civil* and *ecclesiastical*. The first contains the history of mankind in their various relations to one another, and their behaviour, for their own emolument, or that of others, in common life; the second considers them as acting, or pretending to act, in obedience to what they believe to be the will of the Supreme Being. Civil history, therefore, includes an account of all the different states that have existed in the world, and likewise of those men who in different ages of the world have most eminently distinguished themselves either for their good or evil actions. This last part of civil history is usually termed BIOGRAPHY.

History is now considered as a very considerable branch of polite literature: few accomplishments are more valued than an accurate knowledge of the histories of different nations; and scarce any literary production is more regarded than a well-written history of any nation.

With regard to the study of history, we must consider, that all the revolutions which have happened in the world, have been owing to two causes. 1. The connections between the different states existing together in the world at the same time, or their different situations with regard to one another; and, 2. The different characters of the people who in all ages constituted these states, their different geniuses and dispositions, &c. by which they were either prompted to undertake such and such actions of themselves, or were easily induced to it by others. The person who would study history, therefore, ought in the first place to make himself acquainted with the state of the world in general in all different ages; what nations inhabited the different parts of it; what their extent of territory was; at what particular time they arose, and when they declined. He is then to inform himself of the various events which have happened to each particular nation; and, in so doing, he will discover many of the causes of those revolutions, which before he only knew as facts. Thus, for instance, a person may know the Roman history from the time of Romulus, without knowing in the least why the city of Rome happened to be built at that time. This cannot be understood without a particular knowledge of the former state of Italy, and even of Greece and Asia; seeing the origin of the Romans is commonly traced as high as Æneas, one of the heroes of Troy. But when all this is done, which indeed requires no small labour, the historian hath yet to study the genius and dispositions of the different nations, the characters of those who were the principal directors of their actions, whether kings, ministers, generals, or priests; and when this is accomplished, he will discover the causes of those transactions in the different nations which have given rise to the great revolutions above mentioned: after which, he may assume the character of one who is perfectly versed in history.

The first *outline* of history, as it may be called, is most easily obtained by the inspection of an historical chart; and that subjoined to the present treatise will answer the purpose as well as any. See Plate 11. and the explanation at the end of this Treatise. Along with this it will be proper to peruse a short abridgement of general history, from the creation of the world to the present time; but in this way there have been but very few publications attended with any tolerable success. The following is collected from respectable authorities, and may serve to help the ideas of the reader on this subject.

C H A P. I.

Of CIVIL HISTORY.

HISTORY, though seemingly incapable of any natural division, will yet be found, on a nearer inspection, to resolve itself into the following periods, at each of which a great revolution took place, either with regard to the whole world, or a very considerable part of it. 1. The creation of man. 2. The flood. 3. The beginning of profane history, *i. e.* when all the fabulous relations of heroes, demi-gods, &c. were expelled from historical narrations, and men began to relate facts with some regard to truth and credibility. 4. The conquest of Babylon by Cyrus, and the destruction of the Babylonian empire. 5. The reign of Alexander the Great, and the overthrow of the Persian empire. 6. The destruction of Carthage by the Romans, when the latter had no longer any rival capable of opposing their designs. 7. The reign of the emperor Trajan, when the Roman empire was brought to its utmost extent. 8. The division of the empire under Constantine. 9. The destruction of the western empire by the Heruli, and the settlement of the different European nations. 10. The rise of Mahomet, and the conquests of the Saracens and Turks. 11. The crusades, and all the space intervening between that time and the present.

Concerning the number of years which have elapsed since the creation of the world, there have been many disputes. The compilers of the Universal History determine it to have taken place in the year 4305 B. C. so that, according to them, the world is now in the 6096th year of its age. Others think it was created only 4000 years B. C. so that it hath not yet attained its 6000th year. Be this as it will, however, the whole account of the creation rests on the truth of the Mosaic history; and which we must of necessity accept, because we can find no other which does not either abound with the grossest absurdities, or lead us into absolute darkness. The Chinese and Egyptian pretensions to antiquity are so absurd and ridiculous, that the bare reading must be a sufficient confutation of them to every reasonable person. See the articles CHINA and EGYPT. Some historians and philosophers are inclined to discredit the Mosaic accounts, from the appearances of volcanoes, and other natural phænomena: but their objections are by no means sufficient to invalidate the authority of the sacred writings; not to mention that every one of their own systems is liable to insuperable objections. It is therefore reasonable for every person to accept of the Mosaic account of the creation as truth: but an historian is under an absolute necessity of doing it, because, without it, he is quite destitute of any standard or scale by which he might reduce the chronology of different nations to any agreement; and, in short, without receiving this account as true, it would be in a manner impossible at this day to write a general history of the world.

1. The transactions during the first period, *viz.* from the creation to the flood, are very much unknown, nothing indeed being recorded of them but what is to be found in the first six chapters of Genesis. In general, we know, that men were not at that time in a savage state; they had made some progress in the arts, had invented music, and found out the method of working metals. They seem also to have lived in one vast community, without any of those divisions into different nations which have since taken place, and which evidently proceeded from the confusion of languages. The most material part of their history, however, is, that having once begun to transgress the divine commands, they proceeded to greater and greater lengths of wickedness, till at last the Deity thought proper to send a flood on the earth, which destroyed the whole human race except eight persons, *viz.* Noah and his family.

This terrible catastrophe happened, according to the Hebrew copy of the Bible, 1656 years after the creation; according to the Samaritan copy, 1307. For the different conjectures concerning the natural causes of the flood, see the article DE-LUGE.

2. For the history of the second period we must again have recourse to the Scriptures, almost as much as for that of the first. We now find the human race reduced to eight persons possessed of nothing but what they had saved in the ark, and the whole world to be stored with animals from those which had been preserved along with these eight persons. In what country their original settlement was, no mention is made. The ark is supposed to have rested on Mount Ararat in Armenia; but it is impossible to know whether Noah and his sons made any stay in the neighbourhood of this mountain or not. Certain it is, that, some time after, the whole or the greatest part of the human race were assembled in Babylonia, where they engaged in building a tower. This gave offence to the Deity; so that he punished them by confounding their language; whence the division of mankind into different nations.

According to a common opinion, Noah, when dying, left the whole world to his sons, giving Asia to Shem, Africa to Ham, and Europe to Japhet. But this hath not the least foundation in Scripture. By the most probable accounts, Gomer the son of Japhet was the father of the Gomerians or Celtes; that is, all the barbarous nations who inhabited the northern parts of Europe under the various names of *Gauls*, *Cimbrians*, *Gotbs*, &c. and who also migrated into Spain, where they were called *Celtiberians*. From Magog, Meshech, and Tubal, three of Gomer's brethren, proceeded the Scythians, Sarmatians, Tartars, and Moguls. The three other sons of Japhet, Madai, Javan, and Tiras, are said to have been the fathers of the Medes, the Ionians, Greeks, and Thracians.

The children of Shem were Elam, Ashur, Arphaxad, Lud, and Aram. The first settled in Persia, where he was the father of that mighty nation: The descendants of Ashur peopled Assyria, (now *Curdestan*): Arphaxad settled in Chaldæa. Lud is supposed by Josephus to have taken up his residence in Lydia: though this is much controverted. Aram, with more certainty, is thought to have settled in Mesopotamia and Syria.

The children of Ham were Cush, Mizraim, Phut, and Canaan. The first is thought to have remained in Babylonia, and to have been king of the south-eastern parts of it, afterwards called *Kbuzestan*. His descendants are supposed to have removed into the eastern parts of Arabia; from whence they by degrees migrated into the corresponding part of Africa. The second peopled Egypt, Ethiopia, Cyrenaica, Libya, and the rest of the northern parts of the same continent. The place where Phut settled is not known: but Canaan is universally allowed to have settled in Phœnicia; and to have founded those nations who inhabited Judea, and were afterwards exterminated by the Jews.

Almost all the countries of the world, at least of the eastern continent, being thus furnished with inhabitants, it is probable that for many years there would be few or no quarrels between the different nations. The paucity of their numbers, their distance from one another, and their diversity of language, would contribute to keep them from having much communication with each other. Hence, according to the different circumstances in which the different tribes were placed, some would be more civilized and others more barbarous. In this interval also, the different nations probably acquired different characters, which afterwards they obstinately retained, and manifested on all occasions; hence the propensity of some nations to monarchy, as the Asiatics, and the enthusiastic desire of the Greeks for liberty and republicanism, &c.

The beginning of monarchical government was very early; Nim-

rod the son of Cush having found means to make himself king of Babylonia. In a short time Ashur emigrated from the new kingdom; built Nineveh, afterwards capital of the Assyrian empire; and two other cities called *Resen* and *Reboboib*, concerning the situation of which we are now much in the dark. Whether Ashur at this time set up as a king for himself, or whether he held these cities as vassal to Ninrod, is now unknown. It is probable, however, that about the same time various kingdoms were founded in different parts of the world; and which were great or small according to different circumstances. Thus the Scripture mentions the kings of Egypt, Gerar, Sodom, Gomorrah, &c. in the time of Abraham; and we may reasonably suppose, that these kings reigned over nations which had existed for some considerable time before.

The first considerable revolution we read of is the migration of the Israelites out of Egypt, and their establishment in the land of Canaan. For the history of these transactions we must refer to the Old Testament, where the reader will see that it was attended with the most terrible catastrophe to the Egyptians, and with the utter extermination of some nations, the descendants of Ham, who inhabited Judæa. Whether the overthrow of Pharaoh in the Red Sea could affect the Egyptian nation in such a manner as to deprive them of the greatest part of their former learning, and to keep them for some ages after in a barbarous state, is not easily determined; but unless this was the case, it seems exceedingly difficult to account for the total silence of their records concerning such a remarkable event, and indeed for the general confusion and uncertainty in which the early history of Egypt is involved. The settlement of the Jews in the promised land of Canaan is supposed to have happened about 1491 B. C.

For near 200 years after this period we find no accounts of any other nations than those mentioned in Scripture. About 1280 B. C. the Greeks began to make other nations feel the effects of that enterprising and martial spirit for which they were so remarkable, and which they had undoubtedly exercised upon one another long before. Their first enterprise was an invasion of Colchis (now *Mingrelia*), for the sake of the golden fleece. Whatever was the nature of this expedition, it is probable they succeeded in it; and it is likewise probable, that it was this specimen of the riches of Asia which inclined them so much to Asiatic expeditions ever after. All this time we are totally in the dark about the state of Asia and Africa, except in so far as can be conjectured from Scripture. The ancient empires of Babylon, Assyria, and Persia, probably still continued in the former continent, and Egypt and Ethiopia seem to have been considerable kingdoms in the latter.

About 1184 years B. C. the Greeks again distinguished themselves by their expedition against Troy, a city of Phrygia Minor; which they plundered and burnt, massacring the inhabitants with the most unrelenting cruelty. Æneas, a Trojan prince, escaped with some followers into Italy, where he became the remote founder of the Roman empire. At this time Greece was divided into a number of small principalities, most of which seem to have been in subjection to Agamemnon, king of Mycenæ. In the reign of Atreus, the father of this Agamemnon, the Heraclidæ, or descendants of Hercules, who had been formerly banished by Eurystheus, were again obliged to leave this country. Under their champion Hylus they claimed the kingdom of Mycenæ as their right, pretending that it belonged to their great ancestor Hercules, who was unjustly deprived of it by Eurystheus. See HERCULES. The controversy was decided by single combat; but Hylus being killed, they departed, as had been before agreed, under a promise of not making any attempt to return for 50 years. About the time of the Trojan war, also, we find the Lydians, Mysians, and some other nations of Asia Minor, first mentioned in history.

The names of the Greek states mentioned during this uncertain period are: 1. Sicyon. 2. Leleg. 3. Messina. 4. Athens. 5. Crete. 6. Argos. 7. Sparta. 8. Pelasgia. 9. Theflaly. 10. Attica. 11. Phocis. 12. Locris. 13. Ozela. 14. Corinth. 15. Eleufina. 16. Elis. 17. Pilus. 18. Arcadia. 19. Egina. 20. Ithaca. 21. Cephalone. 22. Phthia. 23. Phocidia. 24. Ephyra. 25. Eolia. 26. Thebes. 27. Calista. 28. Etolia. 29. Doloppa. 30. Oechalia. 31. Mycenæ. 32. Eubœa. 33. Mynia. 34. Doris. 35. Phera. 36. Iola. 37. Trachina. 38. Thrasprocia. 39. Myrmidonia. 40. Salamina. 41. Scyros. 42. Hyperia or Melité. 43. The Vulcanian ifles. 44. Megara. 45. Epirus. 46. Achaia. 47. The ifles of the Egean Sea. Concerning many of thefe we know nothing beyond their names: the moft remarkable particulars concerning the reft may be found under their refpective articles.

About 1048 B. C. the kingdom of Judea under king David approached its utmoft extent of power. In its moft flourishing condition, however, it never was remarkable for the largeneſs of its territory. In this reſpect it ſcarce exceeded the kingdom of Scotland; though, according to the accounts given in Scripture, the magnificence of Solomon was ſuperior to that of the moft potent monarchs on earth. This extraordinary wealth was owing partly to the ſpoils amaffed by king David in his conqueſts over his various enemies, and partly to the commerce with the Eaſt Indies which Solomon had eſtabliſhed. Of this commerce he owed his ſhare to the friendſhip of Hiram king of Tyre, a city of Phœnicia, whoſe inhabitants were now the moſt famed for commerce and ſkill in maritime affairs of any in the whole world.

After the death of Solomon, which happened about 975 B. C. the Jewiſh empire began to decline, and ſoon after many powerful ſtates aroſe in different parts of the world. The diſpoſition of mankind in general ſeems now to have taken a new turn, not eaſily accounted for. In former times, whatever wars might have taken place between neighbouring nations, we have no account of any extenſive empire in the whole world, or that any prince undertook to reduce far diſtant nations to his ſubjection. The empire of Egypt indeed is ſaid to have been extended immenſely to the eaſt, even before the days of Sefoſtris. Of this country, however, our accounts are ſo imperfect, that ſcarce any thing can be concluded from them. But now, as it were all at once, we find almoſt every nation aiming at univerſal monarchy, and refuſing to ſet any bounds whatever to its ambition. The firſt ſhock given to the Jewiſh grandeur was the diviſion of the kingdom into two through the imprudence of Rehoboam. This rendered it more eaſily a prey to Shifhak king of Egypt; who five years after came and pillaged Jeruſalem, and all the fortified cities of the kingdom of Judah. The commerce to the Eaſt Indies was now diſcontinued, and conſequently the ſources of wealth in a great meaſure ſtopped; and this, added to the perpetual wars between the kings of Iſrael and Judah, contributed to that remarkable and ſpeedy decline which is now ſo eaſily to be obſerved in the Jewiſh affairs.

Whether this king Shifhak was the Sefoſtris of profane writers or not, his expedition againſt Jeruſalem, as recorded in Scripture, ſeems very much to reſemble the deſultory conqueſts aſcribed to Sefoſtris. His infantry is ſaid to have been innumerable, compoſed of different African nations; and his cavalry, 60,000, with 1200 chariots; which agrees pretty well with the mighty armament attributed to Sefoſtris. Indeed his cavalry are ſaid to have been only 24,000; but the number of his chariots has alſo been reckoned at 27,000: which laſt may not unreaſonably be deemed an exaggeration, and theſe ſupernumerary chariots may have been only cavalry: but unleſs we allow Sefoſtris to be the ſame with Shifhak, it ſeems impoſſible to fix

on any other king of Egypt that can be ſuppoſed to have undertaken this expedition in the days of Solomon.

Though the Jews obtained a temporary deliverance from Shifhak, they were quickly after attacked by new enemies. In 541 B. C. one Zerah an Ethiopian invaded Judea with an army of a million of infantry and 300 chariots; but was defeated with great ſlaughter by Aſa king of Judah, who engaged him with an army of 580,000 men. About this time alſo we find the Syrians grown a conſiderable people, and bitter enemies both to the kings of Iſrael and Judah; aiming in fact at the conqueſt of both nations. Their kingdom commenced in the days of David, under Hadadezer, whoſe capital was Zobah, and who probably was at laſt obliged to become David's tributary, after having been defeated by him in ſeveral engagements. Before the death of David, however, one Rezon, who it ſeems had rebelled againſt Hadadezer, having found means to make himſelf maſter of Damafcus, erected there a new kingdom, which ſoon became very powerful. The Syrian princes being thus in the neighbourhood of the two rival ſtates of Iſrael and Judah (whoſe capitals were Samaria and Jeruſalem), found it an eaſy matter to weaken them both, by pretending to aſſiſt the one againſt the other; but a detail of the tranſactions between the Jews and Syrians is only to be found in the Old Teſtament, to which we refer. In 740 B. C. however, the Syrian empire was totally deſtroyed by Tiglath Pileſer king of Aſſyria; as was alſo the kingdom of Samaria by Shalmaneſer his ſucceſſor in 721. The people were either maſſacred, or carried into captivity into Media, Perſia, and the countries about the Caſpian Sea.

While the nations of the eaſt were thus deſtroying each other, the foundations of very formidable empires were laid in the weſt, which in proceſs of time were to ſwallow up almoſt all the eaſtern ones. In Africa, Carthage was founded by a Tyrian colony, about 869 B. C. according to thoſe who aſcribe the higheſt antiquity to that city; but, according to others, it was founded only in 769 or 770 B. C. In Europe a very conſiderable revolution took place about 900 B. C. The Heraclidæ, whom we have formerly ſeen expelled from Greece by Atreus the father of Agamemnon, after ſeveral unſucceſſful attempts, at laſt conquered the whole Peloponneſus. From this time the Grecian ſtates became more civilized, and their hiſtory becomes leſs obſcure. The inſtitution, or rather the revival and continuance, of the Olympic games, in 776 B. C. alſo greatly facilitated the writing not only of their hiſtory, but that of other nations; for as each Olympiad conſiſted of four years, the chronology of every important event became indubitably fixed by referring it to ſuch and ſuch an Olympiad. In 748 B. C. or the laſt year of the ſeventh Olympiad, the foundations of the city of Rome were laid by Romulus; and, 43 years after, the Spartan ſtate was new modelled, and received from Lycurgus thoſe laws, by obſerving of which it afterwards arrived at ſuch a pitch of ſplendour.

3. With the beginning of the 28th Olympiad, or 568 B. C. commences the third general period above mentioned, when profane hiſtory becomes ſomewhat more clear, and the relations concerning the different nations may be depended upon with ſome degree of certainty. The general ſtate of the world was at that time as follows.—The northern parts of Europe were either thinly inhabited, or filled with unknown and barbarous nations, the anceſtors of thoſe who afterwards deſtroyed the Roman empire. France and Spain were inhabited by the Gomerians or Celtes. Italy was divided into a number of petty ſtates, ariſing partly from Gauliſh and partly from Grecian colonies; among which the Romans had already become formidable. They were governed by their king Servius Tullius; had increaſed their city by the demolition of Alba Longa, and the removal of its inhabitants to Rome; and had enlarged their

dominions by several cities taken from their neighbours. Greece was also divided into a number of small states, among which the Athenians and Spartans, being the most remarkable, were rivals to each other. The former had, about 599 B. C. received an excellent legislation from Solon, and were enriching themselves by navigation and commerce: the latter were become formidable by the martial institutions of Lycurgus; and having conquered Messina, and added its territory to their own, were justly esteemed the most powerful people in Greece. The other states of most consideration were Corinth, Thebes, Argos, and Arcadia.—In Asia great revolutions had taken place. The ancient kingdom of Assyria was destroyed by the Medes and Babylonians, its capital city Nineveh utterly ruined, and the greatest part of its inhabitants carried to Babylon. Nay, the very materials of which it was built were carried off, to adorn and give strength to that stately metropolis, which was then undoubtedly the first city in the world. Nebuchadnezzar, a wife and valiant prince, now sat on the throne of Babylon. By him the kingdom of Judea was totally overthrown in 587 B. C. Three years before this he had taken and razed the city of Tyre, and over-run all the kingdom of Egypt. He is even said by Josephus to have conquered Spain, and reigned there nine years, after which he abandoned it to the Carthaginians; but this seems by no means probable. The extent of the Babylonian empire is not certainly known: but, from what is recorded of it, we may conclude that it was not at all inferior even in this respect to any that ever existed; as the Scripture tells us it was superior in wealth to any of the succeeding ones. We know that it comprehended Phœnicia, Palestine, Syria, Babylonia, Media, and Persia, and not improbably India also; and from a consideration of this vast extent of territory, and the riches with which every one of these countries abounded, we may form some idea of the wealth and power of this monarch. When we consider also, that the whole strength of this mighty empire was employed in beautifying the metropolis, we cannot look upon the wonders of that city as related by Herodotus to be at all incredible. As to what passed in the republic of Carthage about this time, we are quite in the dark; there being a chasm in its history for no less than 300 years.

4. The fourth general period of history, namely, from the end of the fabulous times to the conquest of Babylon by Cyrus, is very short, including no more than 31 years. This sudden revolution was occasioned by the misconduct of Evil-merodach, Nebuchadnezzar's son, even in his father's lifetime. For having, in a great hunting match on occasion of his marriage, entered the country of the Medes, and some of his troops coming up at the same time to relieve the garrisons in those places, he joined them to those already with him, and without the least provocation began to plunder and lay waste the neighbouring country. This produced an immediate revolt, which quickly extended over all Media and Persia. The Medes, headed by Astyages and his son Cyaxares, drove back Evil-merodach and his party with great slaughter; nor doth it appear that they were afterwards reduced even by Nebuchadnezzar himself. The new empire continued daily to gather strength; and at last Cyrus, Astyages's grandson, a prince of great prudence and valour, being made generalissimo of the Median and Persian forces, took Babylon itself in the year 538. B. C.

During this period, the Romans increased in power under the wise administration of their king Servius Tullius, who, though a pacific prince, rendered his people more formidable by a peace of 20 years than his predecessors had done by all their victories. The Greeks, even at this early period, began to interfere with the Persians, on account of the Ionians or Grecian colonies in Asia Minor. These had been subdued by Crœsus king of Lydia about the year 562, the time of

Nebuchadnezzar's death. Whether the Lydians had been subdued by the Babylonish monarch or not, is not now to be ascertained; though it is very probable that they were either in subjection to him, or greatly awed by his power, as before his death nothing considerable was undertaken by them. It is indeed probable, that during the infancy of Nebuchadnezzar, spoken of by Daniel, the affairs of his kingdom would fall into confusion; and many of those princes whom he formerly retained in subjection would set up for themselves. Certain it is, however, that if the Babylonians did not regard Crœsus as their subject, they looked upon him to be a very faithful ally; inasmuch that they celebrated an annual feast in commemoration of a victory obtained by him over the Scythians. After the death of Nebuchadnezzar, Crœsus subdued many nations in Asia Minor, and among the rest the Ionians, as already related. They were, however, greatly attached to his government; for, though they paid him tribute, and were obliged to furnish him with some forces in time of war, they were yet free from all kind of oppression. When Cyrus therefore was proceeding in his conquests of different parts of the Babylonish empire, before he proceeded to attack the capital, the Ionians refused to submit to him, though he offered them very advantageous terms. But soon after, Crœsus himself being defeated and taken prisoner, the Ionians sent ambassadors to Cyrus, offering to submit on the terms which had formerly been proposed. These terms were now refused; and the Ionians, being determined to resist, applied to the Spartans for aid. Though the Spartans at that time could not be prevailed upon to give their countrymen any assistance, they sent ambassadors to Cyrus with a threatening message; to which he returned a contemptuous answer, and then forced the Ionians to submit at discretion, five years before the taking of Babylon. Thus commenced the hatred between the Greeks and Persians; and thus we see, that in the two first great monarchies the seeds of their destruction were sown even before the monarchies themselves were established. For while Nebuchadnezzar was raising the Babylonish empire to its utmost height, his son was destroying what his father built up; and at the very time when Cyrus was establishing the Persian monarchy, by his ill-timed severity to the Greeks he made that warlike people his enemies, whom his successors were by no means able to resist, and who would probably have overcome Cyrus himself, had they united in order to attack him. The transactions of Africa during this period are almost entirely unknown; though we cannot doubt that the Carthaginians enriched themselves by means of their commerce, which enabled them afterwards to attain such a considerable share of power.

5. Cyrus having now become master of all the east, the Asiatic affairs continued for some time in a state of tranquillity. The Jews obtained leave to return to their own country, rebuild their temple, and again establish their worship, of all which an account is given in the sacred writings, though undoubtedly they must have been in a state of dependance on the Persians from that time forward. Cambyfes, the successor of Cyrus, added Egypt to his empire, which had either not submitted to Cyrus, or revolted soon after his death. He intended also to have subdued the Carthaginians; but as the Phœnicians refused to supply him with ships to fight against their own countrymen, he was obliged to lay this design aside.

In 517 B. C. the Babylonians finding themselves grievously oppressed by their Persian masters, resolved to shake off the yoke, and set up for themselves. For this purpose, they took care to store their city with all manner of provisions; and when Darius Hystaspes, then king of Persia, advanced against them, they took the most barbarous method that can be imagined, of preventing an unnecessary consumption of those provisions which they had so carefully amassed. Having collected all the women, old men, and children, into one place, they strangled them with-

out distinction, whether wives, fathers, mothers, brothers, or sisters; every one being allowed to save only the wife he liked best, and a maid servant to do the work of the house. This cruel policy did not avail them: their city was taken by treachery (for it was impossible to take it by force); after which the king caused the walls of it to be beat down from 200 to 50 cubits height, that their strength might no longer give encouragement to the inhabitants to revolt. Darius then turned his arms against the Scythians; but finding that expedition turn out both tedious and unprofitable, he directed his course eastward, and reduced all the country as far as the river Indus. In the mean time, the Ionians revolted; and being assisted by the Greeks, a war commenced between the two nations, which was not thoroughly extinguished but by the destruction of the Persian empire in 330 B. C. The Ionians, however, were for this time obliged to submit, after a war of six years; and were treated with great severity by the Persians. The conquest of Greece itself was then projected: but the expeditions for that purpose ended most unfortunately for the Persians, and encouraged the Greeks to make reprisals on them, in which they succeeded according to their utmost wishes; and had it only been possible for them to have agreed among themselves, the downfall of the Persian empire would have happened much sooner than it did.

In 459 B. C. the Egyptians made an attempt to recover their liberty, but were reduced after a war of six years. In 413 B. C. they revolted a second time; and, being assisted by the Sydonians, drew upon the latter that terrible destruction foretold by the prophets; while they themselves were so thoroughly humbled, that they never after made any attempt to recover their liberty.

The year 403 B. C. proved remarkable for the revolt of Cyrus against his brother Artaxerxes Mnemon; in which, through his own rashness, he miscarried, and lost his life at the battle of Cunaxa in the province of Babylon. Ten thousand Greek mercenaries, who served in his army, made their way back into Greece, though surrounded on all sides by the enemy, and in the heart of a hostile country. In this retreat they were commanded by Xenophon, who has received the highest praises on account of his conduct and military skill in bringing it to a happy conclusion. Two years after, the invasions of Agesilaus king of Sparta threatened the Persian empire with total destruction; from which, however, it was relieved by his being recalled in order to defend his own country against the other Grecian states; and after this the Persian affairs continued in a more prosperous way till the time of Alexander.

During all this time, the volatile and giddy temper of the Greeks, together with their enthusiastic desire of romantic exploits, were preparing fetters for themselves, which indeed seemed to be absolutely necessary to prevent them from destroying one another. A zeal for liberty was what they all pretended; but, on every occasion, it appeared that this love of liberty was only a desire of dominion. No state in Greece could bear to see another equal to itself; and hence their perpetual contests for pre-eminence, which could not but weaken the whole body, and render them an easy prey to an ambitious and politic prince, who was capable of taking advantage of those divisions. Being all equally impatient of restraint, they never could bear to submit to any regular government; and hence their determinations were nothing but the decisions of a mere mob, of which they had afterwards almost constantly reason to repent. Hence also their base treatment of those eminent men whom they ought most to have honoured; as Miltiades, Aristides, Themistocles, Alcibiades, Socrates, Phocion, &c. The various transactions between the Grecian states, though they make a very considerable figure in particular history, make none at all in a general sketch of the history of the

world. We shall therefore only observe, that in 404 B. C. the Athenian power was in a manner totally broken by the taking of their city by the Spartans. In 370 that of the Spartans received a severe check from the Thebans at the battle of Leuctra; and eight years after was still further reduced by the battle of Mantinea. Epaminondas, the great enemy of the Spartans, was killed; but this only proved a more speedy means of subjugating all the states to a foreign, and at that time despicable, power. The Macedonians, a barbarous nation, lying to the north of the states of Greece, were two years after the death of Epaminondas reduced to the lowest ebb by the Illyrians, another nation of barbarians in the neighbourhood. The king of Macedon being killed in an engagement, Philip his brother departed from Thebes, where he had studied the art of war under Epaminondas, in order to take possession of his kingdom. Being a man of great prudence and policy, he quickly settled his own affairs; vanquished the Illyrians; and, being no stranger to the weakened situation of Greece, began almost immediately to meditate the conquest of it. The particulars of this enterprise are related in the ancient history of *Macedon*: here it is sufficient to take notice, that by first attacking those he was sure he could overcome, by corrupting those whom he thought it dangerous to attack, by sometimes pretending to assist one state and sometimes another, and by imposing upon all as best served his turn, he at last put it out of the power of the Greeks to make any resistance, at least such as could keep him from gaining his end. In 338 B. C. he procured himself to be elected general of the Amphictyons, or council of the Grecian states, under pretence of settling some troubles at that time in Greece; but having once obtained liberty to enter that country with an army, he quickly convinced the states that they must all submit to his will. He was opposed by the Athenians and Thebans; but the intestine wars of Greece had cut off all her great men, and no general was now to be found capable of opposing Philip with success.

The king of Macedon, being now master of all Greece, projected the conquest of Asia. To this he was encouraged by the ill success which had attended the Persians in their expeditions against Greece, the successes of the Greeks in their invasions, and the retreat of the ten thousand under Xenophon. All these events showed the weakness of the Persians, their vast inferiority to the Greeks in military skill, and how easily their empire might be overthrown by a proper union among the states.

Philip was preparing to enter upon his grand design, when he was murdered by some assassins. His son Alexander was possessed of every quality necessary for the execution of so great a plan: and his impetuosity of temper made him execute it with a rapidity unheard of either before or since. It must be confessed, indeed, that the Persian empire was now ripe for destruction, and could not in all probability have withstood an enemy much less powerful than Alexander. The Asiatics have in all ages been much inferior to the European nations in valour and military skill. They were now sunk in luxury and effeminacy; and what was worse, they seem at this period to have been seized with that infatuation and distraction of counsels which scarce ever fails to be a forerunner of the destruction of any nation. The Persian ministers persuaded their sovereign to reject the prudent advice that was given him, of distressing Alexander by laying waste the country, and thus forcing him to return for want of provisions. Nay, they even prevented him from engaging the enemy in the most proper manner, by dividing his forces; and persuaded him to put Charidemus the Athenian to death, who had promised, with 100,000 men, of whom one third were mercenaries, to drive the Greeks out of Asia. In short, Alexander met with only two checks in his Persian expedition. The one was from the city of Tyre,

which for seven months resisted his utmost efforts; the other was from Memnon the Rhodian, who had undertaken to invade Macedonia. The first of these obstacles Alexander at last got over, and treated the governor and inhabitants with the utmost cruelty. The other was scarce felt; for Memnon died after reducing some of the Grecian islands, and Darius had no other general capable of conducting the undertaking. The power of the Persian empire was totally broken by the victory gained over Darius at Arbela in 331 B. C. and next year a total end was put to it by the murder of the king by Bessus one of his subjects.

The ambition of Alexander was not to be satisfied with the possession of the kingdom of Persia, or indeed of any other on earth. Nothing less than the total subjection of the world itself seemed sufficient to him; and therefore he was now prompted to invade every country of which he could only learn the name, whether it had belonged to the Persians or not. In consequence of this disposition he invaded and reduced Hyrcania, Bactria, Sogdia, and all that vast tract of country now called *Bukharia*. At last, having entered India, he reduced all the nations to the river Hyphasis, one of the branches of the Indus. But when he would have proceeded farther, and extended his conquests quite to the eastern extremities of Asia, his troops positively refused to follow him farther, and he was constrained to return. In 323, this mighty conqueror died of a fever; without having time to settle the affairs of his vast extended empire, or even to name his successor.

While the Grecian empire thus suddenly sprang up in the east, the rival states of Rome and Carthage were making considerable advances in the west. The Romans were establishing their empire on the most solid foundations; to which their particular situation naturally contributed. Being originally little better than a parcel of lawless banditti, they were despised and hated by the neighbouring states. This soon produced wars; in which, at first from accidental circumstances, and afterwards from their superior valour and conduct, the Romans proved almost constantly victorious. The jealousies which prevailed among the Italian states, and their ignorance of their true interest, prevented them from combining against that aspiring nation, and crushing it in its infancy, which they might easily have done; while in the mean time the Romans, being kept in a state of continual warfare, became at last such expert soldiers, that no other state on earth could resist them. During the time of their kings, they had made a very considerable figure among the Italian nations; but after their expulsion, and the commencement of the republic, their conquests became much more rapid and extensive. In 501 B. C. they subdued the Sabines; eight years after, the Latins; and in 399 the city of Veii, the strongest in Italy excepting Rome itself, was taken after a siege of ten years. But in the midst of their successes a sudden irruption of the Gauls had almost put an end to their power and nation at once. The city was burnt to the ground in 383 B. C. and the capitol on the point of being surprised, when the Gauls, who were climbing up the walls in the night, were accidentally discovered and repulsed. In a short time Rome was rebuilt with much greater splendor than before, but now a general revolt and combination of the nations formerly subdued took place. The Romans, however, still got the better of their enemies; but, even at the time of the celebrated Camillus's death, which happened about 352 B. C. their territories scarce extended six or seven leagues from the capital. The republic from the beginning was agitated by those dissensions which at last proved its ruin. The people had been divided by Romulus into two classes, namely *Patricians* and *Plericians*, answering to our nobility and commonalty. Between these two bodies were perpetual jealousies and contentions; which retarded the progress of the Roman conquests, and revived

the hopes of the nations they had conquered. The tribunes of the people were perpetually opposing the consuls and military tribunes. The senate had often recourse to a dictator endowed with absolute power; and then the valour and experience of the Roman troops made them victorious: but the return of domestic seditions gave the subjugated nations an opportunity of shaking off the yoke. Thus had the Romans continued for near 400 years, running the same round of wars with the same enemies, and reaping very little advantage from their conquests, till at last matters were compounded by choosing one of the consuls from among the plebeians; and from this time chiefly we may date the prosperity of Rome, so that by the time that Alexander the Great died they were held in considerable estimation among foreign nations.

The Carthaginians in the mean time continued to enrich themselves by commerce; but, being less conversant in military affairs, were by no means equal to the Romans in power, though they excelled them in wealth. A new state, however, makes its appearance during this period, which may be said to have taught the Carthaginians the art of war, and, by bringing them into the neighbourhood of the Romans, proved the first source of contention between these two powerful nations. This was the island of Sicily. At what time people were first settled on it, is not now to be ascertained. The first inhabitants we read of were called *Sicani*, *Siculi*, *Læstrigones*, &c. but of these we know little or nothing. In the second year of the 17th Olympiad, or 710 B. C. some Greek colonies are said to have arrived on the island, and in a short time founded several cities, of which Syracuse was the chief. The Syracusans at last subdued the original inhabitants; though it does not appear that the latter were ever well affected to their government, and therefore were on all occasions ready to revolt. The first considerable prince, or (as he is called by the Greeks) *tyrant* of Syracuse, was Gelon, who obtained the sovereignty about the year 483 B. C. At what time the Carthaginians first carried their arms into Sicily is not certainly known; only we are assured, that they possessed some part of the island as early as 505 B. C. For in the time of the first consuls, the Romans and Carthaginians entered into a treaty chiefly in regard to matters of navigation and commerce; by which it was stipulated, that the Romans should touch at Sardinia, or that part of Sicily which belonged to Carthage, should be received there in the same manner as the Carthaginians themselves. Whence it appears, that the dominion of Carthage already extended over Sardinia and part of Sicily: but in 28 years after, they had been totally driven out by Gelon; which probably was the first exploit performed by him. This appears from his speech to the Athenian and Spartan ambassadors, who desired his assistance against the forces of Xerxes king of Persia. The Carthaginians made many attempts to regain their possessions in this island, which occasioned long and bloody wars between them and the Greeks. This island also proved the scene of much slaughter and bloodshed in the wars of the Greeks, with one another. Before the year 323 B. C. however, the Carthaginians had made themselves masters of a very considerable part of the island; from whence all the power of the Greeks could not dislodge them. It is proper also to observe, that after the destruction of Tyre by Alexander the Great, almost all the commerce in the western part of the world fell to the share of the Carthaginians. Whether they had at this time made any settlements in Spain, is not known. It is certain, that they traded to that country for the sake of the silver, in which it was very rich; as they probably also did to Britain for the tin with which it abounded.

6. The beginning of the sixth period presents us with a state of the world entirely different from the foregoing. We now behold all the eastern part of the world, from the confines of

Italy to the river Indus, and beyond it, newly united into one vast empire, and at the same time ready to fall to pieces for want of a proper head; the western world filled with fierce and savage nations, whom the rival republics of Carthage and Rome were preparing to enslave as fast as they could. The first remarkable events took place in the Macedonian empire.—Alexander, as already observed, had not distinctly named any successor; but he had left behind him a victorious, and, we may say, invincible army, commanded by most expert officers, all of them ambitious of supreme authority. It is not to be supposed that peace could long be preserved in such a situation. For a number of years, indeed, nothing was to be seen or heard of but the most horrid slaughters, and wickedness of every kind; until at last the mother, wives, children, brothers, and even sisters of Alexander were cut off; not one of the family of that great conqueror being left alive. When matters were a little settled, four new empires, each of them of no small extent, had arisen out of the empire of Alexander. Cassander, the son of Antipater, had Macedonia, and all Greece; Antigonus, Asia Minor; Seleucus had Babylon, and the eastern provinces; and Ptolemy Lagus, Egypt, and the western ones. One of these empires, however, quickly fell; Antigonus being defeated and killed by Seleucus and Lysimachus at the battle of Ipsus, in 301 B. C. The greatest part of his dominions then fell to Seleucus: but several provinces took the opportunity of these confusions to shake off the Macedonian yoke altogether; and thus were formed the kingdoms of Pontus, Bithynia, Pergamus, Armenia, and Cappadocia. The two most powerful and permanent empires, however, were those of Syria founded by Seleucus, and Egypt by Ptolemy Lagus. The kings of Macedon, though they did not preserve the same authority over the Grecian states that Alexander, Antipater and Cassander had done, yet effectually prevented them from those outrages upon one another, for which they had formerly been so remarkable. Indeed it is somewhat difficult to determine, whether their condition was better or worse than before they were conquered by Philip; since, though they were now prevented from destroying one another, they were most grievously oppressed by the Macedonian tyrants.

While the eastern parts of the world were thus deluged with blood, and the successors of Alexander were pulling to pieces the empire which he had established; the Romans and Carthaginians proceeded in their attempts to enslave the nations of the west. The Romans, ever engaged in war, conquered one city and state after another, till about the year 253 B. C. they had made themselves masters of almost the whole of Italy. During all this time they had met only with a single check in their conquests; and that was the invasion of Pyrrhus king of Epirus. That ambitious and fickle prince had projected the conquest of Italy, which he fancied would be an easy matter. Accordingly, in 271 B. C. he entered that country, and maintained a war with the Romans for six years; till at last, being utterly defeated by Curius Dentatus, he was obliged to return.

The Romans had no sooner made themselves masters of Italy, than they wanted only a pretence to carry their arms out of it; and this pretence was soon found out. Being invited into Sicily to assist the Mamertines against Hiero king of Syracuse and the Carthaginians, they immediately commenced a war with the latter, which continued with the utmost fury for 23 years. The war ended greatly to the disadvantage of the Carthaginians, chiefly owing to the bad conduct of their generals: none of whom, Hamilcar Barcas alone excepted, seem to have been possessed of any degree of military skill; and the state had suffered too many misfortunes before he entered upon the command, for him or any other to retrieve it at that time. The consequence of this war was the entire loss of Sicily to the Carthaginians; and soon after, the Romans seized on the island of Sardinia.

Hamilcar perceiving that there was now no alternative, but that in a short time either Carthage must conquer Rome, or Rome would conquer Carthage, bethought himself of a method by which his country might become equal to that haughty republic. This was by reducing all Spain, in which the Carthaginians had already considerable possessions, and from the mines of which they drew great advantages. He had, therefore, no sooner finished the war with the mercenaries, which succeeded that with the Romans, than he set about the conquest of Spain. This, however, he did not live to accomplish, though he made great progress in it. His son Asdrubal continued the war with success; till at last, the Romans, jealous of his progress, persuaded him to enter into a treaty with them, by which he engaged himself to make the river Iberus the boundary of his conquests. This treaty probably was never ratified by the senate of Carthage; nor, though it had, would it have been regarded by Hannibal, who succeeded Asdrubal in the command, and had sworn perpetual enmity with the Romans. The transactions of the second Punic war are perhaps the most remarkable which the history of the world can afford. Certain it is, that nothing can show more clearly the slight foundations upon which the greatest empires are built. We now see the Romans, the nation most remarkable for their military skill in the whole world, and who, for more than 500 years, had been constantly victorious, unable to resist the efforts of one single man. At the same time we see this man, though evidently the first general in the world, lost solely for want of a little support. In former times, the republic of Carthage supplied her generals in Sicily with hundreds of thousands, though their enterprises were almost constantly unsuccessful; but now Hannibal, the conqueror of Italy, was obliged to abandon his design, merely for want of 20 or 30,000 men. That degeneracy and infatuation, which never fails to overwhelm a falling nation, or rather which is the cause of its fall, had now infected the counsels of Carthage, and the supplies were denied. Neither was Carthage the only infatuated nation at this time. Hannibal, whose prudence never forsook him either in prosperity or adversity, in the height of his good fortune had concluded an alliance with Philip king of Macedon. Had that prince sent an army to the assistance of the Carthaginians in Italy immediately after the battle of Cannæ, there can be no doubt but the Romans would have been forced to accept of that peace which they so haughtily refused; and indeed, this offer of peace, in the midst of so much success, is an instance of moderation which perhaps does more honour to the Carthaginian general than all the military exploits he performed. Philip, however, could not be roused from his indolence, nor see that his own ruin was connected with that of Carthage. The Romans had now made themselves masters of Sicily: after which they recalled Marcellus, with his victorious army, to be employed against Hannibal; and the consequence at last was, that the Carthaginian armies, unsupported in Italy, could not conquer it, but were recalled into Africa, which the Romans had invaded. The southern nations seem to have been as blind to their own interest as the northern ones. They ought to have seen, that it was necessary for them to preserve Carthage from being destroyed; but instead of this, Masinissa king of Numidia allied with the Romans, and by his means Hannibal was overcome at the battle of Zama, which finished the second Punic war, in the year 188 B. C.

The event of the second Punic war determined the fate of almost all the other nations in the world. All this time, indeed, the empires of Egypt, Syria, and Greece, had been promoting their own ruin by mutual wars and intestine divisions. The Syrian empire was now governed by Antiochus the Great, who seems to have had little right to such a title. His empire, though diminished by the defection of the Parthians, was still

very powerful; and to him Hannibal applied, after he was obliged to leave his country. Antiochus, however, had not sufficient judgment to see the necessity of following that great man's advice; nor would the Carthaginians be prevailed upon to contribute their assistance against the nation which was soon to destroy them without any provocation. The pretence for war on the part of the Romans was, that Antiochus would not declare his Greek subjects in Asia to be free and independent states; a requisition which neither the Romans nor any other nation had a right to make. The event of all was, that Antiochus was every where defeated, and forced to conclude a peace upon very disadvantageous terms.

In Europe, matters went on in the same way; the states of Greece, weary of the tyranny of the Macedonians, entered into a resolution of recovering their liberties. For this purpose was framed the Achæan League; but, as they could not agree among themselves, they at last came to the imprudent determination of calling in the Romans to defend them against Philip king of Macedon. This produced a war, in which the Romans were victorious. The Macedonians, however, were still formidable; and, as the intention of the Romans to enslave the whole world could no longer be doubted, Perseus, the successor of Philip, renewed the war. Through his own cowardice he lost a decisive engagement, and with it his kingdom, which submitted to the Romans in 167 B. C.

Macedon being thus conquered, the next step was utterly to exterminate the Carthaginians; whose republic, notwithstanding the many disasters that had befallen it, was still formidable. It is true, the Carthaginians were giving no offence; nay, they even made the most abject submissions to the republic of Rome: but all was not sufficient. War was declared a third time against that unfortunate state; there was now no Hannibal to command their armies, and the city was utterly destroyed 146 B. C. The same year the Romans put an end to the liberties they had pretended to grant the cities of Greece, by the entire destruction of *Corinth*.

After the death of Antiochus the Great, the affairs of Syria and Egypt went on from bad to worse. The degenerate princes which filled the thrones of those empires, regarding only their own pleasures, either spent their time in oppressing their subjects, or in attempting to deprive each other of their dominions, by which means they became a more easy prey to the Romans. So far indeed were they from taking any means to secure themselves against the overgrown power of that republic, that the kings both of Syria and Egypt sometimes applied to the Romans as protectors. Their downfall, however, did not happen within the period of which we now treat.—The only other transaction which makes any considerable figure in the Syrian empire is the oppression of the Jews by Antiochus Epiphanes. After their return from the Babylonish captivity, they continued in subjection to the Persians till the time of Alexander. From that time they were subject to the kings of Egypt or Syria, as the fortune of either happened to prevail. Egypt being reduced to a low ebb by Antiochus Epiphanes, the Jews fell under his dominion; and being severely treated by him, imprudently showed some signs of joy on a report of his death. This brought him against them with a powerful army; and in 170 B. C. he took Jerusalem by storm, committing the most horrid cruelties on the inhabitants, insomuch that they were obliged to hide themselves in caverns and in holes of rocks to avoid his fury. Their religion was totally abolished, their temple profaned, and an image of Jupiter Olympius set up on the altar of burnt-offerings: which profanation is thought to be the *abomination of desolation* mentioned by the prophet Daniel. This revolution, however, was of no long continuance. In 167 B. C. Mattathias restored the true worship in most of the cities of Judea; and in 165 the temple was purified, and the worship

there restored by Judas Maccabæus. This was followed by a long series of wars between the Syrians and Jews, in which the latter were almost always victorious; and before these wars were finished, the destruction of Carthage happened, which puts an end to the sixth general period formerly mentioned.

7. The beginning of the seventh period presents us with a view of the ruins of the Greek empire in the declining states of Syria and Egypt; both of them much circumscribed in bounds. The empire of Syria at first comprehended all Asia to the river Indus, and beyond it; but in 312 B. C. most of the Indian provinces were by Seleucus ceded to one *Sandrocottus*, or *Androcottus*, a native, who in return gave him 500 elephants. Of the empire of Sandrocottus we know nothing farther than that he subdued all the countries between the Indus and the Ganges; so that from this time we may reckon the greatest part of India independent on the Syro-Macedonian princes. In 250 B. C. however, the empire sustained a much greater loss by the revolt of the Parthians and Bactrians from Antiochus Theus. The former could not be subdued; and as they held in subjection to them the vast tract which now goes under the name of *Persia*, we must look upon their defection as an irreparable loss. Whether any part of their country was afterwards recovered by the kings of Egypt or Syria, is not very certain; nor is it of much consequence, since we are assured that in the beginning of the seventh period, i. e. 146 B. C. the Greek empires of Syria and Egypt were reduced by the loss of India, Persia, Armenia, Pontus, Bithynia, Cappadocia, Pergamus, &c. The general state of the world in 146 B. C. therefore was as follows. In Asia were the empires of India, Parthia, and Syria, with the lesser states of Armenia, Pontus, &c. above mentioned; to which we must add that of Arabia, which during the sixth period had grown into some consequence, and had maintained its independence from the days of Ishmael the son of Abraham. In Africa were the kingdoms of Egypt and Ethiopia; the Carthaginian territories, now subject to the Romans; and the kingdoms of Numidia, Mauritania, and Getulia, ready to be swallowed up by the same ambitious and insatiable power, now that Carthage was destroyed, which served as a barrier against it. To the south lay some unknown and barbarous nations, secure by reason of their situation and insignificance, rather than their strength, or distance from Rome. In Europe we find none to oppose the progress of the Roman arms, except the Gauls, Germans, and some Spanish nations. These were brave indeed; but through want of military skill, incapable of contending with such masters in the art of war as the Romans then were.

The Spaniards had indeed been subdued by Scipio Africanus in the time of the second Punic war: but, in 155 B. C. they revolted; and, under the conduct of one Viriathus, formerly a robber, held out for a long time against all the armies the Romans could send into Spain. Him the consul Cæpio caused to be murdered about 138 B. C. because he found it impossible to reduce him by force. The city of Numantia defied the whole Roman power for six years longer; till at last, by dint of treachery, numbers, and perseverance, it was not taken, but the inhabitants, reduced to extremity by famine, set fire to their houses, and perished in the flames, or killed one another, so that not one remained to grace the triumph of the conqueror: and this for the present quieted the rest of the Spaniards. About the same time Attalus, king of Pergamus, left by will the Roman people heirs to all his goods; upon which they immediately seized on his kingdom as part of those goods, and reduced it to a Roman province, under the name of *ſua Proper*. Thus they continued to enlarge their dominions on every side, without the least regard to justice, to the means they employed, or to the miseries they brought upon the conquered people. In 122 B. C. the Balearic islands, now called *Majorca*, *Minorca*, and *Ivica*, were subdued, and the inhabitants exterminated; and, soon

after, several of the nations beyond the Alps were obliged to submit.

In Africa the crimes of Jugurtha soon gave this ambitious republic an opportunity of conquering the kingdoms of Numidia and Mauritania: and indeed this is almost the only war in which we find the Romans engaged where their pretensions had the least colour of justice; though in no case whatever could a nation show more degeneracy than the Romans did on this occasion. The event of it was the total reduction of the former about the year 105 B. C. but Mauritania and Getulia preserved their liberty for some time longer.

In the east, the empire of Syria continued daily to decline; by which means the Jews not only had an opportunity of recovering their liberty, but even of becoming as powerful, or at least of extending their dominions as far as in the days of David and Solomon. This declining empire was still farther reduced by the civil dissensions between the two brothers Antiochus Grypus and Antiochus Cyzicenus; during which the cities of Tyre, Sidon, Ptolemais, and Gaza, declared themselves independent, and in other cities tyrants started up who refused allegiance to any foreign power. This happened about 100 B. C.; and 17 years after, the whole was reduced by Tigranes king of Armenia. On his defeat by the Romans, the latter reduced Syria to a province of their empire. The kingdom of Armenia itself, with those of Pontus, Cappadocia, and Bithynia, soon shared the same fate; Pontus, the most powerful of them all, being subdued about 64 B. C. The kingdom of Judea also was reduced under the same power much about this time. This state owed the loss of its liberty to the same cause that had ruined several others, namely, calling in the Romans as arbitrators between two contending parties. The two sons of Alexander Jannæus (Hyrcanus and Aristobulus) contended for the kingdom. Aristobulus, being defeated by the party of Hyrcanus, applied to the Romans. Pompey the Great, who acted as ultimate judge in this affair, decided it against Aristobulus, but at the same time deprived Hyrcanus of all power as a king; not allowing him even to assume the regal title, or to extend his territory beyond the ancient borders of Judea. To such a length did Pompey carry this last article, that he obliged him to give up all those cities in Cœlosyria and Phœnicia which had been gained by his predecessors, and added them to the newly acquired Roman province of Syria.

Thus the Romans became masters of all the eastern parts of the world, from the Mediterranean sea to the borders of Parthia. In the west, however, the Gauls were still at liberty, and the Spanish nations bore the Roman yoke with great impatience. The Gauls infested the territories of the republic by their frequent incursions, which were sometimes very terrible; and though several attempts had been made to subdue them, they always proved insufficient till the time of Julius Cæsar. By him they were totally reduced, from the river Rhine to the Pyrenean mountains, and many of their nations almost exterminated. He carried his arms also into Germany and the southern parts of Britain; but in neither of these parts did he make any permanent conquests. The civil wars between him and Pompey gave him an opportunity of seizing on the kingdom of Mauritania and those parts of Numidia which had been allowed to retain their liberty. The kingdom of Egypt alone remained, and to this nothing belonged except the country properly so called. Cyrenaica was bequeathed by will to the Romans about 58 B. C. and about the same time the island of Cyprus was seized by them without any pretence, except a desire of possessing the treasure of the king.—The kingdom of Egypt continued for some time longer at liberty; which in some measure must be ascribed to the internal dissensions of the republic, but more especially to the amours of Pompey, Julius Cæsar, and Marc Antony, with the famous Cleopatra queen of Egypt. The

battle of Actium, however, determined the fate of Antony, Cleopatra, and Egypt itself; which last was reduced to a Roman province about 9 B. C.

While the Romans thus employed all means to reduce the world to their obedience, they were making one another feel the same miseries at home which they inflicted upon other nations abroad. The first civil dissensions took their rise at the siege of Numantia in Spain. We have already observed, that this small city resisted the whole power of the Romans for six years. Once they gave them a most terrible and shameful defeat, wherein 30,000 Romans fled before 4000 Numantines. Twenty thousand were killed in the battle, and the remaining ten thousand so shut up that there was no possibility of escaping. In this extremity they were obliged to negotiate with the enemy, and a peace was concluded upon the following terms: 1. That the Numantines should suffer the Romans to retire unmolested; and, 2. That Numantia should maintain its independence, and be reckoned among the Roman allies.—The Roman senate, with an injustice and ingratitude hardly to be matched, broke this treaty, and in return ordered the commander of their army to be delivered up to the Numantines: but they refused to accept of him, unless his army was delivered along with him; upon which the war was renewed; and ended as already related. The fate of Numantia, however, was soon revenged. Tiberius Sempronius Gracchus, brother-in-law to Scipio Africanus the second, had been a chief promoter of the peace with the Numantines already mentioned, and of consequence had been in danger of being delivered up to them along with the commander in chief. This disgrace he never forgot; and, in order to revenge himself, undertook the cause of the Plebeians against the Patricians, by whom the former were greatly oppressed. He began with reviving an old law, which had enacted that no Roman citizen should possess more than 500 acres of land. The overplus he designed to distribute among those who had no lands, and to reimburse the rich out of the public treasury. This law met with great opposition, bred many tumults, and at last ended in the death of Gracchus and the persecution of his friends, several hundreds of whom were put to cruel deaths without any form of law.

The disturbances did not cease with the death of Gracchus. New contests ensued on account of the Sempronian law, and the giving to the Italian allies the privilege of Roman citizens. This last not only produced great commotions in the city, but occasioned a general revolt of the states of Italy against the republic of Rome. This rebellion was not quelled without the utmost difficulty: and in the mean time, the city was deluged with blood by the contending factions of Sylla and Marius; the former of whom sided with the Patricians, and the latter with the Plebeians. These disturbances ended in the perpetual dictatorship of Sylla, about 80 B. C.

From this time we may date the loss of the Roman liberty; for though Sylla resigned his dictatorship two years after, the succeeding contests between Cæsar and Pompey proved equally fatal to the republic. These contests were decided by the battle of Pharfalia, by which Cæsar became in effect master of the empire in 43 B. C. Without loss of time he then crossed over into Africa; totally defeated the republican army in that continent; and, by reducing the country of Mauritania to a Roman province, completed the Roman conquests in these parts. His victory over the sons of Pompey at Munda 40 B. C. secured him from any further apprehensions of a rival. Being therefore sole master of the Roman empire, and having all the power of it at his command, he projected the greatest schemes; tending, according to some, not less to the happiness than to the glory of his country: when he was assassinated in the senate-house, in the 56th year of his age, and 39 B. C.

Without investigating the political justice of this action, or

the motives of the perpetrators, it is impossible not to regret the death of this great man, when we contemplate his virtues, and the designs which he is said to have formed. Nor is it possible to justify, from ingratitude at least, even the most virtuous of the conspirators, when we consider the obligations under which they lay to him. And as to the measure itself, even in the view of expediency, it seems to be generally condemned. In fact, from the transactions which had long preceded, as well as those which immediately followed the murder of Cæsar, it is evident that Rome was incapable of preserving its liberty any longer, and that the people had become unfit for being free. The efforts of Brutus and Cassius were therefore unsuccessful, and ended in their own destruction and that of great numbers of their followers in the battle of Philippi. The defeat of the republicans was followed by numberless disturbances, murders, proscriptions, &c. till at last Octavianus, having cut off all who had the courage to oppose him, and finally got the better of his rivals by the victory at Actium, put an end to the republic in the year 27 B. C.

The destruction of the Roman commonwealth proved advantageous to the few nations of the world who still retained their liberty. That outrageous desire of conquest, which had so long marked the Roman character, now in a great measure ceased; because there was now another way of satisfying the desires of ambitious men, namely, by courting the favour of the emperor. After the final reduction of the Spaniards, therefore, and the conquest of the countries of Mæsia, Pannonia, and some others adjacent to the Roman territories, and which in a manner seemed naturally to belong to them, the empire enjoyed for some time a profound peace.

The only remarkable transactions which took place during the remainder of the period of which we treat, were the conquest of Britain by Claudius and Agricola, and the destruction of Jerusalem by Vespasian and Titus. The war with the Jews began A. D. 67; and was occasioned by their obstinately claiming the city of Cæsarea, which the Romans had added to the province of Syria. It ended in 73, with the most terrible destruction of their city and nation; since which time they have never been able to assemble as a distinct people. The southern parts of Britain were totally subdued by Agricola about ten years after.

In the 98th year of the Christian era, Trajan was created emperor of Rome; and being a man of great valour and experience in war, carried the Roman conquests to their utmost extent. Having conquered the Dacians, a German nation beyond the Danube, and who had of late been very troublesome, he turned his arms eastward; reduced all Mesopotamia, Chaldæa, Assyria; and having taken Ctesiphon, the capital of the Parthian empire, appointed them a king, which he thought would be a proper method of keeping that warlike people in subjection. After this, he proposed to return to Italy, but died by the way; and with his reign the seventh general period above mentioned is concluded.

8. The beginning of the eighth period presents us with a view of one vast empire, in which almost all the nations of the world were swallowed up. This empire comprehended the best part of Britain, all Spain, France, the Netherlands, Italy, part of Germany, Egypt, Barbary, Bildulgerid, Turkey in Europe, Turkey in Asia, and Persia. The state of India at this time is unknown. The Chinese lived in a remote part of the world, unheard of and unmolested by the western nations who struggled for the empire of the world. The northern parts of Europe and Asia were filled with barbarous nations, already formidable to the Romans, and who were soon to become more so. The vast empire of the Romans, however, had no sooner attained its utmost degree of power, than, like others before it, it began to decline. The provinces of Babylonia, Mesopotamia, and As-

syria, almost instantly revolted, and were abandoned by Adrian the successor of Trajan in the empire. The Parthians, having recovered their liberty, continued to be very formidable enemies, and the barbarians of the northern parts of Europe continued to increase in strength; while the Romans, weakened by intestine divisions, became daily less able to resist them. At different times, however, some warlike emperors arose, who put a stop to the incursions of these barbarians; and about the year 215, the Parthian empire was totally overthrown by the Persians, who had long been subject to them. This revolution proved of little advantage to the Romans. The Persians were enemies still more troublesome than the Parthians had been; and though often defeated, they still continued to infest the empire on the east, as the barbarous nations of Europe did on the north. In 260, the defeat and captivity of the emperor Valerian by the Persians, with the disturbances which followed, threatened the empire with utter destruction. Thirty tyrants seized the government at once, and the barbarians pouring in on all sides in prodigious numbers ravaged almost all the provinces of the empire. By the vigorous conduct of Claudius, Aurelian, Tacitus, Probus, and Carus, the empire was restored to its former lustre; but as the barbarians were only repulsed, and never thoroughly subdued, this proved only a temporary relief. What was worse, the Roman soldiers, grown impatient of restraint, commonly murdered those emperors who attempted to revive among them the ancient military discipline which alone could ensure the victory over their enemies. Under Dioclesian, the disorders were so great, that though the government was held by two persons, they found themselves unable to bear the weight of it, and therefore took other two partners in the empire. Thus was the Roman empire divided into four parts; which by all historians is said to have been productive of the greatest mischiefs. As each of the four sovereigns would have as many officers both civil and military, and the same number of forces that had been maintained by the state when governed only by one emperor, the people were not able to pay the sums necessary for supporting them. Hence the taxes and imposts were increased beyond measure, the inhabitants in several provinces reduced to beggary, the land left untilld for want of hands, &c. An end was put to these evils when the empire was again united under Constantine the Great; but in 330 a mortal blow was given to it, by removing the imperial seat to Byzantium, now Constantinople, and making it equal to Rome. The introduction and establishment of Christianity, already corrupted with the grossest superstitions, proved also a most grievous detriment to the empire. Instead of that ferocious and obstinate valour in which the Romans had so long been accustomed to put their trust, they now imagined themselves secured by signs of the cross, and other external symbols of the Christian religion. These they used as a kind of magical incantations, which of course proved at all times ineffectual; and hence also in some measure proceeded the great revolution which took place in the next period.

9. The ninth general period shows us the decline and miserable end of the western part of the Roman empire. We see that mighty empire, which formerly occupied almost the whole world, now weakened by division, and surrounded by enemies. On the east, the Persians; on the north, the Scythians, Sarmatians, Goths, and a multitude of other barbarous nations, watched all occasions to break into it; and miscarried in their attempts, rather through their own barbarity, than the strength of their enemies. The devastations committed by those barbarians when they made their incursions are incredible, and the relation shocking to human nature. Some authors seem much inclined to favour them; and even insinuate, that barbarity and ignorant ferocity were their chief if not their only faults: but from their history it plainly appears, that not only barbarity and the most shocking cruelty, but the highest degrees of avarice, per-

fidy, and disregard to the most solemn promises, were to be numbered among their vices. It was ever a sufficient reason for them to make an attack, that they thought their enemies could not resist them. Their only reason for making peace, or for keeping it, was because their enemies were too strong; and their only reason for committing the most horrid massacres, rapes, and all manner of crimes, was because they had gained a victory. The Romans, degenerate as they were, are yet to be esteemed much better than these savages; and therefore we find not a single province of the empire that would submit to the barbarians while the Romans could possibly defend them.

Some of the Roman emperors indeed withstood this inundation of savages; but as the latter grew daily more numerous, and the Romans continued to weaken themselves by their intestine divisions, they were at last obliged to take large bodies of barbarians into their pay, and teach them their military discipline, in order to drive away their countrymen, or others who invaded the empire. This at last proved its total destruction; for, in 476, the barbarians who served in the Roman armies, and were dignified with the title of *allies*, demanded the third part of the lands of Italy as a reward for their services: but meeting with a refusal, they revolted, and made themselves masters of the whole country, and of Rome itself, which from that time ceased to be the head of an empire of any consequence.

This period exhibits a most unfavourable view of the western parts of the world: The Romans, from the height of grandeur, sunk to the lowest slavery, nay, in all probability, almost exterminated; the provinces they formerly governed, inhabited by human beings scarce a degree above the brutes; every art and science lost; and the savage conquerors even in danger of starving for want of a sufficient knowledge of agriculture, having now no means of supplying themselves by plunder and robbery as before. Britain had long been abandoned to the mercy of the Scots and Picts; and in 450 the inhabitants had called in the Saxons to their assistance, whom they soon found worse enemies than those against whom they had implored their aid. Spain was held by the Goths and Suevians; Africa (that is, Barbary and Bildulgerid), by the Vandals; the Burgundians, Goths, Franks, and Alans, had erected several small states in Gaul; and Italy was subjected to the Heruli under Odoacer, who had taken upon him the title of *king of Italy*. In the east, indeed, matters wore an aspect somewhat more agreeable. The Roman empire continued to live in that of Constantinople, which was still very extensive. It comprehended all Asia Minor and Syria, as far as Persia; in Africa, the kingdom of Egypt; and Greece in Europe. The Persians were powerful, and rivalled the emperors of Constantinople; and beyond them lay the Indians, Chinese, and other nations, who, unheard of by the inhabitants of the more western parts, enjoyed peace and liberty.

The Constantinopolitan empire continued to decline by reason of its continual wars with the Persians, Bulgarians, and other barbarous nations; to which also superstition and relaxation of military discipline largely contributed. The Persian empire also declined from the same causes, together with the intestine broils from which it was seldom free more than that of Constantinople. The history of the eastern part of the world during this period, therefore, consists only of the wars between these two great empires, which we cannot here enter upon, and which were productive of no other consequence than that of weakening them both, and making them a more easy prey to those enemies who were now as it were in embryo, but shortly about to erect an empire almost as extensive as that of the Greeks or Romans.

Among the western nations, the revolutions, as might natu-

rally be expected from the character of the people, succeeded one another with rapidity. The Heruli under Odoacer were driven out by the Goths under Theodoric. The Goths were expelled by the Romans; and, while the two parties were contending, both were attacked by the Franks, who carried off an immense booty. The Romans were in their turn expelled by the Goths: the Franks again invaded Italy, and made themselves masters of the province of Venetia; but at last the superior fortune of the emperor of Constantinople prevailed, and the Goths were finally subdued in 553. Narfus, the conqueror of the Goths, governed Italy as a province of the eastern empire till the year 568, when Longinus his successor made considerable alterations. The Italian provinces had ever since the time of Constantine the Great been governed by *consulares*, *correctores*, and *presides*; no alteration having been made either by the Roman emperors or the Gothic kings. But Longinus, being invested with absolute power by Justinian, suppressed those magistrates; and, instead of them, placed in each city of note a governor, whom he distinguished with the title of *duke*. The city of Rome was not more honoured than any other; for Longinus, having abolished the very name of *senate* and *consuls*, appointed a *duke* of Rome as well as of other cities. To himself he assumed the title of *exarch*; and, residing at Ravenna, his government was styled the *exarchate of Ravenna*. But while he was establishing this new empire, the greatest part of Italy was conquered by the Lombards.

In France a considerable revolution also took place. In 487 Clovis, the founder of the late French monarchy, possessed himself of all the countries lying between the Rhine and the Loire. By force or treachery, he conquered all the petty kingdoms which had been erected in that country. His dominions had been divided, re-united, and divided again; and were on the point of being united a second time, when the great impostor Mahomet began to make a figure in the world.

In Spain, the Visigoths erected a kingdom ten years before the conquest of Rome by the Heruli. This kingdom they had extended eastward, about the same time that Clovis was extending his conquests to the west; so that the two kingdoms met at the river Loire. The consequence of this approach of such barbarous conquerors towards each other was an immediate war. Clovis proved victorious, and subdued great part of the country of the Visigoths, which put a final stop to their conquests on that side.

Another kingdom had been founded in the western parts of Spain by the Suevi, a considerable time before the Romans were finally expelled from that country. In 409 this kingdom was entirely subverted by Theodoric king of the Goths; and the Suevi were so pent up in a small district of Lusitania and Galicia, that it seemed impossible for them to recover themselves. During the above-mentioned period, however, while the attention of the Goths was turned another way, they had found means again to erect themselves into an independent state, and to become masters of considerably extended territories. But this success proved of short duration. In 584 the Goths attacked them; totally destroyed their empire a second time; and thus became masters of all Spain, except some small part which still owned subjection to the emperors of Constantinople. Of this part, however, the Goths became masters also in the year 623; which concludes the ninth general period.

Africa, properly so called, had changed its masters three times during this period. The Vandals had expelled the Romans, and erected an independent kingdom, which was at last overturned by the emperors of Constantinople; and from them the greatest part of it was taken by the Goths in 620.

10. At the commencement of the tenth general period (which begins with the flight of Mahomet in the year 622, from whence his followers date their era called the *Hegira*), we see every thing prepared for the great revolution which was now to take place: the Roman empire in the west annihilated; the Persian empire and that of Constantinople weakened by their mutual wars and intestine divisions; the Indians and other eastern nations unaccustomed to war, and ready to fall a prey to the first invader; the southern parts of Europe in a distracted and barbarous state; while the inhabitants of Arabia, from their earliest origin accustomed to war and plunder, and now united by the most violent superstition and enthusiastic desire of conquest, were like a flood pent up, and ready to overwhelm the rest of the world. The northern nations of Europe and Asia, however formidable in after times, were at present unknown, and peaceable, at least with respect to their southern neighbours; so that there was in no quarter of the globe any power capable of opposing the conquests of the Arabs. With amazing celerity, therefore, they over-ran all Syria, Palestine, Persia, Bukharia, and India, extending their conquests farther to the eastward than ever Alexander had done. On the west side, their empire extended over Egypt, Barbary, and Spain, together with the islands of Sicily, Sardinia, Majorca, Minorca, &c. and many of the Archipelago islands: nor were the coasts of Italy itself free from their incursions; nay, they are even said to have reached the distant and barren country of Iceland. At last this great empire, as well as others, began to decline. Its ruin was very sudden, and owing to its internal divisions. Mahomet had not taken care to establish the apostleship in his family, or to give any particular directions about a successor. The consequence of this was, that the caliphate, or succession to the apostleship, was seized by many usurpers in different parts of the empire; while the true caliphs, who resided at Bagdad, gradually lost all power, and were regarded only as a kind of high-priests. Of these divisions the Turks took advantage, to establish their authority in many provinces of the Mohammedan empire: but as they embraced the same religion with the Arabs, and were filled with the same enthusiastic desire of conquest, it is of little consequence to distinguish between them; as indeed it signified little to the world in general whether the Turks or Saracens were the conquerors, since both were cruel, barbarous, ignorant, and superstitious.

While the barbarians of the east were thus grasping at the empire of the whole world, great disturbances happened among the no less barbarous nations of the west. Superstition seems to have been the ruling motive in both cases. The Saracens and Turks conquered for the glory of God, or of his apostle Mahomet and his successors; the western nations professed an equal regard for the divine glory, but which was only to be perceived in the respect they paid to the pope and clergy. Ever since the establishment of Christianity by Constantine, the bishops of Rome had been gradually extending their power; and attempting not only to render themselves independent, but even to assume an authority over the emperors themselves. The destruction of the empire was so far from weakening their power, that it afforded them opportunities of greatly extending it, and becoming judges of the sovereigns of Italy themselves, whose barbarity and ignorance prompted them to submit to their decisions. All this time, however, they themselves had been in subjection to the emperors of Constantinople; but on the decline of that empire, they found means to get themselves exempted from this subjection. The principal authority in the city of Rome was then engrossed by the bishop; though of right it belonged to the duke appointed by the exarch of Ravenna. But though they had now little to fear from the eastern emperors, they were in great danger from the

ambition of the Lombards, who aimed at the conquest of all Italy. This aspiring people the bishops of Rome determined to check; and therefore, in 726, when Luitprand king of the Lombards had taken Ravenna and expelled the exarch, the pope undertook to restore him. For this purpose he applied to the Venetians, who are now first mentioned in history as a state of any consequence; and by their means the exarch was restored. Some time before, a quarrel had happened between the pope (Gregory II.) and Leo emperor of the east, about the worship of images. Leo, who it seems, in the midst of so much barbarism, had still preserved some share of common sense and reason, reprobated the worship of images in the strongest terms, and commanded them to be destroyed throughout his dominions. The pope, whose cause was favoured by the most absurd superstitions, and by these only, refused to obey the emperor's commands. The exarch of Ravenna, as a subject of the emperor, was ordered to force the pope to a compliance, and even to seize or assassinate him in case of a refusal. This excited the pious zeal of Luitprand to assist the pope, whom he had formerly designed to subdue: the exarch was first excommunicated, and then torn in pieces by the enraged multitude: the duke of Naples shared the same fate; and a vast number of the *Iconoclasts*, or Image-breakers, as they were called, were slaughtered without mercy: and to complete all, the subjects of the exarchate, at the instigation of the pope, renounced their allegiance to the emperor.

Leo was no sooner informed of this revolt than he ordered a powerful army to be raised, in order to reduce the rebels, and take vengeance on the pope. Alarmed at these warlike preparations, Gregory looked round for some power on which he might depend for protection. The Lombards were possessed of sufficient force, but they were too near and too dangerous neighbours to be trusted; the Venetians, though zealous Catholics, were as yet unable to withstand the force of the empire; Spain was over-run by the Saracens: the French seemed, therefore, the only people to whom it was advisable to apply for aid; as they were able to oppose the emperor, and were likewise enemies to his edict. Charles Martel, who at that time governed France as mayor of the palace, was therefore applied to; but before a treaty could be concluded, all the parties concerned were removed by death. Constantine Copronymus, who succeeded Leo at Constantinople, not only persisted in the opposition to image-worship, begun by his predecessor, but prohibited also the invocation of saints. Zachary, who succeeded Gregory III. in the pontificate, proved as zealous an adversary as his predecessors. Pepin, who succeeded Charles Martel in the sovereignty of France, proved as powerful a friend to the pope as his father had been. The people of Rome had nothing to fear from Constantinople; and therefore drove out all the emperor's officers. The Lombards, awed by the power of France, for some time allowed the pope to govern in peace the dominions of the exarchate; but in 752, Astolphus king of Lombardy not only reduced the greatest part of the pope's territories, but threatened the city of Rome itself. Upon this an application was made to Pepin, who obliged Astolphus to restore the places he had taken, and gave them to the pope, or, as he said, to St. Peter. The Greek emperor, to whom they of right belonged, remonstrated to no purpose. The pope from that time became possessed of considerable territories in Italy; which, from the manner of their donation, go under the name of *St. Peter's Patrimony*. It was not, however, before the year 774 that the pope was fully secured in these new dominions. This was accomplished when the kingdom of the Lombards was totally destroyed by Charlemagne, who was thereupon crowned king of Italy. Soon after, this monarch made himself master of all the Low Countries, Germany, and part of Hungary; and in

the year 800, was solemnly crowned emperor of the west by the pope.

Thus was the world once more shared among three great empires. The empire of the Arabs or Saracens extended from the river Ganges to Spain; comprehending almost all of Asia and Africa which has ever been known to Europeans, the kingdoms of China and Japan excepted. The eastern Roman empire was reduced to Greece, Asia Minor, and the provinces adjoining to Italy. The empire of the west under Charlemagne, comprehended France, Germany, and the greatest part of Italy. The Saxons, however, as yet possessed Britain unmolested by external enemies, though the seven kingdoms erected by them were engaged in perpetual contests. The Venetians also enjoyed a nominal liberty; though it is probable that their situation would render them very much dependent on the great powers which surrounded them. Of all nations on earth, the Scots and Picts, and the remote ones of China and Japan, seem to have enjoyed, from their situation, the greatest share of liberty; unless, perhaps, we except the Scandinavians, who, under the names of *Danes* and *Normans*, were soon to infest their southern neighbours. But of all the European potentates, the popes certainly exercised the greatest authority; since even Charlemagne himself submitted to accept the crown from their hands, and his successors made them the arbiters of their differences.

Matters, however, did not long continue in this state. The empire of Charlemagne was on the death of his son Lewis divided among his three children. Endless disputes and wars ensued among them, till at last the sovereign power was seized by Hugh Capet in 987. The Saxon heptarchy was dissolved in 827, and the whole kingdom of England reduced under one head. The Danes and Normans began to make depredations, and infest the neighbouring states. The former conquered the English Saxons, and seized the government, but were in their turn expelled by the Normans in 1066. In Germany and Italy the greatest disturbances arose from the contests between the popes and the emperors. To all this if we add the internal contests which happened through the ambition of the powerful barons of every kingdom, we can scarce form an idea of times more calamitous than those of which we now treat. All Europe, nay, all the world, was one great field of battle; for the empire of the Mahometans was not in a more settled state than that of the Europeans. Caliphs, sultans, emirs, &c. waged continual war with each other in every quarter; new sovereignties every day sprung up, and were as quickly destroyed. In short, through the ignorance and barbarity with which the whole world was overspread, it seemed in a manner impossible that the human race could long continue to exist; when happily the crusades, by directing the attention of the Europeans to one particular object, made them in some measure suspend their slaughters of one another.

11. The crusades originated from the superstition of the two grand parties into which the world was at that time divided, namely, the Christians and Mahometans. Both looked upon the small territory of Palestine, which they called the *Holy Land*, to be an invaluable acquisition, for which no sum of money could be an equivalent; and both took the most unjustifiable methods to accomplish their desires. The superstition of Omar the second caliph had prompted him to invade this country, part of the territories of the Greek emperor, who was doing him no hurt; and now when it had been so long under the subjection of the Mahometans, a similar superstition prompted the pope to send an army for the recovery of it. The crusaders accordingly poured forth in multitudes, like those with which the kings of Persia formerly invaded Greece; and their fate was pretty similar. Their impetuous valour at first, indeed, carried every thing before them: they recovered

all Palestine, Phœnicia, and part of Syria, from the infidels; but their want of conduct soon lost what their valour had obtained, and very few of that vast multitude which had left Europe ever returned to their native countries. A second, a third, and several other crusades, were preached, and were attended with a like success in both respects: vast numbers took the cross, and repaired to the Holy Land; which they polluted by the most abominable massacres and treacheries, and from which very few of them returned. In the third crusade Richard I. of England was embarked, who seems to have been the best general that ever went into the east; but even his valour and skill were not sufficient to repair the faults of his companions; and he was obliged to return even after he had entirely defeated his antagonists, and was within sight of Jerusalem.

But while the Christians and Mahometans were thus superstitiously contending for a small territory in the western parts of Asia, the nations in the more easterly parts were threatened with total extermination. Jenghiz Khan, the greatest as well as the most bloody conqueror that ever existed, now makes his appearance. The rapidity of his conquests seemed to emulate those of Alexander the Great; and the cruelties he committed were altogether unparalleled. It is worth observing, that Jenghiz Khan and all his followers were neither Christians nor Mahometans, but strict Deists. For a long time even the sovereign had not heard of a temple, or any particular place on earth appropriated by the Deity to himself, and treated the notion with ridicule when it was first mentioned to him.

The Moguls, over whom Jenghiz Khan assumed the sovereignty, were a people of East Tartary, divided into a great number of petty governments as they are at this day, but who owned a subjection to one sovereign, whom they called *Vang-Khan*, or the Great Khan. Temujin, afterwards *Jenghiz-Khan*, was one of these petty princes; but unjustly deprived of the greatest part of his inheritance at the age of 13, which he could not recover till he arrived at that of 40. This corresponds with the year 1201, when he totally reduced the rebels; and, as a specimen of his lenity, caused 70 of their chiefs to be thrown into as many caldrons of boiling water. In 1202 he defeated and killed Vang-khan himself (known to the Europeans by the name of *Prester John of Asia*); and possessing himself of his vast dominions, became from thenceforward altogether irresistible. In 1206, having still continued to enlarge his dominions, he was declared khan of the Moguls and Tartars; and took upon him the title of *Jenghiz Khan*, or *The most great Khan of khans*. This was followed by the reduction of the kingdom of Hya in China, Tangut, Kitay, Turkestan, Karazm (the kingdom of *GAZNA* founded by Mahmud Gazni), Great Bukharia, Persia, and part of India, and all these vast regions were reduced in 26 years. The devastations and slaughters with which they were accompanied are unparalleled, no fewer than 14,470,000 persons being computed to have been massacred by Jenghiz Khan during the last 22 years of his reign. In the beginning of 1227 he died, thereby freeing the world from a most bloody tyrant. His successors completed the conquest of China and Korea; but were foiled in their attempts on Cochin-China, Tong-king, and Japan. On the western side the Tartar dominions were not much enlarged till the time of Hulaku, who conquered Media, Babylonia, Mesopotamia, Assyria, Syria, Georgia, Armenia, and almost all Asia Minor; putting an end to the empire of the Saracens by the taking of Bagdad in 1258.

The empire of Jenghiz Khan had the fate of all others. Being far too extensive to be governed by one head, it split into a multitude of small kingdoms, as it had been before his time. All these princes, however, owned allegiance to the family of Jenghiz Khan till the time of Timur Bek, or Tamer-

lane. The Turks, in the mean time, urged forward by the inundation of Tartars who poured in from the east, were forced upon the remains of the Greek empire; and at the time of Tamerlane above-mentioned, they had almost confined this once mighty empire within the walls of Constantinople.

In the year 1335, the family of Jenghiz Khan becoming extinct in Persia, a long civil war ensued; during which Timur Bek, one of the petty princes among which the Tartar dominions were divided, found means to aggrandize himself in a manner similar to what Jenghiz Khan had done about 150 years before. Jenghiz Khan, indeed, was the model whom he proposed to imitate; but it must be allowed that Timur was more merciful than Jenghiz Khan, if indeed the word can be applied to such inhuman tyrants. The plan on which Jenghiz Khan conducted his expeditions was that of total extermination. For some time he utterly extirpated the inhabitants of those places which he conquered, designing to people them anew with his Moguls; and in consequence of this resolution, he would employ his army in beheading 100,000 prisoners at once. Timur's cruelty, on the other hand, seldom went farther than the pounding of 3000 or 4000 people in large mortars, or building them among bricks and mortar into a wall. We must observe, however, that Timur was not a Deist, but a Mahometan, and conquered expressly for the purpose of spreading the Mahometan religion; for the Moguls had now adopted all the superstitions and absurdities of Mahomet. Thus was all the eastern quarter of the world threatened anew with the most dreadful devastations, while the western nations were exhausting themselves in fruitless attempts to regain the Holy Land. The Turks were the only people who seem at this period to have been gathering strength, and by their perpetual encroachments threatened to swallow up the western nations as the Tartars had done the eastern ones.

In 1362 Timur invaded Bukharia, which he reduced in five years. He proceeded in his conquests, though not with the same celerity as Jenghiz Khan, till the year 1387, when he had subdued all Persia, Armenia, Georgia, Karazm, and great part of Tartary. After this he proceeded westward, subduing all the countries to the Euphrates; made himself master of Bagdad; and even entered Russia, where he pillaged the city of Moscow. From thence he turned his arms to the east, and totally subdued India. In 1393 he invaded and reduced Syria; and having turned his arms against the Turks, forced their sultan Bajazet to raise the siege of Constantinople. This brought on an engagement, in which Bajazet was entirely defeated and taken prisoner; which broke the power of the Turks to such a degree, that they were not for some time able to recover themselves. At last this great conqueror died in the year 1405, while on his way to conquer China, as Jenghiz Khan had done before him.

The death of Timur was followed almost immediately by the dissolution of his empire. Most of the nations he had conquered recovered their liberty. The Turks had now no further obstacle to their conquest of Constantinople. The western nations having exhausted themselves in the *holy wars*, as they were called, had lost that insatiable thirst after conquest which for so long time possessed the minds of men. They had already made considerable advances in civilization, and began to study the arts of peace. Gunpowder was invented, and its application to the purposes of war already known; and, though no invention threatened to be more destructive, perhaps none was ever more beneficial to the human race. By the use of fire-arms, nations are put more on a level with each other than formerly they were; war is reduced to a regular system, which may be studied with as much success as any other science. Conquests are not now to be made with the same ease as formerly; and hence the last ages of the world have

been much more quiet and peaceable than the former ones. In 1453 the conquest of Constantinople by the Turks fixed that wandering people to one place; and though now they possess very large regions both in Europe, Asia, and Africa, an effectual stop hath long been put to their further progress.

About this time, also, learning began to revive in Europe, where it had been long lost; and the invention of PRINTING, which happened about the same time, rendered it in a manner impossible for barbarism ever to take place in such a degree as formerly. All nations of the world, indeed, seem now at once to have laid aside much of their former ferocity; and, though wars have by no means been uncommon, they have not been carried on with such circumstances of fury and savage cruelty as before. Instead of attempting to enrich themselves by plunder, and the spoils of their neighbours, mankind in general have applied themselves to commerce, the only true and durable source of riches. This soon produced improvements in navigation; and these improvements led to the discovery of many regions formerly unknown. At the same time, the European powers, being at last thoroughly sensible that extensive conquests could never be permanent, applied themselves more to provide for the security of those dominions which they already possessed, than to attempt the conquest of one another: and this produced the policy to which so much attention was lately paid, namely, the *preserving of the balance of Europe*; that is, preventing any one of the nations from acquiring sufficient strength to overpower another.

In the end of the 15th century, the vast continent of America was discovered; and, almost at the same time, the passage to the East Indies by the Cape of Good-Hope. The discovery of these rich countries gave a new turn to the ambition of the Europeans. To enrich themselves, either by the gold and silver produced in these countries, or by traffic with the natives, now became the object. The Portuguese had the advantage of being the first discoverers of the eastern, and the Spaniards of the western countries. The former did not neglect so favourable an opportunity of enriching themselves by commerce. Many settlements were formed by them in the East-India islands, and on the continent; but their avarice and perfidious behaviour towards the natives proved at last the cause of their total expulsion. The Spaniards enriched themselves by the vast quantities of the precious metals imported from America, which were not obtained but by the most horrid massacres committed on the natives, and of which history gives an account under the different names of the American countries. These possessions of the Spaniards and Portuguese soon excited other European nations to make attempts to share with them in their treasures, by planting colonies in different parts of America, and making settlements in the East-Indies: and thus has the rage of war in some measure been transferred from Europe to these distant regions; and, after various contests, the British at last obtained a great superiority both in America and the East-Indies.

In Europe the only considerable revolutions which happened during this period, were, The total expulsion of the Moors and Saracens from Spain, by the taking of Grenada in 1491; the union of the kingdoms of Arragon and Castile, by the marriage of Ferdinand and Isabella; and the revolt of the states of Holland from the Spaniards. After much contention and bloodshed, these last obtained their liberty, and were declared a free people in 1609; since which time they have continued an independent and very considerable nation of Europe.

In Asia nothing of importance hath happened since the taking of Constantinople by the Turks. That continent is now divided among the following nations. The most northerly part, called *Siberia*, extending to the very extremity of the con-

continent, is under the power of Russia. To the southward, from Asia Minor to China and Korea, are the Tartars, formidable indeed from their numbers, but, by reason of their barbarity and want of union, incapable of attempting any thing. The Turks possess the western part of the continent called *Asia Minor*, to the river Euphrates. The Arabs are again confined within their own peninsula; which they possess, as they have ever done, without owing subjection to any foreign power. To the east of Turkey in Asia lies Persia, now more confined in its limits than before; and to the eastward of Persia lies India, or the kingdom late of the Mogul, comprehending all the country from the Indus to the Ganges, and beyond that river. Still farther to the east lie the kingdoms of Siam, Pegu, Thibet, and Cochin-China, little known to the Europeans. The vast empire of China occupies the most easterly part of the continent; while that of Japan comprehends the islands which go by that name, and which are supposed to lie at no great distance from the western coasts of America.

In Africa the Turks possess Egypt, which they conquered in 1517, and have a nominal jurisdiction over the states of Barbary. The interior parts are filled with barbarous and unknown nations, as they have always been. On the western coasts are many settlements of the European nations, particularly the British and Portuguese; and the southern extremity is possessed by the Dutch. The eastern coasts are almost totally unknown. The Asiatic and African islands are either possessed by the Europeans, or inhabited by savage nations.

The European nations at the beginning of the 17th century were, Sweden, Muscovy, Denmark, Poland, Britain, Germany, Holland, France, Spain, Portugal, Italy, and Turkey in Europe. Of these the Russians, though the most barbarous, were by far the most considerable, both in regard to numbers and the extent of their empire; but their situation made them little feared by the others, who lay at a distance from them. The kingdom of Poland, which was first set up in the year 1000, proved a barrier betwixt Russia and Germany; and at the same time the policy above mentioned, of keeping up the balance of power in Europe, rendered it probable that no one European nation, whatever wars it might be engaged in, would have been totally destroyed, or ceased to exist as a distinct kingdom. The late dismemberment of Poland, however, or its partition between the three powers Russia, Hungary, and Prussia, was a step very inconsistent with the above political system; and it is surprising with what tameness it was acquiesced in by the other powers. Subsequent circumstances, particularly the passiveness with which the ambitious designs of Russia against the Porte have been so long beheld, seem to indicate a total dereliction of that scheme of equilibrium, formerly so wisely, though perhaps sometimes too anxiously, attended to.

The revolt of the British colonies in America, it was hoped by the enemies of Britain, would have given a fatal shock to her strength and wonted superiority. The consequences, however, have been very different. Those colonies, it is true, have been disjoined from the mother-country, and have attained an independent rank among the nations. But Britain has had no cause to repine at the separation. Divested only of a splendid encumbrance, an expensive and invidious appanage, she has been left to enjoy the undivided benefits of her native vigour, and to display new energies, which, but for the present devastating and expensive war, of which the termination and consequences cannot at present even be conjectured, seemed to promise her mild empire a long and prosperous duration. On the other hand, the flame which was to have blazed only to her prejudice, has entailed a lengthened ruin on her chief foe. The French, indeed, by the establishment of their Republic, have become a nation of freemen as well as ourselves, and as well as the Americans; who, by the way, as some think,

were never otherwise, nor ever knew what oppression was. But neither is the French revolution an event which Britons, as lovers of liberty and friends to the rights of mankind, should regret; or which, even in a political view, if duly considered, ought to excite either their jealousy or apprehension. In fine, we seem to be advancing to a great era in the history of human affairs. The emancipation of France, it is highly probable, notwithstanding the address which the Directory have manifested in making Spain take part against us in the war, will in time be followed by a revolution in the latter; and perhaps also in some other countries of Europe. The papal power too, that scourge of nations, has suffered a fatal blow; and the period seems to be approaching when the Roman pontiff will be reduced to nothing. More liberal ideas both in politics and religion are every where gaining ground. The regulation, and perhaps in time the abolition, of the slave-trade, with the endeavours of the societies for fertilizing Africa, may lead to the civilization of some parts of that immense continent, and open new markets for our manufactures.

CH A P. II.

Of ECCLESIASTICAL HISTORY.

THE history of religion, among all the different nations that have existed in the world, is a subject no less important and interesting than that of civil history. It is, however, less fertile of great events, affords an account of fewer revolutions, and is much more uniform, than civil history. The reason of this is plain. Religion is conversant about things which cannot be seen; and which of consequence cannot suddenly and strongly affect the senses of mankind, as natural things are apt to do. The expectation of worldly riches can easily induce one nation to attack another; but it is not easy to find any thing which will induce a nation to change its religion. The invisible nature of spiritual things, the prejudice of habit and of early education, all stand in the way of changes of this kind. Hence the revolutions in religion have been but few, and the duration of almost any religion of longer standing than the most celebrated empires; the changes which have happened, in general have acquired a long time to bring them about, and history scarce affords an instance of the religion of any nation being essentially and suddenly changed for another.

With regard to the origin of religion, we must have recourse to the Scriptures; and are as necessarily constrained to adopt the account there given, as we are to adopt that of the creation given in the same book; namely, because no other hath made its appearance which seems in any degree rational, or consistent with itself. In what manner the true religion given to Adam was falsified or corrupted by his descendants before the flood, doth not clearly appear from Scripture. Idolatry is not mentioned: nevertheless we are assured that the inhabitants of the world were then exceedingly wicked; and as their wickedness did not consist in worshipping false gods, it may be concluded that they worshipped none at all: i. e. that the crime of the antediluvians was a species of atheism.

After the flood, idolatry quickly made its appearance; but what gave rise to it is not certainly known. This superstition indeed seems to be natural to man, especially when placed in such a situation that he hath little opportunity of instruction, or of improving his rational faculties. This seems also probable from a caution given to the Jews, lest, when they looked up to the sun, moon, and stars, and the rest of the host of heaven, they should be *driven to worship them*. The origin of idolatry among the Syrians and Arabians, and also in Greece, is therefore accounted for with great probability in the following manner by the author of *The Ruins of Balbec*. "In those uncomfortable deserts, where the day presents nothing to the view but the uniform, tedious, and melancholy prospect of barren

sands, the night discloses a most delightful and magnificent spectacle, and appears arrayed with charms of the most attractive kind. For the most part unclouded and serene, it exhibits to the wondering eye the host of heaven in all their variety and glory. In the view of this stupendous scene, the transition from admiration to idolatry was too easy to uninstructed minds; and a people whose climate offered no beauties to contemplate but those of the firmament, would naturally look thither for the objects of their worship. The form of idolatry in Greece was different from that of the Syrians; which perhaps may be attributed to that smiling and variegated scene of mountains, valleys, rivers, woods, groves, and fountains, which the transported imagination, in the midst of its pleasing astonishment, supposed to be the seats of invisible deities."

A difficulty, however, arises on this supposition; for if idolatry is naturally produced in the mind of uninstructed and savage man from a view of the creation, why hath not idolatry of some kind or other taken place among all the different nations of the world? This certainly hath not been the case; of which the most striking examples are the Persians of old, and the Moguls in more modern times. Both these nations were strict deists: so that we must allow some other causes to concur in producing idolatry besides these already mentioned; and of these causes an imperfect and obscure notion of the true religion seems to be the most probable.

Though idolatry, therefore, was formerly very prevalent, it neither extended over the whole earth, nor were the superstitions of the idolaters all of one kind. Every nation had its respective gods, over which one more excellent than the rest was said to preside; yet in such a manner, that this supreme deity himself was controuled by the rigid empire of the fates, or by what philosophers called *eternal necessity*. The gods of the east were different from those of the Gauls, the Germans, and the other northern nations. The Grecian divinities differed widely from those of the Egyptians, who deified plants, animals, and a great variety of the productions both of nature and art. Each people also had their own particular manner of worshipping and appeasing their respective deities, entirely different from the sacred rites of other countries. All this variety of religions, however, produced neither wars nor dissensions among the different nations; each nation suffered its neighbours to follow their own method of worship, without discovering any displeasure on that account. There is nothing surprising in this mutual toleration, when we consider, that they all looked upon the world as one great empire, divided into various provinces, over each of which a certain order of divinities presided; for which reason they imagined that none could behold with contempt the gods of other nations, or force strangers to pay homage to theirs. The Romans exercised this toleration in the most ample manner; for though they would not allow any change to be made in the religions that were publicly professed in the empire, nor any new form of worship to be openly introduced, yet they granted to their citizens a full liberty of observing in private the sacred rites of other nations, and of honouring foreign deities as they thought proper.

The heathen deities were honoured with rites and sacrifices of various kinds, according to their respective natures and offices. Their rites were absurd and ridiculous; while the priests, appointed to preside over this strange worship, abused their authority, by deceiving and imposing upon the people in the grossest manner.

From the time of the flood to the coming of Christ, idolatry prevailed among almost all the nations of the world, the Jews alone excepted; and even they were on all occasions ready to run into it, as is evident from their history in the Old Testament. At the time of Christ's appearance, the religion of the Romans, as well as their empire, extended over a great part of

the world. Some people there were among the heathens who perceived the absurdities of that system; but being destitute of means, as well as of abilities, to effect a reformation, matters went on in their old way. Though there were at that time various sects of philosophers, yet all of them proceeded upon false principles, and consequently could be of no service to the advancement or reformation of religion. Nay, some, among whom were the Epicureans and Academics, declared openly against every kind of religion whatever.

Two religions at this time flourished in Palestine, viz. The Jewish and Samaritan; between whose respective followers reigned the most violent hatred and contempt. The difference between them seems to have been chiefly about the place of worship; which the Jews would have to be in Jerusalem, and the Samaritans on mount Gerizzim. But though the Jews were certainly right as to this point, they had greatly corrupted their religion in other respects. They expected a Saviour indeed, but they mistook his character; imagining that he was to be a powerful and warlike prince, who should set them free from the Roman yoke, which they bore with the utmost impatience. They also imagined that the whole of religion consisted in observing the rites of Moses, and some others which they had added to them, without the least regard to what is commonly called *morality* or *virtue*; as is evident from the many charges our Saviour brings against the Pharisees, who had the greatest reputation for sanctity among the whole nation. To these corrupt and vicious principles they added several absurd and superstitious notions concerning the divine nature, invisible powers, magic, &c. which they had partly imbibed during the Babylonian captivity, and partly derived from their neighbours in Arabia, Syria, and Egypt. The principal sects among them were the *ESSENES* or *Essenians*, *PHARISEES*, and *SADDUCEES*. The Samaritans, according to the most general opinion, had corrupted their religion still more than the Jews.

When the true religion was preached by the Saviour of mankind, it is not to be wondered at if he became on that account obnoxious to a people so deeply sunk in corruption and ignorance as the Jews then were. It is not here requisite to enter into the particulars of the doctrine advanced by him, or of the opposition he met with from the Jews; as a full account of these things, and likewise of the preaching of the gospel by the Apostles, may be found in the New Testament. The rapid progress of the Christian religion, under these faithful and inspired ministers, soon alarmed the Jews, and raised various persecutions against its followers. The Jews, indeed, seem at first to have been every where the chief promoters of persecution; for we find that they officiously went from place to place, wherever they heard of the increase of the gospel, and by their calumnies and false suggestions endeavoured to stir up the people against the Apostles. The Heathens, however, though at first they showed no very violent spirit of persecution against the Christians, soon came to hate them as much as the Jews themselves. Tacitus acquaints us with the causes of this hatred, when speaking of the first general persecution under Nero. That inhuman emperor having, as was supposed, set fire to the city of Rome, to avoid the imputation of this wickedness, transferred it on the Christians. Our author informs us, that they were already abhorred on account of their many and enormous crimes. "The author of this name (*Christians*)," says he, "was CHRIST, who, in the reign of Tiberius, was executed under Pontius Pilate, procurator of Judaea. The pestilent superstition was for a while suppressed: but it revived again, and spread, not only over Judaea, where this evil was first broached, but reached Rome, whither from every quarter of the earth is constantly flowing whatever is hideous and abominable amongst men, and is there readily embraced and practised. First, therefore, were apprehended such as openly avowed themselves to be

of that sect; then by them were discovered an immense multitude; and all were convicted, not of the crime of burning Rome, but of hatred and enmity to mankind. Their death and tortures were aggravated by cruel derision and sport; for they were either covered with the skins of wild beasts and torn in pieces by devouring dogs, or fastened to crosses, or wrapped up in combustible garments, that, when the day-light failed, they might, like torches, serve to dispel the darkness of the night. Hence, towards the miserable sufferers, however guilty and deserving the most exemplary punishment, compassion arose; seeing they were doomed to perish, not with a view to the public good, but to gratify the cruelty of one man."

That this account of Tacitus is downright misrepresentation and calumny, must be evident to every one who reads it. It is impossible that any person can be convicted of hatred and enmity to mankind, without specifying a number of facts by which this hatred shewed itself. The burning of Rome would indeed have been a very plain indication of enmity to mankind; but of this Tacitus himself clears them, and mentions no other crime of which they were guilty. It is probable, therefore, that the only reason of this charge against the Christians, was their absolute refusal to have any share in the Roman worship, or to countenance the absurd superstitions of Paganism in any degree.

The persecution under Nero was succeeded by another under Domitian; during which the apostle John was banished to Patmos, where he saw the visions, and wrote the book called his *Revelations*, which completes the canon of Scripture. This persecution commenced in the 95th year of the Christian era; and John is supposed to have written his Revelation the year after, or in the following one.

During the *first century*, the Christian religion spread over a great number of different countries; but as we have now no authentic records concerning the travels of the apostles, or the success which attended them in their ministry, it is impossible to determine how far the gospel was carried during this period. We are, however, assured, that even during this early period many corruptions were creeping in, the progress of which was with difficulty prevented even by the apostles themselves. Some corrupted their profession by a mixture of Judaism; others by mixing it with the oriental philosophy; while others were already attempting to deprive their brethren of liberty, setting themselves up as eminent pastors, in opposition even to the apostles, as we learn from the epistles of St. Paul, and the third epistle of St. John. Hence arose the sects of the Gnostics, Cerinthians, Nicolaitans, Nazarenes, Ebionites, &c. with which the church was agitated during this century.

Concerning the ceremonies and method of worship used by the Christians of the first century, it is impossible to say any thing with certainty. Neither is the church order, government, and discipline, during this period, ascertained with any degree of exactness. Each of those parties, therefore, which exist at this day, contends with the greatest earnestness for that particular mode of worship which they themselves have adopted; and some of the most bigoted would willingly monopolize the word *church* in such a manner as to exclude from all hope of salvation every one who is not attached to their particular party. It doth not however appear that, excepting baptism, the Lord's supper, and anointing the sick with oil, any external ceremonies or symbols were properly of divine appointment. According to Dr. Mosheim, "there are several circumstances which incline us to think, that the friends and apostles of our blessed Lord either tolerated through necessity, or appointed for wise reasons, many other external rites in various places. At the same time, we are not to imagine, that they ever conferred upon any person a perpetual, indelible, pontifical authority, or that they enjoined the same rites in all churches. We learn, on the contrary, from authentic records, that the Christian worship

was from the beginning celebrated in a different manner in different places; and that, no doubt, by the orders, or at least with the approbation, of the apostles and their disciples. In those early times, it was both wise and necessary to shew, in the establishment of outward forms of worship, some indulgence to the ancient opinions, manners and laws of the respective nations to whom the gospel was preached."

The *second century* commences with the third year of the emperor Trajan. The Christians were still persecuted; but as the Roman emperors were for the most part of this century princes of a mild and moderate turn, they persecuted less violently than formerly. Marcus Aurelius, notwithstanding the clemency and philosophy for which he is so much celebrated, treated the Christians worse than Trajan, Adrian, or even Severus himself did, who was noted for his cruelty. This respite from rigorous persecution proved a very favourable circumstance for the spreading of the Christian religion; yet it is by no means easy to point out the particular countries through which it was diffused. We are, however, assured, that in the second century, Christ was worshipped as God almost through the whole east; as also among the Germans, Spaniards, Celtes, and many other nations: but which of them received the gospel in the first century, and which in the second, is a question unanswerable at this distance of time. The writers of this century attribute the rapid progress of Christianity chiefly to the extraordinary gifts that were imparted to the first Christians, and the miracles which were wrought at their command; without supposing that any part of the success ought to be ascribed to the intervention of human means, or secondary causes. Many of the moderns, however, are so far from being of this opinion, that they are willing either to deny the authenticity of all miracles said to have been wrought since the days of the apostles, or to ascribe them to the power of the devil. To enter into the particulars of this controversy is foreign to our present purpose; for which reason we must refer to the writers of polemic divinity, who have largely treated of this and other points of a similar nature.

The corruptions which had been introduced in the first century, and which were almost coeval with Christianity itself, continued to gain ground in the second. Ceremonies, in themselves futile and useless, but which must be considered as highly pernicious when joined to a religion incapable of any other ornament than the upright and virtuous conduct of its professors, were multiplied for no other purpose than to please the ignorant multitude. The immediate consequence of this was, that the attention of Christians was drawn aside from the important duties of morality; and they were led to imagine, that a careful observance of the ceremonies might make amends for the neglect of moral duties. This was the most pernicious opinion that could possibly be entertained; and was indeed the very foundation of that enormous system of ecclesiastical power which afterwards took place, and held the whole world in slavery and barbarism for many ages.

Another mischief was the introduction of *mysteries*, as they were called, into the Christian religion; that is, insinuating that some parts of the worship in common use had a hidden efficacy and power far superior to the plain and obvious meaning assigned to them by the vulgar: and by paying peculiar respect to these mysteries, the pretended teachers of the religion of Jesus accommodated their doctrines to the taste of their heathen neighbours, whose religion consisted in a heap of mysteries, of which nobody knew the meaning.

By these, and other means of a similar kind, the Christian pastors greatly abridged the liberty of their flock. Being masters of the ceremonies and mysteries of the Christian religion, they had it in their power to make their followers worship and believe whatever they thought proper; and this they did not fail to make use of for their own advantage. They persuaded

the people, that the ministers of the Christian church succeeded to the character, rights, and privileges, of the Jewish priesthood; and accordingly the bishops considered themselves as invested with a rank and character similar to those of the high-priest among the Jews, while the presbyters represented the priests, and the deacons the Levites. This notion, which was first introduced in the reign of Adrian, proved a source of very considerable honour and profit to the clergy.

The form of ecclesiastical government was in this century rendered permanent and uniform. One inspector or bishop presided over each Christian assembly, to which office he was elected by the voices of the whole people. To assist him in his office, he formed a council of presbyters, which was not confined to any stated number. To the bishops and presbyters the ministers or *deacons* were subject; and the latter were divided into a variety of classes, as the different exigencies of the church required. During a great part of this century, the churches were independent of each other; nor were they joined together by association, confederacy, or any other bonds but those of charity. Each assembly was a little state governed by its own laws; which were either enacted, or at least approved of, by the society. But in process of time all the Christian churches of a province were formed into one large ecclesiastical body, which, like confederate states, assembled at certain times, in order to deliberate about the common interests of the whole. This institution had its origin among the Greeks; but in a short time it became universal, and similar assemblies were formed in all places where the gospel had been planted. These assemblies, which consisted of the deputies or commissioners from several churches, were called *synods* by the Greeks, and *councils* by the Latins; and the laws enacted in these general meetings were called *canons*, i. e. *rules*.

These councils, of which we find not the smallest trace before the middle of this century, changed the whole face of the church, and gave it a new form; for by them the ancient privileges of the people were considerably diminished, and the power and authority of the bishops greatly augmented. The humility, indeed, and prudence, of these pious prelates hindered them from assuming all at once the power with which they were afterwards invested. At their first appearance in these general councils, they acknowledged that they were no more than the delegates of their respective churches, and that they acted in the name and by the appointment of their people. But they soon changed this humble tone; imperceptibly extended the limits of their authority; turned their influence into dominion, their counsels into laws; and at length openly asserted, that Christ had empowered them to prescribe to his people *authoritative rules of faith and manners*. Another effect of these councils was the gradual abolition of that perfect equality which reigned among all bishops in the primitive times: for the order and decency of these assemblies required, that some one of the provincial bishops met in council should be invested with a superior degree of power and authority; and hence the rights of Metropolitans derive their origin. In the mean time, the bounds of the church were enlarged; the custom of holding councils was followed wherever the sound of the gospel had reached; and the universal church had now the appearance of one vast republic formed by a combination of a great number of little states. This occasioned the creation of a new order of ecclesiastics, who were appointed in different parts of the world as heads of the church, and whose office it was to preserve the consistence and union of that immense body, whose members were so widely dispersed throughout the nations. Such was the nature and office of the *Patriarchs*; among whom, at length, ambition, being arrived at its most insolent period, formed a new dignity, investing the bishop of Rome with the title and authority of the *Prince of the Patriarchs*.

During the second century, all the sects continued which had sprung up in the first, with the addition of several others; the most remarkable of which were the *Ascetics*. These owed their rise to an error propagated by some doctors of the church, who asserted that Christ had established a *double rule of sanctity and virtue* for two different orders of Christians. Of these rules, one was ordinary, the other extraordinary; the one of a lower dignity, the other more sublime: the first for persons in the active scenes of life; the other for those who, in a sacred retreat, aspired after the glory of a celestial state. In consequence of this system, they divided into two parts all those moral doctrines and instructions which they had received either by writing or tradition. One of these divisions they called *precepts*, and the other *counsels*. They gave the name of *precepts* to those laws that were universally obligatory upon all orders of men; and that of *counsels* to those which related to Christians of a more sublime rank, who proposed to themselves great and glorious ends, and breathed after an intimate communion with the Supreme Being. Thus were produced all at once a new set of men, who made pretensions to uncommon sanctity and virtue, and declared their resolution of obeying all the *precepts* and *counsels* of Christ, in order to their enjoyment of communion with God here, and also that, after the dissolution of their mortal bodies, they might ascend to him with the greater facility, and find nothing to retard their approach to the centre of happiness and perfection. They looked upon themselves as prohibited from the use of things which it was lawful for other Christians to enjoy; such as wine, flesh, matrimony, and commerce. They thought it their indispensable duty to extenuate their body by watchings, abstinence, labour, and hunger. They looked for felicity in solitary retreats, and desert places; where, by severe and assiduous efforts of sublime meditation, they raised the soul above all external objects, and all sensual pleasures. They were distinguished from other Christians, not only by their title of *Ascetics*, *Σπυδαίοι*, *Εκλεκτοί*, and philosophers, but also by their garb. In this century, indeed, those who embraced such an austere kind of life, submitted themselves to all these mortifications in private, without breaking asunder their social bands, or withdrawing themselves from mankind; but in process of time they retired into deserts, and, after the example of the Essenes and Therapeutæ, they formed themselves into select companies.

This austere sect arose from an opinion which has been more or less prevalent in all ages and in all countries, namely, that religion consists more in prayers, meditations, and a kind of secret intercourse with God, than in fulfilling the social duties of life in acts of benevolence and humanity to mankind. Nothing can be more evident than that the Scripture reckons the fulfilling of these infinitely superior to the observance of all the ceremonies that can be imagined: yet it somehow or other happens, that almost every body is more inclined to observe the ceremonial part of devotion than the moral; and hence, according to the different humours or constitutions of different persons, there have been numberless forms of Christianity, and the most virulent contentions among those who professed themselves followers of the Prince of Peace. It is obvious, that if the moral conduct of Christians was to be made the standard of faith, instead of speculative opinions, all these divisions must cease in a moment; but while Christianity, or any part of it, is made to consist in speculation, or the observance of ceremonies, it is impossible there can be any end of sects or heresies. No opinion whatever is so absurd, but some people have pretended to argue in its defence; and no ceremony so insignificant, but it hath been explained and sanctified by hot-headed enthusiasts: and hence ceremonies, sects, and absurdities, have been multiplied without number, to the prejudice of society and of the Christian religion. This short relation of the rise of the Ascetic sect will also serve to

account for the rise of any other; so that we apprehend it is needless to enter into particulars concerning the rest, as they all took their origin from the same general principle variously modified, according to the different dispositions of mankind.

The Ascetic sect began first in Egypt, from whence it passed into Syria and the neighbouring countries. At length it reached the European nations: and hence that train of austere and superstitious vows and rites which totally obscured, or almost annihilated, Christianity; the celibacy of the clergy, and many other absurdities of the like kind. The errors of the Ascetics, however, did not stop here: In compliance with the doctrines of some Pagan philosophers, they affirmed, that it was not only lawful, but even praise-worthy, to deceive, and to use the expedient of a lie, in order to advance the cause of piety and truth; and hence the *pious frauds* for which the church of Rome hath been so notorious, and with which she hath been so often and justly reproached.

As Christians thus deviated more and more from the true practice of their religion, they became more zealous in the external profession of it. Anniversary festivals were celebrated in commemoration of the death and resurrection of Christ, and of the effusion of the Holy Ghost on the apostles. Concerning the days on which these festivals were to be kept, there arose violent contests. The Asiatic churches in general differed in this point from those of Europe: and towards the conclusion of the second century, Victor, bishop of Rome, took it in his head to force the eastern churches to follow the rules laid down by the western ones. This they absolutely refused to comply with: upon which Victor cut them off from communion with the church of Rome; though, by means of the intercession of some prudent people, the difference was made up for a time.

During most of the *third century*, the Christians were allowed to enjoy their religion, such as it was, without molestation. The emperors Maximinus and Decius, indeed, made them feel all the rigours of a severe persecution; but their reigns were short, and from the death of Decius to the time of Dioclesian the church enjoyed tranquillity. Thus vast multitudes were converted: but at the same time the doctrine grew daily more corrupt, and the lives of professed Christians more wicked and scandalous. New ceremonies were invented in great numbers, and an unaccountable passion now prevailed for the oriental superstitions concerning demons; whence proceeded the whole train of exorcisms, spells, and fears for the apparition of evil spirits, which to this day are nowhere eradicated. Hence also the custom of avoiding all connections with those who were not baptised, or who lay under the penalty of excommunication, as persons supposed to be under the dominion of some evil spirit. And hence the rigour and severity of that discipline and penance imposed upon those who had incurred, by their immoralities, the censures of the church. Several alterations were now made in the manner of celebrating the Lord's supper. The prayers used on this occasion were lengthened, and the solemnity and pomp with which it was attended were considerably increased. Gold and silver vessels were used in the celebration; it was thought essential to salvation, and for that reason administered even to infants.—Baptism was celebrated twice a year to such as, after a long course of trial and preparation, offered themselves candidates. The remission of sins was thought to be its immediate consequence; while the bishop, by prayer and imposition of hands, was supposed to confer those sanctifying gifts of the Holy Ghost that are necessary to a life of righteousness and virtue. An evil demon was supposed naturally to reside in every person, who was the author and source of all the corrupt dispositions and unrighteous actions of that person. The driving out of this demon was therefore an essential property of baptism; and, in consequence

of this opinion, the baptized persons returned home clothed in white garments, and adorned with crowns, as sacred emblems, the former of their inward purity and innocence, and the latter of their victory over sin and the world.—Fasting began now to be held in more esteem than formerly. A high degree of sanctity was attributed to this practice; it was even looked upon as indispensably necessary, from a notion that the demons directed their force chiefly against those who pampered themselves with delicious fare, and were less troublesome to the lean and hungry who lived under the severities of a rigorous abstinence.—The sign of the cross also was supposed to administer a victorious power over all sorts of trials and calamities; and was more especially considered as the surest defence against the snares and stratagems of malignant spirits: for which reason, no Christian undertook any thing of moment, without arming himself, as he imagined, with the power of this triumphant sign. The heresies which troubled the church during this century, were the Gnostics, (whose doctrines were new-modelled and improved by Manes, from whom they were afterwards chiefly called *Manicheans*), the Hieracites, Noetians, Sabellians, and Novatians; for an account of which, see those articles.

The *fourth century* is remarkable for the establishment of Christianity by law in the Roman empire; which, however, did not take place till the year 324. In the beginning of the century, the empire was governed by four chiefs, viz. Dioclesian, Maximian, Constantius Chlorus, and Galerius, under whom the church enjoyed a perfect toleration. Dioclesian, though much addicted to superstition, had no ill-will against the Christians; and Constantius Chlorus, having abandoned polytheism, treated them with condescension and benevolence. This alarmed the Pagan priests, whose interests were so closely connected with the continuance of the ancient superstitions; and who apprehended, not without reason, that the Christian religion would at length prevail throughout the empire. To prevent the downfall of the Pagan superstition, therefore, they applied to Dioclesian and Galerius Cæsar; by whom a most bloody persecution was commenced in the year 303, and continued till 311. An asylum, however, was opened for the Christians in the year 304. Galerius having dethroned Dioclesian and Maximian, declared himself emperor in the east; leaving all the western provinces, to which great numbers of Christians resorted to avoid the cruelty of the former, to Constantius Chlorus. At length Galerius, being afflicted with an incurable and dreadful disease, published an edict ordering the persecution to cease, and restoring freedom to the Christians, whom he had most inhumanly oppressed for eight years. Galerius died the same year; and in a short time after, when Constantine the Great ascended the throne, the Christians were freed from any farther uneasiness, by his abrogating all the penal laws against them; and afterwards issuing edicts, by which no other religion than the Christian was tolerated throughout the empire.

This event, however, so favourable to the outward peace of the church, was far from promoting its internal harmony, or the reformation of its leaders. The clergy, who had all this time been augmenting their power at the expence of the liberty of the people, now set no bounds to their ambition. The bishop of Rome was the first in rank, and distinguished by a sort of pre-eminence above the rest of the prelates. He surpassed all his brethren in the magnificence and splendor of the church over which he presided, in the riches of his revenues and possessions, in the number and variety of his ministers, in his credit with the people, and in his sumptuous and splendid manner of living. Hence it happened, that when a new pontiff was to be chosen by the presbyters and people, the city of Rome was generally agitated with dissensions, tumults, and cabals, which

often produced fatal consequences. The intrigues and disturbances which prevailed in that city in the year 366, when, upon the death of Liberius, another pontiff was to be chosen in his place, are a sufficient proof of what we have advanced. Upon this occasion, one faction elected Damasus to that high dignity; while the opposite party chose Ursicinus, a deacon of the vacant church, to succeed Liberius. This double election gave rise to a dangerous schism, and to a sort of civil war within the city of Rome; which was carried on with the utmost barbarity and fury, and produced the most cruel massacres and desolations. The inhuman contest ended in the victory of Damasus; but whether his cause was more just than that of Ursicinus, is not easily to be determined.

Notwithstanding the pomp and splendor which surrounded the Roman see, it is certain that the bishops of Rome had not yet acquired that pre-eminence of power and jurisdiction which they afterwards enjoyed. In the ecclesiastical commonwealth, indeed, they were the most eminent order of citizens; but still they were citizens as well as their brethren, and subject, like them, to the laws and edicts of the emperors. All religious causes of extraordinary importance were examined and determined, either by judges appointed by the emperors, or in councils assembled for that purpose; while those of inferior moment were decided in each district by its respective bishop. The ecclesiastical laws were enacted either by the emperor or councils. None of the bishops acknowledged that they derived their authority from the permission and appointment of the bishop of Rome, or that they were created bishops by the favour of the *apostolic see*. On the contrary, they all maintained that they were the ambassadors and ministers of Jesus Christ, and that their authority was derived from above. It must, however, be observed, that even in this century several of those steps were laid by which the bishops of Rome mounted afterwards to the summit of ecclesiastical power and despotism. This happened partly by the imprudence of the emperors, partly by the dexterity of the Roman prelates themselves, and partly by the inconsiderate zeal and precipitate judgment of certain bishops. The imprudence of the emperor, and precipitancy of the bishops, were remarkably obvious in the following event, which favoured extremely the ambition of the Roman pontiff. About the year 372, Valentinian enacted a law, empowering the bishop of Rome to examine and judge other bishops, that religious disputes might not be decided by any profane or secular judges. The bishops assembled in council at Rome in 378, not considering the fatal consequences that must arise from this imprudent law both to themselves and to the church, declared their approbation in the strongest terms, and recommended the execution of it in their address to the emperor Gratian. Some think, indeed, that this law empowered the Roman bishop to judge only the bishops within the limits of his jurisdiction; others, that his power was given only for a certain time, and for a particular purpose. This last notion seems the most probable: but still this privilege must have been an excellent instrument in the hands of sacerdotal ambition.

By the removal of the seat of empire to Constantinople, the emperor raised up, in the bishop of this new metropolis, a formidable opponent to the bishop of Rome, and a bulwark which threatened a vigorous opposition to his growing authority. For as the emperor, in order to render Constantinople a second Rome, enriched it with all the rights and privileges, honours and ornaments, of the ancient capital of the world; so its bishop, measuring his own dignity and rank by the magnificence of the new city, and its eminence as the residence of the emperor, assumed an equal degree of dignity with the bishop of Rome, and claimed a superiority over the rest of the episcopal order. Nor did the emperors disapprove of these high pretensions, since they considered their own dignity as con-

nected in a certain measure with that of the bishop of their imperial city. Accordingly, in a council held at Constantinople in the year 381, by the authority of Theodosius the Great, the bishop of that city was, during the absence of the bishop of Alexandria, and against the consent of the Roman prelate, placed by the third canon of that council in the first rank after the bishop of Rome, and consequently above those of Alexandria and Antioch. Nectarius was the first bishop who enjoyed these new honours accumulated upon the see of Constantinople. His successor, the celebrated John Chrysostom, extended still farther the privileges of that see, and submitted to its jurisdiction all Thrace, Asia, and Pontus; nor were the succeeding bishops of that imperial city destitute of a fervent zeal to augment their privileges and extend their dominion. By this unexpected promotion, the most disagreeable effects were produced. The bishops of Alexandria were not only filled with the most inveterate hatred against those of Constantinople, but a contention was excited between the bishops of Rome and Constantinople; which, after being carried on for many ages, concluded at last in the separation of the Greek and Latin churches.

Constantine the Great, in order to prevent civil commotions, and to fix his authority on a stable and solid foundation, made several changes not only in the laws of the empire, but also in the form of the Roman government. And as there were many important reasons which induced him to suit the administration of the church to these changes in the civil constitution, this necessarily introduced among the bishops new degrees of eminence and rank. The four bishops, of Rome, Constantinople, Antioch, and Alexandria, were distinguished by a certain degree of pre-eminence over the rest. These four prelates answered to the four prætorian prefects created by Constantine; and it is possible, that even in this century they were distinguished by the Jewish title of *patriarchs*. After these followed the *exarchs*, who had the inspection of several provinces, and answered to the appointment of certain civil officers who bore the same title. In a lower class were the *metropolitans*, who had only the government of one province; under whom were the *archbishops*, whose inspection was confined to certain districts. In this gradation the *bishops* brought up the rear; but the sphere of their authority was not in all places equally extensive; being in some considerably ample, and in others confined within narrow limits. To these various ecclesiastical orders we might add that of the *chorëpiscopi*, or superintendants of the country churches; but this last order was in most places suppressed by the bishops, with a design to extend their own authority, and enlarge the sphere of their power and jurisdiction. The administration of the church itself was divided by Constantine into an *external* and *internal* inspection. The latter, which was committed to bishops and councils, related to religious controversies, the forms of divine worship, the offices of priests, the vices of the ecclesiastical orders, &c. The external administration of the church the emperor assumed to himself. This comprehended all those things which related to the outward state and discipline of the church; it likewise extended to all contests that should arise between the ministers of the church, superior as well as inferior, concerning their possessions, their reputation, their rights and privileges, their offences against the laws, &c. but no controversies that related to matters purely spiritual were cognizable by this external inspection. In consequence of this artful division of the ecclesiastical government, Constantine and his successors called councils, presided in them, appointed the judges of religious controversies, terminated the differences which arose between the bishops and the people, fixed the limits of the ecclesiastical provinces, took cognizance of the civil causes that subsisted between the ministers of the church, and punished the crimes committed against the laws by the ordinary judges appointed for that purpose; giving over

all causes purely ecclesiastical to the bishops and councils. But this famous division of the administration of the church was never explained with sufficient accuracy; so that both in the fourth and fifth centuries, there are frequent instances of the emperors determining matters purely ecclesiastical, and likewise of bishops and councils determining matters which related merely to the external form and government of the church.

After the time of Constantine many additions were made by the emperors and others to the wealth and honours of the clergy; and these additions were followed by a proportionable increase of their vices and luxury, particularly among those who lived in great and opulent cities. The bishops, on the one hand, contended with each other in the most scandalous manner concerning the extent of their respective jurisdictions: while, on the other, they trampled on the rights of the people, violated the privileges of the inferior ministers, and imitated in their conduct and in their manner of living the arrogance, voluptuousness, and luxury of magistrates and princes. This pernicious example was soon followed by the several ecclesiastical orders. The presbyters, in many places, assumed an equality with the bishops in point of rank and authority. Many complaints are also made by the authors of this century about the vanity and effeminacy of the deacons. Those more particularly of the presbyters and deacons who filled the first stations of these orders, carried their pretensions to an extravagant length, and were offended at the notion of being placed on an equality with their colleagues. For this reason they not only assumed the titles of *arch-presbyters* and *arch-deacons*, but also claimed a degree of authority and power much superior to that which was vested in the other members of their respective orders.

In the *fifth century*, the bishops of Constantinople having already reduced under their jurisdiction all the Asiatic provinces, began to grasp at still further accessions of power. By the 28th canon of the council held at Chalcedon in 451, it was resolved, that the same rights and honours which had been conferred on the bishop of Rome were due to the bishop of Constantinople, on account of the equal dignity and lustre of the two cities in which these prelates exercised their authority. The same council confirmed also, by a solemn act, the bishop of Constantinople in the spiritual government of those provinces over which he had usurped the jurisdiction. Leo the Great, bishop of Rome, opposed with vehemence the passing of these laws; and his opposition was seconded by that of several other prelates. But their efforts were vain, as the emperors threw their weight into the balance, and thus supported the decisions of the Grecian bishops. In consequence, then, of the decisions of this famous council, the bishop of Constantinople began to contend obstinately for the supremacy with the Roman pontiff, and to crush the bishops of Antioch and Alexandria. About the same time, Juvenal, bishop of Jerusalem, attempted to withdraw himself and his church from the jurisdiction of the bishop of Casarea, and aspired after a place among the first prelates of the Christian world. The high degree of veneration and esteem in which the church of Jerusalem was held among all other Christian societies (on account of its rank among the apostolical churches, and its title to the appellation of *mother-church*, as having succeeded the first Christian assembly formed by the Apostles), was extremely favourable to the ambition of Juvenal, and rendered his project much more practicable than it would otherwise have been. Encouraged by this, and likewise by the protection of Theodosius the younger, this aspiring prelate not only assumed the dignity of patriarch of all Palestine, a rank which rendered him independent of all spiritual authority; but also invaded the rights of the bishop of Antioch, and usurped his jurisdiction over the provinces of Phœnicia and Arabia. Hence arose a warm contest between Juvenal and Maximus bishop of Antioch; which the council of Chalcedon

decided, by restoring to the latter the provinces of Phœnicia and Arabia, and confirming the former in the spiritual possession of all Palestine, and in the high rank which he had assumed in the church.

In 588, John bishop of Constantinople, surnamed the *Faster*, either by his own authority or that of the emperor Mauritius, summoned a council at Constantinople to inquire into an accusation brought against Gregory bishop of Antioch; and upon this occasion assumed the title of *œcumenical* or *universal bishop*. This title had been formerly enjoyed by the bishops of Constantinople without any offence; but now, Gregory the Great, at that time bishop of Rome, suspecting that John was aiming at the supremacy over all the churches, opposed his claim with the greatest vigour. For this purpose he applied by letters to the emperor, and others whom he thought capable of assisting him in his opposition: but all his efforts were without effect; and the bishops of Constantinople were allowed to enjoy the disputed title, though not in the sense which had alarmed the Roman pontiff.

Gregory, however, adhered tenaciously to his purpose, raised new tumults and dissensions among the clergy, and aimed at nothing less than an unlimited supremacy over the Christian church. This ambitious design succeeded in the west; while, in the eastern provinces, his arrogant pretensions were scarcely respected by any but those who were at enmity with the bishop of Constantinople. How much the people were at this time deluded by the Roman pontiffs, appears from the expression of Ennodius, one of the flatterers of Symmachus (who was a prelate of but ambiguous fame), that the Roman pontiff was constituted judge in the place of God, which he filled as the vicergerent of the Most High. On the other hand it is certain, from a variety of the most authentic records, that both the emperors and the nations in general were far from being disposed to bear with patience the yoke of servitude which the see of Rome was arrogantly imposing on the whole church.

In the beginning of the *seventh century*, according to the most learned historians, Boniface III. engaged Phocas, emperor of Constantinople, to take from the bishop of that metropolis the title of *œcumenical* or *universal bishop*, and to confer it upon the Roman pontiff; and thus was first introduced the supremacy of the pope. The Roman pontiffs used all methods to maintain and enlarge this authority and pre-eminence which they had acquired from one of the most odious tyrants that ever disgraced the annals of history.

In the *eighth century*, the power of the bishop of Rome, and of the clergy in general, increased prodigiously. The chief cause of this, besides the superstition of the people, was the method at that time used by the European princes to secure themselves on their thrones. All these princes being then employed either in usurpation or in self-defence, and the whole continent being in the most unsettled and barbarous condition, they endeavoured to attach warmly to their interests those whom they considered as their friends and clients. For this purpose they distributed among them extensive territories, cities, and fortresses, with the various rights and privileges belonging to them; reserving only to themselves the supreme dominion and the military service of these powerful vassals. For this reason it was by the European princes reckoned a high instance of political prudence to distribute among the bishops and other Christian doctors the same sort of donations which had formerly been given to their generals and clients. By means of the clergy, they hoped to check the seditions and turbulent spirits of their vassals; and to maintain them in their obedience by the influence and authority of their bishops, whose commands were highly respected, and whose spiritual thunderbolts, rendered formidable by ignorance, struck terror into the boldest and most resolute hearts.

This prodigious accession to the opulence and authority of the clergy in the west, began at their head, viz. the Roman pontiff; from whence it spread gradually among the inferior sacerdotal orders. The barbarous nations who had received the gospel, looked upon the bishop of Rome as the successor of their chief druid or high priest: and as this tremendous druid had enjoyed, under the darkness of Paganism, a kind of boundless authority; so these barbarous nations thought proper to confer upon the chief bishop the same authority which had belonged to the chief druid. The pope received these august privileges with great pleasure; and lest, upon any change of affairs, attempts should be made to deprive him of them, he strengthened his title to these extraordinary honours by a variety of passages drawn from ancient history, and, what is still more astonishing, by arguments of a religious nature. This swelled the Roman druid to an enormous size; and gave to the see of Rome that high pre-eminence and despotic authority in civil and political matters, that were unknown to former ages. Hence, among other unhappy circumstances, arose that monstrous and pernicious opinion, that such persons as were excluded from the communion of the church by the pontiff himself, or any of the bishops, forfeited thereby, not only their civil rights and advantages as citizens, but even the common claims and privileges of humanity. This horrid opinion, which was a fatal source of wars, massacres, and rebellions, without number, and which contributed more than any thing else to confirm and augment the papal authority, was borrowed by the clergy from the Pagan superstitions.—Though excommunication, from the time of Constantine the Great, was in every part of the Christian world attended with many disagreeable effects; yet its highest terrors were confined to Europe, where its aspect was truly formidable and hideous. It acquired also, in the eighth century, new accessions of terror; so that from that period the excommunication practised in Europe differed entirely from that which was in use in other parts of Christendom. Excommunicated persons were indeed considered in all places as objects of hatred both to God and man: but they were not, on that account, robbed of the privileges of citizens, nor of the rights of humanity; much less were those kings and princes, whom an insolent bishop had thought proper to exclude from the communion of the church, supposed to forfeit on that account their crowns or their territories. But from this century it was quite otherwise in Europe. Excommunication received that infernal power which dissolved all connections; so that those whom the bishops, or their chief, excluded from church communion, were degraded to a level with the beasts. The origin of this unnatural and horrid power was as follows. On the conversion of the barbarous nations to Christianity, these ignorant profelytes confounded the excommunication in use among Christians with that which had been practised in the times of Paganism, and which was attended with all the dreadful effects above mentioned. The Roman pontiffs, on the other hand, were too artful not to encourage this error; and therefore employed all sorts of means to gain credit to an opinion so well calculated to gratify their ambition, and to aggrandize in general the episcopal order.

The annals of the French nation furnish us with the following instance of the enormous power which was at this time vested in the Roman pontiff. Pepin, who was mayor of the palace to Childeric III. king of France, and who in the exercise of that high office was possessed in reality of the royal power and authority, aspired to the titles and honours of majesty also, and formed a scheme of dethroning his sovereign. For this purpose he assembled the states in 751; and though they were devoted to the interests of this ambitious usurper, they gave it as their opinion that the bishop of Rome was previously to be consulted whether the execution of such a scheme was lawful or not. In

consequence of this, ambassadors were sent by Pepin to Zachary, the reigning pontiff, with the following question, "Whether the divine law did not permit a valiant and warlike people to dethrone a pusillanimous and indolent prince who was incapable of discharging any of the functions of royalty; and to substitute in his place one more worthy to rule, and who had already rendered most important services to the state?" The situation of Zachary, who stood much in need of the succours of Pepin against the Greeks and Lombards, rendered his answer such as the usurper desired: and when this favourable decision of the Roman oracle was published in France, the unhappy Childeric was stripped of his royalty without the least opposition; and Pepin, without the smallest resistance, stepped into the throne of his master and his sovereign. This decision was solemnly confirmed by Stephen II. the successor of Zachary; who undertook a journey into France in the year 754, in order to solicit assistance against the Lombards. The pontiff at the same time dissolved the obligation of the oath of fidelity and allegiance which Pepin had sworn to Childeric, and violated by his usurpation in the year 751; and to render his title to the crown as sacred as possible, Stephen anointed and crowned him, with his wife and two sons, for the second time. This complaisance of the pope was rewarded with the exarchate of Ravenna and all its dependencies, as has been already related.

In the succeeding centuries, the Roman pontiffs continued to increase their power by every kind of artifice and fraud; and, by continually taking advantage of the civil dissensions which prevailed throughout Italy, France, and Germany, their influence in civil affairs arose to an enormous height. The increase of their authority in religious matters was not less rapid. The wisest and most impartial among the Roman Catholic writers acknowledge, that from the time of Louis the Meek the ancient rules of ecclesiastical government were gradually changed in Europe by the counsels and instigation of the church of Rome, and new laws substituted in their place. The European princes suffered themselves to be divested of the supreme authority in religious matters, which they had derived from Charlemagne; the power of the bishops was greatly diminished, and even the authority of both provincial and general councils began to decline. The popes, elated with their overgrown prosperity, and become arrogant beyond measure by the daily accessions that were made to their authority, were eagerly bent upon establishing the maxim, That the bishop of Rome was constituted and appointed by Jesus Christ supreme legislator and judge of the church universal; and that therefore the bishops derived all their authority from him. This opinion, which they inculcated with the utmost zeal and ardour, was opposed in vain by such as were acquainted with the ancient ecclesiastical constitutions, and the government of the church in the earlier ages. In order to gain credit to this new ecclesiastical code, and to support the pretensions of the popes to supremacy, it was necessary to produce the authority of ancient deeds, in order to stop the mouths of such as were disposed to set bounds to their usurpations. The bishops of Rome were aware of this; and as those means were looked upon as the most lawful that tended best to the accomplishment of their purposes, they employed some of their most ingenious and zealous partisans in forging conventions, acts of councils, epistles, and such-like records, by which it might appear, that in the first ages of the church the Roman pontiffs were clothed with the same spiritual majesty and supreme authority which they now assumed. There were not, however, wanting among the bishops some men of prudence and sagacity, who saw through these impious frauds, and perceived the chains that were forging both for them and the church. The French bishops distinguished themselves eminently in this respect: but their opposition was soon quashed; and as all Europe was sunk in the grossest ignorance and darkness, none re-

mained who were capable of detecting these odious impostures, or disposed to support the expiring liberty of the church.

This may serve as a general specimen of the character and behaviour of the pretended vicegerents of Jesus Christ to the 16th century. In the 11th century, indeed, their power seems to have risen to its utmost height. They now received the pompous titles of *Masters of the World*, and *Popes*, i. e. *universal fathers*. They presided every where in the councils by their legates, assumed the authority of supreme arbiters in all controversies that arose concerning religion or church discipline, and maintained the pretended rights of the church against the encroachments and usurpations of kings and princes. Their authority, however, was confined within certain limits: for, on the one hand, it was restrained by sovereign princes, that it might not arrogantly aim at civil dominion; and, on the other, it was opposed by the bishops themselves, that it might not arise to a spiritual despotism, and utterly destroy the privileges and liberty of synods and councils. From the time of Leo IX. the popes employed every method which the most artful ambition could suggest to remove those limits, and to render their dominion both despotic and universal. They not only aspired to the character of supreme legislators in the church, to an unlimited jurisdiction over all synods and councils whether general or provincial, to the sole distribution of all ecclesiastical honours and benefices, as divinely authorized and appointed for that purpose; but they carried their insolent pretensions so far as to give themselves out for lords of the universe, arbiters of the fate of kingdoms and empires, and supreme rulers over the kings and princes of the earth. Hence we find instances of their giving away kingdoms, and loosing subjects from their allegiance to their sovereigns; among which the history of John king of England is very remarkable. At last they plainly assumed the whole earth as their property, as well where Christianity was preached as where it was not; and therefore, on the discovery of America and the East Indies, the pope, by virtue of this spiritual property, granted to the Portuguese a right to all the countries lying eastward, and to the Spaniards all those lying to the westward, of Cape Non in Africa, which they were able to conquer by force of arms; and that nothing might be wanting to complete their character, they pretended to be lords of the future world also, and to have a power of restraining even the divine justice itself, and remitting that punishment which the Deity hath denounced against the workers of iniquity.

All this time the powers of superstition reigned triumphant over those remains of Christianity which had escaped the corruptions of the first four centuries. In the fifth century began the invocation of the happy souls of departed saints. Their assistance was entreated by many fervent prayers, while none stood up to oppose this preposterous kind of worship. The images of those who during their lives had acquired the reputation of uncommon sanctity, were now honoured with a particular worship in several places; and many imagined that this drew into the images the propitious presence of the saints or celestial beings which they were supposed to represent. A singular and irresistible efficacy was attributed to the bones of martyrs, and to the figure of the cross, in defeating all the attempts of Satan, removing all sorts of calamities, and in healing not only the diseases of the body, but also those of the mind. The famous Pagan doctrine concerning the *purification of departed souls* by means of a certain kind of fire, i. e. purgatory, was also confirmed and explained more fully than it had formerly been; and every one knows of how much consequence this absurd doctrine once was to the wealth and power of the Romish clergy.

In the *sixth century*, Gregory the Great advanced an opinion, That all the *words* of the sacred writings were *images* of invisible and spiritual things; for which reason he loaded the churches with a multitude of ceremonies the most insignificant and futile

that can be imagined; and hence arose a new and most difficult science, namely, the explication of these ceremonies, and the investigation of the causes and circumstances whence they derived their origin. A new method was contrived of administering the Lord's supper, with a magnificent assemblage of pompous ceremonies. This was called the *canon of the mass*. Baptism, except in cases of necessity, was administered only on the great festivals. An incredible number of temples were erected in honour of the saints. The places set apart for public worship were also very numerous: but now they were considered as the means of purchasing the protection and favour of the saints; and the ignorant and barbarous multitude were persuaded, that these departed spirits defended and guarded against evils and calamities of every kind, the provinces, lands, cities, and villages in which they were honoured with temples. The number of these temples was almost equalled by that of the festivals, which seem to have been invented in order to bring the Christian religion as near the model of Paganism as possible.

In the *seventh century*, religion seemed to be altogether buried under a heap of superstitious ceremonies; the worship of the true God and Saviour of the world was exchanged for the worship of bones, bits of wood (said to be of the cross), and the images of saints. The eternal state of misery threatened in Scripture to the wicked was exchanged for the temporary punishment of purgatory; and the expressions of faith in Christ by an upright and virtuous conduct, for the augmentation of the riches of the clergy by donations to the church, and the observance of a heap of idle ceremonies. New festivals were still added; one in particular was instituted in honour of the *true cross* on which our Saviour suffered: and churches were declared to be sanctuaries to all such as fled to them, whatever their crimes might have been.

Superstition, it would seem, had now attained its highest pitch; nor is it easy to conceive a degree of ignorance and degeneracy beyond what we have already mentioned. If any thing can possibly be imagined more contrary to true religion, it is an opinion which prevailed in the eighth century, namely, That Christians might appease an offended Deity by voluntary acts of mortification, or by gifts and oblations lavished on the church; and that people ought to place their confidence in the works and merits of the saints. The piety in this and some succeeding ages consisted in building and embellishing churches and chapels; in endowing monasteries and basilics; hunting after the relics of saints and martyrs, and treating them with an absurd and excessive veneration; in procuring the intercession of the saints by rich oblations, or superstitious rites; in worshipping images; in pilgrimages to those places which were esteemed holy, particularly to Palestine, &c. The genuine religion of Jesus was now utterly unknown both to clergy and people, if we except a few of its general doctrines contained in the creed. In this century also, the superstitious custom of *solitary masses* had its origin. These were celebrated by the priest alone in behalf of souls detained in purgatory, as well as upon some other occasions. They were prohibited by the laws of the church, but proved a source of immense wealth to the clergy. Under Charlemagne they were condemned by a synod assembled at Mentz, as criminal effects of avarice and sloth. A new superstition, however, still sprung up in the tenth century. It was imagined, from Rev. xx. 1. that Antichrist was to make his appearance on the earth, and that soon after the world itself would be destroyed. An universal panic ensued; vast numbers of people, abandoning all their connections in society, and giving over to the churches and monasteries all their worldly effects, repaired to Palestine, where they imagined that Christ would descend from heaven to judge the world. Others devoted themselves by a solemn and voluntary oath to the service of the churches, convents, and priesthood, whose slaves they became,

in the most rigorous sense of that word, performing daily their heavy tasks; and all this from a notion that the supreme judge would diminish the severity of their sentence, and look upon them with a more favourable and propitious eye, on account of their having made themselves the slaves of his ministers. When an eclipse of the sun or moon happened to be visible, the cities were deserted, and their miserable inhabitants fled for refuge to hollow caverns, and hid themselves among the craggy rocks, and under the bending summits of steep mountains. The opulent attempted to bribe the Saints and the Deity himself by rich donations conferred upon the sacerdotal tribe, who were looked upon as the immediate vicegerents of heaven. In many places, temples, palaces, and noble edifices both public and private, were suffered to decay, nay, were deliberately pulled down, from a notion that they were no longer of any use, as the final dissolution of all things was at hand. In a word, no language is sufficient to express the confusion and despair that tormented the minds of miserable mortals upon this occasion. The general delusion was indeed opposed and combated by the discerning few, who endeavoured to dispel these terrors, and to efface the notion from which they arose in the minds of the people. But their attempts were ineffectual; nor could the dreadful apprehensions of the superstitious multitude be removed before the end of the century, and this terror became one of the accidental causes of the *CRUSADES*.

That nothing might now be wanting to complete that anti-christian system of religion which had overspread all Europe, it was in the 11th century determined that divine worship should be celebrated in the Latin tongue, though now unknown throughout the continent. During the whole of this century, also, Christians were employed in the rebuilding and ornamenting their churches, which they had destroyed through the superstitious fear already taken notice of.

In much the same way with what is above related, or worse if possible, matters went on till the time of the reformation. The clergy were immersed in crimes of the deepest dye; and the laity, imagining themselves able to purchase pardon of their sins for money, followed the example of their pastors without remorse. The absurd principle formerly mentioned, namely, that religion consists in acts of austerity, and an unknown mental correspondence with God, produced the most extravagant and ridiculous behaviour in the devotees and reputed saints. They not only lived among the wild beasts, but also after the manner of those savage animals: they ran naked through the lonely deserts with a furious aspect, and all the agitations of madness and phrensy; they prolonged a wretched life by grass and wild herbs, avoided the sight and conversation of men, remained almost motionless in certain places for several years exposed to the rigour and inclemency of the seasons, and towards the conclusion of their lives shut themselves up in narrow and miserable huts; and all this was considered as true piety, the only acceptable method of worshipping the Deity and attaining a share in his favour.—But of all the instances of superstitious phrensy which disgraced the times we now speak of, none was held in higher veneration, or excited more the wonder of the multitude, than that of a certain order of men who were called *Stilites* by the Greeks, and *Sancti Columnares*, or Pillar Saints, by the Latins. These were persons of a most singular and extravagant turn of mind, who stood motionless on the tops of pillars expressly raised for this exercise of their patience, and remained there for several years amidst the admiration and applause of the stupid populace. The inventor of this strange discipline was one *Simon* a Syrian, who began his follies by changing the agreeable employment of a shepherd for the austerities of a monkish life. He began his devotion on the top of a pillar six cubits high; but as he increased in sanctity, he also increased the height of his pillar,

till, towards the conclusion of his life, he had got up on the top of a pillar 40 cubits in height. Many of the inhabitants of Syria and Palestine, seduced by a false ambition and an utter ignorance of true religion, followed the example of this fanatic, though not with the same degree of austerity. This superstitious practice began in the fifth century, and continued in the east for 600 years. The Latins, however, had too much wisdom and prudence to imitate the Syrians and Orientals in this whimsical superstition: and when a certain fanatic, or impostor, named *Wulfilaicus*, erected one of these pillars in the country of Treves, and proposed to live on it after the manner of *Simon*, the neighbouring bishops ordered it to be pulled down.

The practices of austere worship and discipline in other respects, however, gained ground throughout all parts of Christendom. Monks of various kinds were to be found in every country in prodigious numbers. But though their discipline was at first exceedingly severe, it became gradually relaxed, and the monks gave into all the prevailing vices of the times. Other orders succeeded, who pretended to still greater degrees of sanctity, and to reform the abuses of the preceding ones; but these in their turn became corrupted, and fell into the same vices they had blamed in others. The most violent animosities, disputes, and hatred, also reigned among the different orders of monks; and, indeed, between the clergy of all ranks and degrees, whether we consider them as classed in different bodies, or as individuals of the same body. To enter into a detail of their wranglings and disputes, the methods which each of them took to aggrandise themselves at the expence of their neighbours, and to keep the rest of mankind in subjection, would require many volumes. We shall only observe, therefore, that even the external profession of the austere and absurd piety which took place in the fourth and fifth centuries, continued gradually to decline. Some there were, indeed, who boldly opposed the torrent of superstition and wickedness which threatened to overflow the whole world: but their opposition proved fruitless, and all of these towards the era of the reformation had been either silenced or destroyed: so that, at that time, the pope and clergy reigned over mankind without controul, had made themselves masters of almost all the wealth in every country of Europe, and may truly be said to have been the only *sovereigns*; the rest of the human race, even kings and princes, being only their vassals and slaves.

While the Popish superstition reigned thus violently in the west, the absurd doctrines of Mahomet overspread all the east. The rise of this impostor is well known. His successors conquered in order to establish the religion of their apostle; and thus the very name of Christianity was extinguished in many places where it had formerly flourished. The conquests of the Tartars having intermingled them with the Mahometans, they greedily embraced the superstitions of that religion, which thus almost entirely overspread the whole continents of Asia and Africa; and, by the conquest of Constantinople by the Turks in 1453, was likewise established throughout a considerable part of Europe.

About the beginning of the 16th century, the Roman pontiffs lived in the utmost tranquillity; nor had they, according to the appearance of things at that time, any reason to fear an opposition to their authority in any respect, since the commotions which had been raised by the Waldenses, Albigenses, &c. were now entirely suppressed. We must not however conclude, from this apparent tranquillity and security of the pontiffs and their adherents, that their measures were universally applauded. Not only private persons, but also the most powerful princes and sovereign states, exclaimed loudly against the tyranny of the popes, and the unbridled licentiousness of the clergy of all denominations. They demanded, therefore, a reformation of the church in its head and members, and a general council to accomplish that

necessary purpose. But these complaints and demands were not carried to such a length as to produce any good effect; since they came from persons who never entertained the least doubt about the supreme authority of the pope in religious matters, and who of consequence, instead of attempting themselves to bring about that reformation which was so ardently desired, remained entirely inactive, or looked for redress to the court of Rome, or to a general council. But while the so much desired reformation seemed to be at such a great distance, it suddenly arose from a quarter whence it was not at all expected. A single person, Martin Luther, a monk of the order of St. Augustine, ventured to oppose himself to the whole torrent of papal power and despotism. This bold attempt was first made public on the 30th of September 1517; and, notwithstanding all the efforts of the pope and his adherents, the doctrines of Luther continued daily to gain ground. Others, encouraged by his success, lent their assistance in the work of reformation; which at last produced new churches, founded upon principles quite different from that of Rome, and which still continue. But for some account of the transactions of the first reformers, see the articles LUTHER and REFORMATION.

The state of religion in other parts of the world seems as yet to be but little altered. Asia and Africa are sunk in the grossest superstitions either of the Mahometan or Pagan kinds. The southern continent of America, belonging to the Spaniards, continues immersed in the most absurd superstitions of Popery. The northern continent, being mostly peopled with colonies from Great Britain, professes the reformed religion. At the same time it must be owned, that some kind of reformation hath taken place even in Popery and Mahometanism themselves. The popes have no longer that authority over states and princes, even those most bigoted to Popery, which they formerly had. Neither are the lives either of the clergy or laity so corrupt as they were before. The increase of learning in all parts of the world has contributed to make men open their eyes to the light of reason, and this hath been attended with a proportional decrease of superstition. Even in Mahometan countries, that furious enthusiasm which formerly emboldened the inhabitants to face the greatest dangers, hath now almost vanished; so that the credit of Mahomet himself seems to have sunk much in the estimation of his followers. This is to be understood even of the most ignorant and bigoted multitude; and the sensible part of the Turks are said to incline much towards Deism. With regard to those nations which still profess Paganism, the intercourse of Europeans with them is so small, that it is impossible to say any thing concerning them. As none of them are in a state of civilization, however, it may be conjectured that their religion is of the same unpolished cast with their manners; and that it consists of a heap of barbarous superstitions which have been handed down among them from time immemorial, and which they continue to observe merely on that account.

C H A P. III.

Of the COMPOSITION of HISTORY.

CICERO has given us the whole art of composing history, in a very short and comprehensive manner. We shall first quote what he says, and then consider the several parts of it in their proper order. "No one is ignorant (says he), that the first law in writing history is, Not to dare to say any thing that is false; and the next, Not to be afraid to speak the truth: that on the one hand there be no suspicion of affection, nor of prejudice on the other. These foundations are what all are acquainted with. But the superstructure consists partly in things, and partly in the style or language. The

former require an order of times, and descriptions of places. And because in great and memorable events we are desirous to know first their causes, then the actions themselves, and lastly their consequences; the historian should take notice of the springs or motives that occasioned them; and, in mentioning the facts themselves, should not only relate what was done or said, but likewise in what manner; and, in treating upon their consequences, shew if they were the effects of chance, wisdom, or imprudence. Nor should he only recite the actions of great and eminent persons, but likewise describe their characters. The style ought to be silent, smooth, and even, free from that harshness and poignancy which is usual at the bar." Thus far Cicero. An history written in this manner, and furnished with all these properties, must needs be very entertaining, as well as instructive. And perhaps few have come nearer this plan than Tacitus; though his subject is attended with this unhappy circumstance, or at least unpleasant one, that it affords us examples rather of what we ought to avoid than what to imitate. But it is the business of the historian, as well as of the philosopher, to represent both virtues and vices in their proper colours; the latter doing it by precepts, and the former by examples. Their manner is different; but the end and design of both is, or should be, the same: and therefore history has not improperly been said by some to be moral philosophy exemplified in the lives and actions of mankind.

We shall reduce these several things mentioned by Cicero under three heads, Matter, Order, and Style; and treat upon each of them separately. But as Truth is the basis and foundation of all history, it will be necessary to consider that in the first place.

SECT. I. *Of Historical Truth.*

TRUTH is, as it were, the very life and soul of history, by which it is distinguished from fable or romance. An historian therefore ought not only to be a man of probity, but void of all passion or bias. He must have the steadiness of a philosopher, joined with the vivacity of a poet or orator. Without the former, he will be insensibly swayed by some passion to give a false colouring to the actions or characters he describes, as favour or dislike to parties or persons affects his mind. Whereas he ought to be of no party, nor to have either friend or foe while writing; but to preserve himself in a state of the greatest indifference to all, that he may judge of things as they really are in their own nature, and not as connected with this or that person or party. And with this firm and sedate temper, a lively imagination is requisite; without which his descriptions will be flat and cold, nor will he be able to convey to his readers a just and adequate idea of great and generous actions. Nor is the assistance of a good judgment less necessary than any of the former qualities, to direct him what is proper to be said and what to be omitted, and to treat every thing in a manner suitable to its importance. And since these are the qualifications necessary for an historian, it may perhaps seem the less strange that we have so few good histories extant.

But historical truth consists of two parts; one is, Not to say any thing we know to be false. Though it is not sufficient to excuse an historian in relating a falsehood that he did not know it was so when he wrote it, unless he first used all the means in his power to inform himself of the truth; for then, undoubtedly, an invincible error is as unpardonable in history as in morality. But the generality of writers of this kind content themselves with taking their accounts from hearsay, or transcribing them from others; without duly weighing the evidence on which they are founded, or giving themselves the trouble of a strict inquiry. Few will use the diligence necessary to inform themselves of the certainty of what they undertake

to relate. And as the want of this greatly abates the pleasure of reading such writers, while persons read with diffidence; so nothing more recommends an historian than such industry. Thus we are informed of Thucydides, that when he wrote his history of the Peloponnesian war, he did not satisfy himself with the best accounts he could get from his countrymen the Athenians, fearing they might be partial in their own cause; but spared no expence to inform himself how the same facts were related by their enemies the Lacedemonians; that, by comparing the relations of both parties, he might better judge of the truth. And Polybius took greater pains than he, in order to write his history of the Roman affairs; for he travelled into Africa, Spain, Gaul, and other parts of the world, that, by viewing the several scenes of action, and informing himself from the inhabitants, he might come at a greater certainty of the facts, and represent them in a juster light. But as a historian ought not to assert what he knows to be false; so he should likewise be cautious in relating things which are doubtful, and acquaint his readers with the evidence he goes upon in such facts, from whence they may be able to judge how far it is proper to credit them. So Herodotus tells us what things he saw himself in his travels, and what he heard from the information of the Egyptian priests and others with whom he conversed. And Curtius, in the Life of Alexander, speaking of the affairs of India, ingenuously confesses, that he wrote more than he fully believed. "For (says he) I neither dare to affirm positively what I doubt of, nor can I think it proper to omit what I have been told." By such a conduct the author secures his credit, whether the things prove really true or false; and gives room for further enquiry, without imposing on his readers.

The other branch of historical truth is, Not to omit any thing that is true, and necessary to set the matter treated of in a clear and full light. In the actions of past ages or distant countries, wherein the writer has no personal concern, he can have no great inducement to break in upon this rule. But where interest or party is engaged, it requires no small candour, as well as firmness of mind, constantly to adhere to it. Affection to some, aversion to others, fear of disobliging friends or those in power, will often interpose and try his integrity. Besides, an omission is less obnoxious to censure, than a false assertion: for the one may be easily ascribed to ignorance or forgetfulness; whereas the other will, if discovered, be commonly looked upon as design. He therefore, who in such circumstances, from a generous love to truth, is superior to all motives to betray or stifle it, justly deserves the character of a firm as well as honest man. What Polybius says upon this head is very well worth remarking: "A good man ought to love his friends and his country, and to have a like disposition with them, both towards their friends and enemies. But when he takes upon him the character of an historian, they must all be forgot. He must often speak well of his enemies, and commend them when their actions deserve it; and sometimes blame, and even upbraid his greatest friends, when their conduct makes it necessary. Nor must he forbear sometimes to reprove, and at other times to commend, the same persons; since all are liable to mistake in their management, and there are scarce any persons who are always in the wrong. Therefore, in history, all personal considerations should be laid aside, and regard had only to their actions."

What a different view of mankind and their actions should we have were these rules observed by all historians? Integrity is undoubtedly the principal qualification of an historian; when we can depend upon this, other imperfections are more easily passed over. Suetonius is said to have written the lives of the first twelve Roman emperors with the same freedom wherewith they themselves lived. What better character can be given of a writer? The same ingenuous temper appears in the two Grecian historians above mentioned, Thucydides and Polybius:

the former of whom, though banished by his countrymen the Athenians, yet expresses no marks of repentment in his history, either against them in general, or even against the chief authors of it, when he has occasion to mention them; and the latter does not forbear censuring what he thought blameable in his nearest relations and friends. But it is often no easy matter to know whether an historian speaks truth or not, and keeps up to the several characters here mentioned; though it seems reasonable, upon the common principles of justice due to all mankind, to credit him where no marks of partiality or prejudice appear in his writings. Sometimes, indeed, a judgment may in a good measure be formed of the veracity of an author, from his manner of expressing himself. A certain candour and frankness, that is always uniform and consistent with itself, runs through their writings who have nothing in view but truth, which may be justly esteemed as a very good evidence of their sincerity. Whereas those who have partial designs to answer are commonly more close and covert; and if at other times they assume an air of openness and freedom, yet this is not constant and even, but soon followed again with the appearance of some bias and reserve: for it is very difficult to act a part long together without lying open to a discovery. And therefore, though craft and design is exceeding various, and, Proteus-like, assumes very different shapes, there are certain characters by which it may often be perceived and detected. Thus, where things are uncertain because of their being reported various ways, it is partiality in an historian to give into the most unfavourable account, where others are as well known and equally credible. Again, it is a proof of the same bad temper, when the facts themselves are certain and evident, but the design and motives of those concerned in them are unknown and obscure, to assign some ill principle, such as avarice, ambition, malice, interest, or any other vicious habit, as the cause of them. This conduct is not only unjust to the persons whose actions they relate; but hurtful to mankind in general, by endeavouring to destroy the principal motive to virtue, which springs from example. Others, who affect to be more covert, content themselves with suspicions and sly insinuations; and then endeavour to come off, by intimating their unwillingness to believe them, though they would have their readers do so. And to mention no more, there are others, who, when they have loaded persons with unjust calumnies and reflections, will allow them some slight commendations, to make what they have said before look more credible, and themselves less partial. But the honest and faithful historian contemns all such low and mean arts; he considers things as they are in themselves, and relates them as he finds them, without prejudice or partiality.

SECT. II. *Of the Subject of History.*

By the *subject* of history we mean facts themselves, together with such things as are either connected with them, or may at least be requisite to set them in a just and proper light. But although the principal design of history be to record facts, yet all facts do not merit the regard of an historian; but such only as may be thought of use in regulating the conduct of human life. Nor is it allowable for him, like the poet, to form the plan and scheme of his work as he pleases. His business is to report things as he finds them, without any colouring or disguise to make them more pleasing and palatable to his reader, which would be to convert his history into a novel. Indeed, some histories afford more pleasure and entertainment than others, from the nature of things of which they consist; and it may be esteemed the happiness of an historian to meet with such a subject, but it is not his fault if it be otherwise. Thus Herodotus begins his history with showing, that the barbarians gave the first occasion to the wars between them and the Greeks, and ends it with an account of the punishment which, after some ages,

they suffered from the Greeks on that account. Such a relation must not only be very agreeable to his countrymen the Grecians, for whose sakes it was written; but likewise very instructive, by informing them of the justice of Providence in punishing public injuries in this world, wherein societies, as such, are only capable of punishment. And therefore those examples might be of use to caution them against the like practices. On the contrary, Thucydides begins his history with the unhappy state of his countrymen the Athenians; and in the course of it plainly intimates, that they were the cause of the calamitous war between them and the Lacedemonians. Whereas, had he been more inclined to please and gratify his countrymen than to write the truth, he might have set things in such a light as to have made their enemies appear the aggressors. But he scorned to court applause at the expence of truth and justice, and has set a noble example of integrity to all future historians. But as all actions do not merit a place in history, it requires no small judgment in an historian to select such only as are proper. Cicero observes very justly, that history "is conversant in great and memorable actions." For this reason, an historian should always keep posterity in view; and relate nothing which may not, upon some account or other, be worth the notice of after-ages. To descend to trivial and minute matters, such as frequently occur in the common affairs of life, is below the dignity of history. Such writers ought rather to be deemed journalists than historians, who have no view or expectation that their works should survive them. But the skilful historian is fired with a more noble ambition. His design is to acquaint succeeding ages with what remarkable occurrences happened in the world before them; to do justice to the memory of great and virtuous men; and at the same time to perpetuate his own. Pliny the younger has some fine reflections upon this head, in a letter to a friend. "You advise me (says he) to write an history; and not you only, for many others have done the same, and I am myself inclined to it. Not that I believe myself qualified for it, which would be rash to think till I have tried it; but because I esteem it a generous action not to suffer those to be forgotten, whose memory ought to be eternized; and to perpetuate the names of others, together with one's own. For there is nothing I am so desirous or ambitious of, as to be remembered hereafter; which is a thing worthy of a man, especially of one who, conscious of no guilt, has nothing to fear from posterity." This was Pliny's opinion with regard to the use and advantage of history; the subjects of which are generally matters of weight and importance. And therefore, when a prudent historian thinks it convenient to take notice of things in themselves less considerable, he either does it with brevity, or for some apparent reason, or accounts for it by some just apology. So Dion Cassius, when he has mentioned some things of less moment in the life of Commodus (as indeed that emperor's life was chiefly filled up with cruelty and folly), makes this excuse for himself: "I would not have it thought that I descend below the gravity of history in writing these things: for, as they were the actions of an emperor, and I was present and saw them all, and both heard and conversed with him, I did not think it proper to omit them." He seems to think those actions, when performed by an emperor, might be worth recording, which, if done by a person of inferior rank, would scarce have deserved notice. Nor does he appear to have judged amiss, if we consider what an influence the conduct and behaviour of princes, even in the common circumstances of life, have upon all beneath them; which may sometimes render them not unworthy the regard of an historian, as examples either for imitation or abhorrence.

But although facts in general are the proper subject of history, yet they may be differently considered with regard to the extent of them, as they relate either to particular persons or communities of men. And from this consideration history has

been distinguished into three sorts, viz. *biography*, *particular* and *general history*. The lives of single persons is called *biography*. By *particular history* is meant that of particular states, whether for a shorter or longer space of time. And *general history* contains an account of several states existing together in the same period of time.

1. The subjects of *biography* are the lives either of public or private persons; for many observations useful in the conduct of human life may be made from just accounts of those who have been eminent and beneficial to the world in either station. Nay, the lives of vicious persons are not without their use, as warnings to others, by observing the fatal consequences which sooner or later generally follow such practices. But, for those who exposed their lives, or otherwise employed their time and labour, for the service of their fellow-creatures, it seems but a just debt that their memories should be perpetuated after them, and posterity acquainted with their benefactors. The expectation of this was no small incentive to virtue in the Pagan world. And perhaps every one, upon due reflection, will be convinced how natural this passion is to mankind in general. And it was for this reason, probably, that Virgil places not only his heroes, but also the inventors of useful arts and sciences, and other persons of distinguished merit, in the Elysian Fields, where he thus describes them:

Here patriots live, who, for their country's good,
In fighting fields were prodigal of blood:
Priests of unblemish'd lives here make abode,
And poets worthy their inspiring god;
And searching wits of more mechanic parts,
Who grac'd their age with new-invented arts;
Those who to worth their bounty did extend,
And those who knew that bounty to commend:
The heads of these with holy fillets bound,
And all their temples were with garlands crown'd.

ÆNEID, l. vi. v. 66.

In the lives of public persons, their public characters are principally, but not solely, to be regarded. The world is inquisitive to know the conduct of princes and other great men, as well in private as in public; and both, as has been said, may be of service, considering the influence of their examples. But to be over-inquisitive in searching into the weaknesses and infirmities of the greatest or best of men, is, to say no more of it, but a needless curiosity. Among writers of this kind, Plutarch is justly allowed to excel.

But it has been a matter of dispute among the learned, whether any one ought to write his own history. It may be pleaded in favour of this, that no one can be so much master of the subject as the person himself: and besides, there are many instances, both ancient and modern, to justify such a conduct. But on the other hand it must be owned, that there are many inconveniencies which attend it; some of which are mentioned by Cicero. "If (says he) there is any thing commendable, persons are obliged to speak of themselves with greater modesty, and to omit what is blameable in others. Besides, what is said is not so soon credited, and has less authority; and after all, many will not stick to censure it." *Ad Fam. lib. v. ep. 12.* And Pliny says what is to the same purpose, "Those who proclaim their own virtues, are thought not so much to proclaim them because they did them, as to have done them that they might proclaim them. So that which would have appeared great if told by another, is lost when related by the party himself. For when men cannot deny the fact, they reflect upon the vanity of its author. Wherefore, if you do things not worth mentioning, the actions themselves are blamed; and if the things you do are commendable, you are blamed for men-

tioning them." *Lib. viii. Ep. 1.* These reflections will be generally allowed to be very just; and yet considering how natural it is for men to love themselves, and to be inclined in their own favour, it seems to be a very difficult task for any one to write an impartial history of his own actions. There is scarce any treatise of this kind that is more celebrated than Cæsar's Commentaries. And yet Suetonius tells us, that "Asinius Pollio (who lived at that time) thought they were neither written with due care nor integrity: that Cæsar was often too credulous in his accounts of what was done by other persons; and misrepresented his own actions, either designedly, or through forgetfulness: and therefore he supposes he would have revised and corrected them." However, at some times it may doubtless be justifiable for a person to be his own historian. Plutarch mentions two cases wherein it is allowable for a man to commend himself, and be the publisher of his own merits. These are, when the doing of it may be of considerable advantage either to himself or others. It is indeed less invidious for other persons to undertake the province. And especially for a person to talk or write of his own virtues, at a time when vice and a general corruption of manners prevails, let what he says be ever so true, it will be apt at least to be taken as a reflection upon others. "Anciently (says Tacitus), many wrote their own lives, rather as a testimony of their conduct than from pride." Upon which he makes this judicious remark: "That the more virtue abounds, the sooner the reports of it are credited." But the ancient writers had a way of taking off the reader's attention from themselves in recording their own actions, and so rendering what they said less invidious: and that was, by speaking of themselves in the third person, and not in the first. Thus Cæsar never says, "I did," or, "I said, this or that;" but always *Cæsar* did, or said, so and so." Why the moderns have not more chosen to follow them in this, we know not, since it seems less exceptionable.

2. In a continued history of *particular* states, some account may be given of their original, and founders; the nature of their soil, and situation; what advantages they have for their support or improvement, either within themselves, by foreign traffic, or conquests; with the form of their government. Then notice should be taken of the methods by which they increased in wealth or power, till they gradually advanced to their highest pitch of grandeur; whether by their virtue, the goodness of their constitution, trade, industry, wars, or whatever cause. After this the reasons of their declensions should be shown; what were the vices that principally occasioned it (for that is generally the case); whether avarice, ambition, luxury, discord, cruelty, or several of these in conjunction. And lastly, where that has been their unhappy fate, how they received their final ruin and subversion. Most of these things Livy had in view when he wrote his history of the Roman state, as he acquaints his readers in the preface. "The accounts (says he) of what happened either before or while the city was building, consisting rather of poetical fables than any certain records of facts, I shall neither assert nor confute them. Let antiquity be allowed to make the origin of their cities more venerable, by uniting things human and divine. But if any nation may be suffered to teach their origin from the gods, such is the military glory of the Romans, that when they represent Mars as the father of their founder, other nations may as easily acquiesce in this as they do in their government. But I lay no great stress upon these things, and others of the like nature, whatever may be thought of them. What I am desirous every one should carefully attend to, are our lives and manners: by what men, and what arts, civil and military, the empire was both acquired and enlarged: then let him observe, how our manners gradually declined with our discipline; afterwards grew worse and worse; and at length so far degenerated, that at present we can neither

bear with our vices, nor suffer them to be remedied. 'This is the chief benefit and advantage to be reaped from history, to fetch instruction from eminent examples of both kinds; in order to imitate the one, which will be of use both to yourself and your country, and avoid the other, which are equally base in their rise and event.'" Thus far Livy. And how well he has executed this design, must be acknowledged by all who will be at the pains to peruse his work.

3. But as a particular history consists in a number of facts relating to the same state, suitably connected and laid together in a proper series; so a *general* history is made up of several particular histories, whose separate transactions within the same period of time, or part of it, should be so distinctly related as to cause no confusion. Such was the history of Diodorus Siculus, which contained an account of most of the eminent states and kingdoms in the world, though far the greatest part of it is now unhappily lost. Of the same nature is the history of Herodotus, though not so extensive; to whom we are especially indebted for the Persian affairs. And to this kind may likewise be referred Justin's history, though it be only the epitome of a larger work written by another hand. The rules proper for conducting such histories are much the same as those above mentioned concerning particular histories; excepting what relates to the *order*, of which we shall have occasion to speak hereafter.

But the histories both of particular states and those which are more general frequently contain only the affairs of some short period of time. Thus the history of the Peloponnesian war, written by Thucydides, comprises only what was done in the first twenty years of that war, which lasted seven years longer than his account reaches; though indeed the reason of that might be, because Thucydides died before the war was finished, otherwise he would very probably have continued his history to the conclusion of it. But the history of the war between the Romans and king Jugurtha in Africa, given us by Sallust, as also Cæsar's histories of the Gallic and civil wars, are all confined within a much less number of years than that of Thucydides. Nay, sometimes one single transaction is thought sufficient to furnish out an history. Such was the conspiracy of Catiline to subvert the Roman state, written likewise by Sallust. As to more general histories, Xenophon's history of Greece may be esteemed as such; which in order of time succeeds that of Thucydides, and contains the affairs of forty-eight years. And Polybius called his a *general history*; which, though it principally contained the Roman affairs, yet took in the most remarkable transactions of several other states, for the space of fifty-three years: though it has met with the same hard fate as that of Diodorus Siculus, so that only the first five books out of forty, of which it consisted at first, now remain entire. And to mention no more, the celebrated history of Thuanus is another instance of this sort, in which the principal transactions of Europe for about 60 years, chiefly in the 16th century, are described with that judgment and fidelity, and in a manner so accurate and beautiful, that he has been thought scarcely inferior to any of the ancient historians. Now, in such histories as these, to go farther back than is necessary to set the subject in a just light, seems as improper as it is unnecessary.

The general subject or argument of history, in its several branches, may be reduced to these four heads; *narration, narration, regression, speeches, and digressions.*

1. By *NARRATION* is meant a description of facts or actions, with such things as are necessarily connected with them; namely, persons, time, place, design, and event.

As to *actions* themselves, it is the business of the historian to acquaint his readers with the manner in which they were performed; what measures were concerted on all sides, and how they were conducted, whether with vigilance, courage, pra-

dence, and caution, or the contrary, according to the nature of the action; as likewise, if any unforeseen accidents fell out, by which the designed measures were either promoted or impeded. All actions may be referred to two heads, military and civil. And as war arises from injustice and injuries received on one side or the other, it is fit the reader should be informed who were the aggressors. For though war is never to be desired, yet it is sometimes necessary. In the description of battles, regard should be had equally to both parties; the number of forces, conduct of the generals, in what manner they engaged, what turns and chances happened in the engagement, either from accidents, courage, or stratagem, and what the event. The like circumstances should all be observed in sieges and other actions. But the most agreeable scene of history arises from a state of peace. Here the writer acquaints us with the constitution of states, the nature of their laws, the manners and customs of the inhabitants, the advantages of concord and unanimity, with the disadvantages of contention and discord; the invention of arts and sciences, in what manner they were improved and cultivated, and by whom; with many other things, both pleasant and profitable in the conduct of human affairs.

As to *persons*, the characters of all those should be described who act any considerable part in an history. This excites the curiosity of the reader, and makes him more attentive to what is said of them; as every one is more inquisitive to hear what relates to others in proportion to his knowledge of them. And it will likewise be of use to observe, how their actions agree with their characters, and what were the effects of their different qualifications and abilities.

The circumstances of *time* and *place* are carefully to be regarded by an historian, without which his accounts of facts will be frequently very lame and imperfect. And therefore chronology and geography seem not improperly to have been called *the two eyes of history*. Besides, they very much assist the memory: for it is much easier to remember any thing said to be done at such a time, and in such a place, than if only related in general; nay, the remembrance of these often recalls those things to mind which otherwise had been obliterated. By time is meant not only the year of any particular era or period; but likewise the season, as summer or winter; and the age of particular persons. For it is oftentimes from hence that we are principally enabled to make a just estimate of facts. Thus Cicero commends Pompey for undertaking and finishing the Piratic war at a season of the year when other generals would not have thought it safe to venture out at sea. This double danger, as well from the weather as the enemy, considering the necessity of the case, heightens the glory of the action; since to have done the same thing in summer would not have been an equal proof of the courage and intrepidity of the general. And there is nothing more surprising in the conquests of Alexander than that he should subdue so large a part of the world by the time he was little more than 30 years old; an age at which few other generals have been much distinguished. Had we not known this, a considerable part of his character had been lost.

The like advantages arise from the other circumstances of place. And therefore in marches, battles, and other military actions, the historian should take notice of the nature of the country, the passes, rivers, distances of places, situation of the armies, and strength of the towns either by nature or art; from which the reader may the better form a judgment of the difficulties and greatness of any enterprise. Cæsar is generally very particular in these things, and seems to have thought it highly requisite in order to give his readers a just idea of his actions. The descriptions of countries, cities, and rivers, are likewise both useful and pleasant; and help us to judge of the probability of what is related concerning the temper and genius

of the inhabitants, their arts, traffic, wealth, power, or whatever else is remarkable among them.

But an accurate historian goes yet further, and considers the *causes* of actions, and what were the *designs* and views of those persons who were principally concerned in them. Some, as Polybius has well observed, are apt to confound the beginnings of actions with their springs and causes, which ought to be carefully separated. For the causes are often very remote, and to be looked for at a considerable distance from the actions themselves. Thus, as he tells us, some have represented Hannibal's besieging Saguntum in Spain, and passing the Ebro, contrary to a former agreement between the Romans and Carthaginians, as causes of the second Punic war. But these were only the beginnings of it. The true causes were the jealousies and fears of the Carthaginians from the growing power of the Romans; and Hannibal's inveterate hatred to them, with which he had been impressed from his infancy. For his father, whom he succeeded in the command of the Carthaginian army, had obliged him, when but nine years old, to take a most solemn oath upon an altar never to be reconciled to the Romans: and therefore he was no sooner at the head of the army, than he took the first opportunity to break with them. Again, the true springs and causes of actions are to be distinguished from such as are only feigned and pretended. For generally the worse designs men have in view, the more solicitous they are to cover them with specious pretences. It is the historian's business, therefore, to lay open and expose to view these arts of politicians. So, as the same judicious historian remarks, we are not to imagine Alexander's carrying over his army into Asia to have been the cause of the war between him and the Persians. That had its being long before. The Grecians had formerly two armies in Asia, one under Xenophon, and the other commanded by Agesilaus. Now the Asiatics did not venture to oppose or molest either of these armies in their march. This made king Philip, Alexander's father, who was an ambitious prince, and aspired after universal monarchy, think it might be a practicable thing to make a conquest of Asia. Accordingly, he kept it in his view, and made preparations for it; but did not live to execute it. That was left for his son. But as king Philip could not have done this without first bringing the other states of Greece into it, his pretence to them was only to avenge the injuries they had all suffered from the Persians; though the real design was an universal government, both over them and the Persians, as appeared afterwards by the event. But in order to our being well assured of a person's real designs, and to make the accounts of them more credible, it is proper we should be acquainted with his disposition, manners, way of life, virtues, or vices; that by comparing his actions with these, we may see how far they agree and suit each other. For this reason Sallust is so particular in his description of Catiline, and Livy of Hannibal; by which it appears credible, that the one was capable of entering into such a conspiracy against his country, and the other of performing such great things as are related concerning him. But if the causes of actions lie in the dark, and unknown, a prudent historian will not trouble himself or his readers with vain and trifling conjectures unless something very probable offers itself.

Lastly, an historian should relate the *issue* and *event* of the actions he describes. This is undoubtedly the most useful part of history; since the greatest advantage arising from it is to teach us experience from what has happened in the world before us. When we learn from the examples of others the happy effects of wisdom, prudence, integrity, and other virtues, it naturally excites us to an imitation of them, and to pursue the same measures in our own conduct. And, on the contrary, by perceiving the unhappy consequences which have followed from violence, deceit, rashness, or the like vices, we are deterred from

such practices. But since the wisest and most prudent measures do not always meet with the desired success, and many cross accidents may happen to frustrate the best-concerted designs; when we meet with instances of this nature, it prepares us for the like events, and keeps us from too great a confidence in our own schemes. However, as this is not commonly the case, but in the ordinary course of human affairs like causes usually produce like effects; the numerous examples of the happy consequences of virtue and wisdom recorded in history are sufficient to determine us in the choice of our measures, and to encourage us to hope for an answerable success, though we cannot be certain we shall in no instance meet with a disappointment. And therefore Polybius very justly observes, that "he who takes from history the causes, manner, and end of actions; and omits to take notice whether the event was answerable to the means made use of, leaves nothing in it but a bare amusement, without any benefit or instruction." These, then, are the several things necessary to be attended to in historical narrations; but the proper disposition of them must be left to the skill and prudence of the writer.

2. REFLECTIONS made by the writer have been condemned by many, as having a tendency to bias the reader; who should be left to draw such conclusions from the accounts of facts as he sees proper. But since all readers are not capable of doing this for themselves, what disadvantage is it for the author to suggest to them such observations as may assist them to make the best use of what they read? And if the philosopher is allowed to draw such inferences from his precepts as he thinks just and proper, why has not the historian an equal right to make reflections upon the facts he relates? The reader is equally at liberty to judge for himself in both cases, without danger of being prejudiced. And therefore we find, that the best historians have allowed themselves this liberty. It would be easy to prove this by a large number of instances, but one or two here may suffice. After Sallust has given a very distinct account of the designs of Catiline, and of the whole scheme of the conspiracy, he concludes it with this reflection: "All that time the empire of the Romans seems to me to have been in a very unhappy state. For when they had extended their conquests through the whole world from east to west, and enjoyed both peace and plenty, which mankind esteem their greatest happiness; some persons were obstinately bent upon their own ruin, and that of their country. For notwithstanding two decrees were published by the senate, not one out of so great a multitude was prevailed with, by the rewards that were offered, either to discover the conspiracy or to leave the army of Catiline—So desperate a disease, and as it were infection, had seized the minds of most people!" *Bell. Catil. c. 37.* And it is a very suitable observation that Livy makes upon the ill-conduct of Hannibal in quartering his army in Capua after the battle of Cannæ; by which means they lost their martial vigour through luxury and ease. "Those (says he) who are skilled in military affairs reckon this a greater fault in the general, than his not marching his army immediately to Rome after his victory at Cannæ; for such a delay might have seemed only to defer the victory, but this ill step deprived him of the power to gain it." *Lib. xxiii. c. 18.* The modesty of the historian in this passage is worth remarking, in that he does not represent this as his own private opinion, and by that means undertake to censure the conduct of so great a general as Hannibal was, but as the sense of those who were skilled in such affairs. However, an historian should be brief in such remarks; and consider, that although he does not exceed his province by applauding virtue, expressing a just indignation against vice, and interposing his judgment upon the nature and consequences of the facts he relates; yet there ought to be a difference between his reflections and the encomiums or declamations of an orator,

3. SPEECHES inserted by historians are of two sorts, namely, oblique and direct. The former are such as the historian recites in his own person, and not in that of the speaker. Of this kind is that of Hannibal in Justin; by which he endeavours to persuade king Antiochus to carry the seat of the war against the Romans into Italy. It runs thus: "Having desired liberty to speak (he said), none of the present counsels and designs pleased him; nor did he approve of Greece for the seat of the war, which might be managed in Italy to greater advantage: because it was impossible to conquer the Romans but by their own arms, or to subdue Italy but by its own forces; since both the nature of those men, and of that war, was different from all others. In other wars, it was of great importance to gain an advantage of place or time, to ravage the countries and plunder the towns; but though you gain some advantage over the Romans, or defeat them, you must still fight with them when beaten. Wherefore, should any one engage with them in Italy, it was possible for him to conquer them by their own power, strength, and arms, as he himself had done; but should he attempt it out of Italy, the source of their power, he would be as much deceived, as if he endeavoured to alter the course of a river, not at the fountain-head, but where its streams were largest and deepest. This was his judgment in private, and what he had offered as his advice, and now repeated in the presence of his friends; that all might know in what manner a war ought to be carried on against the Romans, who were invincible abroad, but might be conquered at home. For they might sooner be driven out of their city than their empire, and from Italy than their province; having been taken by the Gauls, and almost subdued by himself. That he was never defeated till he withdrew out of their country; but upon his return to Carthage, the fortune of the war was changed with the place."—*Lib. xxxi. c. 5.* He seems to intimate by this speech, that the Romans were like some fierce and impetuous animals, which are no otherwise to be subdued than by wounding them in some vital part. In speeches related after this manner, we are not necessarily to suppose the historian gives us the very words in which they were at first delivered, but only the sense. But in direct speeches, the person himself is introduced as addressing his audience; and therefore the words as well as the sense are to be suited to his character. Such is the speech of Eumenes, one of Alexander's captains and successors, made to his soldiers when they had traitorously bound him in chains, in order to deliver him up to his enemy Antigonus, as we have it in the same writer. "You see, soldiers (says he), the habits and ornaments of your general, which have not been put upon me by mine enemies; that would afford me some comfort: it is by you, that of a conqueror I am become conquered, and of a general a captive; though you have sworn to be faithful to me four times within the space of a year. But I omit that, since reflections do not become persons in calamity. One thing I entreat, that, if Antigonus must have my life, you would let me die among you. For it no way concerns him how or where I suffer, and I shall escape an ignominious death. If you grant me this, I free you from your oath, with which you have been so often engaged to me. Or, if shame restrains you from offering violence to me at my request, give me a sword, and suffer your general to do that for you without the obligation of an oath which you have sworn to do for your general." *Lib. 14. c. 4.*

But this likewise is a matter in which critics have been divided in their sentiments; whether any, or what kind, of speeches ought to be allowed in history. Some have thought all speeches should be excluded: and the reason given for that opinion is this; that it breaks the thread of the discourse, and interrupts the reader, when he is desirous to come to the end of an action, and know how it issued. This is true, indeed, when speeches are either very long or too frequent; but otherwise

they are not only entertaining, but likewise instructive. For it is of service to know the springs and reasons of actions; and these are frequently opened and explained in the speeches of those by whom they were performed. Others therefore have not been against all speeches in general, but only direct ones. And this was the opinion of Trogius Pompeius, as Justin informs us; though he did not think fit to follow him in that opinion, when he abridged him, as we have seen already by the speech of king Eumenes. The reason offered against direct speeches is, because they are not true; and truth is the foundation of all history, from which it ought never to depart. Such speeches, therefore, are said to weaken the credit of the writer; since he who will tell us that another person spoke such things which he does not know that he ever did speak, and in such language as he could not use, may take the same liberty in representing his actions. Thus, for example, when Livy gives us the speeches of Romulus, the Sabine women, Brutus, and others, in the first ages of the Roman state, both the things themselves are imaginary, and the language wholly disagreeable to the times in which those persons lived. Accordingly we find, that when several historians relate some particular speech of the same person, they widely differ both in the subject-matter and expressions. So the speech of Veturia, by which she dissuaded her son Coriolanus from besieging Rome, when he came against it with an army of Volscians to avenge the injuries he had received, is very differently related by Livy, Dionysius of Halicarnassus, and Plutarch. Such fictitious speeches therefore are judged more fit for poets, who are allowed a greater liberty to indulge their fancy than historians. And if any direct speeches are to be inserted, they should be such only as were really spoken by the persons to whom they are ascribed, where any such have been preserved. These have been the sentiments of some critics both ancient and modern. See Voss. *Ars Hist.* c. 20. However, there is scarce an ancient historian now extant, either Greek or Latin, who has not some speeches, more or less, in his works; and those not only oblique, but also direct. They seem to have thought it a necessary ornament to their writings: and even where the true speeches might be come at, have chosen rather to give them in their own words; in order, probably, to preserve an equality in the style. Since therefore the best and most faithful historians have generally taken this liberty, we are to distinguish between their accounts of facts and their speeches. In the former, where nothing appears to the contrary, we are to suppose they adhere to truth, according to the best information they could get; but in the latter, that their view is only to acquaint us with the causes and springs of actions, which they chose to do in the form of speeches, as a method most ornamental to the work, and entertaining to the reader: though the best historians are cautious of inserting speeches, but where they are very proper, and upon some solemn and weighty occasions. Thucydides is said to have been the first who brought complete and finished speeches into history, those of Herodotus being but short and imperfect. And though Dionysius of Halicarnassus, in his censure upon Thucydides, seems then to have disliked that part of his conduct; yet he afterwards thought fit to imitate it in his *Antiquities of Rome*, where we find many not only oblique, but also direct orations.

What has been said of speeches, may likewise be understood of letters, which we sometimes meet with in histories; as that of Alexander to Darius in Q. Curtius, those of Tiberius and Drusus in Tacitus, and many others. Some letters are wholly fictitious; and in others perhaps the historian represents the substance of what was really said, but gives it his own dress. Thus we find that short letter of Lentulus to Catiline at the time of his conspiracy differently related by Cicero and Sallust.

The reason of which seems to be this: That as Cicero recited it publicly to the people of Rome in his third oration against Catiline, it is reasonable to imagine he did it in the very words of the letter which he had by him: whereas Sallust, as an historian, might think it sufficient to give the sense of it in his own words.

4. **DIGRESSIONS.** These, if rightly managed, afford the reader both delight and profit. Like speeches, they should neither be too long nor frequent; lest they interrupt the course of the history, and divert the reader from the main design of the work. But now and then to introduce a beautiful description, or some remarkable incident, which may give light to the subject, is so far from an interruption, that it is rather a relief to the reader, and excites him to go on with greater pleasure and attention. See further on this head, the article **ORATORY.**

SECT. III. *Of Order.*

SINCE most histories consist of an introduction and the body of the work, in each of which some order is requisite, we shall speak of them separately.

1. The design of the introduction is the same here as in orations. For the historian proposes three things by his introduction, which may be called its parts; to give his reader some general view of the subject, to engage his attention, and to possess him with a candid opinion of himself and his performance. Some have thought this last unnecessary for an historian; but if we consider how differently mankind are apt to judge of the same persons and actions, it seems as requisite for an historian to be well esteemed as an orator; and therefore we find some of the best historians have not omitted this part. Livy's introduction has been very much applauded by the learned, as a master-piece in its kind. It begins with an account of his design. "Whether (says he) it may answer any valuable end for me to write the history of the Roman affairs from the beginning of the city, I neither am certain, nor if I was should I venture to declare it." Soon after he endeavours to prepare the reader's attention, by representing the grandeur and usefulness of the subject in the following words: "Either I am prejudiced in favour of my subject, or there never was any state greater, more virtuous, and fruitful of good examples, or in which avarice and luxury had a later admittance, or poverty and thriftiness were either more highly or longer esteemed, they always coveting less the less they enjoyed." And then he presently proceeds to ingratiate himself with his readers, and gain their favourable opinion: "Although my name is obscure in so great a number of writers, yet it is a comfort that they cloud it by their fame and character. But I shall gain this advantage by my labour, that I shall be diverted for a time from the prospect of those evils which the age has seen for so many years; while my mind is wholly intent upon former times, free from all that care which gives the writer an uneasiness, though it cannot bias him against the truth." In this passage we see he endeavours to gain the good esteem of his readers from two very powerful motives, modesty and a strict regard to truth. It may scarce seem necessary to observe, that those introductions are esteemed the best which are most natural; that is, such as are taken from the subject-matter of the history itself, and closely connected with it. Such are those of Herodotus, Thucydides, Livy, Tacitus, and others. And therefore Sallust is greatly blamed by Quintilian on the account of his introductions, which are so general, that they might suit other histories as well as those to which they are prefixed. Introductions should likewise be proportioned to the length of the work. We meet with some few histories, in which the writers immediately enter upon their subject, without any introduction; as Xenophon in his

Expedition of the younger Cyrus, and Cæsar in his Commentaries of the Gallic and Civil Wars. But the latter does not profess to write a just history; and therefore left himself more at liberty, as well in this respect as in some others.

2. But order is principally to be regarded in the body of the work. And this may be managed two ways; either by attending to the time in a chronological series, or the different nature and circumstances of the things contained in the history. However, as these two methods do not equally suit all subjects, we shall a little consider to what kind of histories each of them seems more properly adapted. All history then, as we have observed already, may be reduced to three sorts; *biography*, the *history of particular states*, and the *general history of several states* existing at the same time.

In biography, or the lives of particular persons, most writers follow the order of time; though some reduce them to certain general heads, as their virtues and vices, or their public and private character. Plutarch and Cornelius Nepos have taken the former method, and Suetonius the latter.

As to the history of particular states, the order of time is generally best, as being most natural and easy. And therefore it has usually been observed by the best historians, as Thucydides, Livy, and others. Tacitus, indeed, wrote two distinct works; one of which he called *Annals*, and the other *Histories*. And as in both he has kept to the order of time, critics have been at a loss to assign any other reason for these different titles, unless that in the former work he confines himself more closely to the facts themselves, and does not treat so largely upon the causes, manner, or event of them, as he has done in the latter. And even in the circumstances of facts, there is a certain order proper to be observed, for rendering the account more plain and intelligible. Thus, for instance, in the description of a battle or siege, the time should first be known, then the chief person or persons who conducted it, then the number of forces, and other requisites, afterwards the nature of the place, then the action itself, and lastly the event. But sometimes it is necessary to add the time in which several of the other circumstances happened, especially in actions of any considerable length. Where the order of these circumstances is confused, it perplexes the account, and renders it both less entertaining to the reader, and more difficult to remember.

In a general history, the order of time cannot always be preserved; though, where the actions of different communities have respect to one as the principal, they should all, as far as possible, be referred to the transactions of that state. But even here the several affairs of those different states ought to be related separately, which will necessarily occasion the anticipating some things, and postponing others, so that they cannot all stand in the order of time in which they were performed. However, Velleius Paterculus says very justly with regard to this subject, "That every entire action, placed together in one view, is much better apprehended than if divided by different times." In this case, therefore, for better preserving the chronology, it is usual with historians, when they have finished any particular narrative, in passing to the next, to express the time by some short and plain transition; and sometimes to apologize for themselves, by assigning the reasons of their conduct. So Polybius, whose history is of this kind, says concerning himself: "As in writing the actions of each year, in the order of time, I endeavour to represent the affairs of the same nation together in one summary view, it is plain that inconvenience must of course attend this way of writing." Curtius professes only to write the actions of Alexander king of Macedon; but his history contains in it the principal affairs of the greatest states in the world during that period. Now although, in the course of those transactions, the war between Archelaus governor of Macedonia and Agis king of Sparta happened

before the battle of Alexander at Arbela; yet the historian not only relates that battle first, but carries on the account of Alexander's affairs in Asia to the death of Darius without interruption; for which he gives this reason: "If I should relate the affairs of Alexander, which happened in the mean time, either in Greece or Illyrium and Thrace, each in their proper order and time, I must interrupt the affairs of Asia; which it is much better to represent together in one continued series as they fell out, to the flight and death of Darius." *Lib. v. init.* Such anachronisms, therefore, are nothing more than what necessarily arise sometimes from the nature of the subject: as every thing, the more complex it is, and containing under it a greater number of parts, is more difficult to be digested in a regular order. But in an history composed of several states, whose affairs are independent of one another, the actions of each nation must necessarily be separated, in order to represent them in a just view, and prevent confusion. This is the method which Herodotus has taken, as likewise Diodorus Siculus and Justin. Now both the pleasure and benefit which such histories afford, arise from observing the conduct of each state separately in the course of their affairs, and then comparing one with the other. And as the order of time must frequently be interrupted, it is not unusual to continue the chronology at proper distances in relating the affairs of each nation; which preserves an unity in the whole, and connects it in one consistent body.

The division of histories into books was designed only for the better distinction of the subject and ease of the reader. The dividing these books again into chapters, is rather a practice of later editors (founded, as they have thought, on the same reasons) than countenanced by the example of ancient writers.

SECT. IV. Of Style.

AN historical style is said to be of a middle nature, between that of a poet and an orator, differing from both not only in the ornamental parts, but likewise in the common idioms and forms of expression.

Cicero observes, (*De Clar. Orat. c. 75*), that "nothing is more agreeable in history than brevity of expression, joined with purity and perspicuity." Purity indeed is not peculiar to history, but yet is absolutely necessary; for no one will ever think him fit to write an history who is not master of the language in which he writes: and therefore when Albinus had written an history of the Roman affairs in Greek, and apologized for any slips or improprieties that might be found in the language upon the account of his being a Roman, Cato called him a trifler, for choosing to do that which, after he had done it, he was obliged to ask pardon for doing. Nor is perspicuity less requisite in an historical style. The nature of the subject plainly directs to this. For as history consists principally in narration, clearness and perspicuity is nowhere more necessary than in a relation of facts. But these two properties are to be accompanied with brevity, since nothing is more disagreeable than a long and tedious narrative. And in this respect an historical style differs both from that of poetry and oratory. For the poet frequently heightens and enlarges his descriptions of facts, by dwelling upon every circumstance, placing it in different views, and embellishing it with the finest ornaments of wit and language, to render his images more agreeable; and the orator often does the like, with a design to interest the passions. But such colouring is not the province of an historian, who aims at nothing more than a just and faithful representation of what he relates, in a way best suited to its nature, and in such language as is most proper to set it in a plain and satisfactory light.

Again, Cicero, (*De Orat. lib. ii. c. 17. 20*), treating of an historical style, says: "It ought to be fluent, smooth, and

even; free from that harshness and poignancy which is usual at the bar." The properties here mentioned distinguish this style from that of judicial discourses, in which the orator often finds it necessary to vary his manner of speaking, in order to answer different views, either of pursuing an argument, pressing an adversary, addressing a judge, or recommending the merits of his cause. This occasions an inequality in his style, while he speaks sometimes directly, at other times by way of question, and intermixes short and concise expressions with round and flowing periods. But the historian has no necessity for such variations in his style. It is his province to espouse no party, to have neither friend nor foe, but to appear wholly disinterested and indifferent to all; and therefore his language should be smooth and equal in his relations of persons and their actions.

But further: Dionysius (*Epist. ad Cu. Pompeium*) makes "decency a principal virtue in an historian;" which he explains by saying, that "he ought to preserve the characters of the persons and dignity of the actions of which he treats." And to do this it seems necessary that an historical style should be animated with some degree of life and vigour; without which neither the characters of eminent persons, nor their remarkable actions, which make up the main business of history, can be duly represented: for even things in themselves great and excellent, if related in a cold and lifeless manner, often do not affect us in a degree suitable to their dignity and importance. And this seems particularly necessary in speeches, in order to represent what every one says, according to his different country, age, temper, and station of life, in the same manner we may suppose he either really did, or would have spoken himself on that occasion. Besides, there are some scenes of action which require very pathetic and moving language to represent them agreeably to their nature: and in descriptions, the most beautiful tropes and lively figures are often necessary to set the ideas of things in a proper light. From whence it appears, that painting and imagery make up no small part of the historian's province, though his colours are not so strong and glittering as those either of the poet or orator. He ought therefore to be well acquainted with the manners of men and the nature of the passions, since he is often obliged to describe both; in the former of which Herodotus excels, and Thucydides in the latter, as Dionysius has observed,

Now from these several properties laid down by ancient writers, as requisite for an historical style, it seems upon the whole to agree best with the middle character. And this will further appear, by what they say relating to the ornamental parts of style; namely, composition and dignity. As to the former of these, which respects the structure of sentences, and the several parts of them, Demetrius remarks, that "An historical period ought neither to rise very high, nor sink very low, but to preserve a medium." This simplicity (he says) "becomes the gravity and credit of history; and distinguishes it from oratory on the one hand, and dialogue on the other." His meaning is, that historical periods should neither be so full and sonorous as is frequent in oratory; nor yet so short and flat as in dialogue: the former of which, as he says, require a strong voice to pronounce them; and the latter have scarce the appearance of periods. So that according to this judicious writer, the periods best suited for history are those which, being of a moderate length, will admit of a just rise and cadency, and may be pronounced with ease. And Dionysius tells us, that "History should flow smoothly and evenly, every where consistent with itself, without roughness or chafms in the sound." This relates to the harmony of periods, which arises from such a position of the words, as renders the sound pleasant and agreeable, and, as he thinks, ought to be attended

to in history. And as to dignity, which respects the use of tropes and figures, the same author says, that "History should be embellished with such figures as are neither vehement nor carry in them the appearance of art." This is agreeable to what Cicero observes, in comparing Xenophon and Calisthenes, two Greek historians. "Xenophon the Socratic (says he) was the first philosopher, and after him Calisthenes, the scholar of Aristotle, who wrote an history: the latter almost like a rhetorician; but the style of the former is more moderate, and has not the force of an orator, less vehement perhaps, but in my opinion more sweet and pleasant." The difference between these two writers, with regard to their style, consisted chiefly in the choice of their figures; which in Xenophon were more gentle and moderate, and therefore in the judgment of Cicero more agreeable to history.

But notwithstanding this general account of the several properties which constitute an historical style, it admits of considerable varieties from the different nature and dignity of the subject. The lives of particular persons do not require such strength and majesty of expression, nor all those ornaments of language, as an history of the Roman empire. And accordingly we find the style of Nepos and Suetonius very different from that of Livy. The former is smooth and easy, scarce rising above the low character: but the latter often approaches near to the sublime; and other historians again have kept a medium between these. Upon the whole, therefore, we may conclude, that the middle style is the proper character for history; though historians may sometimes sink into the low character, and at other times rise to the grandeur and magnificence of the sublime, from the different nature of their subject, or of particular parts of it: for that is to be esteemed the proper character of any writing which in general best suits it. And this distinction may help us in some measure to reconcile the sentiments of writers upon this head who seem to attribute different characters to an historical style, or at least to judge where the truth lies; since a variety of style is not only requisite in different subjects, but likewise in different parts of the same work.

EXPLANATION OF THE CHART OF HISTORY.

By the plan set forth in plate II. events may be referred to the year of the world; and, within the proper periods, to the areas of the Olympiads, of Nabonassar, and of Rome; but the principal reference is to the birth of Christ, marked by a deep black line.

The plan extends only to the Flood; the preceding period of 1656 years is therefore left blank in the chart.

There being 2348 years from the Flood to the birth of Christ, the space between them is divided into 23 parts, each representing an hundred years or century, and a fraction representing the remaining 48 years.

As we are now in the 18th century, the space from the birth of Christ downwards is divided into eighteen parts or centuries: and all these parts, together with some centuries preceding the birth of Christ, are subdivided into tens.

The vertical columns, titled at top, are geographical divisions; and events are marked in their proper centuries and proper columns. Thus the rise of any state, as that of Assyria, is marked in its proper geographical column, and in that place of the 21st century before Christ at which the beginning of its history is dated; from thence we trace its continuance to the end of the 7th century before Christ, when it became extinct. The building of Rome is marked about the middle of the 8th century before Christ. Its territory extends by degrees to the conquest of all Italy; next to Spain, Macedonia, &c. until it comes to extend from Britain to Egypt. It con-

times of this greatness until about the middle of the 5th century after Christ, when it begins to lose those provinces out of which the modern kingdoms of Europe have been formed in the order here set down. As the order in which states have risen or fallen, relatively to one another, appears on mere inspection, it will be more easily remembered than when it is conveyed in numbers only.

The dates are taken chiefly from Blair's Chronological Tables. Use has likewise been made of the Chart of Universal History, formed on a design like this, but differently executed. Perhaps compared to that chart, the present may be thought incomplete; yet it would not have been difficult to have extended it considerably, and filled it up with remarkable events, successions of kings, and lives of great men; but clearness and simplicity seemed more an object, and therefore it was thought

proper to leave to every person the filling up of his own plan with such articles as are most in the way of his curiosity and study. We have given indeed a few specimens in the succession of the Roman emperors, of the kings of England and France; and in the lives of one or two remarkable men, as in those of Tacitus the historian, and Attila. One person may choose to fill his plan with the names of statesmen and warriors, another with scholars and men of letters. To attempt inserting all that deserve being recorded, however, would crowd and embarrass the whole.

As space is here employed to represent time, it is material that equal periods should be represented by equal spaces; and, if possible, that the parts of the same empire should be placed together. Both these circumstances are neglected in the Chart of Universal History.

H I T

HISTORY of Nature, or *Natural History*. See NATURAL History.

HISTRIO, in the ancient drama, signified an actor or comedian; but more especially a pantomime, who exhibited his part by gestures and dancing. Livy informs us, that the histriones were brought to Rome from Etruria, in the year of the city 391, (Dec. i. lib. 7.)

HISTRIX. See HYSTRIX.

HITCHING, a large and populous town of Hertfordshire in England, situated near a large wood called *Hitchwood*. It is 15 miles W. N. W. of Hertford, and 34 N. W. of London. The manor was the ancient demesne of the kings of England, as it continues at this day; and it has been the dower of several of their queens. The town is reckoned the second in the county for number of streets, houses, and inhabitants. It was formerly famous for the staple commodities of the kingdom, and divers merchants of the staple of Calais resided here, since which that trade is lost. The inhabitants now make large quantities of malt; and the market is one of the greatest in England for wheat. W. lon. 0. 20. N. lat. 51. 55.

HITHE, a town of Kent in England, 70 miles from London. It is one of the cinque ports; and had formerly five parishes, but by the choaking up of its harbour and other accidents these are now reduced to one. In the reign of Henry IV. numbers of its inhabitants were cut off by a pestilence, 200 of their houses consumed by fire, and five of their ships sunk at sea, with the loss of 100 men; so that the people were going to abandon the town, had not the king by his charter generously released to them, for five turns next following, their service of five ships of 100 men and five horse, which they were to have furnished out and kept at their own charge in the king's wars for 15 days. It was first incorporated by the name of *barons of the town and port of Hith*; but the government was afterwards changed. It was incorporated by Queen Elizabeth with the name of the mayor, jurats, and commonalty of the town and port of Hith, who, with the freemen, elect the members of parliament. The mayor is chosen yearly on Candlemas-day. Here is a market on Saturdays, and fairs in July and December. From hence to Canterbury is a paved Roman military-way, called *Stoney-Street*; and at a little distance from hence are the remains of the walls of a castle, which included 10 acres. There is a remarkable pile of dry bones in the town, 28 feet long, 6 broad, and 8 high; they are kept in a vault under the church in as good order as books in a library, consisting of several thousand heads, arms, legs, thigh-bones, &c. some very gigantic, and appear by an inscription to be the remains of the Danes and Britons killed in a battle near this place, before

Vol. IV.

H O A

the Norman conquest. From hence to Boulogne is reckoned the shortest cut to France. E. lon. 1. 17. N. lat. 51. 6.

HITTITES, the descendants of Heth the father of the Hittites. Heth was the eldest son of Canaan (Gen. x. 15.), and dwelt southward of the promised land, at Hebron, or thereabouts. Ephron, an inhabitant of Hebron, was of the race of Heth, and this whole city in Abraham's time was peopled by the children of Heth. There are some who maintained that there was a city called Heth, but we find no traces of it in the Scriptures.

HIVE, in country affairs, a convenient receptacle for bees. See APIS and BEE.

HIVITES, a people descended from Canaan. They dwelt at first in the country which was afterwards possessed by the Capthorims, or Philistines. There were Hivites likewise at Shechem and Gibeon, and consequently in the centre of the promised land; for the inhabitants of Shechem and the Gibeonites were Hivites, (Josh. xi. 19. Gen. xxxiv. 12.) Lastly, there were some beyond Jordan, at the foot of mount Hermon, (Josh. xi. 3.) Bochart is of opinion, that Cadmus, who carried a colony of Phœnicians into Greece, was an Hivite. His name *Cadmus*, comes from the Hebrew *Kedem*, "the east," because he was of the eastern part of the land of Canaan. The name of his wife *Hermione*, comes from mount Hermon, at the foot whereof the Hivites had their dwelling. The metamorphosis of Cadmus's companions into serpents is grounded on the signification of the name *Hivites*, which in Phœnician signifies "serpents."

HOACHE, in natural history, a kind of earth approaching to the nature of chalk, but harder, and feeling like soap; whence some think that it is either the same with the soap-rock of Cornwall, or very like it. The Chinese dissolve it in water till the liquor is of the consistence of cream, and then varnish their China-ware with it.

HOADLEY (Benjamin), successively bishop of Bangor, Hereford, Salisbury, and Winchester, was born in 1676. His first preferment in the church was the rectory of St. Peter le Poor, and the lectureship of St. Mildred's in the Poultry. In the year 1706 he published some Remarks on the late bishop Atterbury's sermon at the funeral of Mr. Bennet, in which Dr. Atterbury had, in the opinion of Mr. Hoadley, laid down some dangerous propositions. Two years after, Mr. Hoadley again entered the lists against this formidable antagonist; and in his *exceptions* against a sermon published by Dr. Atterbury, intitled "The Power of Charity to cover Sin," he attacked the doctor with his usual strength of reasoning and dispassionate inquiry. In 1709 another dispute arose between these two

learned combatants, concerning the doctrine of non-resistance, occasioned by a performance of Mr. Hoadley's, intitled "The Measures of Obedience;" some positions in which Dr. Atterbury endeavoured to confute in his elegant Latin sermon, preached that year before the London clergy. In this debate Mr. Hoadley signalized himself in so eminent a degree, that the honourable house of commons gave him a particular mark of their regard, by representing, in an address to the queen, the signal services he had done to the cause of civil and religious liberty.—The principles, however, which he espoused being repugnant to the general temper of those times, drew on him the virulence of a party; yet it was at this period (1710, when, as he himself expressed it, *fiery seemed to be let loose upon him*) that the late Mrs. Howland presented him to the rectory of Streat-ham in Surry, unasked, unapplied to, and without his either having seen her or been seen by her. Soon after the accession of king George I. Mr. Hoadley was consecrated to the see of Bangor; and, 1717, having broached some opinions concerning the nature of Christ's kingdom, &c. he again became the object of popular clamour. At this juncture he was distinguished by another particular mark of the royal regard, by means of which the convocation was successively prorogued, and it was not permitted to sit, nor do any business, till that resentment was entirely subsided. In 1721 he was translated to Hereford; and from thence, in 1723, to Salisbury. In 1734 he was translated to Winchester (on the demise of Dr. Willis), and published his *Plain Account of the Sacrament*: a performance which served as a butt for his adversaries to shoot at, yet impartially owns it to be clear, rational, and manly, written with great candour and judgment, and suited to the capacity of every serious and considerate inquirer after truth.—His latter days were embittered by a most vile instance of fraud and ingratitude. The bishop took a French priest, who pretended to abjure his religion, under his protection, with no other recommendation than that of his necessities; in return for which act of humanity, the priest found an opportunity of getting the bishop's name written by his own hand, and, causing a note of some thousand pounds to be placed before it, offered it in payment. But the bishop denying it to be his, it was brought before a court of justice, and was there found to be a gross imposition. The ungrateful villain had now recourse to a pamphlet, in which he charged the bishop with being a drunkard; and alleged that he had the note of him when he was in liquor. To this calumny the bishop made a full and nervous answer; in which he exposed the man's falsehood, and solemnly averred that he was never drunk in his whole life. The world with becoming candour embraced his defence, and he had the happiness to find himself perfectly acquitted even of any suspicion of such a charge. As a writer, he possessed uncommon abilities. His sermons (published in 1754 and 1755) are esteemed inferior to few writings in the English language, for plainness and perspicuity, energy and strength of reasoning, and a free and masterly style. In private life, he was naturally facetious, easy, and complying; fond of company, yet would frequently leave it for the purposes of study or devotion. He was every where happy; and particularly in his own family, where he took all opportunities of instructing by his influence and example. He died in 1761, aged 83. Besides the works already mentioned, he wrote, 1. *Terms of Acceptance*, 8vo. 2. *Reasonableness of Conformity*. 3. *On the Sacrament*. His tracts and pamphlets are extremely numerous; and the reader may see a complete catalogue of them in his Life inserted in the Supplement to the *Biographia Britannica*.

HOADLEY (Benjamin, M. D.), son of the former, was born in 1706; and studied at Bennet-college Cambridge, under the tuition of Dr. Herring afterwards archbishop of Canterbury. He took his degree in physic; and particularly applying him-

self to mathematical and philosophical studies, was, when very young, admitted a member of the Royal Society. He was made register of Hereford while his father filled that see, and was early appointed physician to his majesty's household, but died at his house in Chelsea in 1757. He wrote, 1. *Three Letters on the organs of respiration*, 4to. 2. *The Suspicious Husband*, a comedy. 3. *Observations on a series of electrical experiments*; and, 4. *Oratio anniverfaria, in Theatro Col. Med. Londin. ex Harveii instituto habita die Oct. b. 1742*.

HOAI-NGAN FOU, a city of China, in the province of Hiang-nan. According to Grosier, it is situated in a marsh, and is enclosed by a triple wall. As the ground on which it stands is lower than the bed of the canal, the inhabitants live in continual dread of an inundation. The suburbs extend to the distance of a league on each side of the canal, and form at their extremity a kind of port on the river Hoang-ho. This place is very populous, and every thing in it announces an active and brisk trade. One of those great mandarins who have the inspection of the canals and navigation, and who are also obliged to supply the court with necessary provisions, resides here. This city has eleven other under its jurisdiction; two of which are of the second, and nine of the third class.

HOARSENESS, in medicine, a diminution or temporary loss of the voice, sometimes attended with a preternatural asperity or roughness of utterance. The parts affected are the trachea and larynx. It is occasioned by a slight inflammation of the mucous membrane covering those parts; and is relieved by mucilaginous linctuses; warm diluting drinks, such as bran tea, linseed tea, &c.; assisted by opiate and sudorific medicines taken at bed-time.

HOBAL, in mythology, an idol of the ancient Arabs, the worship of which at Mecca was destroyed by Mahomet.

HOBBS (Thomas), a famous writer, born at Malmesbury in 1588, was the son of a clergyman. He completed his studies at Oxford, and was afterwards governor to the eldest son of William Cavendish, earl of Devonshire. He travelled through France and Italy with that young nobleman, and at length applied himself entirely to the study of polite literature. He translated Thucydides into English; and published his translation in 1628, in order to show his countrymen, from the Athenian history, the disorders and confusions of a democratical government. In 1626 his patron the earl of Devonshire died; and in 1628 his son died also: which loss affected Mr. Hobbes to such a degree, that he very willingly accepted an offer made him of going abroad a second time with the son of Sir Gervase Clifton; whom he accordingly accompanied into France, where he staid some time. But while he continued there, he was solicited to return to England, and to resume his concern for the hopes of that family to whom he had attached himself so early, and to which he owed so many and so great obligations. In 1631 the countess dowager of Devonshire desired to put the young earl under his care, who was then about the age of 13. This was very suitable to Mr. Hobbes's inclinations, who discharged that trust with great fidelity and diligence. In 1634 he republished his translation of Thucydides, and prefixed to it a dedication to that young nobleman, in which he gives a long character of his father, and represents in the strongest terms the obligations he was under to that illustrious family. The same year he accompanied his noble pupil to Paris, where he applied his vacant hours to the study of natural philosophy, and more especially to the perfect understanding of mechanism, and the causes of animal motion. He had frequent conversations upon these subjects with father Marin Mersenne; a man deservedly famous, and who kept up a correspondence with almost all the learned in Europe. From Paris he attended his pupil into Italy, where at Pisa he became known to that great astronomer Galileo Galilei, who communicated to him his notions very freely; and

after having seen all that was remarkable in that country, he returned with the earl of Devonshire into England. Afterwards, foreseeing the civil wars, he went to seek a retreat at Paris; where, by the good offices of his friend father Merfenne, he became known to the famous Renatus Des Cartes, and afterwards held a correspondence with him upon several mathematical subjects, as appears from the letters of Mr. Hobbes published in the works of Des Cartes. But when this philosopher printed afterwards his *Meditations*, wherein he attempted to establish points of the highest consequence from innate ideas, Mr. Hobbes took the liberty of dissenting from him; as did also the French king's mathematical professor, the illustrious Peter Gassendi, with whom Mr. Hobbes contracted a very close friendship, which was not interrupted till the death of the former. In 1642, Mr. Hobbes printed a few copies of his famous book *De Cive*, which, in proportion as it became known, raised him many adversaries, who charged him with instilling principles which had a dangerous tendency. Among many illustrious persons who, upon shipwreck of the royal cause, retired to France for safety, was Sir Charles Cavendish, brother to the duke of Newcastle: and this gentleman, being skilled in every branch of the mathematics, proved a constant friend and patron to Mr. Hobbes; who, by embarking in 1645 in a controversy about squaring the circle, was grown so famous for it, that in 1647 he was recommended to instruct Charles prince of Wales, afterwards king Charles II. in that kind of learning. His care in the discharge of this office gained him the esteem of that prince in a very high degree: and though he afterwards withdrew his public favour to Mr. Hobbes on account of his writings, yet he always retained a sense of the services he had done him; showed him various marks of his favour after he was restored to his dominions; and, as some say, had his picture hanging in his closet. This year also was printed in Holland, by the care of M. Sorbiere, a second and more complete edition of his book *De Cive*; to which are prefixed two Latin letters to the editor, the one by Mr. Gassendi, the other by father Merfenne, in commendation of it: and in 1650 was published at London a small treatise of Mr. Hobbes's, intitled, *Human Nature*; and another, *De corpore politico*, or, "Of the elements of the law."

All this time Mr. Hobbes had been digesting, with great care and pains, his religious, political, and moral principles, into a complete system, which he called the *Leviathan*, and which was printed in English at London in 1650 and 1651. After the publication of his *Leviathan* he returned to England, and passed the summer commonly at his patron the earl of Devonshire's seat in Derbyshire, and some of his winters in town, where he had for his intimate friends some of the greatest men of the age. In 1660, upon the restoration, he quitted the country, and came up to London, where he obtained from the king assurance of protection, and had an annual pension of 100*l.* settled upon him out of the privy purse. Yet this did not render him entirely safe: for, in 1666, his *Leviathan*, and his treatise *De Cive*, were censured by parliament; which alarmed him very much, as did also the bringing in of a bill into the house of commons to punish atheism and profaneness. When this storm was a little blown over, he began to think of procuring a beautiful edition of his pieces that were in Latin; but finding this impracticable in England, he caused it to be undertaken abroad, where they were published in quarto in 1668, from the press of John Bleau. In 1669 he was visited by Cosmo de Medicis, then prince, afterwards duke of Tuscany, who gave him ample marks of his esteem and respect; and having received his picture, and a complete collection of his writings, caused them to be repositied, the former among his curiosities, the latter in his noble library at Florence. The like visits he received from foreign ambassadors and other strangers of distinction; who were curious to see a person whose singular opi-

nions and numerous writings had made so much noise all over Europe. In 1672 he wrote his own life in Latin verse, when, as he observes, he had completed his 84th year: and, in 1647, he published in English verse four books of Homer's *Odyssey*; which was so well received, that it encouraged him to undertake the whole *Iliad* and *Odyssey*, which he likewise performed and published in 1675. About this time he took his leave of London, and went to spend the remainder of his days in Derbyshire: where, however, he did not remain inactive, notwithstanding his advanced age; but published from time to time several pieces, to be found in the collection of his works. He died in 1679, aged 92.

As to his character and manners, they are thus described by Dr. White Kennet, in his *Memoirs of the Cavendish family*. "The earl of Devonshire (says he) for his whole life entertained Mr. Hobbes in his family, as his old tutor, rather than as his friend or confidant. He let him live under his roof in ease and plenty, and in his own way, without making use of him in any public, or so much as domestic affairs. He would often express an abhorrence of some of his principles in policy and religion; and both he and his lady would frequently put off the mention of his name, and say, 'He was a humorist, and nobody could account for him.' There is a tradition in the family, of the manners and customs of Mr. Hobbes, somewhat observable. His professed rule of health was to dedicate the morning to his exercise, and the afternoon to his studies. And therefore, at his first rising, he walked out, and climbed any hill within his reach; or if the weather was not dry, he fatigued himself within doors by some exercise or other, to be in a sweat: recommending that practice upon this opinion, that an old man had more moisture than heat, and therefore by such motion heat was to be acquired and moisture expelled. After this, he took a comfortable breakfast; and then went round the lodgings to wait upon the earl, the countess, and the children, and any considerable strangers, paying some short addresses to all of them. He kept these rounds till about 12 o'clock, when he had a little dinner provided for him, which he ate always by himself without ceremony. Soon after dinner he retired to his study, and had his candle with 10 or 12 pipes of tobacco laid by him; then shutting his door, he fell to smoking, thinking, and writing, for several hours. He retained a friend or two at court, and especially the lord Arlington, to protect him if occasion should require. He used to say, that it was lawful to make use of ill instruments to do ourselves good: 'If I were cast (says he) into a deep pit, and the devil should put down his cloven foot, I would take hold of it to be drawn out by it.' After the restoration he watched all opportunities to ingratiate himself with the king and his prime ministers; and looked upon his pension to be more valuable as an earnest of favour and protection, than upon any other account. His future course of life was to be free from danger. He could not endure to be left in an empty house. Whenever the earl removed, he would go along with him, even to his last stage, from Chatsworth to Hardwick. When he was in a very weak condition, he dared not to be left behind, but made his way upon a feather-bed in a coach, though he survived the journey but a few days. He could not bear any discourse of death, and seemed to cast off all thoughts of it: he delighted to reckon upon longer life. The winter before he died, he made a warm coat, which he said must last him three years, and then he would have such another. In his last sickness his frequent questions were, Whether his disease was curable? and when intimations were given, that he might have ease, but no remedy, he used this expression, 'I shall be glad to find a hole to creep out of the world at;' which are reported to have been his last sensible words; and his lying some days following in a silent stupefaction, did seem owing to his mind more than to his body."

The reverend Mr. Granger observes, that Hobbes's style is incomparably better than that of any other writer in the reign of Charles I. and was for its uncommon strength and purity scarcely equalled in the succeeding reign. "He has in translation (says he) done Thucydides as much justice as he has done injury to Homer; but he looked upon himself as born for much greater things than treading in the steps of his predecessors. He was for striking out new paths in science, government, and religion; and for removing the land-marks of former ages. His ethics have a strong tendency to corrupt our mora's, and his politics to destroy that liberty which is the birthright of every human creature. He is commonly represented as a sceptic in religion, and a dogmatist in philofophy; but he was a dogmatist in both. The main principles of his Leviathan are as little founded in moral or evangelical truths, as the rules he has laid down for squaring the circle are in mathematical demonstration. His book on human nature is esteemed the best of his works."

HOBBIMA (Minderhout), an eminent landscape painter, was born about the year 1611 at Antwerp; but the master from whom he received his instruction is not known. He studied entirely after nature, sketching every scene that afforded him pleasure, and his choice was exceedingly picturesque. His grounds are always agreeably broken, and he was particularly fond of describing slopes diversified with shrubs, plants, or trees, which conducted the eye to some building, ruin, grove, or piece of water, and frequently to a delicate remote distance, every object perspectively contributing to delude our observation to that point. The figures which he himself designed are but indifferent, which was a defect imputable to Claude Lorraine and Gaspar Poussin as well as to Hobbima; but the latter, conscious of his inability in that respect, admitted but few figures into his designs, and those he usually placed somewhat removed from the immediate view at a prudent distance from the front line. However, most of his pictures were supplied with figures by Ostade, Teniers, and other very famous masters, which must always give them a great additional value. They are now exceedingly scarce, and industriously sought for.

HOBBY, the name of a hawk called by some authors *sub-butco*. See **FALCO**. It is a hawk of the lure, and not of the fist; and is very like the faker, only much less. It makes excellent sport with net and spaniels; for when the birds see the hobby, they dare not commit themselves to the wing, but lie close to the ground, and so are taken in nets.

HOBBY is also a name formerly given to strong active horses of a middling size: they are reported to have been originally natives of Ireland, and were much liked and used. Nags answer the same description as to size, qualities, and employments.

HOBGOBLIN is a name vulgarly applied to fairies or apparitions. Skinner calls the word *robgooblin*, and derives it from Robin Goodfellow, Hob being the nick-name of Robin: but Wallis and Junius, with greater probability, derive it from *bopgoblins*, *empusæ*, because they are supposed to hop without moving both their feet.

HOBLERS, or **HOBILERS**, *Hobelarii*, in our ancient customs, were men who, by their tenure, were obliged to maintain a light horse or hobby, for the certifying any invasion towards the sea-side. The name was also used for certain Irish knights, who used to serve as light horsemen upon hobbies.

HOB-NAIL, a nail with a thick strong head, used in shoeing a hobby or little horse.

HOB-NOB, or **HAB-NAB**, a cant word formed from *hap ne hap*, and denoting an event which happens at random or by mere chance.

HOBOO, a name given by the people of Otaheite, and in the neighbouring islands of the South Sea, to their superfluous

cloth. It is the thinnest and most finished preparation of the aouta.

HOBSSHEE-COFFREES, a kind of Abyssinian slaves very frequent in the empire of Hindoostan. They come mostly from a province subject to the Negus of Ethiopia, called Innariah, to the south of his other dominions, and bordering upon Negroland in Africa; from whence they are selected, and a great traffic made of them over all Mogolistan and Persia; but it is chiefly from the ports of Arabia and the Red Sea that they are brought. Nothing can be imagined more smooth or glossy, and perfectly black, than their skin; in which they far surpass the negroes on the coast of Guinea; and, generally speaking, have not any thing of their thick lips, though otherwise as woolly haired as they. They are highly valued for their courage, fidelity, and shrewdness; in which they so far excel, as often to rise to posts of great honour, and are made governors of places under the title *Siddes*.

HOBSON'S CHOICE, a vulgar proverbial expression, applied to that kind of choice in which there is no alternative. It is said to be derived from the name of a carrier at Cambridge, who let out hackney horses, and obliged each customer to take in his turn that horse which stood next the stable door.

HOCHBERG, a marquisate of Brisgaw, in Germany, in the circle of Suabia. It belongs to the prince of Baden Dourlach.

HOCHSTET, a town of Germany, in the circle of Suabia, remarkable for the great battle gained near it by the duke of Marlborough in 1704, and which the English call the battle of Blenheim, from a village of that name 3 miles S. W. of this. It is seated on the Danube, 22 miles N. E. of Ulm. E. lon. 10. 33. N. lat. 38. 48.

HO-CHUN, a town of China, of the third rank, in the province of Chan-si: thirty-two miles S. of Ping-ting.

HOCHWEISH, a town of Hungary, twenty miles W. S. W. of Kremnitz.

HOCUS-POCUS, a cant expression with which the exhibitors of legerdemain tricks generally preface their feats. The word is thought to be derived from that arch legerdemain trick of the Romish priests converting the sacramental bread into Deity; in which wonderful metamorphosis the words *boc est corpus* make a conspicuous part of the ceremony, and which words may be considered as the probable root of our modern *bocus pocus*.

HOD, a sort of tray for carrying mortar, in use among Bricklayers.

HODDESDON, a town of England, in the county of Hertford, near the river Lea, with a weekly market on Wednesday: four miles S. of Hertford, and seventeen N. of London.

HODEGOS, a term purely Greek, *ὁδηγος*, signifying *guide*. The word is chiefly used as the title of a book composed by Anastasius the Sinate, towards the close of the fifth century; being a method of disputing against the heretics, particularly the Acephali. Mr. Toland has also published a dissertation under the same title. Its subject is the pillar of fire, &c. which went before the Israelites as a guide in the desert.

HODGE-PODGE. See **HOTCH-POT**.

HODMAN, a cant term formerly used for a young scholar admitted from Westminster school to be student in Christ-church in Oxford.

HODY (Humphry), a learned English divine, was born in 1659. At 21 years of age he published his celebrated Dissertation against Aristæus's history of the 70 interpreters; which was received with great applause by all the learned, Isaac Vossius excepted, who could not bear to have his opinions opposed by such a youth. Twenty years after, he treated the subject more fully in his *De Bibliorum textibus originalibus, versionibus Græcis & Latina vulgata, libri IV.* In 1689 he wrote the

Prolegomena to John Melala's Chronicle, printed at Oxford; and the year after was made chaplain to Dr. Stillingfleet bishop of Worcester. The deprivation of the nonjuring bishops engaged him in a controversy with Mr. Dodwell; which recommended him to archbishop Tillotson, to whom, and his successor Dr. Tennison, he was domestic chaplain. In 1698 he was made regius professor of the Greek tongue at Oxford, and archdeacon of Oxford in 1704. On occasion of the controversy about the convocation, he in 1701 published a history of English councils and convocations, and of the clergy's sitting in parliament, &c. He died in 1706, leaving in MS. An account of those learned Grecians who retired to Italy on the taking of Constantinople, &c. which was published in 1742 by Dr. Jebb.

HOE, a husbandman's tool, somewhat like a cooper's adz, to cut up weeds in gardens, fields, &c. This instrument is of great use, and ought to be much more employed than it is in hacking and clearing the several corners and patches of land in spare times of the year, which would be no small advantage to it.

Horse-Hoe a large kind of hoe drawn by horses, and used to stir the intervals in the new husbandry, and clear the corn from weeds. See HUSBANDRY.

HOEING, in the new husbandry, is the breaking or dividing the soil by tillage while the corn or other plants are growing thereon. It differs from common tillage (which is always performed before the corn or plants are sown or planted) in the time of performing it; and it is much more beneficial to the crops than any other tillage. This sort of tillage is performed various ways, and by means of different instruments, as described under the article HUSBANDRY.

HOEI-TCHEOU, the most southern city of the province of Kiang-nan of China, and one of the richest of the empire. The people are economical and temperate, but they are active and enterprising in trade. They boast of their tea, varnish, and engravings, which are indeed the most esteemed in China. It has dependent upon it six cities of the third class; the mountains which surround this canton contain gold, silver, and copper mines.

HOEMATOPUS, in ornithology; a genus of birds, of the order of grallæ. See plate 3. It has a long compressed bill, with the end cuneated; the nostrils are linear, and the feet have only three toes. There is but one species, the *ostralegus*, sea-pie, or oyster-catcher. They are very common on most of our coasts; feeding on marine insects, oysters, limpets, &c. Their bills, which are compressed sideways and end obtusely, are very fit instruments to insinuate between the limpet and the rock to which these shells adhere; which they do with great dexterity to get at the fish. On the coast of France, where the tides recede so far as to leave the beds of oysters bare, these birds feed on them, forcing the shells open with their bills. They keep in summer time in pairs, laying their eggs on the bare ground: they lay four of a whitish-brown hue, thinly spotted and striped with black; and when any one approaches their young, they make a loud and shrill noise. In winter they assemble in vast flocks, and are very wild. The head, neck, scapulars, and coverts of the wings of this bird, are of a fine black; in some the neck is marked with white; the wings dusky, with a broad transverse band of white; the bill three inches long, and of a rich orange colour.

HOENZOLLERN, a principality of Germany, in the circle of Suabia, divided into branches Hoenzollern, Heckingen, and Hoenzollern Sigmaringen. Each of these princes has a revenue of about 30,000 florins; they are assailed in the matricula of the empire at 290 florins, and taxed to the Imperial chamber forty-three rixdollars twenty-five kruitzers.

HOESHT, a town of Germany, in the circle of the Lower Rhine and electorate of Mentz, seated in a plain, on the river Maine, three miles from Frankfort.

HOFFMAN (MAURICE), was born of a good family, at Furstenwalde, in the electorate of Brandenburg, Sept. 20, 1621; and was driven early from his native country by the plague, and also by the war that followed it. His parents, having no great notion of breeding him up to letters or science, contented themselves with having him taught writing and arithmetic: but Hoffman's taste for books and study made him very impatient under this, and he was resolved to be a scholar at all adventures. He first gained over his mother to his scheme; but she died when he was only fifteen. This, however, was luckily no impediment to his purpose; for the schoolmaster of Fustenwalde, to which after many sojournings he was now returned, was so touched with his good natural parts and violent propensity to learning, that he was at the pains of instructing him in secret. His father, convinced of his very uncommon abilities, permitted him at length to follow his inclinations, and in 1637 sent him to study in the college of Colun. Famine and the plague drove him from hence to Kopnik, where he buried his father; and in 1638 he went to Altorf, to an uncle by his mother's side, who was a professor of physic. Here he finished his studies in classical learning and philosophy, and then applied himself with the utmost ardour to physic. In 1641, when he had made some progress, he went to the university of Padua, which then abounded with men very learned in all sciences. Anatomy and botany were the great objects of his pursuit; and he became very deeply skilled in them both. When he had been at Padua about three years, he returned to Altorf, to assist his uncle, now growing infirm, in his business; and taking the degree of M. D. he applied himself very diligently to practice, in which he had great success, and acquired great fame. In 1648 he was made professor extraordinary in anatomy and chirurgery; in 1649, professor of physic, and soon after member of the college of physicians; in 1653, professor of botany, and director of the physic-garden. He acquitted himself excellently in these various employments, not neglecting in the mean time the business of his profession; in which his reputation was so high and extensive, that many princes of Germany appointed him their physician. He died of an apoplexy in 1698, aged 76, after having published a great number of works, and married three wives, by whom he had eighteen children.

HOFFMAN (John-Maurice), son of the preceding, by his first wife, was born at Altorf in 1653; and sent to a school at Herzprugk, where having acquired a competent knowledge of the Greek and Latin tongues, he returned to his father at Altorf at sixteen, and studied first philosophy, and then physic. He went afterwards to Frankfort upon the Oder, and proposed to visit the United Provinces and England; but the wars hindering, he went to Padua, where he studied two years. Then making a tour of part of Italy, he returned to Altorf in 1674, and was admitted to the degree of M. D. He spent two years in perfecting the knowledge he had acquired; and then, in 1677, was made professor extraordinary in physic, which title, in 1681, was changed to that of professor in ordinary. He now applied himself in good earnest to the practice of physic; and in process of time his fame was spread so far and wide, that he was sought after by persons of the first rank. George Frederic, marquis of Anspach, of the house of Brandenburg, chose him in 1695 for his physician; and about the latter end of the year, Hoffman attended this prince into Italy, and renewed his acquaintance with the learned there. Upon the death of his father in 1698, he was chosen to succeed him in his places of botanic professor and director of the physic-garden. He was elected also the same year rector of the university of Altorf: a post, which he had occupied in 1685. He lost his great friend and patron, the marquis of Anspach, in 1703; but found the same kindness from his successor William Frederic, who pressed

him so earnestly to reside nearer, and made him likewise such advantageous offers, that Hoffman, in 1713, removed from Altorf to Anspach, where he died in 1727. He had married a wife in 1681, by whom he had five children. He published a great number of works, which are highly esteemed by those of his own profession.

HOFFMAN (Frederic), an eminent physician, was born at Hall near Magdeburg in 1660; took a doctor of physic's degree in 1681; was made professor of physic at Hall in 1693; and filled the chair till his death, which happened in 1742. His works were collected at Geneva in six large folios, 1748 and 1754. The most remarkable incidents of his life are,—his journey into Holland and England, where he became intimately acquainted with Paul Herman and Robert Boyle;—his never taking any fees, as he was supported by an annual stipend;—his curing those great personages of inveterate diseases, the empress, the emperor Charles VI. and Frederic I. king of Prussia;—his teaching that acid and mineral waters might be drunk with milk with safety and advantage, which physicians before had generally reckoned pernicious;—his discovering the virtues of Seltzer and Lauchstad waters in preventing and curing stubborn diseases;—his preparing and recommending an acid cathartic salt from the waters of Sedlic, which was commonly used in Germany. He survived his eightieth year.

HOFFMANNISTS, in ecclesiastical history, denote those who espoused the sentiments of Daniel Hoffmann, professor of the university of Helmstadt, who, from the year 1598, maintained, that philosophy was a mortal enemy to religion; and that what was true in philosophy was false in theology. These absurd and pernicious tenets occasioned a warm and extensive controversy. At length Hoffmann was compelled by Julius duke of Brunswick to retract his invectives against philosophy, and to acknowledge, in the most open manner, the harmony and union of sound philosophy with true and genuine theology.

HOG, in zoology. See SUS.

Hog's *Dung*, is by Mortimer reckoned one of the richest manures we are acquainted with, and the next in value to sheep's dung; and is found to be equal in virtue to twice the quantity of any other dung except that. The ancients seem to have been displeased with it on account of its fostering weeds; but this is only accusing it of being too rich, for any dung will do that when laid too thick. It is an excellent manure for pasture-grounds, and excels all other kinds of dung for trees. The farmers who use this dung for their lands, generally take care to save it, by well paving the styes; and increase the quantity by throwing in bean-stalks, stubble, and many other things of a like nature: and, by good management of this kind, many farmers have procured 50 or 60 loads of excellent manure a year out of a small stye. The very best way of using this dung is by mixing it with horse dung; and for this reason it is best to have the stye near the stable, that the two cleansings may be mixed in one heap, and used together.

They have, in many parts of Staffordshire, a poor, light, shallow land, on which they sow a kind of white pea: the land is neither able to bear this nor any thing else to advantage for their reaping; but, when the peas are ripe, they turn in as many hogs as the quantity of pease will fatten, suffering them to live at large, and to remain there day and night: in consequence of this, the land will produce good crops of hay for several years afterwards; or, if too poor for that, it will at worst raise grass enough to make it good pasture-ground.

Hog's *Lard*. See AXUNGIA.

HOG, on board of a ship, is a sort of flat scrubbing broom, formed by inclosing a number of short twigs of birch or such wood between two pieces of plank fastened together, and cutting off the ends of the twigs. It is used to scrape the filth from a ship's bottom under water, particularly in the act of boot-

topping. For this purpose they fit to this broom a long staff with two ropes; one of which is used to thrust the hog under the ship's bottom, and the other to guide and pull it up again close to the planks. This business is commonly performed in the ship's boat, which is confined as close as possible to the vessel's side during the operation, and shifted from one part of the side to another till the whole is completed.

HOGARTH (William), a truly great and original genius, is said by Dr. Burn to have been the descendant of a family originally from Kirkby Thore, in Westmoreland. His father, who had been a schoolmaster in the same county, went early to London, where he was employed as a corrector of the press; and appears to have been a man of some learning, a dictionary in Latin and English, which he composed for the use of schools, being still existing in MS. He married in London; and kept a school in Ship-Court, in the Old-Bailey. Our hero was born in 1697 or 1698, in the parish of St. Martin Ludgate. The outset of his life, however, was unpromising. "He was bound," says Mr. Walpole, "to a mean engraver of arms on plate." Hogarth probably chose this occupation, as it required some skill in drawing; to which his genius was particularly turned, and which he contrived assiduously to cultivate. His master, it since appears, was Mr. Ellis Gamble, a silversmith of eminence, who resided in Cranbourn-street, Leicester-fields. In this profession it is not unusual to bind apprentices to the single branch of engraving arms and ciphers on every species of metal; and in that particular department of the business young Hogarth was placed; "but, before his time was expired, he felt "the impulse of genius, and that it directed him to painting." During his apprenticeship, he set out one Sunday, with two or three companions, on an excursion to Highgate. The weather being hot, they went into a public-house, where they had not been long before a quarrel arose between some persons in the same room. One of the disputants struck the other on the head with a quart pot, and cut him very much. The blood running down the man's face, together with the agony of the wound, which had distorted his features into a most hideous grin, presented Hogarth, who showed himself thus early "apprised of the mode Nature had intended he should pursue," with too laughable a subject to be overlooked. He drew out his pencil, and produced on the spot one of the most ludicrous figures that ever was seen. What rendered this piece the more valuable was, that it exhibited an exact likeness of the man, with the portrait of his antagonist, and the figures in caricature of the principal persons gathered round him.

How long he continued in obscurity we cannot exactly learn; but the first piece in which he distinguished himself as a painter is supposed to have been a representation of Wanstead Assembly. The figures in it, we are told, were drawn from the life, and without any circumstances of burlesque. The faces were said to be extremely like, and the colouring rather better than in some of his late and more highly finished performances. From the date of the earliest plate that can be ascertained to be the work of Hogarth, it may be presumed that he began business on his own account at least as early as 1720.

His first employment seems to have been the engraving of arms and shop bills. The next was to design and furnish plates for booksellers. Mr. Bowles, at the Black Horse in Cornhill, was one of his earliest patrons, whose prices were very low. His next friend in that line was Mr. Philip Overton, who paid him somewhat better for his labour and ingenuity.

There are many family pictures by Hogarth, in the style of serious conversation pieces, still existing. What the prices of his portraits were, Mr. Nichols strove in vain to discover; but he suspects they were originally very low, as the people who are best acquainted with them choose to be silent on that subject.

It happened, in the early part of Hogarth's life, that a nobleman who was uncommonly ugly and deformed came to sit to him for his picture. It was executed with a skill that did honour to the artist's abilities; but the likeness was rigidly observed, without even the necessary attention to compliment or flattery. The peer, disgusted at this counterpart of his dear self, never once thought of paying for a reflector that would only insult him with his deformities. Some time was suffered to elapse before the artist applied for his money; but afterwards many applications were made by him (who had then no need of a banker) for payment, without success. The painter, however, at last hit upon an expedient, which he knew must alarm the nobleman's pride, and by that means answer his purpose. It was couched in the following card: "Mr. Hogarth's dutiful respects to lord —: finding that he does not mean to have the picture which was drawn for him, is informed again of Mr. H.'s necessity for the money: if, therefore, his lordship does not send for it in three days, it will be disposed of, with the addition of a tail, and some other little appendages, to Mr. Hare, the famous wild-beast man; Mr. H. having given that gentleman a conditional promise of it for an exhibition picture on his lordship's refusal." This intimation had the desired effect. The picture was sent home, and committed to the flames.

Mr. Walpole has remarked, that if our artist "indulged his spirit of ridicule in personalities, it never proceeded beyond sketches and drawings;" and wonders "that he never, without intention, delivered the very features of any identical person." Mr. Nichols assures us, from unquestionable authority, that almost all the personages who attend the levee of the Rake were undoubted portraits; and that in "Southwark Fair," and the "Modern Midnight Conversation," as many more were discoverable. While Hogarth was painting the "Rake's Progress," he had a summer residence at Isleworth; and never failed to question the company who came to see these pictures, if they knew for whom one or another figure was designed. When they guessed wrong, he set them right.

The Duke of Leeds has an original scene in the "Beggar's Opera," painted by Hogarth. It is that in which Lucy and Polly are on their knees, before their respective fathers, to intercede for the life of the hero of the piece. All the figures are either known or supposed to be portraits. If we are not misinformed, the late Sir Thomas Robinson (perhaps better known by the name of Long Sir Thomas) is standing in one of the side-boxes. Macheath, unlike his spruce representative on our present stage, is a slouching bully; and Polly appears happily disencumbered of such a hoop as the daughter of Peachum within our younger memories has worn. Mr. Walpole has a picture of a scene in the same piece, where Macheath is going to execution. In this also the likenesses of Walker and Miss Fenton, afterwards duchess of Bolton (the first and original Macheath and Polly) are preserved. In the year 1726, when the affair of Mary Tofts, the rabbit breeder of Godalming, engaged the public attention, a few of our principal surgeons subscribed their guinea a piece to Hogarth, for an engraving from a ludicrous sketch he had made on that very popular subject. This plate, amongst other portraits, contains that of M. St. André, then anatomist to the royal household, and in high credit as a surgeon. In 1727, Hogarth agreed with Morris, an upholsterer, to furnish him with a design on canvas, representing the element of earth, as a pattern for tapestry. The work not being performed to the satisfaction of Morris, he refused to pay for it; and our artist, by a suit at law, recovered the money.

In 1730 Mr. Hogarth married the only daughter of Sir James Thornhill, by whom he had no child. This union, indeed, was a stolen one, and consequently without the approbation of Sir James, who, considering the youth of his daughter, then barely 18, and the slender finances of her husband, as yet

an obscure artist, was not easily reconciled to the match. Soon after this period, however, he began his "Harlot's Progress" (the coffin in the last plate is inscribed Sept. 2. 1731); and was advised by lady Thornhill to have some of the scenes in it placed in the way of his father-in-law. Accordingly, one morning early, Mrs. Hogarth undertook to convey several of them into his dining-room. When he awoke, he inquired from whence they came; and being told by whom they were introduced, he cried out, "Very well; the man who can furnish representations like these can also maintain a wife without a portion." He designed this remark as an excuse for keeping his purse-strings close; but, soon after, became both reconciled and generous to the young people. An allegorical ceiling by Sir James Thornhill is at the house of the late Mr. Huggins, at Headly Park, Hants. The subject of it is the story of Zephyrus and Flora; and the figure of a satyr and some others were painted by Hogarth.

In 1732 Hogarth ventured to attack Mr. Pope, in a plate called "The Man of Taste;" containing a view of the Gate of Burlington-house, with Pope whitewashing it and bespattering the duke of Chandos's coach. This plate was intended as a satire on the translator of Homer, Mr. Kent the architect, and the earl of Burlington. It was fortunate for Hogarth that he escaped the lash of the former. Either Hogarth's obscurity at that time was his protection, or the bard was too prudent to exasperate a painter who had already given such proof of his abilities for satire.

Soon after his marriage, Hogarth had summer lodgings at South-Lambeth; and being intimate with Mr. Tyers, contributed to the improvement of the Spring Gardens at Vauxhall, by the hint of embellishing them with paintings, some of which were the suggestions of his own truly comic pencil. For his assistance, Mr. Tyers gratefully presented him with a gold ticket of admission for himself and his friends.

In 1733 his genius became conspicuously known. The third scene of his "Harlot's Progress" introduced him to the notice of the great. At a board of treasury which was held a day or two after the appearance of that print, a copy of it was shown by one of the lords, as containing, among other excellencies, a striking likeness of Sir John Gonsou. It gave universal satisfaction: from the treasury each lord repaired to the print-shop for a copy of it, and Hogarth rose completely into fame.

The ingenious Abbé Du Bos has often complained that no history painter of his time went through a series of actions, and thus, like an historian, painted the successive fortune of an hero from the cradle to the grave. What Du Bos wished to see done, Hogarth performed. He launches out his young adventurer a simple girl upon the town, and conducts her through all the vicissitudes of wretchedness to a premature death. This was painting to the understanding and to the heart; none had ever before made the pencil subservient to the purposes of morality and instruction: a book like this is fitted to every soil and every observer; and he that runs may read. Nor was the success of Hogarth confined to his persons. One of his excellencies consisted in what may be termed the furniture of his pieces; for as, in sublime and historical representations, the fewer trivial circumstances are permitted to divide the spectator's attention from the principal figures, the greater is their force; so, in scenes copied from familiar life, a proper variety of little domestic images contributes to throw a degree of verisimilitude on the whole. "The Rake's levee-room," says Mr. Walpole, "the nobleman's dining-room, the apartments of the husband and wife in Marriage à la Mode, the alderman's parlour, the bed-chamber, and many others, are the history of the manners of the age."

In 1745 Hogarth sold about 20 of his capital pictures by auction; and in the same year acquired additional reputation

by the six prints of "Marriage à la Mode," which may be regarded as the ground-work of a novel called "The Marriage A&," by Dr. Shebbeare, and of "The Clandestine Marriage."

Soon after the peace of Aix la Chapelle, he went over to France, and was taken into custody at Calais while he was drawing the gate of that town; a circumstance which he has recorded in his picture, intitled, "O the Roast Beef of Old England!" published March 26, 1749. He was actually carried before the governor as a spy, and after a very strict examination committed a prisoner to Granfire, his landlord, on his promising that Hogarth should not go out of his house till he was to embark for England.

In 1753 he appeared to the world in the character of an author, and published a quarto volume, intitled, "The Analysis of Beauty, written with a view of fixing the fluctuating ideas of taste." In this performance he shows, by a variety of examples, that a curve is the line of beauty, and that round swelling figures are most pleasing to the eye; and the truth of his opinion has been countenanced by subsequent writers on the same subject. In this work, the leading idea of which was hieroglyphically thrown out in a frontispiece to his works in 1745, he acknowledges himself indebted to his friends for assistance, and particularly to one gentleman for his corrections and amendments of at least a third part of the *wording*. This friend was Dr. Benjamin Hoadley the physician, who carried on the work to about the third part, Chap. IX. and then, through indisposition, declined the friendly office with regret. Mr. Hogarth applied to his neighbour Mr. Ralph; but it was impossible for two such persons to agree, both alike vain and positive. He proceeded no farther than about a sheet, and they then parted friends, and seem to have continued such. The kind office of finishing the work, and superintending the publication, was lastly taken up by Dr. Morell, who went through the remainder of the book. The preface was in like manner corrected by the Rev. Mr. Townley. The family of Hogarth rejoiced when the last sheet of the "Analysis" was printed off; as the frequent disputes he had with his coadjutors, in the progress of the work, did not much harmonize his disposition. This work was translated into German by Mr. Mylins, when in England, under the author's inspection; and the translation was printed in London, price five dollars. A new and correct edition was in 1754 proposed for publication at Berlin, by Ch. Fr. Vok, with an explanation of Mr. Hogarth's satirical prints, translated from the French; and an Italian translation was published at Leghorn in 1761.

Hogarth had one failing in common with most people who attain wealth and eminence without the aid of liberal education.—He affected to despise every kind of knowledge which he did not possess. Having established his fame with little or no obligation to literature, he either conceived it to be needless, or decried it because it lay out of his reach. His sentiments, in short, resembled those of Jack Cade, who pronounced sentence on the clerk of Chatham because he could write and read. Till, in evil hour, this celebrated artist commenced author, and was obliged to employ the friends already mentioned to correct his "Analysis of Beauty," he did not seem to have discovered that even spelling was a necessary qualification; and yet he had ventured to ridicule the late Mr. Rich's deficiency as to this particular, in a note which lies before the Rake whose play is refused while he remains in confinement for debt. Previous to the time of which we are now speaking, one of our artist's common topics of declamation was the uselessness of books to a man of his profession. In "Beer-street," among other volumes consigned by him to the pastry cook, we find Turnbull "on Ancient Painting;" a treatise which Hogarth should have been able to understand before he ventured to condemn. Garrick himself, however, was not more ductile to flattery. A

word in praise of "Sigismunda," his favourite work, might have commanded a proof print, or forced an original sketch out of our artist's hands. The following authenticated story of our artist will also serve to show how much more easy it is to detect ill placed or hyperbolic adulation respecting others than when applied to ourselves. Hogarth being at dinner with the great Chefelden and some other company, was told that Mr. John Freke, surgeon of St. Bartholomew's hospital, a few evenings before, at Dick's Coffee-house, had asserted that Greene was as eminent in composition as Handel. "That fellow Freke," replied Hogarth, "is always shooting his bolt absurdly one way or another! Handel is a giant in music; Greene only a light Florimel kind of a composer."—"Aye," says our artist's informant; "but at the same time Mr. Freke declared you were as good a portrait-painter as Vandyck."—"There he was in the right," adds Hogarth; "and so by G—I am, give me my time, and let me choose my subject!"

A specimen of Hogarth's propensity to merriment, on the most trivial occasions, is observable in one of his cards requesting the company of Dr. Arnold King to dine with him at the Mitre. Within a circle, to which a knife and fork are the supporters, the written part is contained. In the centre is drawn a pye, with a mitre on the top of it: and the invitation of our artist concludes with the following words in Greek letters—to *Eta Beta Pi*. The rest of the inscription is not very accurately spelled. A quibble by Hogarth is surely as respectable as a conundrum by Swift.

In one of the early exhibitions at Spring-Gardens, a very pleasing small picture by Hogarth made its first appearance. It was painted for the Earl of Charlemont, in whose collection it remains, and was intitled "Picquet, or Virtue in Danger;" and shows us a young lady who during a *tête-à-tête* had just lost all her money to a handsome officer of her own age. He is represented in the act of returning her a handful of bank-bills, with the hope of exchanging them for a softer acquisition and more delicate plunder. On the chimney-piece a watch-case and a figure of Time over it, with this motto—NUNC. Hogarth has caught his heroine during this moment of hesitation, this struggle with herself, and has marked her feelings with uncommon success.

In the "Miser's Feast," Mr. Hogarth thought proper to pillory Sir Isaac Shard, a gentleman proverbially avaricious. Hearing this, the son of Sir Isaac, the late Isaac Pacatus Shard, Esq. a young man of spirit, just returned from his travels, called at the painter's to see the picture; and, among the rest, asking the Cicerone "whether that odd figure was intended for any particular person?" On his replying "that it was thought to be very like one Sir Isaac Shard," he immediately drew his sword and flashed the canvas. Hogarth appeared instantly in great wrath: to whom Mr. Shard calmly justified what he had done, saying "that this was a very unwarrantable licence; that he was the injured party's son, and that he was ready to defend any suit at law;" which, however, was never instituted.

About 1757, his brother-in-law, Mr. Thornhill, resigned the place of king's serjeant-painter in favour of Mr. Hogarth.

The last remarkable circumstance of his life was his contest with Mr. Churchill. It is said that both met at Westminster-hall; Hogarth to take by his eye a ridiculous likeness of the poet, and Churchill to furnish a description of the painter. But Hogarth's print of the poet was not much esteemed, and the poet's letter to him was but little admired. Some pretend, indeed, to say, that it broke the painter's heart; but this we can from good authority say is not true. Indeed the report falls of itself; for we may as well say, that Hogarth's pencil was as efficacious as the poet's pen, since neither long survived the contest.

It may be truly observed of Hogarth, that all his powers of delighting were restrained to his pencil. Having rarely been admitted into polite circles, none of his sharp corners had been rubbed off, so that he continued to the last a gross uncultivated man. The slightest contradiction transported him into rage. To some confidence in himself he was certainly entitled: for, as a comic painter, he could have claimed no honour that would not most readily have been allowed him; but he was at once unprincipled and variable in his political conduct and attachments. He is also said to have beheld the rising eminence and popularity of Sir Joshua Reynolds with a degree of envy; and, if we are not misinformed, frequently spoke with asperity both of him and his performances. Justice, however, obliges us to add, that our artist was liberal, hospitable, and the most punctual of paymasters; so that, in spite of the emoluments his works had procured to him, he left but an inconsiderable fortune to his widow. His plates indeed are such resources to her as may not speedily be exhausted. Some of his domestics had lived many years in his service; a circumstance that always reflects credit on a master. Of most of these he painted strong likenesses on a canvas, still in Mrs. Hogarth's possession.

Of Hogarth's letter plates many were destroyed. When he wanted a piece of copper on a sudden, he would take any from which he had already worked off such a number of impressions as he supposed he should sell. He then sent it to be effaced, beat out, or otherwise altered to his present purpose. The plates which remained in his possession were secured to Mrs. Hogarth by his will dated, Aug. 12. 1764, chargeable with an annuity of 80*l.* to his sister Anne, who survived him. When, on the death of his other sister, she left off the business in which she was engaged, he kindly took her home, and generously supported her, making her at the same time useful in the disposal of his prints. Want of tenderness and liberality to his relations was not among the failings of Hogarth.

The following character of Hogarth, as an artist, is given by Mr. Gilpin in his *Essay on Prints*. "The works of this master abound in true humour; and satire, which is generally well directed: they are admirable moral lessons, and a fund of entertainment suited to every taste; a circumstance which shews them to be just copies of nature. We may consider them too as valuable repositories of the manners, customs, and dresses of the present age. What a fund of entertainment would a collection of this kind afford, drawn from every period of the history of Britain?—How far the works of Hogarth will bear a *critical examination*, may be the subject of a little more enquiry.

"In *design*, Hogarth was seldom at a loss. His invention was fertile, and his judgment accurate. An improper incident is rarely introduced, a proper one rarely omitted. No one could tell a story better, or make it in all its circumstances more intelligible. His genius, however, it must be owned, was suited only to *low* or *familiar* subjects; it never soared above *common* life: to subjects naturally sublime, or which from antiquity or other circumstances borrowed dignity, he could not rise. In *composition* we see little in him to admire. In many of his prints the deficiency is so great as plainly to imply a want of all principle; which makes us ready to believe, that when we do meet with a beautiful group, it is the effect of chance. In one of his minor works, the Idle 'Prentice, we seldom see a crowd more beautifully managed than in the last print. If the sheriff's officers had not been placed in a line, and had been brought a little lower in the picture, so as to have formed a pyramid with the cart, the composition had been unexceptionable; and yet the first print of this work is such a striking instance of disagreeable composition, that it is amazing how an artist who had any idea of beautiful forms could suffer so unmasterly a performance to leave his hands. Of the *distribution of light*

Hogarth had as little knowledge as of *composition*. In some of his pieces we see a good effect, as in the *Execution* just mentioned; in which, if the figures at the right and left corners had been *kept down* a little, the light would have been beautifully distributed on the fore-ground, and a fine secondary light spread over part of the crowd. But at the same time there is so obvious a deficiency in point of effect in most of his prints, that it is very evident he had no principles. Neither was Hogarth a master in *drawing*. Of the muscles and anatomy of the head and hands he had perfect knowledge; but his trunks are often badly moulded, and his limbs ill set on: yet his figures, upon the whole, are inspired with so much life and meaning, that the eye is kept in good-humour in spite of its inclination to find fault. The author of the *Analysis of Beauty*, it might be supposed, would have given us more instances of *grace* than we find in the works of Hogarth; which shows strongly that theory and practice are not always united. Many opportunities his subjects naturally afford of introducing graceful attitudes, and yet we have very few examples of them. With instances of picturesque grace his works abound. Of his *expression*, in which the force of his genius lay, we cannot speak in terms too high. In every mode of it he was truly excellent. The passions he thoroughly understood, and all the effects which they produce in every part of the human frame. He had the happy art also of conveying his ideas with the same precision with which he conceived them. He was excellent too in expressing any humorous oddity which we often see stamped upon the human face. All his heads are cast in the very mould of nature. Hence that endless variety which is displayed through his works; and hence it is that the difference arises between *his* heads and the affected caricatures of those masters who have sometimes amused themselves with patching together an assemblage of features from their own ideas. Such are Spaniolet's; which, though admirably executed, appear plainly to have no archetypes in nature. Hogarth's, on the other hand, are collections of natural curiosities. The *Oxford-heads*, the *Physician's arms*, and some of his other pieces, are expressly of this humorous kind. They are truly comic, though ill-natured effusions of mirth: more entertaining than Spaniolet's, as they are pure nature; but less innocent, as they contain ill-directed ridicule.—But the species of expression in which this master perhaps most excels, is that happy art of catching those peculiarities of art and gesture which the ridiculous part of every profession contract, and which for that reason become characteristic of the whole. His counsellors, his undertakers, his lawyers, his usurers, are all conspicuous at sight. In a word, almost every profession may see in his works that particular species of affectation which they should most endeavour to avoid.

The *execution* of this master is well suited to his subjects and manner of treating them. He etched with great spirit, and never gave one unnecessary stroke."

HOGSHEAD, in commerce, a measure of capacity containing 63 gallons.

HOGUE, a town and cape on the north-west point of Normandy in France; near which admiral Rook burnt the French admiral's ship, called the *Rising Sun*, with 12 more large men of war, the day after the victory obtained by admiral Russel near Cherbourg in May 1692. W. long. 2. 0. N. lat. 49. 53.

HOIST, in sea-language, denotes the perpendicular height of a flag or ensign, as opposed to the fly, which signifies its breadth from the staff to the outer edge.

HOISTING signifies the operation of drawing up any body by the assistance of one or more tackles. Hoisting is never applied to the act of pulling up any body by the help of a single block, except in the exercise of extending the falls by drawing them upwards along the masts or stays, to which it is invariably applied.

HOKE-DAY, *Hock-Day*, or *Hock-Tuesday*, in our ancient customs (*dies Martis, quem quindenam paschæ vocant*), the second Tuesday after Easter week; a solemn festival celebrated for many ages in England in memory of the great slaughter of the Danes in the time of king Ethelred, they having been in that reign almost all destroyed in one day in different parts of the kingdom, and that principally by women. This is still kept up in some counties; and the women bear the principal sway in it, stopping all passengers with ropes and chains, and exacting some small matter from them to make merry with. This day was very remarkable in former times, insomuch as to be used on the same footing with Michaelmas for a general term or time of account. We find leases without date reserving so much rent payable *ad duos anni terminos, scil. ad le hoke-day, & ad festum sancti Michaelis*. In the accounts of Magdalen-college, Oxford, there is yearly an allowance *pro mulieribus bochantibus* of some manors of theirs in Hampshire; where the men hock the women on Mondays, and the women hock them on Tuesdays. The meaning of it is, that on that day the women in merriment stopped the way with ropes, and pulled passengers to them, desiring something to be laid out for pious uses.

HOKE-Day Money, or *Hock-Tuesday Money*, a tribute anciently paid the landlord, for giving his tenants and bondmen leave to celebrate hock-day, or hoke-day, in memory of the expulsion of the domineering Danes.

HO-KIEN-FOU, a city of China, and one of the principal in the province of Pe-tcheli. It has two cities of the second, and fifteen of the third, class in its district, but is remarkable for nothing but the neatness of its streets.

HOLBECHE, a town in Lincolnshire, with a market on Thursday; 12 miles S. of Boston, and 108 N. of London.

HOLBEIN (Hans), a celebrated painter, born at Basil in Switzerland in 1498, learned the rudiments of his art from his father, who was a painter; but soon showed his superior genius. In the town house of Basil he painted our Saviour's Passion; and in the fish market of the same city Death's Dance, and a Dance of Peasants, which were extremely admired; and Erasmus was so pleased with them, that he desired him to draw his picture, and was ever after his friend. He staid some years longer at Basil, till his necessities, occasioned by his own extravagance and an increasing family, made him comply with Erasmus's persuasions to go to England. In his journey he staid some days at Strasburg, where it is said he applied to a very great painter for work, who took him in, and ordered him to give a specimen of his skill. Upon this, Holbein finished a piece with great care, and painted a fly on the most eminent part of it; after which he privately withdrew in the absence of his master, and pursued his journey, without saying any thing to any body. When the painter returned home, he was astonished at the beauty and elegance of the drawing; and especially at the fly, which he at first took for a real one, and endeavoured to remove it with his hand. He now sent all over the city for his journeyman; but after many enquiries, discovered that he had been thus deceived by the famous Holbein.—Holbein having in a manner begged his way to England, presented a letter of recommendation from Erasmus to Sir Thomas More, and also showed him Erasmus's picture. Sir Thomas, who was then lord chancellor, received him with all the joy imaginable, and kept him in his house between two and three years; in which time he drew Sir Thomas's picture, and those of many of his relations and friends. Holbein one day happening to mention a nobleman who had some years before invited him to England, Sir Thomas was very solicitous to know who it was. Holbein said that he had forgot his title, but remembered his face so well, that he believed he could draw his likeness; which he did so perfectly, that the nobleman it is said was immediately known

by it. The chancellor having now adorned his apartments with the productions of this great painter, resolved to introduce him to Henry VIII. For this purpose, he invited that prince to an entertainment; having, before he came, hung up all Holbein's pieces in the great hall, in the best order, and placed in the best light. The king, on his first entrance into this room, was so charmed with the sight, that he asked whether such an artist was now alive, and to be had for money? Upon this, Sir Thomas presented Holbein to his majesty; who immediately took him into his service, and brought him into great esteem with the nobility and gentry, by which means he drew a vast number of portraits. But while he was here, there happened an affair which might have proved fatal to him, had he not been protected by the king. On the report of this painter's character, a lord of the first quality came to see him when he was drawing a figure after the life. Holbein sent to desire his lordship to defer the honour of his visit to another day; which the nobleman taking for an affront, broke open the door, and very rudely went up stairs. Holbein hearing a noise, came out of his chamber; and meeting the lord at his door, fell into a violent passion, and pushed him backwards from the top of the stairs to the bottom. However, immediately reflecting on what he had done, he escaped from the tumult he had raised, and made the best of his way to the king. The nobleman, much hurt, though not so much as he pretended, was there soon after him; and upon opening his grievance, the king ordered Holbein to ask his pardon. But this only irritated the nobleman the more, who would not be satisfied with less than his life; upon which the king sternly replied, "My lord, you have not now to do with Holbein, but with me: whatever punishment you may contrive by way of revenge against him, shall certainly be inflicted on yourself. Remember, pray, my lord, that I can whenever I please make seven lords of seven ploughmen, but I cannot make one Holbein of even seven lords." Holbein died of the plague at his lodgings at Whitehall, in 1554. "It is amazing (says De Piles), that a man born in Switzerland, and who had never been in Italy, should have so good a *gusto*, and so fine a genius for painting." He painted alike in every manner; in fresco, in water-colours, in oil, and in miniature. His genius was sufficiently shewn in the historical style, by two celebrated compositions which he painted in the hall of the Stillyard company. He was also eminent for a rich vein of invention, which he shewed in a multitude of designs which he drew for engravers, statuaries, jewellers, &c. and he had this singularity, that he painted with his left hand.

HOLCUS, **INDIAN MILLET** or **CORN**; a genus of the monœcia order, belonging to the polygamia class of plants; and in the natural method ranking under the 4th order, *Gramina*. The calyx of the hermaphrodite is an uniflorous or biflorous glume; the corolla is a glume with an awn; there are three stamina, two styles, and one seed. The male calyx is a bivalved glume; there is no corolla, but three stamina.

Of this genus there are 13 species, two of which are natives of Britain. The most remarkable of these is the *lanatus*, or creeping soft-grass of Hudson; for the description and properties of which see **HUSBANDRY**. The most remarkable of the foreign species is the *forghum*, or Guinea-corn. The stalks are large, compact, and full eight feet high. In Senegal the fields are entirely covered with it. See pl. 10. The negroes, who call it *guiarnot*, cover the ears when ripe with its own leaves to shelter it from the sparrows, which are very mischievous in that country. The grain made into bread, or otherwise used, is esteemed very wholesome. With this the slaves in the West Indies are generally fed, each being allowed from a pint to a quart every day. The juice of the stalks is so agreeably luscious, that, if prepared as the sugar-canes, they would afford an excellent sugar. The negroes on the coast of Guinea make of

two kinds of millet a thick-grained pap called *couscous*, which is their common food.

HOLD, the whole interior cavity or belly of a ship, or all that part of her inside which is comprehended between the floor and the lower-deck throughout her whole length. This capacious apartment usually contains the ballast, provisions, and stores of a ship of war, and the principal part of the cargo in a merchantman. The disposition of these articles with regard to each other, naturally falls under consideration in the article **STOWAGE**; it suffices in this place to say, that the places where the ballast, water, provisions, and liquors are stowed, are known by the general name of the *hold*. The several store-rooms are separated from each other by *bulk-heads*, and are denominated according to the articles which they contain, the *sail-room*, the *bread-room*, the *fish-room*, the *spirit-room*, &c.

HOLDER (William), a learned and philosophical Englishman, was born in Nottinghamshire, educated in Pembroke-hall, Cambridge, and in 1642 became rector of Blechingdon, Oxford. In 1660 he proceeded D. D. was afterwards canon of Ely, fellow of the Royal Society, canon of St. Paul's, sub-dean of the royal chapel, and sub-almoner to his majesty. He was a very accomplished person, and withal a great virtuoso: and he wonderfully distinguished himself, by making a young gentleman of distinction, who was born deaf and dumb, to speak. This gentleman's name was Alexander Popham, son of colonel Edward Popham, who was some time an admiral in the service of the long parliament. The cure was performed by him in his house at Blechingdon in 1659; but Popham losing what he had been taught by Holder after he was called home to his friends, was sent to Dr. Wallis, who brought him to his speech again. Holder published a book, intitled "The Elements of Speech; an essay of inquiry into the natural Production of Letters: with an appendix concerning persons that are deaf and dumb, 1669," 8vo. In the appendix he relates how soon, and by what methods, he brought Popham to speak. In 1678 he published in 4to "a Supplement to the Philosophical Transactions of July 1670, with some reflections on Dr. Wallis's letter there inserted." This was written to claim the glory of having taught Popham to speak, which Wallis in the said letter had claimed to himself; upon which the Doctor soon after published "a Defence of the Royal Society, and the Philosophical Transactions, particularly those of July 1670, in answer to the Cavils of Dr. William Holder, 1678," 4to. Holder was skilled in the theory and practice of music, and wrote "a Treatise of the natural Grounds and Principles of Harmony, 1694," 8vo. He wrote also "a Discourse concerning Time, with Application of the natural Day, lunar Month, and solar Year, &c. 1694," 8vo. He died at Amen Corner in London, January 24, 1696-7, and was buried in St. Paul's.

HOLDERNESS, a peninsula in the east-riding of Yorkshire, having the German sea on the east, and the Humber on the south. It had the title of an earldom, now extinct.

HOLDSWORTH (Edward), a very polite and elegant scholar, was born about 1688, and trained at Winchester school. He was thence elected demy of Magdalen college, Oxford, in July 1705; took the degree of M. A. in April 1711; became a college-tutor, and had many pupils. In 1715, when he was to be chosen into a fellowship, he resigned his demyship and left the college, because unwilling to swear allegiance to the new government. The remainder of his life was spent in travelling with young noblemen and gentlemen as tutor: in 1741 and 1744 he was at Rome in this capacity. He died of a fever at Lord Digby's house at Colehill in Warwickshire, December 30, 1747. He was the author of the "Muscipula," a poem, esteemed a master piece of its kind, and of which there is a good English translation by Dr. John Hoadley, in vol. 5. of *Dodley's Miscellanies*. He was the author also of a disserta-

tion, intitled "Pharfalia and Philippi; or the two Philippi in Virgil's Georgics attempted to be explained and reconciled to History, 1741," 4to: and of "Remarks and Dissertations on Virgil; with some other classical observations, published with several notes and additional remarks by Mr. Spence, 1768," 4to. Mr. Spence speaks of him in *Polymetis*, as one who understood Virgil in a more masterly manner than any person he ever knew.

HOLDSWORTHY, a large town in Devonshire, with a market on Saturday. It is seated between two branches of the Tamar, 43 miles E. N. E. of Exeter, and 215 miles W. by S. of London. W. lon. 2. 42. N. lat. 50. 50.

HOLERACEÆ, (from *bolus*, "pot-herbs"); the name of the 12th order in Linnæus's fragments of a natural method, consisting of plants which are used for the table, and enter into the economy of domestic affairs. See **BOTANY**, p. 50.

HOLIBUT, in ichthyology. See **PLEURONECTES**.

HOLIDAY (Dr. Barten), a learned divine and poet, was the son of a taylor in Oxford, and born there about the year 1593. He studied at Christ-church college, and in 1615 took orders. He was before admired for his skill in poetry and oratory; and now distinguishing himself by his eloquence and popularity as a preacher, he had two benefices conferred on him in the diocese of Oxford. In 1618 he went as chaplain to Sir Francis Stewart, when he accompanied Count Gondamore to Spain. Afterwards he became chaplain to the king, and before the year 1626 was promoted to the archdeaconry of Oxford. In 1642 he took the degree of doctor of divinity at Oxford; near which place he sheltered himself during the time of the rebellion; but after the restoration returned to his archdeaconry, where he died in 1661. His works are, 1. Twenty sermons, published at different times. 2. *Philosophiæ politico barbaræ specimen*, quarto. 3. Survey of the world, a poem in ten books, octavo. 4. A translation of the fables of Juvenal and Persius. 5. *Technogamia, or the Marriage of the Arts*, a comedy.

HOLINESS, or **SANCTITY**; a quality which constitutes or denominates a person or thing *holy*; i. e. pure, or exempt from sin. The word is also used in respect of persons and things that are sacred, i. e. set apart to the service of God, and the uses of religion.

HOLINESS, is also a title or quality attributed to the pope; as that of *majesty* is to kings. Even kings, when writing to the pope, address him under the venerable appellation of *Your Holiness*, or *Holy Father*; in Latin, *Sanctissime*, or *Beatissime Pater*. Anciently the same title was given to all bishops. The Greek emperors also were addressed under the title of *Holiness*, in regard of their being anointed with holy oil at their coronation. Du Cange adds, that some of the kings of England have had the same attribute; and that the orientals have frequently refused it to the pope.

HOLINSHED (Raphael), an English historian famous for the *Chronicles* under his name, was descended from a family that lived at Bosely in Cheshire; but neither the time of his birth, nor scarcely any circumstances of his life, are known. However, he appears to have been a man of considerable learning, and to have had a genius particularly adapted for history. His *Chronicles of England, Scotland, and Ireland*, were first published at London in 1570, in 2 vols folio; and then in 1587, in 3 vols. In this second edition several sheets in the 2d and 3d vols were castrated for containing some passages disagreeable to queen Elizabeth and her ministers; but the castrations have since been printed apart. Holinshed was not the sole compiler of this work, being assisted in it by several other hands. The time of his death is unknown; but from his will, which is prefixed to Hearne's edition of *Cambden's Annals*, it appears to have happened between 1578 and 1582.

HOLLAND (Philemond), M. D. commonly called the

Translator-general of his age, was educated in the university of Cambridge. He was for many years a schoolmaster at Coventry, where he also practised physic. He translated Livy, Pliny's Natural History, Plutarch's Morals, Suetonius, Ammianus Marcellinus, Xenophon's Cyropædia, and Camden's Britannia, into English; and the geographical part of Speed's Theatre of Great Britain into Latin. The Britannia, to which he made many useful additions, was the most valuable of his works. It is surprising, that a man of two professions could find time enough to translate so much; but it appears from the date of the Cyropædia, that he continued to translate till he was 80 years of age. He died in 1636, aged 85. He made the following epigram upon writing a large folio with a single pen:

With one sole pen I wrote this book,
 Made of a gray goose quill;
 A pen it was when it I took,
 And a pen I leave it still.

HOLLAND, a celebrated republic of Europe, and principal of the Dutch States, or as they are commonly, though no longer properly called, the Seven United Provinces. Holland is a peninsula, bounded on the north and west by the German Ocean, on the east by the Zuyder See and the state of Utrecht, and on the south by the river Meuse and Brabant. It is divided into North and South. North Holland includes all to the north of Amsterdam. South Holland extends from the state of Zealand and Brabant to the river Ye; the length of the whole, including the island of Texel and the islands in the Meuse, is about ninety miles; the breadth is various, from fifteen to forty-eight. It contains twenty-nine walled towns, with many others that enjoy municipal privileges, and above 400 villages. Six large cities have seats in the States General, viz. Dort, Haerlem, Delft, Leyden, Amsterdam, and Gouda. The number of inhabitants is estimated at 800,000. The soil of the country is so soft and marshy, that but for the constant care in forming ditches and canals, it would be hardly capable of cultivation; some part of it lies even lower than the sea, from which it is secured by dykes or dams. The meadow-grounds are rich, and great numbers of milch cows are kept by the farmers, and the making of butter and cheese is one of their principal occupations. These meadows are generally under water during the winter, and the water would remain there at all times, if the inhabitants of the country had not found means to discharge them, by mills invented for this purpose, into the ditches and canals. The Hollanders are affable, industrious, laborious, absorbed in trade, excellent sailors, moderate politicians, and lovers of liberty. A free exercise of religion is allowed to all persuasions except the Roman Catholics; but Calvinism is the most prevailing. This country was anciently inhabited by the Batavians, who derived their origin from the Catti, a people of Germany. Having been obliged to abandon their country on account of civil wars, they came to establish themselves in an island, formed by the waters of the Rhine and the Wahal or Leck, and named their country *Batavia*, or *Betuwe*, from *Batton*, the son of their king. These people served in the Roman armies in quality of auxiliary troops; and historians inform us, that some of them were at the battle of Pharfallia. They formed the ordinary guard of the emperor Augustus. The services which they rendered Germanicus in Germany, were so important, that the senate gave them the appellation of *brothers*. They had afterwards a considerable share in the conquest of Britain, under Plancius and Agricola. They strengthened the party of Galba, and afterwards that of Vitellius, and it was principally to their valour that Julian the Apostate was indebted for the victory which he obtained over the Germans near Strasburg. The name of Holland is by some said to be given it on account of the vast and thick forests of

wood with which it was at one time covered; *Holtlant*, in German, signifying woodland. Others are inclined to think that the Normans, who made a descent here about the year 836, gave the country this name, founding their opinion on the resemblance of names found in this country to those in Denmark and Norway the ancient residence of the Normans, as Zealand, Oland, Schagen, Bergen, &c. On the decline of the Roman empire, the Batavians, or Hollanders, having thrown off their yoke, came under the dominion of the Saxons, and then of the French, under Childeric I, king of France. The Normans and the Danes were the next masters, from the time of Charlemagne, and ravaged the country three times with fire and sword. When they were driven away, Charles the Bald, emperor and king of France, erected Holland into a county, in the year 863, in favour of Thierry, duke of Aquitaine, who, five years after, was also made count of Zealand, by Louis king of Germany. In the year 1299 the county of Holland devolved to the counts of Hainault; and, in 1436 it fell to Philip the Good, duke of Burgundy, and afterwards to the emperor Maximilian, whose descendant, Philip II, king of Spain, was the last count of Holland; the seven provinces revolting from him, and, after a long struggle, forming an independent republic. The states of the province have the title of the states of Holland and West Friesland, and are formed of the nobility and towns. By West Friesland is to be understood North Holland, which is sometimes so called, and not the state or province of Friesland. The number of the nobility admitted into the assembly is not limited, and not always the same; they are elected by a majority of votes, and rarely exceed ten. The towns who have a right to send deputies were originally six; at present they are eighteen, of which seven are in North Holland, and eleven in South Holland. The number of deputies sent by each town is not fixed. In the year 1581 the Hague was appointed to be the place for the assembly of the states, when William of Nassau, prince of Orange, was acknowledged by the states-general of the United Provinces as the chief of their republic, and most certainly to him they were chiefly indebted for their establishment when they threw off their allegiance to Spain. He was assassinated at Delft, on the 10th of July 1584. Maurice, of Nassau, succeeded his father; and, in consideration of his virtue and valour, was made governor or stadtholder of Holland, Zealand, and Utrecht. William Henry of Nassau, the grandson of Frederic Henry, brother of Maurice, obtained the three offices of stadtholder, captain, and admiral-general, with a grant of the same to his descendants for ever. In the year 1677 this prince espoused Mary, daughter of James II, king of England, and in 1689 was crowned king at Westminster. In the present disputes on the French revolution, Holland at first appeared hostile to the new republic, but never heartily to have co-operated with the allies. The stadtholder was most probably influenced by Prussia and England; but a party more powerful than his own were his enemies, and on the invasion of Holland by the French, in the beginning of the year 1795, the stadtholder, with his family, thought it prudent to take refuge in England. Such are the ways of Providence! In the year 1688, a prince of Orange came to England to obtain a crown; and in the year 1795, a prince of Orange fled hither for protection.

HOLLAND, a district of Lincolnshire in England, in the S. E. part of the county. It is divided into Upper and Lower, and lies contiguous to the shallow inlet of the sea called the Wash. In nature, as well as in appellation, it resembles the province of the same name in the Netherlands. It consists entirely of fens and marshes; some in a state of nature, but others cut by numberless drains and canals, and crossed by raised causeways. The lower or southern division is the most watery, and is preserved from constant inundations by nothing but vast banks, raised on the sea-

coast and rivers. The air is unwholesome, and the water in general so brackish as to be unfit for internal purposes; on which account the inhabitants are obliged to make reservoirs of rain-water. In summer, vast swarms of insects fill the air, and prove a great nuisance. Yet even here industry has produced comfort and opulence, by forming excellent pasture land out of the swamps and bogs, and even making them capable of producing large crops of corn. The fens too, in their native state, are not without their utility; and afford various objects of curiosity to the naturalist. The reeds with which their waters are covered, make the best thatch, and are annually harvested in great quantities for that purpose. Prodigious flocks of geese are bred among the undrained fens, forming a considerable object of commerce, as well for their quills and feathers, as for the bird itself, which is driven in great numbers to the London markets. The principal decoys in England for the various kinds of wild ducks, teal, widgeon, and other fowls of the duck kind, are in these parts. Wild geese, grebes, godwhits, whimbrels, coots, ruffs, and rees, and a great variety of other species of water-fowl, breed here in amazing numbers; and stares or starlings resort during winter, in myriads, to roost on the reeds, breaking them down by their weight. Near Spalding is the greatest heronry in England, where the herons build together on high trees, like rooks. The avoet, or yelper, is found in great numbers about Fossdike Wash, as also knots and dotterels.

New Holland, the largest island in the world, reaching from 10 to 44 deg. S. lat. and between 110 and 154 of long. east from London. It received its name from having been chiefly explored by Dutch navigators. The land first discovered in those parts was called *Eendragt* (Concord) Land, from the name of the ship on board which the discovery was made, in 1616; 24 deg. and 25 deg. south. In 1618, another part of this coast, nearly in 15 deg. south, was discovered by Zeachen, who gave it the name of *Arnheim* and *Diemen*; though a different part from what afterwards received the name of Diemen's Land from Tasman, which is the southern extremity, in latitude 43 deg. In 1619, Jan Van Edels gave his name to a southern part of New Holland. Another part, situated between 30 and 33 deg. received the name of *Leuwen*. Peter Van Nuitz gave his name, in 1627, to a coast which communicates to Leuwen's Land towards the westward; and a part of the western coast, near the tropic of Capricorn, bore the name of *De Wit*. In 1628, Peter Carpenter, a Dutchman, discovered the great gulph of Carpentaria, between 10 and 20 deg. south. In 1687, Dampier, an Englishman, sailed from Timor, and coasted the western parts of New Holland. In 1699, he left England with a design to explore this country, as the Dutch suppressed whatever discoveries had been made by them. He sailed along the western coast of it, from 28 to 15 deg. He saw the land of *Eendragt* and of *De Wit*. He then returned to Timor; from whence he went out again, and examined the isles of Papua; coasted New Guinea; discovered the passage that bears his name; called a great island which forms this passage or strait on the east side, *New Britain*; and sailed back to Timor along New Guinea. This is the same Dampier who, between 1683 and 1691, sailed round the world by changing his ships. Notwithstanding the attempts of all these navigators, however, the eastern part of this vast tract was totally unknown till Captain Cook made his voyages; and by fully exploring that part of the coast, gave his country an undoubted title to the possession of it; which accordingly has since been taken possession of under the name of *New South Wales*.

Some have disputed whether the title of *island* can be properly applied to a country of such vast extent, or whether it ought not rather to be denominated a *continent*; while others have replied, that though the word *island*, and others similar to it, do indeed signify a tract of land surrounded by sea, yet in

the usual acceptation it means only a land of moderate extent surrounded in this manner. Were it otherwise, we might call the whole world an island, as it is every where surrounded by the sea; and in fact, Dionysius Perigetes applies this term to it, with the addition of the word *immense*, to distinguish it from other islands. The best rule, according to Mr. Stockdale, for determining when a country ought to lose the name of *island* and begin to be called a *continent*, is when it begins to lose the advantages of an insular situation. The first and principal of these, is the being capable of an union under one government, and thence deriving a security from all external attacks excepting those by sea; but in countries of great extent, this is not only difficult, but impossible. If we consider, therefore, New Holland as extending about a thousand miles every way, we shall find that its claim to be called a continent is undoubted; its length from east to west being about 2400 English miles, and 2300 from north to south.

This coast was first explored by Capt. Cook in the year 1770; but his stay was too short to examine the nature of the country with the accuracy which he would otherwise have done had he continued longer in it. In general, it was found rather barren than otherwise. Many brooks and springs were found along the eastern coast, but no river of any consequence. They found only two kinds of trees useful as timber, the pine, and another which produces a sort of gum. They found three kinds of palm-trees; but few esculent plants, though there are abundance of such as might gratify the curiosity of the botanist. A great variety of birds were met with, which have since been particularly described; but the number of quadrupeds bears but a very small proportion to that of the other animals. The most remarkable insects seen at this time were the green ants. These little animals form their habitations, by bending down the leaves of trees, and gluing the ends of them together so as to form a purse. Though these leaves are as broad as a man's hand, they perform this feat by main strength, thousands of them being employed in holding down the leaves, while multitudes of others apply the glutinous matter. Captain Cook's people ascertained themselves that this was the case, by sometimes disturbing them at their work; in which case the leaf always sprung up with an elasticity which they could not have supposed that such minute insects were capable of overcoming. For this curiosity, however, they smarted pretty severely; for thousands of these little enemies instantly threw themselves upon the aggressors, and revenged themselves by their bites or stings for the interruption they had met with. These were little less painful at first than the sting of a bee; but the pain did not last above a minute. Another species of ants burrow themselves in the root of a plant which grows on the bark of trees like the mistletoe, and which is commonly as big as a large turnip. When this is cut, it appears intersected with innumerable winding passages all filled with these animals; notwithstanding which, the vegetation of the plant suffers no injury. These do not give pain by their stings, but produce an intolerable itching by crawling about on the skin. They are about the size of the small red ant in this country. Another sort, which do not molest in any manner, resemble the white ants of the East Indies, (see *TERMS*). They construct nests three or four times as big as a man's head on the branches of trees; the outsides being composed of some vegetable matter along with a glutinous substance. On breaking the outer crusts of these hives, innumerable cells appear swarming with inhabitants, in a great variety of winding directions, all communicating with each other, and with several other nests upon the same tree. They have also another house built on the ground, generally at the root of a tree; formed like an irregularly sided cone; sometimes more than six feet high, and nearly as much in diameter. The outside of these is of well-tempered clay

about two inches thick; and within are the cells, which have no opening outward. One of these is their summer and the other their winter dwelling, communicating with each other by a large avenue leading to the ground, and by a subterraneous passage. The ground structures are proof against wet, which those on the branches are not.

This country has now become an object of more consequence than formerly, by reason of the establishment of a *British colony* in it; where the *criminals condemned to be transported* are sent to pass their time of servitude. Before this plan was resolved on by government, another had been discussed, *viz.* that of employing these criminals in work-houses; and Judge Blackstone, with Mr. Eden and Mr. Howard, had considered of the best method of putting it in execution: but though this plan had been approved by parliament as early as 1779, some difficulties always occurred, which prevented its going forward; and at length, on the 6th of December 1786, orders were issued by his majesty in council for making a settlement on New Holland, establishing a court of judicature in the colony, and other regulations necessary on the occasion. The whole received the complete sanction of parliament in the beginning of the year 1787. The squadron appointed for putting the design in execution consisted of the *Sirius* frigate, Captain John Hunter; the *Supply* armed tender, Lieutenant H. L. Ball; three store-ships, for carrying provisions and stores for two years; and lastly, six transports to carry 778 convicts, of which 558 were males, with a detachment of marines in each proportioned to the nature of the service. Governor Phillip, having hoisted his flag on board the *Sirius* as commodore of the squadron, weighed anchor on the 13th of May at day-break. They touched at Santa Cruz in the island of Teneriffe on the 3d of June, set sail again on the 10th, and on the 18th came in sight of the Cape Verd islands, where they steered for St. Jago. The want of a favourable wind, however, and other circumstances, prevented their getting in; so that as Governor Phillip did not choose to waste time, they did not touch land till they came to Rio Janeiro on the coast of Brasil. It may seem surprising, that a voyage to the eastward, which of itself may be accounted of sufficient length, should thus be wilfully made so much longer, by sailing twice across the Atlantic. The calms, however, so frequent on the coast of Africa, seem of themselves to be a sufficient inducement for navigators to preserve a westerly course; and even the islands at which it is so necessary to touch, are not far distant from the American coast. The returning tracks of Captain Cook's three voyages are all within a little space of the 45th degree of west longitude, which is even 10 degrees farther west than Cape St. Roque; and that course appears to have been taken voluntarily, without any extraordinary inducement.

During the time of their stay at Santa Cruz the weather had been very moderate; the barometer about 30 inches, and the thermometer never above 72. As they approached the Cape Verd islands it rose to 82, and did not exceed 82° 51' all the way from thence to Rio Janeiro. Here they met with a very favourable reception, contrary to that which Captain Cook experienced on a similar occasion. Provisions were so cheap, that though the allowance of meat was fixed by the governor at 20 ounces per day, the men were victualled completely at 3³/₄d. each, including rice, vegetables, and every other necessary. Wine was not at this time to be had except at an advanced price: but rum was laid in, and such seeds and plants procured as were thought most likely to flourish in New South Wales: particularly coffee, indigo, cotton, and the cochineal fig. An hundred sacks of cassava were likewise purchased as a substitute for bread, if it should happen to be scarce. By the kindness of the viceroy also, some deficiencies in the military stores were made up from the royal arsenal, and every assistance given

which the place could afford. They arrived here on the 5th of August 1787, and set sail on the 4th of September, receiving, as the last compliment from the governor, a salute of 21 guns.

From Rio de Janeiro the fleet had a fine run to Table Bay, in the southern extremity of Africa, which they accomplished in 39 days; where they took in the refreshments meant to supply them during the remainder of the voyage. Here they arrived on the 13th of October; and having provided themselves with a great number of live stock, they set sail on the 12th of November, but were long impeded by contrary winds from the south-east. On the 25th they were only 80 leagues distant from the Cape, when Governor Phillip left the *Sirius* and went aboard the *Supply* tender; in hopes, by leaving the convoy, to gain sufficient time for examining the country round Botany Bay, that the most proper situation for the new colony might be chosen before the transports should arrive. They now met with favourable winds, blowing generally in very strong gales from the north-west, west, and south-west. The wind shifted only once to the east, but did not continue in that direction above a few hours. On the 3d of January 1788 the *Supply* came within sight of New South Wales; but the winds then became variable, and a current, which at times set very strongly to the southward, impeded her course so much, that it was not till the 18th of the month that she arrived at Botany Bay.

Governor Phillip no sooner landed than he had an opportunity of *conversing with the natives*, who were assembled on shore. As it was the intention of this gentleman to conciliate if possible their friendship, he used every method at this first interview to inspire them with a favourable idea of the Europeans. For this purpose he presented them with beads and other trifling ornaments, which they seemed pleased to wear, though Captain Cook found them very indifferent about any kind of finery he could furnish them with. They seemed, according to the account of that celebrated navigator, to be so attached to their own ornaments, that they made no account of any thing else. They received indeed such things as were given them, but made no offer to return any thing in exchange; nor could they be made to comprehend that any thing of the kind was wanted. Many of the presents which they had received were found afterwards thrown away in the woods.

Governor Phillip having parted with his new acquaintance in a friendly manner, next set about an examination of the country about Botany Bay, which had been strongly recommended by Captain Cook as the most eligible place for a settlement. He found, however, that the bay itself was very inconvenient for shipping; being exposed to the easterly winds, and so shallow that ships even of a moderate burden could not get far enough within land to be sheltered from the fury of the ocean. Neither did the land about any part of this bay appear an eligible situation for a colony; being in some places entirely swampy, in others quite destitute of water. Point Sutherland seemed to afford the situation most free from objections, but the ships could not approach it; and even here the ground seemed to be universally damp and spongy: so that, on the whole, finding no place within the compass of the bay proper for the new settlement, they found themselves obliged to remove somewhere else.

The rest of the fleet arrived in two days after the *Supply*; and that no time might be lost, Governor Phillip ordered the ground about Point Sutherland to be cleared, and preparations to be made for landing, while he went with several officers in three boats to examine Port Jackson, which was only three leagues distant. Here they had the satisfaction to find one of the finest harbours in the world, where 1000 sail of the line

might ride in perfect safety. On examining the different coves, one was preferred, which had a fine run of spring water, and where ships could anchor so close to the shore, that at a very small expence quays might be constructed for loading and unloading the largest vessels. This was named by the governor *Sydney Cove*, in honour of Lord Sydney, and the country around it destined for the place of settlement. It is about half a mile long, and a quarter of a mile broad at the entrance. On the governor's return to Botany Bay, the reports made to him concerning the adjacent country were so exceedingly unfavourable, that orders were immediately given for the removal of the fleet to Port Jackson. On the morning of the 25th, therefore, the governor sailed from Botany Bay, and was soon followed by the whole fleet. In the mean time, they were surpris'd by the appearance of two other European vessels, which had been first seen off Botany Bay on the 24th. These were found to be two French ships, named the *Astrolabe* and *Bouffola*, which had left France on a voyage of discovery under the command of M. la Peyrouse, in the year 1785. They had touched at the island of Santa Catharina on the coast of Brazil, and from thence gone by the extremity of South America into the Pacific Ocean, where they had run along by the coasts of Chili and California; after which they had visited Easter Island, Nootka Sound, Cook's River, Kamtschatka, Manilla, the Isles des Navigateurs, Sandwich, and the Friendly Isles. They had also attempted to land on Norfolk Island, but found it impossible on account of the surf. During the whole voyage none were lost by sickness; but two boats crews had unfortunately perished in a surf on the north-west coast of America; and at Masuna, one of the *Isles des Navigateurs*, M. L'Angle, captain of the *Astrolabe*, with 12 of his people, officers and men, were murdered by the savages. This was the more surpris'ing, as there had been an uninterrupted friendship with them from the time the French touched at the island, till the unfortunate moment that M. L'Angle went ashore with two long boats for the purpose of filling some water-casks. His party amounted to 40 men; and the natives, from whom the French had already received abundance of refreshments, did not show any signs of an hostile disposition: but from whatever motive their resentment was excited, the men had no sooner begun to get out the boats, than the savages made a most furious and unexpected assault with stones. In this encounter M. L'Angle himself, with the people above mentioned, fell a sacrifice to the treachery of these barbarians. The remainder of the party escaped with great difficulty; the ships having at that time passed a point of land which intercepted their view of the affair.

The convicts and others destined to remain in New South Wales being landed, no time was lost in beginning to clear ground for an encampment, store-houses, &c. The work, however, went on but slowly, partly owing to the natural difficulties they had to encounter, and partly owing to the habitual indolence of the convicts, which indeed was naturally to be expected considering their former way of life. Nevertheless, by the end of the first week in February, the plan of an encampment was formed, and places were marked out for different purposes, so that the colony already began to assume some appearance of order and regularity. The materials and frame-work of a slight temporary habitation for the governor had been brought out from England ready formed, which were landed and put together with as much expedition as circumstances would allow. Hospital tents were also erected; and the sickness which soon took place showed the propriety of so doing. In the passage from the Cape there had been but little sickness, and few of the convicts had died; but a little time after they landed, a dysentery began to prevail, which proved fatal in several instances, and the scurvy began to rage with

great violence, so that the hospital tents were soon filled with patients. The disorder proved the more virulent as fresh provisions could but rarely be procured; nor were esculent vegetables often obtained in such plenty as could produce any material alleviation of the complaint: the only remedy for the dysentery was found to be a kind of red gum, produced in plenty by the trees growing upon this coast. The yellow gum has the same properties, though in an inferior degree.

In the beginning of February a most violent storm of thunder and lightning destroyed five of the sheep which had a shed erected for them under a tree, which proved a prelude to other misfortunes among the cattle. The encampment, however, was carried on with great alacrity; the foundations of the store-houses were laid, and every thing began to wear a promising appearance. On the 7th of the month a regular form of government was established in the colony, with all the solemnity which could possibly be given; the governor made a proper speech to the convicts, reminding them of the situation in which they stood; and that now, if they continued their former practices, it was impossible they could hope for mercy if detected; neither could they expect to escape detection in so small a society. Offenders, therefore, he said, would certainly be punished with the utmost rigour; though such as behaved themselves in a proper manner, might always depend upon encouragement. He particularly noticed the illegal intercourse betwixt the sexes, as a practice which encouraged profligacy in every respect; for which reason he recommended marriage; and this exhortation seemed not to be altogether in vain, as 14 marriages were celebrated that very week in consequence.

Heavy rains took place during the remainder of this month, which showed the necessity of going on with the work as soon as possible. The want of carpenters, however, prevented this from being done so expeditiously as could have been wished. Only 16 of these could be hired from all the ships; and no more than 12 of the convicts were of this profession, of whom several were sick; so that the party were by far too few for the work they had to perform. An hundred convicts were added as labourers; but with every effort it was found impossible to complete either the barracks or the huts for the officers as soon as could be wished. On the 14th of February a small party was sent out to settle on Norfolk Island, who have since established a colony there which promises to be of considerable utility. It was soon found, however, absolutely necessary to make examples of some of the convicts at Port Jackson. Towards the end of February it was found necessary to convene a criminal court, in which six of the convicts received sentence of death. One who was the head of the gang was executed the same day; one of the rest was pardoned; the other four were reprieved, and afterwards exiled to a small island within the bay, where they were kept on bread and water. They had frequently robbed both the stores and other convicts. The fellow who was executed, and two others, had been detected in stealing the very day on which they received a week's provision, and at the same time that their allowance was the same as that of the soldiers, spirituous liquors only excepted.

In the beginning of March the governor went out with a small party to examine Broken Bay, lying about eight miles to the northward of Port Jackson. This was found very extensive, with many openings. One of the latter ended in several small branches, and a large lagoon, which they could not at that time examine. Most of the land about the upper part of this branch was low and full of swamps, with great numbers of pelicans, and other aquatic birds. Among the rest they met with an uncommon bird called at that time the *Hooded Gull*, but afterwards found to be the species named by Mr. Latham the *Caspian Tern*.

From this north-west branch they proceeded across the bay

to the south-west branch, which is also very extensive, with a second opening to the westward capable of affording shelter to almost any number of ships, with depth of water for vessels of almost any burden. The land was found much higher here than at Port Jackson, more rocky, and equally covered with timber. Large trees were seen growing even on the summits of the mountains, which appeared totally inaccessible to the human species. Round the headland which forms the southern entrance into the bay is a third branch, which governor Phillip thought the finest piece of water he had ever seen; which for that reason he honoured with the name of *Pitt-water*. This branch, as well as the former, is sufficient to contain all the navy of Great Britain; but the latter has a bar at the entrance of only 18 feet at low water. Within are from 7 to 15 fathoms. The land here is more level than on the south-west branch, and some situations are proper for cultivation. The governor determined to have returned by land, in order to explore the country betwixt Port Jackson and Broken Bay, but the continual rains prevented him.

On the 10th of March the French ships departed, little intercourse having passed between them and the English during the time of their stay. While the former remained in Botany Bay, Father Le Receveur, who had come out in the *Astrolabe* as a naturalist, died of the wounds he had received in the battle with the inhabitants of Mafuna. A kind of monument was erected to his memory, with the following inscription:

Hic jacet LE RECEVEUR
E FF. Minimis Galliae sacerdos,
Physicus in circumnavigatione
Mundi
Duce DE LA PEYROUSE,
Ob. 17 Feb. 1788.

This monument, however, was soon after destroyed by the natives; on which Governor Phillip caused the inscription to be engraved on copper and nailed to a neighbouring tree. M. de la Peyrouse had paid a similar tribute to the memory of Captain Clerke at Kamtschatka.

On the 15th of April, the governor, attended by several officers and a small party of marines, set out on an expedition into the interior parts of the country. Their first landing was at the head of a small cove named *Shell-cove*, near the entrance of the harbour on the north side. Proceeding in this direction, they arrived with great labour at a large lake surrounded on all sides with bog and marshy ground to a considerable extent, and in which they frequently plunged up to the waist. Here they observed that bird so rare in other parts of the world, *viz.* a black swan. On being fired at, it rose, and showed that its wings were edged with white, the bill being tinged red. They spent three days in a very laborious manner in passing the marshes and swamps which lie in the neighbourhood of the harbour: and here they had an opportunity of observing, that all the small streams which descend into Port Jackson proceed from swamps, occasioned by the stagnation of the water in the low grounds as it rises from the springs. On leaving these low grounds, they found them succeeded by a rocky and barren country; the hills covered with various flowering shrubs, though frequently inaccessible by reason of various natural obstacles. At about 15 miles distance from the sea, the governor had a fine view of the internal parts of the country, which were mountainous. To the most northerly chain of these he gave the name of *Carmarthen*, and to the most southerly that of *Lansdown, Hills*; and to one which lay between these he gave the name of *Richmond Hill*. It was conjectured, that a large river must rise from these mountains; but there was now a necessity for returning. On the 22d, however, another expedition was undertaken. Governor Phillip with his party landed

near the head of the harbour. Here they found a good country; but in a short time arrived at a close thicket through which they found it impossible to make their way, so that they were obliged to return. Next day, by keeping close to the banks of a small creek, they made a shift to pass that obstacle, and continued their course for three days to the westward. The country was now extremely fine, either entirely level or rising in small hills, the soil excellent, but stony in a few places. The trees grew at the distance of from 20 to 40 feet from each other, in general totally destitute of underwood, which was confined to the barren and stony spots. On the 5th day they saw for the first time in this second expedition *Carmarthen* and *Lansdown hills*; but the country all round was so beautiful, that Governor Phillip gave it the name of *Belle vue*. They were still apparently 30 miles from the mountains which they had intended to reach; but not having been able to carry more than six days provisions along with them, they found it necessary to return; and even with this small stock the officers as well as men were obliged to carry heavy loads. During all this time they had not proceeded farther in a direct line than 30 miles, so great were the obstructions they had met with from deep ravines, &c. Their return, however, was effected with much greater ease, having cleared a track; and marked trees all the way as they went along to direct them in their journey back. The country explored at this time appeared so fine, that Governor Phillip determined to form a settlement there as soon as a sufficient number could be spared from those works which were immediately necessary. On his return he had the mortification to find, that five ewes and a lamb had been killed very near the camp, and in the middle of the day. This mischief was supposed to have been done by some dogs belonging to the natives.

All this time the scurvy had continued to rage with great violence; so that by the beginning of May near 200 people were incapable of work. For this reason, and on account of the great difficulty of clearing the ground, no more than eight or ten acres of wheat and barley had been sown, besides what private individuals had sown for themselves; and it was even feared that this small crop would suffer from the depredations of ants and field-mice. To procure as much relief as possible therefore in the present exigence, the Supply was sent in the beginning of May to Lord Howe Island in hopes of procuring some turtle and other provisions; but unfortunately the vessel returned without any turtle, having met with squally weather, and being obliged to cut away her best bower anchor. The natives now began to show an hostile disposition, which they had not hitherto done. One of the convicts, who had wandered away from the rest in quest of vegetables, returned with a very dangerous wound in the back; giving information also, that another who had gone out for the same purpose had been carried off in his sight by the natives, after being wounded in the head. A shirt and hat were afterwards found in some of the huts of the natives, but no intelligence of the man could be gained. This was followed by other misfortunes of the same nature. On the 30th of the month, two men who had been employed in cutting rushes for thatch at some distance from the camp were found dead. One of them had four spears in his body, one of which had pierced quite through it; but the other had no marks of violence upon him. In this case, however, it was proved that those who suffered had been the aggressors; as they had been seen with one of the canoes of the natives which they had taken from one of the fishing places. All possible enquiry was made after the natives who had been guilty of the murder, but to no purpose. In the course of this enquiry, it was found that one of the natives had been murdered, and several wounded, previous to the attack upon the rush-cutters. The governor promised liberty to any convict who

should discover the aggressors; but no information was procured, though it is probable that it may prevent accidents of that kind for the future. About this time the two bulls and four cows belonging to government and to the governor, having been left for some time by the man who had the charge of them, strayed into the woods and could not be recovered, though they were afterwards traced to some distance.

The 4th of June being his majesty's birth-day, was celebrated with as much festivity as circumstances would allow; and on this occasion it was first made public that the governor had given the name of *Cumberland County* to this part of the territory. The appointed boundaries were Carmarthen and Lansdown hills on the west, the northern parts of Broken Bay on the north, and the southern parts of Botany Bay on the south; thus including these three principal bays, with Sydney Cove nearly in the centre.

The misfortunes which attended those convicts who strayed to too great a distance from the settlement, were not sufficient to prevent some of the rest from rambling into the woods, in hopes of subsisting themselves there and regaining their liberty. One of these, who had been guilty of a robbery, fled into the woods on the 5th of June, but was obliged to return half-starved on the 24th. He had found it impossible to subsist in the woods, and had met with very little relief from the natives. One of them gave him a fish, but made signs for him to go away. According to his account, they themselves were in a very miserable situation; and he pretended to have seen four of them apparently dying of hunger, who made signs to him for something to eat. He pretended also to have fallen in with a party who would have burnt him, and that he made his escape from them with difficulty. He said also, that he had seen the remains of a human body lying on a fire; and endeavoured to inculcate the idea of these savages eating human flesh when other provisions were scarce. This poor wretch was tried and executed for the theft he had committed before his departure, along with another criminal.

By this time the colony was so far advanced, that the plan of a regular town had been marked out. The principal street, when finished, is to be 200 feet wide, terminated by the governor's house, the main guard, and criminal court. The plans of other streets are likewise marked out; and it is the governor's intention, that when houses are built here, the grants of land shall be made with such clauses as will prevent the building of more than one house on one allotment, which is to consist of 60 feet in front and 150 in depth. Thus a kind of uniformity will be preserved in the building, narrow streets prevented, and many inconveniencies avoided, which a rapid increase of inhabitants might otherwise occasion. It has likewise been an object of the governor's attention to place the public buildings in such situations as will be eligible at all times, and particularly to give the storehouses and hospital sufficient space for future enlargement, should it be found necessary. The first huts erected in this place were composed only of the soft wood of the cabbage palm, in order to give immediate shelter, and which had the further inconvenience of being used quite green. The huts of the convicts were constructed only of upright posts wattled with slight twigs, and plastered up with clay. Buildings of stone might easily have been raised, had there been any means of procuring lime for mortar. There were three kinds of stone met with about Sydney Cove, one equal in goodness to Portland-stone, an indifferent kind of sandstone or fire-stone, and a sort which seems to contain iron; but neither chalk nor any species of lime-stone have yet been discovered. Lime was indeed procured from oyster-shells collected in the neighbouring coves to construct a small house for the governor; but it cannot be expected that a sufficient quantity can thus be procured for many or very extensive

buildings. Good clay for bricks has been found near Sydney Cove, and very good bricks have been made of it; the wood also, notwithstanding the many reports to the contrary, is found abundantly fit for various purposes after being thoroughly seasoned. Such specimens as have been sent to England were fine-grained and free of knots, but heavy.

On the point of land that forms the west side of the Cove a small observatory has been erected, the longitude of which has been ascertained to be $159^{\circ} 19' 30''$ east from Greenwich, and the latitude $32^{\circ} 52' 30''$ south. Instead of thatch they now make use of shingles made from a certain tree, which has the appearance of a fir, but produces wood like English oak.

With regard to the *state of this colony* there have been various and discordant accounts. Some of these have represented the country in such a light, that it would seem impossible to subsist on it; and it has been said, that the people who have had the misfortune to go there already were in the utmost danger of starving before any assistance could be sent from Britain. These reports, however, appear not to be well founded. Difficulties must undoubtedly be felt at the first settlement of every uninhabited country; and we are not to expect that a colony, most of whom are wretches exiled for their crimes from their own country, can thrive in an extraordinary manner for some time. It appears, indeed, that so far from the transportation to this place having had any good effect in reforming them, the governor has been obliged to execute the utmost rigour of the law by hanging several of them. A good number of others have unaccountably disappeared, and are supposed to have been murdered by the natives, or perished with hunger in the woods; so that, unless the numbers be recruited by more respectable inhabitants, it is not likely that much can be expected from the Port Jackson settlement for a long time to come. Of this, however, there seems to be little doubt: the general spirit of emigration which prevails through most, indeed we may say all the countries of Europe, will undoubtedly soon supply a sufficient number; and even some of the Americans, notwithstanding the extent and fertility of their own country, and the liberty they enjoy in it, are said to be willing to exchange these blessings for the precarious hopes of what may be obtained in New Holland among British convicts and slaves. This rambling disposition may perhaps be accounted for from an observation which has been made, *viz.* that "it may admit of a doubt whether many of the accommodations of a civilized life be not more than counterbalanced by the artificial wants to which they give birth. That these accommodations do not give a satisfaction equivalent to the trouble with which they are procured, is certain; and it is no wonder then to find numbers of people in every country who are willing to exchange them for independent ease and tranquillity, which belong, comparatively speaking, to few individuals in those countries which are called civilized."

With regard to the geography of this extensive country, which may perhaps be reckoned a fifth general division of the world, Captains Cook and Furneaux so fully explored its coasts, that succeeding navigators have added nothing to their labours. The only part which still remains unknown is that between the latitudes of $37^{\circ} 58'$ and 39° south; and as none of the fleet which lately sailed from Britain could be supposed to undertake any voyage of discovery, it is unknown whether a strait intersects the continent in this place or not. Captain Tench, however, informs us, on the authority of a naval friend, "that when the fleet was off this part of the coast, a strong set-off shore was plainly felt."

A vast chain of lofty mountains run nearly in a north and south direction farther than the eye can trace, about 60 miles inland. The general face of the country is pleasing, diversified with gentle risings and small winding valleys, covered for the

most part with large spreading trees, affording a succession of leaves in all seasons. A variety of flowering shrubs, almost all entirely new to an European, and of exquisite fragrance, abound in those places which are free from trees; and among these, a tall shrub, bearing an elegant flower, which smells like English may, is peculiarly delightful, and perfumes the air to a great distance. There are but few trees; and, as Captain Tench and others relate, of so bad a grain, that they can scarcely be used for any purpose: this, however, Mr. Stockdale ascribes to their being used in an unseasoned state, as has been already mentioned. In return for these bad qualities, however, the trees yield vast quantities of the gum already mentioned as a cure for the dysentery. It is of an acrid quality, and therefore requires to be given along with opiates. The tree which yields it is of very considerable size, and grows to a great height before it puts out any branches. The gum itself is usually compared to *sanguis draconis*, but differs from it in being perfectly soluble in water, which the *sanguis draconis* is not. It may be extracted from the wood by tapping, or taken out of the veins when dry. The leaves are narrow, and not unlike those of a willow; the wood fine grained and heavy, but warps to such a degree, when not properly seasoned, as soon to become entirely useless.

The yellow gum is properly a resin, being entirely insoluble in water. It greatly resembles gamboge, but has not the property of staining. It is produced by a low small plant with long grassy leaves; but the fructification shoots out in a surprising manner from the centre of the leaves on a single straight stem to the height of 12 or 14 feet. This stem is strong and light, and is used by the natives for making their spears. The resin is generally dug up from the soil under the tree, not collected from it, and may perhaps be the same which Tasman calls *gum lac of the ground*. It has been tried by Dr. Blane physician to St. Thomas's hospital, who found it very efficacious in the cure of old fluxes, and that in many very obstinate cases. Many of the New Holland plants have been already imported into Britain, and are now flourishing in perfection at the nursery gardens of Mr. Lee of Hammer Smith.

The soil immediately around Sydney Cove is sandy, with here and there a stratum of clay; but for some time the produce was not remarkable. The principal difficulty hitherto experienced in cleaning the ground arises from the size of the trees, which is said to be so enormous, that 12 men have been employed for five days in grubbing up one. Captain Cook speaks of some fine meadows about Botany Bay; but none of these have been seen by the present settlers, and Governor Phillip supposes them to have been swamps seen at a distance. Grass grows in almost every place, but in the swamps with the greatest vigour and luxuriance, though not of the finest quality. It is found to agree better with cows and horses than sheep. A few wild fruits are sometimes procured; among which is a kind of small purple apple mentioned by Captain Cook; and a fruit which has the appearance of a grape, but tasting like a green gooseberry, and excessively sour.

From the first discovery of this continent, the extreme scarcity of fresh water has been mentioned by every navigator. None have been fortunate enough to enter the mouth of any navigable river such as might be expected in a country of equal extent. The settlers about Port Jackson found enough for the common purposes of life; but Captain Tench informs us, that when he left the country, towards the end of 1788, there had been no discovery of a stream large enough to turn a mill. Since that time, however, Governor Phillip has been more successful; as we are informed by a letter of his to Lord Sydney, dated Feb. 13, 1790. In this letter he relates, that soon after the ships sailed in November 1788, he again made an excursion to Botany Bay, where he staid five days; but the

researches he made there tended only to confirm him in the opinion he already entertained, that the country round it was by no means an eligible situation for a colony. After having visited Broken Bay several times with boats, a river was found, which has since been traced, and all those branches explored which afforded any depth of water. This river has obtained the name of *Hawkesbury*, is from 300 to 800 feet wide, and seems navigable for the largest merchant ships as far up as Richmond hill, at which it becomes very shallow, and divides into two branches; on which account the governor calls Richmond-hill the head of the river. As after very heavy rains, however, the water sometimes rises 30 feet above its level, it would not be safe for ships to go up so far; but 15 or 20 miles below it they would lie in fresh water, and be perfectly safe.

The country about Broken Bay is at first high and rocky, but as we proceed up the river it becomes more level, the banks being covered with timber, and the soil a light rich mould, supposed to be very capable of cultivation. The other branches of this river are shallow, but probably run many miles up into the country. Great numbers of black swans and wild ducks were seen on these rivers, and the natives had several decoys for catching quails.

Richmond-hill, near which a fall prevented the boats from proceeding farther up, is the most southerly of a large range of hills which run to the northward, and probably join the mountains nearly parallel to the coast from 50 to 60 miles inland. The soil of this hill is good, and it lies well for cultivation. There is a very extensive prospect from the top, the whole country around seeming a level covered with timber. There is a flat of six or seven miles between Richmond hill and a break in the mountains which separates Lansdown and Carmarthen hills; in which flat the governor supposes that the Hawkesbury continues its course; though the river could not be seen on account of the timber with which the ground is every where covered where the soil is good. Six miles to the southward of Port Jackson is a small river; and 20 to the westward is one more considerable, which probably empties itself into the Hawkesbury. As far as this river was at that time explored, the breadth was computed at from 300 to 400 feet. It was named the *Nepcan*, and, like the Hawkesbury, sometimes rises 30 feet above its level. A party who crossed the river attempted to reach the mountains, but found it impossible, probably for want of provisions. After the first day's journey they met with such a succession of deep ravines, the sides of which were frequently so inaccessible, that in five days they could not proceed farther than 15 miles. At the time they turned back, they supposed themselves to be 12 miles from the foot of the mountains. With regard to the state of the colony, it appears from this letter to be as flourishing as could in any reasonable manner be expected. Another has been formed at a place called Rosehill, at the head of the harbour of Sydney Cove. At this place is a creek, which at half flood has water for large boats to go three miles up; and one mile higher the water is fresh and the soil good. Some ground having been cleared and cultivated, the governor in the above letter writes, that 27 acres were sown with corn, and that in December the crop was got in: that the corn was exceedingly good; about 200 bushels of wheat and 60 of barley, with a small quantity of flax, Indian corn, and oats; all which is preserved for seed: that if settlers are sent out, and the convicts divided amongst them, this settlement will very shortly maintain itself; but without which this country cannot be cultivated to any advantage. "At present (continues the governor) I have only one person, who has about 100 convicts under his direction, who is employed in cultivating the ground for the public benefit, and he has returned the quantity of corn above mentioned

into the public store: The officers have not raised sufficient to support the little stock they have: some ground I have had in cultivation will return about 40 bushels of wheat into store: so that the produce of the labour of the convicts employed in cultivation has been very short of what might have been expected, and which I take the liberty of pointing out to your lordship in this place; to show as fully as possible the state of this colony, and the necessity of the convicts being employed by those who have an interest in their labour." The country for 20 miles to the westward is very capable of cultivation; though the labour of cutting down the trees is very great. At Sydney Cove the stores had been infested by a swarm of rats, which destroyed no less than 12,000lb. weight of flour and rice. The gardens also had suffered very considerably; so that, having met with such a considerable loss of provision, and a sufficient supply not being procured from the Cape, Governor Phillip thought proper to send a further detachment to Norfolk Island, where the fertility of the soil afforded great hopes of their being able in a short time to subsist themselves independent of any assistance from the stores.

With regard to the civil establishment in this colony, Governor Phillip's jurisdiction extends from 43° 49' to 10° 37' south, being the northern and southern extremities of the continent. It commences again in 135° E. long. from Greenwich; and proceeding in an easterly direction, includes all the islands within the above-mentioned latitudes in the Pacific Ocean; by which partition it is supposed that every source of litigation will be cut off, as all these are indisputably the discovery of the British navigators.

The powers of the governor are absolutely unlimited, no mention being made of a council to assist him in any thing; and as no stated time is appointed for assembling the courts similar to the assizes and gaol deliveries in England, the duration of imprisonment is altogether in his hands. He is likewise invested with a power of summoning general courts martial; but the infection in the marine mutiny act, of a smaller number of officers than 13 being able to compose such a tribunal, has been neglected; so that a military court, should detachments be made from head quarters, or sickness prevail, may not always be found practicable to be obtained, unless the number of officers in the settlement at present be increased. The governor is allowed to grant pardons in all cases, treason and wilful murder excepted; and even in these he has authority to stay the execution of the law until the king's pleasure shall be signified. In case of the governor's death, the lieutenant governor takes his place; and on his decease, the authority is lodged in the hands of the senior officer.

It was not long after the convicts were landed that there appeared a necessity for assembling a criminal court; and it was accordingly convened by warrant from the governor. The members were the judge advocate, who presided, three naval and three marine officers. The number of members is limited by act of parliament to seven; who are expressly ordered to be officers either of his majesty's sea or land forces. The court being met, completely arrayed and armed as at a military tribunal, the judge advocate proceeds to administer the usual oaths taken by jurymen in England to each member; one of whom afterwards swears him in a like manner. This ceremony being over, the crime is laid to the prisoner's charge, and the question "guilty or not guilty" put to him. No law officer being appointed on the part of the crown, the party at whose suit he is tried is left to prosecute the prisoner entirely by himself. All the witnesses are examined on oath; and the decision must be given according to the laws of England, or "as nearly as may be, allowing for the circumstances and situation of the settlement," by a majority of votes, beginning with the youngest member, and ending with

the president of the court. No verdict, however, can be given in cases of a capital nature, unless at least five of the seven members concur therein. The evidence on both sides being finished, and the prisoner's defence heard, the court is cleared, and, on the judgment being settled, is thrown open again, and sentence pronounced. During the time of sitting, the place in which it is assembled is directed to be surrounded by a guard under arms, and admission granted to every one who chooses to enter it. Of late, however, says Captain Tench, our colonists are supposed to be in such a train of subordination, as to make the presence of so large a military force unnecessary; and two sentinels in addition to the provost-martial are considered as sufficient.

The first trials which came before this court were those of three convicts, one of whom was convicted of having struck a marine with a cooper's adze, and behaving otherwise in a most scandalous and riotous manner. For this he was condemned to receive 150 lashes, being a smaller punishment than a soldier would have suffered in a similar case. A second, for having committed a petty theft, was sent to a small barren island, and kept there on bread and water only for a week. The third was sentenced to receive 50 lashes; but being recommended by the court to the governor, had his sentence remitted. The same lenity, however, could not be observed in all cases. One fellow, who had been condemned to be hanged, was pardoned while the rope was about his neck, on condition that he would become the common executioner ever after. He accepted the horrid office, but not without a *pause*. Some examples of severity were undoubtedly necessary; and among these it is impossible to avoid feeling some regret for the fate of one who suffered death for stealing a piece of soap of eight-pence value: but by the last letter of Governor Phillip, we are informed that the convicts in general are now behaving much better: more so indeed than ever he expected. The last statement was of one woman who had suffered for a robbery; five children had died, and 28 been born. The whole amount of the deaths 77, of the births 87.

The number of convicts already sent to New South Wales amounts to 2000 and upwards—above 1800 are since embarked for that settlement. The annual expence of the civil and military establishments at that place is nearly 10,000l.

Besides the criminal court, there is an inferior one composed of the judge advocate, and one or more justices of the peace, for the trial of small misdemeanors. This court is likewise empowered to decide all law-suits; and its verdict is final, except where the sum exceeds 300l. in which case an appeal can be made to England from its decree. In case of necessity, an admiralty court, of which the lieutenant-governor is judge, may also be summoned for the trial of offences committed on the high seas.

The quadrupeds on the continent of New Holland hitherto discovered are principally of the Opossum kind, of which the most remarkable is the Kangaroo. There is also a species of dogs very different from those known in Europe. They are extremely fierce, and never can be brought to the same degree of familiarity with those we are acquainted with. Some of them have been brought to England, but still retain their usual ferocity. There are a great many beautiful birds of various kinds; among which the principal are the black swans already mentioned, and the ostrich or cassowary; which last arrives frequently at the height of seven feet or more. Several kinds of serpents, large spiders, and scorpions, have also been met with. There are likewise many curious fishes; though the finny tribe seem not to be so plentiful on the coast as to give any considerable assistance in the way of provisions for the colony. Some very large sharks have been seen in Port Jackson, and two smaller species, one named the Port Jackson shark, the

other Watts's shark. The latter, notwithstanding its diminutive size, the mouth scarce exceeding an inch in breadth, is excessively voracious. One of them having been taken and flung down upon the deck, lay there quiet for *two hours*; after which Mr. Watts's dog happening to pass by, the fish sprung upon it with all the ferocity imaginable, and seized it by the leg in such a manner that the animal could not disengage himself without assistance.

The climate of this continent appears not to be disagreeable, notwithstanding the violent complaints which some have made about it. The heat has never been excessive in summer, nor is the cold intolerable in winter. Storms of thunder and lightning are frequent; but these are common to all warm countries; and it has been supposed (though upon what foundation does not well appear) that were the country cleared of wood, and inhabited, these would in a great measure cease. A shock of an earthquake has likewise been felt; but these natural calamities are incident to some of the finest countries in the world. It is not known whether there are any volcanoes or not.

The inhabitants of New Holland are by all accounts represented as the most miserable and savage race of mortals, perhaps, existing on the face of the earth. They go entirely naked; and though pleased at first with some ornaments which were given them, they soon threw them away as useless. It does not appear, however, that they are insensible of the benefits of clothing, or of some of the conveniencies which their new neighbours are in possession of. Some of them, whom the colonists partly clothed, seemed to be pleased with the comfortable warmth they derived from it; and they all express a great desire for the iron tools which they see their neighbours make use of. Their colour, in the opinion of Captain Cook, is rather a deep chocolate than a full black; but the filth with which their skins are covered, prevents the true colour of them from appearing. At some of their interviews with the colonists, several droll instances happened of their mistaking the negroes among the colonists for their own countrymen. Notwithstanding their disregard for European finery, they are fond of adorning, or rather deforming, their bodies with scars; so that some of them cut the most hideous figure that can be imagined. The scars themselves have an uncommon appearance. Sometimes the flesh is raised several inches from the skin, and appears as if filled with wind; and all these seem to be reckoned marks of honour among them. Some of them perforate the cartilage of the nose and thrust a large bone through it, an hideous kind of ornament humorously called by the sailors their *sprit-sail yard*. Their hair is generally so much clotted with the red gum already mentioned, that they resemble a mop. They also paint themselves with various colours like most other savages: they will also sometimes ornament themselves with beads and shells, but make no use of the beautiful feathers procurable from the birds of the country. Most of the men want one of the fore teeth in the upper jaw; a circumstance mentioned by Dampier and other navigators; and this also appears to be a badge of honour among them. It is very common among the women to cut off the two lower joints of the little finger; which, considering the clumsiness of the amputating instruments they possess, must certainly be a very painful operation. This was at first supposed to be peculiar to the married women, or those who had borne children, but some of the oldest women were found without this distinction, while it was observed in others who were very young.

The New Hollanders appear extremely deficient in the useful arts. Of the cultivation of the ground they have no notion: nor can they even be prevailed upon to eat bread or dressed meat. Hence they depend entirely for subsistence on the fruits and roots they can gather, with the fish they

catch. Governor Phillip also mentions their frequent setting fire to the grass, in order to drive out the opossums and other animals from their retreats; and we have already taken notice of their using decoys for quails. As all these resources, however, must be at best precarious, it is no wonder that they are frequently distressed for provisions. Thus, in the summer-time they would eat neither the shark nor sting ray; but in winter any thing was acceptable. A young whale being driven ashore, was quickly cut in pieces and carried off. They broiled it only long enough to scorch the outside; and in this raw state they eat all their fish. They broil also the fern root, and another whose species is unknown. Among the fruits used by them is a kind of wild-fig; and they eat also the kernels of a fruit resembling the pine apple. The principal part of their subsistence, however, is fish; and when these happened to be scarce, they would often watch their opportunity when the colonists hauled the seine, and seize on the whole, though a part had formerly been offered or given them. They sometimes strike the fish from the canoes with their spears, sometimes catch them with hooks, and also make use of nets, contrary to the assertion of Dr. Hawkesworth, who says that none of these are to be met with among them. Their nets are generally made of the fibres of the flax plant, with very little preparation, and are strong and heavy; the lines of which they are composed twisted like whip-cord. Some of them, however, appear to be made of the fur of an animal, and others of cotton. The meshes of their nets are made of very large loops artificially inserted into each other, but without any knots. Their hooks are made of the inside of a shell, very much resembling mother-of-pearl. The canoes in which they fish are nothing more than large pieces of bark tied up at both ends with vines; and considering the slight texture of these vessels, we cannot but admire the dexterity with which they are managed, and the boldness with which they venture in them out to sea. They generally carry fire along with them in these canoes, to dress their fish when caught. When fishing with the hook, if the fish appears too strong to be drawn ashore by the line, the canoe is paddled to the shore; and while one man gently draws the fish along, another stands ready to strike it with a spear, in which he generally succeeds. There is no good reason for supposing them to be cannibals, though they never eat animal substances but raw or next to it. Some of their vegetables are poisonous when raw, but deprived of this property when boiled. A convict unhappily experienced this by eating some in an unprepared state; in consequence of which he died in 24 hours. The dislike of the New Hollanders to the European provisions has already been mentioned: if bread be given them, they chew and spit it out again, seldom choosing to swallow it. They like salt beef and pork rather better; but they could never be brought to taste spirits a second time.

The huts of these savages are formed in the most rude and barbarous manner that can be imagined. They consist only of pieces of bark laid together in the form of an oven, open at one end, and very low, though long enough for a man to lie at full length. There is reason, however, to believe, that they depend less on them for shelter than on the caverns with which the rocks abound. They go invariably naked, as has already been observed; though we must not imagine that the custom of going naked injures them so to the climate as to make them insensible to the injuries of the weather. The colonists had repeated opportunities of observing this, by seeing them shivering with cold in the winter time, or huddling together in heaps in their huts or in caverns, till a fire could be kindled to warm them. It is probable, however, notwithstanding their extreme barbarity, that some knowledge of the arts will soon be introduced among them, as some have been seen attentively considering the utensils and conveniencies of the Europeans, with a view, seeming-

ly, of making similar improvements of their own. It has also been observed, that in some things they possess a very great power of imitation. They can imitate the songs and language of the Europeans almost instantaneously, much better than the latter can imitate theirs by long practice. Their talent for imitation is also discernible in their sculptures representing men and other animals every where met with on the rocks; which, though rude, are very surprising for people who have not the knowledge even of constructing habitations in the least comfortable for themselves, or even clothes to preserve them from the cold.

In their persons, the New Hollanders are active, vigorous, and stout, though generally lean. Dampier asserts that they have a dimness of sight; though later navigators have determined this to be a mistake, ascribing to them, on the contrary, a quick and piercing sight. Their sense of smelling is also very acute. One of them having touched a piece of pork, held out his finger for his companion to smell with strong marks of disgust. The only kind of food they eagerly accept of is fish. Their behaviour with regard to the women has been hitherto unaccountable to the colonists. Few of them, comparatively speaking, have been seen; and these have sometimes kept back with the most jealous sensibility; sometimes offered with the greatest familiarity. Such of the females as have been seen, have soft and pleasing voices; and notwithstanding their barbarism and excessive rudeness, seem not to be entirely destitute of modesty.

The New Hollanders generally display great personal bravery on the appearance of any danger. An old man, whom governor Phillip had treated with some familiarity, took occasion to steal a spade; but being taken in the fact, the governor gave him a few slight slaps on the shoulder; on which the old man caught hold of a spear, and, coming up to him, seemed for some time determined to strike, though had he done so it would have been impossible for him to escape, being then surrounded by the officers and soldiers. No encounters between parties of the natives themselves have been observed, though from some circumstances it appears that wars are carried on among them. They have more than once been seen assembled as if bent on some expedition. An officer one day met 14 of them marching along in a regular Indian file through the woods, each man having a spear in one hand and a stone in the other. A chief appeared at their head, who was distinguished from the rest by being painted. They passed on peaceably, though greatly superior in number to our people. On another occasion they offered no hostilities when assembled to the number of 200 or 300, and meeting the governor attended only by a small party. With all their courage, however, they are much afraid of a musket, and almost equally so of a red coat, which they know to be the martial dress of the Europeans. The mischief which they have hitherto done has been exercised only on some straggling convicts, most of whom probably have been the first aggressors.

Though these savages allow their beards to grow to a considerable length, it does not appear that they look upon them to be any ornament, but rather the contrary, as appears from the following instance. Some young gentlemen belonging to the *Sirius*, one day met an old man in the woods with a beard of considerable length. This his new acquaintance let him know that they would rid him of, stroking their chins, and showing him the smoothness of them at the same time. At length the old fellow consented; and one of the youngsters taking a pen-knife from his pocket, and making the best substitute for lather he could, performed the operation with such success that the Indian seemed highly delighted. In a few days he paddled alongside of the *Sirius* again, pointing to his beard; but could not by any means be prevailed upon to enter the ship. On this a barber was sent down to him, who again freed him from his

beard, at which he expressed the utmost satisfaction. It has, however, been found impossible to form any kind of permanent intercourse with the natives, though many attempts have been made for that purpose; but in his letter above quoted, governor Phillip declares that he has not the least apprehension of their doing any damage to the colony. At first the colonists imagined the spears of the New Hollanders to be very trivial weapons; but it now appears that they are capable of inflicting very grievous and mortal wounds. They are sometimes pointed with a sharp piece of the same reed of which the shafts are made, but more frequently with the sharp bone of the sting-ray. They certainly burn their dead; which perhaps has given rise to the report of their being cannibals. Governor Phillip, observing the ground to be raised in several places, caused one of these tumuli to be opened, in which were found a jaw-bone half consumed and some ashes. From the manner in which the ashes are deposited, it appears that the body has been laid at length, raised from the ground a little space, and consumed in that posture; being afterwards lightly covered with mould.

The only domestic animals they have are the dogs already mentioned, which resemble the fox-dog of England. In their language these animals are called *dingo*; but all other quadrupeds without exception they name *kangaroo*.—They seem very little given to thieving in comparison with the inhabitants of most of the South Sea islands; and are very honest among themselves, leaving their spears and other implements open on the beach, in full and perfect security of their remaining untouched. They are very expert at throwing their javelins, and will hit a mark with great certainty at a considerable distance; and it seems that sometimes they kill the kangaroo with this weapon, as a long splinter of one of the spears was taken out of the thigh of one of these animals, the flesh having closed over it completely. The people are more numerous than was at first imagined, though still the number of inhabitants must be accounted few in comparison to the extent of country; and there is great reason to believe that the interior parts are uninhabited.

The New Hollanders bake their provisions by the help of hot stones, like the inhabitants of the South Sea islands. They produce fire with great facility according to Captain Cook, but with difficulty according to later accounts, and spread it in a wonderful manner. To produce it, they take two pieces of dry soft wood; one is a stick about eight or nine inches long, the other piece is flat. The stick they shape into an obtuse point at one end; and pressing it upon the other, turn it nimbly, by holding it between both their hands, as we do a chocolate-mill; often shifting their hands up, and then moving them down upon it, to increase the pressure as much as possible. By this method they get fire in less than two minutes; and from the smallest spark they increase it with great speed and dexterity. "We have often seen (says Captain Cook) one of them run along the shore, to all appearance with nothing in his hand, who stooping down for a moment, at the distance of every fifty or an hundred yards left fire behind him, as we could see, first by the smoke, and then by the flame along the drift of wood and other litter which was scattered along the place. We had the curiosity to examine one of these planters of fire when he set off, and we saw him wrap up a small spark in dry grass, which when he had run a little way, having been fanned by the air that his motion produced, began to blaze; he then laid it down in a place convenient for his purpose, inclosing a spark of it in another quantity of grass, and so continued his course."

HOLLAND in commerce, a fine and close kind of linen, so called from its being first manufactured in Holland.

HOLLAR (Wenceslaus), a celebrated engraver, born at Prague in 1607. His parents were in a genteel line of life; and he was at first designed for the study of the law. But the civil commotions, which happened in his youth, ruining his

family affairs, he was obliged to shift for himself; and by discovering some genius for the arts, he was placed with Marian, a very able designer and engraver of views. Being himself a man of great ingenuity, he profited hastily from the instruction of his tutor. He principally excelled in drawing geometrical and perspective views and plans of buildings, ancient and modern cities and towns; also landscapes, and every kind of natural and artificial curiosities; which he executed with a pen in a very peculiar style, excellently well adapted to the purpose. He travelled through several of the great cities of Germany; and, notwithstanding all his merit, met with so little encouragement, that he found it very difficult to support himself. The earl of Arundel being in Germany took him under his protection, brought him to England, and recommended him to the favour of Charles I. He engraved a variety of plates from the Arundel collection, and the portrait of the earl himself on horseback. The civil wars, which happened soon after in England, ruined his fortune. He was taken prisoner, with some of the royal party, and with difficulty escaped; when he returned to Antwerp, and joined his old patron the earl of Arundel. He settled in that city for a time, and published a considerable number of plates; but his patron going to Italy soon after for the benefit of his health, Hollar fell again into distress, and was obliged to work for the print and booksellers of Antwerp at very low prices. At the restoration he returned into England; where, though he had sufficient employment, the prices he received for his engravings were so greatly inadequate to the labour necessarily required, that he could but barely subsist; and the plague, with the succeeding fire of London, putting for some time an effectual stop to business, his affairs were so much embarrassed, that he was never afterwards able to improve his fortune. It is said that he used to work for the booksellers at the rate of four-pence an hour; and always had an hour-glass before him. He was so very scrupulously exact, that when obliged to attend the calls of nature, or whilst talking, though with the persons for whom he was working and about their own business, he constantly laid down the glass, to prevent the sand from running. Nevertheless, all his great industry, of which his numerous works bear sufficient testimony, could not procure him a sufficient maintenance. It is melancholy to add, that on the verge of his 70th year, he was attached with an execution at his lodgings in Gardener's lane, Westminster; when he desired only the liberty of dying in his bed, and that he might not be removed to any other prison than the grave: a favour which it is uncertain whether he obtained or not. He died, however, in 1677.—His works amount nearly to 24,000 prints, according to Vertue's Catalogue; and the lovers of art are always zealous to collect them. Generally speaking, they are etchings performed almost entirely with the point; and their merits are thus characterised by Mr. Strutt: "They possess great spirit, with astonishing freedom and lightness, especially when we consider how highly he has finished some of them. His views of abbeys, churches, ruins, &c. with his shells, mussels, and every species of still life, are admirable; his landscapes frequently have great merit; and his distant views of towns and cities are not only executed in a very accurate, but a very pleasing manner." A somewhat colder character is given of them by Mr. Gilpin in his Essay on Prints: "Hollar gives us views of particular places, which he copies with great truth, unornamented as he found them. If we are satisfied with exact representations, we have them no where better than in Hollar's works: but if we expect pictures, we must seek them elsewhere. Hollar was an antiquarian and a draughtsman; but seems to have been little acquainted with the principles of painting. Stiffness is his characteristic, and a painful exactness void of taste. His larger views are mere plans. In some of his smaller, at the expence of infinite pains, something of an effect is sometimes produced.

But in general, we consider him as a repository of curiosities, a record of antiquated dresses, abolished ceremonies, and edifices now in ruins."

HOLLOA, in the sea-language, an exclamation of answer, to any person who calls to another to ask some question, or to give a particular order. Thus, if the master intends to give any order to the people in the main top, he previously calls, *Main-top, boay!* to which they answer, *Holloa!* to show that they hear him, and are ready. It is also the first answer in hailing a ship at a distance. See **HAILING**.

HOLLY, in botany. See **ILEX**.

Sea-HOLLY. See **ERYNGIUM**.

HOLM (Sax. *bulmus, insula amnica*), denotes an isle or fen-ny ground, according to Bede; or a river-island. And where any place is called by that name, and this syllable is joined with any other in the names of places, it signifies a place surrounded with water; as the Flatholmes and Stepholmes in the Severn near Bristol: but if the situation of the place is not near the water, it may then signify a hilly place; *holm* in Saxon signifying also "a hill or cliff."

HOLME, a small town of Cumberland, with a market on Saturday. It is sometimes called Abbey-Holme, from an abbey that formerly stood there. It is seated on an arm of the sea, 12 miles N. of Cockermouth, and 310 N. N. W. of London. W. lon. 3. 19. N. lat. 54. 53.

HOLMESDALE, a rough and woody tract in Surrey, lying immediately beneath the hills to the S. and E. of that county, and extending into Kent. Red deer are still found there; and it is said to have taken its name from the holm oak with which it abounds.

HOLocaust, formed from *ὅλος* "whole," and *καίω* "I consume with fire," a kind of sacrifice, wherein the whole offering is burnt or consumed by fire, as an acknowledgement that God, the creator, preserver, and lord of all, was worthy of all honour and worship, and as a token of men's giving themselves entirely up to him. It is called also in Scripture a *burnt offering*. Sacrifices of this sort are often mentioned by the heathens as well as Jews; particularly by Xenophon, *Cyropæd. lib. viii. p. 464. ed. Hutchinsf. 1738*, who speaks of sacrificing holocausts of oxen to Jupiter, and of horses to the sun: and they appear to have been in use long before the institution of the other Jewish sacrifices by the law of Moses; (see Job i. 5. xlii. 8. and Gen. xxii. 13. viii. 20). On this account, the Jews, who would not allow the Gentiles to offer on their altar any other sacrifices peculiarly enjoined by the law of Moses, admitted them by the Jewish priests to offer holocausts; because these were a sort of sacrifices prior to the law, and common to all nations. During their subjection to the Romans, it was no uncommon thing for those Gentiles to offer sacrifices to the God of Israel at Jerusalem. Holocausts were deemed by the Jews the most excellent of all their sacrifices. It is said, that this kind of sacrifice was in common use among the heathens, till Prometheus introduced the custom of burning only a part, and reserving the remainder for his own use. See **SACRIFICE**.

HOLOFERNES, lieutenant general of the armies of Nabuchodonosor king of Assyria, who having in a remarkable encounter overcome Arphaxad king of the Medes, sent to all the neighbouring nations with an intention of obliging them this way to submit to his empire, pretending that there could be no power capable of resisting him. At the same time Holofernes, at the head of a powerful army, passed the Euphrates, entered Cilicia and Syria, and subdued almost all the people of those provinces.

Being resolved to make a conquest of Egypt, he advanced towards Judæa, little expecting to meet with any resistance from the Jews. In the mean time he was informed that they were preparing to oppose him; and Achior the commander of

The Ammonites, who had already submitted to Holofernes, and was with some auxiliary troops in his army, represented to him that the Hebrews were a people protected in a particular manner by God Almighty so long as they were obedient to him; and therefore he should not flatter himself with expectations of overcoming them, unless they had committed some offence against God, whereby they might become unworthy of his protection. Holofernes, disregarding this discourse, commanded Achior to be conveyed within sight of the walls of Bethulia, and tied to a tree, and left there, whither the Jews came and loosed him.

In the mean time Holofernes formed the siege of Bethulia; and having cut off the water which supplied the city, and set guards at the only fountain which the besieged had near the walls, the inhabitants were soon reduced to extremity, and resolved to surrender, if God did not send them succours in five days. Judith, being informed of their resolution, conceived the design of killing Holofernes in his camp. She took her finest clothes, and went out of Bethulia with her maid-servant; and being brought to the general, she pretended that she could no longer endure the sins and excesses of the Jews, and that God had inspired her with the design of surrendering herself to him.—As soon as Holofernes saw her, he was taken with her beauty; and some days after invited her to a great feast, which he prepared for the principal officers of his army. But he drank so much wine, that sleep and drunkenness hindered him from satisfying his passion. Judith, who in the night was left alone in his tent, cut off his head with his own sword; and departing with her servant from the camp, she returned to Bethulia with the head of Holofernes. As soon as it was day, the besieged made a rally upon their enemies, who going into their general's tent, found his headless carcase weltering in its own blood. They then discerned that Judith had deceived them, and fled with precipitation, leaving the camp abounding with rich spoils: the Jews pursued them, killed a great number of them, and returned loaded with booty.

There is a great diversity of opinions concerning the time when this war between Holofernes and the Jews happened. Some date it from the captivity of Babylon, in the reign of Manasseh, and pontificate of Eliakim the high-priest; others place it at some time after the captivity; and some doubt the truth of the whole transaction.

HOLOGRAPHUM, composed of *ὅλος*, all, and *γράφω* I write, in the civil law, something written wholly in the handwriting of the person who signs it. The word is chiefly used in speaking of a testament written wholly in the testator's own hand. The Romans did not approve of holographic testaments; and, though Valentinian authorized them by a novel, they are not used where the civil law is in full force.

HOLOSTEUM, in botany; a genus of the trigynia order, belonging to the triandria class of plants; and in the natural method ranking under the 22d order, *Caryophyllei*. The calyx is pentaphyllous; the petals five; the capsule unilocular, and nearly cylindrical, opening at top.

HOLOTHURIA, in zoology, a genus belonging to the order of vermes mollusca. The body detached, naked, gibbous, terminated by the anus. Many tentacula at the other extremity, surrounding the mouth. There are nine species, (see Plate 10.) all inhabitants of the ocean. The following descriptions of three species are given by Mr. Barbut.

1. The *tremula*, or quivering holothuria, "commonly measures eight inches in length when dead; but alive it extends itself to more than a foot, or contracts its body into a ball. Its figure is cylindrical, the diameter of which is every way equal to an inch and a few lines. The back of a dark brown prondly bears a variety of fleshy pyramid like nipples, of a dark colour likewise at their basis, but white at their apex. They are

observed to be of two different sizes; the larger occupy the length of the back, in number 14 on each side, at the distance of six lines one from the other, when the holothuria is contracted, but the intervening space is full eight lines when the animal is extended. Others like these are placed here and there promiscuously. The less are scattered in like manner, without order, in every part of the back. Out of them all exudes a whitish mucilage serving to lubricate the body. Hence all the foresaid nipples seem to be so many glands furnished with an excretory duct, the aperture of which is so minute as not to be discoverable by the help of a common glass. That they are moreover provided with various muscles follows hence, that the holothuria can raise and obliterate them at pleasure. While the larger papillæ are quite erect, their axis and the diameter of their base measures three lines. The belly or part opposite to the back in the holothuria is of a pale brown and set all over with cylindric tentacula, in such numbers that the head of a pin could scarce find room between. Their diameter is not much above a line, and their length is that of four lines. They are of a shining whiteness, except the extremity, which is of a dark colour and shaped like a socket. By the help of these tentacula the holothuria fixes its body at the bottom of the sea, so as not to be easily forced away by tempests, which would otherwise happen the more frequently, as this zoophite dwells near the shores where the water scarce rises to a fathom's height. Now if it adheres to other bodies by means of its ventral tentacula, their point must necessarily have the form of a socket, as the cuttle-fish, sea-urchins, and star-fish have theirs shaped, by which they lay hold of any other body. From this situation of the holothuria at the bottom of the sea, which it also retains when kept in a vessel filled with sea-water, it must be evident to any one, that I have not groundlessly determined which was its back, and which its belly, which otherwise in a cylindric body would have been a difficult task. But as all animals uniformly walk or rest upon their bellies, and the holothuria has likewise that part of its body turned to the earth on which the cylindric tentacula are to be seen, it is clear that part is the abdomen or belly of this zoophite. However, both the abdominal and dorsal tentacula are raised and obliterated at the animal's pleasure; from which it is no light conjecture to conclude, that they are furnished with elevating and depressing muscles, and particularly because all the foresaid tentacula disappear after the animal's death: and hence it farther appears, that all naturalists have given the representation of a dead holothuria, seeing they have assigned it no tentacula. I entertain some doubt whether the illustrious Linnæus himself did not draw his generical character of the holothuria from a dead subject, as he makes no mention of these tentacula."

2. The *physalis*, or bladder shaped holothuria. The body of this species is oval, approaching to triangular, of a glossy transparency; the back sharp edged, of a dark green colour, whence run out a number of finews: anteriorly the body is of a reddish hue. The trunk spiral, reddish towards the thicker end. Many tentacula of unequal length under that thicker end; the shorter ones are taper and thicker, the middle ones capillary, the point clay colour and in shape like a ball; the rest, which are longer, are filiform, of which the middlemost is thicker and twice as long. Brown, in his Jamaica, calls it a diaphanous bladder with numerous tentacula representing a man's belly; above it is furnished with a comb full of cells; under the other extremity hang a number of branchy tentacula. It inhabits the seas.

3. The *pentactes*, or five-rowed holothuria, has the mouth encompassed with tentacula, the body bearing tentacula five different ways. The animal is of a red colour, nearly oval, or somewhat cylindrical, assuming various shapes. The mouth is set round with ten rays bristly at the points; the body

longitudinally dotted in five places with clay-coloured hollow warts, situate two together. It inhabits the sea of Norway, taking in and casting out again the water, as it either swims or dives to the bottom.

HOLSTEIN, a duchy of Germany, bounded by the German ocean on the west; the Baltic, or the gulph of Lubeck, on the east; the duchy of Mecklenburg on the south-east; that of Bremen, with the river Elbe, on the south-west; and Lauenburg, with the territory of Hamburg, on the south. Its greatest length is about 80 miles, and its breadth 60. The diocese of Eutin, and the county of Ranzau, though they make a part of the duchy of Holstein, yet being lands belonging to the empire and circle, shall be described separately.

A great part of this country consists of rich marsh-land, which being much exposed to inundations both from the sea and rivers, dykes have been raised at a great expence to guard and defend them. The pastures in the marshes are so rich, that cattle are bred in vast numbers and fattened in them, and great quantities of excellent butter and cheese made of their milk. They are also very fruitful in wheat, barley, pease, beans, and rape seed. In the more barren, sandy, and heathy parts of the country, large flocks of sheep are bred and grazed: nor are orchards wanting, or woods, especially of oak and beech; nor turf, poultry, game, and wild-fowl. Here is a variety both of sea and river fish; and the beef, veal, mutton, and lamb, are very fat and palatable. Holstein is also noted for beautiful horses. The gentry usually farm the cows upon their estates to a Hollander, as he is called, who for every cow pays from six to ten rix-dollars; the owner providing pasture for them in summer, and straw and hay in winter. It is no uncommon thing here to drain the ponds and lakes once in three or four years, and sell the carp, lampreys, pikes, and perch, found in them; then sow them for several years after with oats, or use them for pasture; and after that lay them under water again, and breed fish in them. There are hardly any hills in the country; but several rivers, of which the principal are the Eyder, the Stor, and the Trave. The duchy contains about 30 towns, great and small: most part of the peasantry are under villenage, being obliged to work daily for their lords, and not even at liberty to quit their estates. The nobility and the proprietors of manors are possessed of the civil and criminal jurisdiction, with other privileges and exemptions. Formerly there were diets, but now they seem to be entirely laid aside: meetings, however, of the nobility are still held at Kiel. The predominant religion here is Lutheranism, with superintendencies as in other Lutheran countries. In several places the Jews are allowed the exercise of their religion. At Gluckstadt and Altena are both Calvinist and Popish churches; and at Kiel a Greek Russian chapel. Besides the Latin schools in the towns, at Altena is a gymnasium, and at Kiel an university. Notwithstanding this country's advantageous situation for commerce, there are few manufactures and little trade in it. Hamburg and Lubeck supply the inhabitants with what they want from abroad; from whence and Altena they export some grain, malt, groats, starch, buck-wheat, pease, beans, rapeseed, butter, cheese, sheep, swine, horned cattle, horses, and fish. The manufactures of the duchy are chiefly carried on at Altena, Kiel, and Gluckstadt. The duchy of Holstein consists of the ancient provinces of Holstein, Stormar, Ditmarsh, and Wagria. It belongs partly to the king of Denmark and partly to the dukes of Holstein Gottorp and Ploen. Anciently the counts of Holstein were vassals of the dukes of Saxony; but afterwards they received the investiture of their territories from the emperor, or the bishops of Lubeck in the emperor's name, though now the investiture is given by the emperor in person. The king of Denmark appoints a regency over his part of Holstein and the duchy of Sleswick, which has its office at Gluckstadt. The

seat of the great-duke's privy council and regency court, together with the chief consistory, which is united to it, is at Kiel: there are many inferior courts and consistories, from which an appeal lies to the higher. In the duchy of Holstein, the government of the convents and nobility is alternately in the king and duke for a year, from Michaelmas to Michaelmas. The person in whom the government is lodged administers it by his regency. In some cases an appeal lies from this court to the Aulic council or chamber at Wetzlar: the convents, the nobility, and the proprietors of manors in the country, have a civil and criminal jurisdiction over their estates. The revenues of the sovereigns arise principally from their demesnes and regalia; besides which, there is a land and several other taxes and imposts. The duke's income, setting aside his ducal patrimony, has been estimated at 70,000 or 80,000 pounds. The king usually keeps here some regiments of foot and one of horse. With respect to the duke's military force, it amounts to about 800 men. The king, on account of his share in this country, styles himself *duke of Holstein, Stormar, and Ditmarsh*. The dukes both of the royal and princely house style themselves *beirs of Norway, dukes of Sleswick, Holstein, Stormar, and Ditmarsh*, and counts of *Oldenburg and Delmenhorst*. On account of Holstein, both the king of Denmark and the grand duke have a seat and voice in the college of the princes of the empire, and in that of the circle. Together with Mecklenburg they also nominate an assessor for this circle in the Aulic chamber. The matricular assessment of the whole duchy is 40 horse and 80 foot, or 800 florins; to the chamber of Wetzlar both princes pay 189 rix-dollars, 31 kruitzers. In 1735, duke Charles Frederic of Holstein-Gottorp founded an order of knighthood here, viz. that of St. Anne, the ensign of which is a red cross, enamelled, and worn pendent at a red ribbon edged with yellow.—The principal places of that part of the duchy belonging to the king of Denmark and the duke of Ploen are Gluckstadt, Itzhoe, Rendsburg, and Ploen; and that part belonging to the great-duke are Kiel, Oldenburg, Preetz, and Altena.

HOLSTENIUS (Lucas), an ingenious and learned German, born at Hamburg in 1596, was bred a Lutheran; but being converted to popery by father Sirmond the Jesuit, he went to Rome, and attached himself to cardinal Francis Barberini, who took him under his protection. He was honoured by three popes; Urban VIII. gave him a canonry of St. Peter's; Innocent X. made him librarian of the Vatican; and Alexander VII. sent him in 1655 to queen Christina of Sweden, whose formal profession of the Catholic faith he received at Inspruck. He spent his life in study, and was very learned both in sacred and profane antiquity. He died in 1661; and though he was not the author of any great works, his notes and dissertations on the works of others have been highly esteemed for the judgment and precision with which they are drawn up.

HOLT (Sir John), knight, eldest son of Sir Thomas Holt, serjeant at law, was born in 1642. He entered himself of Gray's Inn in 1658; and applied to the common law with so much industry, that he soon became a very eminent barrister. In the reign of James II. he was made recorder of London, which office he discharged with much applause for about a year and a half; but lost his place for refusing to expound the law suitably to the king's designs. On the arrival of the prince of Orange, he was chosen a member of the convention parliament, which afforded him a good opportunity of displaying his abilities; so that, as soon as the government was settled, he was made lord chief justice of the court of king's bench, and a privy countellor. He continued chief justice for 22 years, with great repute for steadiness, integrity, and thorough knowledge in his profession. Upon great occasions he asserted the law with intrepidity, though he thereby ventured to incur by

turn of the indignation of both the houses of parliament. He began to write Reports, and died in 1709.

formerly there was great plenty of *wolgar*. the names of towns
HOLT, a town of England, in the county of Norfolk, with a weekly market on Saturday: twenty-two miles N. W. of Norwich, and 122 N. N. E. of London.

HOLT, a town of Norway, in the diocese of Christiansand: thirty-two miles N. N. E. of Christiansand.

HOLT, a town of North Wales, in the county of Denbigh: three miles N. E. of Wrexham.

HOLT, a town of Germany, in the circle of Westphalia, and duchy of Cleves: twenty-seven miles S. E. of Cleves. Long. 24. 12 E. Ferro. Lat. 51. 39. N.

HOLY GHOST, one of the persons of the Holy Trinity. See **TRINITY**.

Order of the HOLY GHOST, once the principal military order in France, instituted by Henry III. in 1569. It consisted of 100 knights, who were to make proof of their nobility for three descents. The king was the grand-master or sovereign; and, as such, took an oath on his coronation-day to maintain the dignity of the order. The knights wore a golden cross, hung about their necks by a blue silk ribbon or collar. But before they received the order of the Holy-Ghost, that of St. Michael was conferred as a necessary degree; and for this reason their arms were surrounded with a double collar.

HOLYHEAD, a town and cape of the isle of Anglesea in Wales, and in the Irish channel, where people usually embark for Dublin, there being regular packet-boats that sail for that city every Monday, Wednesday, and Friday, wind and weather permitting. It is 276 miles from London, and has a very convenient harbour for the northern trade, when taken short by contrary winds. It is situated near the extremity of the Isle, and is joined to the north-west part of it by a stone bridge of one arch. It has a small market on Saturdays. The parish is about five or six miles long, and two or three broad, bounded nearly by the sea. The church stands above the harbour, within an old quadrangular fortification, with a bastion at each corner built about 450. On a mountain near it is another old fortification called *Turris Munimentum*, which is an old stone wall without mortar; and in its centre is a small turret, that contains a well of water. Holyhead was formerly used to be visited by Irish rovers, and was defended as a place of consequence. There are several remains of old fortifications and Druidical antiquities in its neighbourhood, as well as chapels of religious worship. The parish church of Holyhead was built in the reign of Edward III. and is in the form of a cross, with a porch and steeple very antique. There was an old chapel near the church, now converted into a school-house. A salt-house was erected on an island in the harbour in queen Anne's reign, but it is now in ruins. The town is little more than a fishing town, rendered considerable by being the place of passage to Ireland. It has three good inns. The passage hence to Ireland is in general about twelve hours. There is no fresh water here except from rain, nor any bread sold but what comes from Ireland. A bath and assembly-room were erected here in 1770. Under the mountains that overhang the town is a large cavern in the rock, supported by natural pillars, called the Parliament-house, accessible only by boats, and the tide runs into it. If this harbour was properly repaired, and ware-houses built, it would be very convenient for the Irish to import such of their goods as pay English duty, it being but a few hours sail from Dublin. Besides, the Dublin merchants might come over with the packets to see their goods landed. The commodities are, butter, cheese, bacon, wild-fowl, lobsters, crabs, oysters, razor-fish, shrimps, herrings, cod fish, whittings, whiting-pollacks, cole-

fish, sea tencies, turbot's, soles, flounders, rays; and plenty of other fish. On the rocks the herb grows of which they make kelp, a fixed salt used in making glass, and in alum works. In the neighbourhood there is a large vein of white fullers which may be seen ²⁴ which might be useful to fullers. often seen there; they all come in one night, ^{and} in the same manner.

HOLY-ISLAND, a small island lying on the coast of England, 10 miles south-east of Berwick, in Northumberland. Bede calls it a *semi-island*, being, as he observes, twice an island and twice continent in one day: for at the flowing of the tide, it is encompassed by water; and at the ebb, there is an almost dry passage, both for horses and carriages, to and from the main land; from which, if measured on a straight line, it is distant about two miles eastward; but, on account of some quicksands, passengers are obliged to make so many detours that the length of way is nearly doubled. The water over these flats at spring-tides is only seven feet deep.—This island was by the Britons called *Inis Medicante*; also *Lindisfarne*, from the small rivulet of Lindi or Landi, which here runs into the sea, and the Celtic word *fabren*, or “recess;” and on account of its being the habitation of some of the first monks in this country, it afterwards obtained its present name of *Holy-island*. It measures from east to west about two miles and a quarter, and its breadth from north to south is scarcely a mile and a half. At the north-west part there runs out a spit of land of about a mile in length. The monastery is situated at the southernmost extremity; and at a small distance north of it stands the village. On this island there is plenty of fish and fowl: but the air and soil are bad. There is not a tree on the island. The village, which stands on a rising ground, consists but of a few scattered houses, chiefly inhabited by fishermen; and it has two inns. The north and east coasts are formed of perpendicular rocks, the other sides sink by gradual slopes to the sands. There is a commodious harbour, defended by a block-house; which last was surprised and taken in 1715, but was soon invested and retaken.

Holy-island, though really part of Northumberland, belongs to Durham; and all civil disputes must be determined by the justices of that county.—It was a very ancient episcopal seat. Ardan the first bishop, after presiding in it 14 years, died and was buried here A. D. 651. Finan, his successor, built a wooden church, thatched with reeds, but before the end of the century covered with lead by bishop Eadbert. St. Cuthbert, who from a poor shepherd became monk of Melrose 15 years, was prior here 12 more, when he retired to one of the barren Farn rocks, from whence he was called to this see, which he held only two years, and returned to his retirement, where he died, and was buried at the east end of his oratory, where his stone coffin is still shown. His body was found fresh 11 years after his death. Lindisfarn was ruined by the Danes, A. D. 793, when the monks carried his body about for seven years, and at last settled at Chester-le-tireet, whither the see was translated, and where it continued many years. On a second destruction of the monastery by the Danes they were removing to Rippon, but stopped by a miracle at Durham, where the saint continued till the reformation, when his body was found entire, and privately buried in a wooden coffin, as some pretend, near the clock, but more probably in the ground under where his shrine stood. The entrochi found among the rocks at Lindisfarn, are called St. Cuthbert's beads, and pretended to be made by him in the night. Eighteen bishops sat here till the removal of the see to Chester, which had eight more till the removal to Durham, A. D. 995. Lindisfarn became a cell to that Benedictine monastery, valued at 48*l. per ann.* The north and south walls

of the church are standing, much inclined; part of the west end remains, but the east is down. The columns of the nave are of four different sorts, 12 feet high and 5 feet diameter, massy and richer than those of Durham; the bases and capitals plain, supporting circular arches. ~~Over each arch are three~~ ~~are small~~ ~~is~~ ~~feet,~~ ~~and with the two aisles 36 feet;~~ ~~but it may~~ ~~be doubted whether there ever was a transept. One arch of the centre-tower remains adorned as is its entrance from the nave with Saxon zigzag. Somewhat to the east is the base of a cross, and to the west the present parish-church.~~

HOLYOAK (FRANCIS), author of a Latin dictionary, became rector of South-ham in Warwickshire in 1604; and being greatly esteemed, was chosen member of the convocation in the first year of Charles I.'s reign. He suffered much for the king; and died in 1653, aged 87. His son, Thomas Holyoak, republished the Dictionary, and made many additions to it.

HOLY-ROOD Day, a festival observed by the Roman catholics, in memory of the exaltation of our Saviour's cross. See **CROSS** and **EXALTATION**.

HOLYWELL, a town of North Wales, in the county of Flint, chiefly celebrated for a spring, called *Saint Winnifred's Well*, from whence it takes its name, and concerning which many fables have been told. It issues from the foot of a hill with great impetuosity, and turns several mills erected for working copper, making brass wire, paper, and snuff, and winding cotton, &c. At the back of the town is a hill, in which lead-ore is found. Holywell has a weekly market on Friday: fifty-two miles N. N. W. of Shrewsbury, and 212 N. W. of London.

HOLYWOOD (JOHN), or HALIFAX, or *Sacrobofco*, was, according to Leland, Bale, and Pitts, born at Halifax in Yorkshire: according to Stainhurst, at Holywood near Dublin; and according to Dempster and Mackenzie, in Nithsdale in Scotland. The last-mentioned author informs us, that, having finished his studies, he entered into orders, and was made a canon regular of the order of St. Augustine in the famous monastery of Holywood in Nithsdale. The English biographers, on the contrary, tell us, that he was educated at Oxford. They all agree, however, in asserting that he spent most of his life at Paris; where, says Mackenzie, he was admitted a member of the university on the fifth of June in the year 1221, under the syndics of the Scotch nation; and soon after elected professor of mathematics, which he taught for many years with applause. We are told by the same author, that he died in 1256, as appears from the inscription on his monument in the cloisters of the convent of St. Maturine at Paris. Holywood was certainly the first mathematician of his time. He was cotemporary with Roger Bacon, but probably older by about 20 years. He wrote, 1. *De sphæra mundi*; often reprinted, and illustrated by various commentators. 2. *De anni ratione, seu de computo ecclesiastico*. 3. *De algorismo*, printed with *Comm. Petri Cirvilli Hisp.* Paris 1498.

HOMAGE, in law, is the submission, loyalty, and service, which a tenant promised to his lord when he was first admitted to the land which he held of the lord in fee: also that owing to a king, or to any superior.

HOMBERG (WILLIAM), a celebrated physician, chemist, and philosopher, was the son of a Saxon gentleman, and born in Batavia, in the East Indies, in 1652. His father afterwards settling at Amsterdam, William there prosecuted his studies; and from thence removed to Jena, and afterwards to Leipzig, where he studied the law. In 1642 he was made advocate at Magdeburg, and there applied himself to the study of experimental philosophy. Some time after he travelled into Italy; and

applied himself to the study of medicine, anatomy, and botany, at Padua. He afterwards studied at Bologna; and at Rome learned optics, painting, sculpture, and vended into Germany and vended into France the mines of Saxony, Bohemia, Hungary, and Sweden; and returned to France, where he acquired the esteem of the learned. He was on the point of returning into Germany, when M. Colbert being informed of his merit, made him such advantageous offers, as induced him to fix his residence at Paris. M. Homberg, who was already well known for his phosphorus, for a pneumatic machine of his own invention more perfect than that of Guericke, for his microscopes; for his discoveries in chemistry, and for the great number and variety of his curious observations, was received into the academy of sciences in 1691, and had the laboratory of that academy, of which he was one of its principal ornaments. The duke of Orleans, afterwards regent of the kingdom, at length made him his chemist, settled upon him a pension, gave him the most superb laboratory that was ever in the possession of a chemist, and in 1704 made him his first physician. He had abjured the Protestant religion in 1682, and died in 1715. There are a great number of learned and curious pieces of his writing, in the memoirs of the academy of sciences, and in several journals. He had begun to give the elements of chemistry in the memoirs of the academy, and the rest were found among his papers fit for printing.

HOMBURG, a town of Germany, in the circle of the Upper Rhine, and landgravate of Hesse. It is 60 miles N. W. of Frankfort, and subject to one of the branches of the house of Hesse.

HOMBURG, a town of Germany, in the duchy of Deux-Ponts, 50 miles S. E. of Treves. E. lon. 7. 32. N. lat. 49. 16.

HOME (HENRY), Lord KAMES, an eminent Scottish lawyer, and author of many useful and ingenious works on various subjects, was descended of an ancient family, and born in 1696, in the county of Berwick. His grandfather, Henry Home, was a younger son of Sir John Home of Renton, who held the high office of lord justice-clerk, or chief criminal judge of Scotland, in the year 1663. He received the estate of Kames from his uncle George, brother to the then lord justice-clerk. The family of Renton is descended from that of the earls of Home, the representatives of the ancient princes of Northumberland, as appears from the records of the Lion Office.

In early youth, he was lively, and eager in the acquisition of knowledge. He never attended a public school; but was instructed in the ancient and modern languages, as well as in several branches of mathematics, and the arts necessarily connected with that science, by Mr. Wingate, a man of considerable parts and learning, who spent many years as preceptor or private tutor to Mr. Home.

After studying the civil law and the municipal law of his own country at Edinburgh, Mr. Home early perceived that a knowledge of these alone is not sufficient to make an accomplished lawyer. An acquaintance with the forms and practical business of the courts, and especially of the supreme court, as a member of which he was to seek for fame and emolument, he considered as essentially necessary to qualify him to be a complete barrister. He accordingly attended for some time the chamber of a writer to the signet, where he had an opportunity of learning the styles of legal deeds, and the modes of conducting different species of business. This wise step, independently of his great genius and unwearied application, procured him, after his admission to the bar, peculiar respect from the court, and proportional employment in his profession of an advocate. Whoever peruses the law-papers composed

by Mr. Home when a young man of uncommon genius and a knowledge of the law and constitution of his country. These qualifications, together with the strength and vivacity of his natural abilities, soon raised him to be an ornament to the Scottish bar; and, on the 2d of February 1752, he was advanced to the bench as one of the judges of the court of session, under the title of *Lord Kames*.

Before this period, however, notwithstanding the unavoidable labours of his profession, Mr. Home had become the author of several works. In 1728 he published *Remarkable Decisions of the Court of Session from 1716 to 1728*, in one vol. folio.—In 1732 appeared *Essays upon several subjects in law, viz. Jus tertii; Beneficium eedendarum actionum; Vinco Vincentem; and Prescription*; in one volume 8vo. This first produce of his original genius, and of his extensive views, excited not only the attention, but the admiration of the judges, and of all the other members of the college of justice. This work was succeeded, in the year 1741, by *Decisions of the Court of Session from its first institution to the year 1740, abridged and digested under proper heads, in form of a Dictionary*, in two volumes folio: a very laborious work, and of the greatest utility to the practical lawyer. In 1747 appeared *Essays upon several subjects concerning British Antiquities, viz. 1. Introduction of the feudal law into Scotland. 2. Constitution of parliament. 3. Honour, Dignity. 4. Succession, or Descent; with an appendix upon hereditary and indefeasible right, composed anno 1745, and published 1747*, in one volume 8vo. In a preface to this work, Lord Kames informs us, that in the years 1745 and 1746, when the nation was in great suspense and distraction, he retired to the country; and in order to banish as much as possible the uneasiness of his mind, he planned and executed these Essays.

Though not in the order of time, we shall continue the list of all our author's writings on law, before we proceed to his productions on other subjects. In 1757 he published *The Statute Law of Scotland abridged, with historical notes*, in one volume 8vo; a most useful and laborious work. In the year 1759 he presented to the public a new work under the title of *Historical Law Tracts*, in one vol. 8vo. It contains fourteen interesting tracts, viz. History of the Criminal Law:—History of Promises and Covenants:—History of Property:—History of Securities upon and for Payment of Debt:—History of the Privilege which an Heir-apparent in a feudal Holding has to continue the Possession of his Ancestor:—History of Regalities, and of the Privilege of repledging:—History of Courts:—History of Brieves:—History of Process in Absence:—History of Execution against Moveables and Land for Payment of Debt:—History of Personal Execution for Payment of Debt:—History of Execution for obtaining Payment after the Death of the Debtor:—History of the limited and universal Representation of Heirs:—Old and New Extent. In 1760 he published, in one volume folio, *The Principles of Equity*; a work which shows both the fertility of the author's genius and his indefatigable application. In 1766 he gave to the public another volume in folio of *Remarkable Decisions of the Court of Session, from 1730 to 1752*. In 1777 appeared his *Elucidations respecting the Common and Statute Law of Scotland*, in one volume 8vo. This book contains many curious and interesting remarks upon some intricate and dubious points which occur in the law of Scotland. In 1780 he published a volume, in folio, of *Select Decisions of the Court of Session from 1752 to 1768*.

Lord Kames's mind was very much inclined to metaphysical disquisitions. When a young man, in order to improve himself in his favourite study, he corresponded with the famous Berkeley bishop of Cloyne, Dr. Butler bishop of Durham, Dr.

Samuel Clark, and many other ingenious and learned men both in Britain and Ireland. The letters of correspondence, we are informed, have been carefully preserved by his son George Home-Drummond, Esq.

In the year 1751 appeared *Essays on the Principles of Morality and Natural Religion*, a small volume, but so replete with ingenuity and acute reasoning, as to give rise to much controversy. It contained, in the most explicit terms, the doctrine which then made so much noise under the appellation of *philosophical necessity*. Our author, like some other great and good men, continued a Necessarian to the day of his death; but in a subsequent edition of these essays, he exhibited a remarkable proof of his candour and liberality of sentiment, by altering certain expressions, which, contrary to his intention, had given very general offence.

In 1761 he published an *Introduction to the Art of Thinking*, in one volume 12mo. This small book consists of maxims collected from Rochefoucault and many other authors, illustrated in a variety of stories, fables, and historical anecdotes.

In the department of belles lettres, his *Elements of Criticism* appeared in 1762, in three volumes 8vo. In this valuable work our author attempts to show, that the art of criticism is founded on the principles of human nature. Such a plan, it might be thought, should have produced a dry and phlegmatic performance; but, from the sprightliness of his manner of treating every subject, he has rendered the *Elements of Criticism* not only highly instructive, but one of the most entertaining books in our language. Rollin's *Belles Lettres*, a dull performance, from which a student could derive little advantage, but which had till then been universally recommended as a standard, was wholly superseded by this popular publication.

A farther proof of the genius and various pursuits of his active mind was given in the year 1772, when Lord Kames published a work in one volume 8vo, entitled *The Gentleman Farmer, being an attempt to improve Agriculture by subjecting it to the test of rational principles*. This book met with a very favourable reception in Scotland, where, as a practical farmer, its author gave many proofs of superior skill. After he succeeded, in right of his lady, to the ample estate of Blair-Drummond in the county of Perth, he formed, and in part successfully executed, a plan for turning a large moss, consisting of at least 1500 acres, into arable land.

In 1773, Lord Kames published *Sketches of the History of Man*, in 2 vols. 4to. This work consists of a great variety of facts and observations concerning the nature of man; the produce of much and profitable reading.

His last work, intitled *Loose Hints upon Education, chiefly concerning the Culture of the Heart*, was published in 1781, in one vol. 8vo, when its venerable author was in the 85th year of his age. The intelligent reader will perceive in this composition an uncommon activity of mind at an age so far advanced beyond the usual period of human life, and an earnest desire to form the minds of youth to honour, to virtue, to industry, and to a veneration of the Deity. It must be confessed, however, that in these good intentions chiefly consists the merit of this performance, which certainly betrays some marks of that imbecility which must be expected at so extenuated a period of life.

Beside the books we have enumerated, Lord Kames published many temporary and fugitive pieces in different periodical works. In the *Essays Physical and Literary*, published by a society of gentlemen in Edinburgh, we find compositions of his Lordship *On the Laws of Motion, On the Advantages of Shallow Ploughing, and on Evaporation*; all of which exhibit evident marks of genius and originality of thinking.

Lord Kames was remarkable for public spirit, to which he conjoined activity and great exertion. He for a great length of

time had the principal management of all the societies and boards for promoting the trade, fisheries, and manufactures, in Scotland. As conducive to those ends, he was a strenuous advocate for making and repairing turnpike roads through every part of the country. He took likewise a chief lead in the distribution and application of the funds arising from the estates in Scotland which had unfortunately been annexed to the crown. He was no less zealous in supporting, both with his writings and personal influence, literary associations. He was in some measure the parent of what was called the *Physical and Literary Society*. This society was afterwards incorporated into the *Royal Society of Edinburgh*, which received a charter from the crown.

As a private gentleman, Lord Kames was admired by both sexes. His vivacity and wit, even when advanced in years, rendered his company not only agreeable, but greatly solicited by the literati, and esteemed by ladies of the highest rank and accomplishments. He told very few stories; and rarely, if ever, repeated the same story to the same person. From the necessity of retailing anecdotes, the miserable refuge of those who, without genius, attempt to shine in conversation, the abundance of his own mind set him free; for his wit or his learning always suggested what the occasion required. He could with equal ease and readiness combat the opinions of a metaphysician, unravel the intricacies of law, talk with a farmer on improvements in agriculture, or estimate with a lady the merits of the dress in fashion. Instead of being jealous of rivals, the characteristic of little minds, Lord Kames fostered and encouraged every symptom of merit that he could discover in the scholar, or in the lowest mechanic. Before he succeeded to the estate of Blair-Drummond, his fortune was small. Notwithstanding this circumstance, he, in conjunction with Mrs. Drummond, his respectable and accomplished spouse, did much more service to the indigent than most families of greater opulence. If the present necessity was pressing, they gave money. They did more: When they discovered that male or female petitioners were capable of performing any art or labour, both parties exerted themselves in procuring that species of work which the poor people could perform. In cases of this kind, which were very frequent, the Lady took charge of the women and his Lordship of the men. From what has been said concerning the various productions of his genius, it is obvious that there could be few idle moments in his long protracted life. His mind was incessantly employed; either teeming with new ideas, or pursuing active and laborious occupations. At the same time, with all this intellectual ardour, one great feature in the character of Lord Kames, beside his literary talents and public spirit, was a remarkable innocency of mind. He not only never indulged in detraction, but when any species of scandal was exhibited in his company, he either remained silent, or endeavoured to give a different turn to the conversation. As a natural consequence of this amiable disposition, he never meddled with politics, even when parties ran to indecent lengths in this country; and, what is still more remarkable, he never wrote a sentence, notwithstanding his numerous publications, without a direct and manifest intention to benefit his fellow creatures. In his temper he was naturally warm, though kind and affectionate. In the friendships he formed, he was ardent, zealous, and sincere. So far from being inclined to irreligion, as some ignorant bigots insinuated, few men possessed a more devout habit of thought. A constant sense of Deity, and a veneration for Providence, dwelt upon his mind. From this source arose that propensity which appears in all his writings, of investigating final causes, and tracing the wisdom of the Supreme Author of nature. But here we must stop. Lord Kames, to the great regret of the public, died, on the 27th day of December 1782. As he had no marked disease

but the debility necessary,

few days before his death he wearied from extreme old age, & addressed all the Judges separately, told them he was speedily to depart, and took a solemn and an affectionate farewell.

HOMER, the prince of the Greek poets, flourished, according to Dr. Blair, about 900 B. C. according to Dr. Prieftley 850, according to the Arundelian marbles 300, after the taking of Troy; and agreeable to them all, above 400 years before Plato and Aristotle. Seven cities disputed the glory of having given him birth, viz. Smyrna, Rhodes, Colophon, Salamis, Chios, Argos, and Athens; which has been expressed by the following distich:

*Smyrna, Rhodes, Colophon, Salamis, Chios, Argos, Athenæ;
Orbis de patria certat, Homere, tua.*

We have nothing that is very certain in relation to the particulars of his life. The most regular account is that which goes under the name of Herodotus, and is usually printed with his history: and though it is generally supposed to be a spurious piece, yet, as it is ancient, was made use of by Strabo, and exhibits that idea which the later Greeks, and the Romans in the age of Augustus, entertained of Homer, we must content ourselves with giving an abstract of it.

A man of Magnesia, whose name was *Menalippus*, went to settle at Cumæ, where he married the daughter of a citizen called *Homyres*, and had by her a daughter called *Critheis*. The father and mother dying, the young woman was left under the tuition of Cleonax her father's friend, and suffering herself to be deluded was got with child. The guardian, though his care had not prevented the misfortune, was however willing to conceal it; and therefore sent Critheis to Smyrna, which was then building, 18 years after the founding of Cumæ, and about 168 after the taking of Troy. Critheis being near her time, went one day to a festival, which the town of Smyrna was celebrating on the banks of the river Meles; where her pains coming upon her, she was delivered of Homer, whom she called *Meligenes*, because he was born on the banks of that river. Having nothing to maintain her, she was forced to spin: and a man of Smyrna called *Phemius*, who taught literature and music, having often seen Critheis, who lodged near him, and being pleased with her housewifery, took her into his house to spin the wool he received from his scholars for their schooling. Here she behaved herself so modestly and discreetly, that Phemius married her; and adopted her son, in whom he discovered a wonderful genius, and the best natural disposition in the world. After the death of Phemius and Critheis, Homer succeeded to his father-in-law's fortune and school; and was admired, not only by the inhabitants of Smyrna, but by strangers, who resorted from all parts to that place of trade. A shipmaster called *Mentes*, who was a man of learning and a lover of poetry, was so taken with Homer, that he persuaded him to leave his school, and to travel with him. Homer, who had then begun his poem of the Iliad, and thought it of great consequence to see the places he should have occasion to treat of, embraced the opportunity. He embarked with Mentes, and during their several voyages never failed carefully to note down all that he thought worth observing. He travelled into Egypt; from whence he brought into Greece the names of their gods, the chief ceremonies of their worship, and a more improved knowledge in the arts than what prevailed in his own country. He visited Africa and Spain; in his return from whence he touched at Ithaca, where he was much troubled with a rheum falling upon his eyes. Mentes being in haste to take a turn to Leucadia his native country, left Homer well recommended to Mentor, one of the chief men of the island of Ithaca, who took all possible care of him. There Homer was informed of many things relating to Ulysses, which he afterwards made use of in composing his *Odyssey*.

Mentes returning to Ithaca, found Homer cured. They embarked together; and after much time spent in visiting the coasts of Peloponnesus and the islands, they arrived at Colophon, where Homer was again troubled with the defluxion upon his eyes, which proved so violent, that he is said to have lost his sight. This misfortune made him resolve to return to Smyrna, where he finished his Iliad. Some time after, the ill posture of his affairs obliged him to go to Cumæ, where he hoped to have found some relief. Here his poems were highly applauded: but when he proposed to immortalize their town, if they would allow him a salary, he was answered, "that there would be no end of maintaining all the *ὄψονοι* or "blind men;" and hence got the name of *Homer*. He afterwards wandered through several places, and stopped at Chios, where he married, and composed his *Odyssey*. Some time after, having added many verses to his poems in praise of the cities of Greece, especially of Athens and Argos, he went to Samos, where he spent the winter, singing at the houses of the great men, with a train of boys after him. From Samos he went to Ios, one of the Sporades, with a design to continue his voyage to Athens; but landing by the way at Chios, he fell sick, died, and was buried on the sea-shore.

The only incontrollable works which Homer has left behind him are the *ILIAD* and *ODYSSEY*. The *Batrachomyomachia*, or battle of the frogs and mice, has been disputed. The hymns have been disputed also, and attributed by the scholiasts to Cynæthus the rhapsodist: but neither Thucydides, Lucian, nor Pausanias, has scrupled to cite them as genuine. Many other pieces are ascribed to him; viz. epigrams, the *Eartiges*, the *Cecropes*, and the destruction of *Oechalia*, of which only the names are remaining.

Nothing was ever comparable to the clearness and majesty of Homer's style; to the sublimity of his thoughts; to the strength and sweetness of his verses. All his images are striking; his descriptions just and exact, the passions so well expressed, and nature so just and finely painted, that he gives to every thing motion, life, and action. But he more particularly excels in invention, and in the different characters of his heroes, which are so varied, that they affect us in an inexpressible manner. In a word, the more he is read by a person of good taste, the more he is admired. Nor are his works to be esteemed merely as entertaining poems, or as the monuments of a sublime and varied genius. He was in general so accurate with respect to costume, that he seldom mentioned persons or things that we may not conclude to have been known during the times of which he writes; and it was Mr. Pope's opinion, that his account of people, princes, and countries, was purely historical, founded on the real transactions of those times, and by far the most valuable piece of history and geography left us concerning the state of Greece in that early period. His geographical divisions of that country were thought so exact, that we are told of many controversies concerning the boundaries of Grecian cities which have been decided upon the authority of his poems.

Alcibiades gave a rhetorician a box on the ear for not having Homer's writings in his school. Alexander was ravished with them, and commonly placed them under his pillow with his sword: he inclosed the Iliad in the precious casket that belonged to Darius; "in order (said he to his courtiers) that the most perfect production of the human mind might be inclosed in the most valuable casket in the world." And one day seeing the tomb of Achilles in *Sigæa*, "Fortunate hero! (cried he), thou hast had a Homer to sing thy victories!" Lycurgus, Solon, and the kings and princes of Greece, set such a value on Homer's works, that they took the utmost pains in procuring correct editions of them, the most esteemed of which is that of Aristarchus. Didymus was the first who wrote notes

on Homer; and Eustathius, archbishop of Thessalonica, in the 12th century, is the most celebrated of his commentators. Mr. Pope has given an elegant translation of the Iliad, adorned with the harmony of poetic numbers; and Mad. Dacier has translated both the Iliad and *Odyssey* in prose.

Those who desire to know the several editions of Homer, and the writers who have employed themselves on the works of that great poet, may consult Fabricius, in the first volume of his *Bibliotheca Græca*.

A very singular discovery, however, which was made a few years ago in Russia, deserves to be here mentioned, together with the circumstances that attended it. Christian Frederic Matthæi, who had been educated by the learned Ernesti, and did credit to the instructions of that celebrated master by the great erudition he displayed, being invited to settle at Moscow, and to assist in a plan of literature for which his abilities and acquisitions eminently qualified him; on his arrival at that city was informed, equally to his astonishment and satisfaction, that a very copious treasure of Greek manuscripts was deposited in the library of the Holy Synod, which no person in that country had either the abilities to make use of, or the curiosity to examine. Struck with the relation of a circumstance so unexpected, and at the same time so peculiarly agreeable to his classical taste, he immediately seized the opportunity that was fortunately offered him, to explore this repository of hidden treasure. After having examined several curious books, he discovered a manuscript copy of the works of Homer, written about the conclusion of the 14th century, but evidently a transcript from a very ancient and most valuable copy, which, besides the Iliad and the Odyssey, contains also 16 of the hymns, which have been long published under the name of *Homer*. Nor was this all. Twelve lines of a lost hymn to Bacchus, and the hymn to Ceres, which was also lost, were preserved in this curious and long unnoticed manuscript. The hymn to Ceres appears to be entire, excepting a few lines towards the close: and it is surely remarkable, that a Greek poem, attributed to Homer, which had been lost for ages, should be at length discovered in Muscovy, the rudest and most unclassical country in Europe. M. Matthæi, exulting in an acquisition so unexpected, and at the same time so valuable, communicated it, with singular disinterestedness, to his learned friend M. Ruhnkenius, with whose talents and extraordinary erudition he was well acquainted, that this gentleman might present it to the world without those delays which would probably have retarded the publication of it at Moscow. He was rather induced to employ M. Ruhnkenius in the publication of this curious and beautiful remnant of antiquity, because he knew that this gentleman had been particularly engaged in the study of the hymns of Homer, in order to give the public a complete edition of them. The hymn to Ceres, and the fragment of the hymn to Bacchus, were printed in 1780 at Leyden, under the care of M. Ruhnkenius, who has added some very valuable notes and observations on the hymn to Ceres, which tend to illustrate its beauties, and to throw a light on some of its obscurities. The learned editor observes, that nothing was more distant from his expectations than the discovery of this hymn to Ceres. He knew indeed that a poem bearing that title, and ascribed to Homer, existed in the second century; but as it had long been considered as irretrievably lost, he had formed no hopes of ever seeing it rescued from the obscurity to which it had been consigned. He acknowledges, that he has many doubts with respect to the high and illustrious origin ascribed to this hymn: but as no positive external evidence can be produced to determine the point, he chooses to rest his argument on what appears to him the more certain ground of internal proof; and observes, that though the poem be exquisitely beautiful, yet that it is evidently deficient in some of Homer's more striking

and predominant characteristics. It wants his energy and spirit; that vigour, that inspiration, which animate and give an irresistible power, as well as an enchanting beauty, to the poems of that sublime and inimitable bard. This opinion, as we have already seen, hath been given by other critics of all the hymns of Homer. But though M. Ruhnkenius is not inclined to attribute the hymn of Ceres to Homer, he yet acknowledges, that the structure of its language is founded on the model of that great poet, and he hesitates not to give it the honour of very high antiquity. He is of opinion, that it was written immediately after Homer, or at least in the age of Hesiod: and he congratulates the age on the discovery of so curious a poem, rescued by mere accident from the darkest retreats of oblivion, and perhaps but at a slight distance from inevitable perdition. He deems it to be an acquisition, not only calculated to gratify the curiosity of the connoisseurs in classic antiquity, or to entertain those lovers of Greek poetry whose studies are made subservient to a refined and elegant species of amusement, but he also esteems it to be of particular use to the critic, as it tends to illustrate some obscure passages both in the Greek and Latin poets.

HOMER, OMER, or CHOMER, a Jewish measure, containing the tenth part of the epha. See CORUS and MEASURE.

HOMESOKEN. See HAMESECKEN.

HOMICIDE, signifies in general, the taking away of any person's life. It is of three kinds; *justifiable*, *excusable*, and *felonious*. The first has no share of guilt at all; the second very little; but the third is the highest crime against the law of nature that man is capable of committing.

I. Justifiable homicide is of different kinds.

1. Such as is owing to some unavoidable *necessity*, without any will, intention, or desire, and without any inadvertence or negligence, in the party killing, and therefore without any shadow of blame; as, for instance, by virtue of such an office as obliges one, in the execution of public justice, to put a malefactor to death, who hath forfeited his life by the laws and verdict of his country. This is an act of necessity, and even of civil duty; and therefore not only justifiable, but commendable, where the law requires it. But the law must *require* it, otherwise it is not justifiable: therefore wantonly to kill the greatest of malefactors, a felon, or a traitor, attainted or outlawed, deliberately, uncompelled, and extrajudicially, is murder. And farther, if judgment of death be given by a judge not authorized by lawful commission, and execution is done accordingly, the judge is guilty of murder. Also such judgment, when legal, must be executed by the proper officer, or his appointed deputy; for no one else is *required* by law to do it, which requisition it is that justifies the homicide. If another person doth it of his own head, it is held to be murder: even though it be the judge himself. It must farther be executed, *servato juris ordine*; it must pursue the sentence of the court. If an officer beheads one who is adjudged to be hanged, or *vice versa*, it is murder: for he is merely ministerial, and therefore only justified when he acts under the authority and compulsion of the law. But, if a sheriff changes one kind of punishment for another, he then acts by his own authority, which extends not to the commission of homicide: and besides, this licence might occasion a very gross abuse of his power. The king indeed may remit part of a sentence, as in the case of treason, all but the beheading: but this is no change, no introduction of a new punishment; and in the case of felony, where the judgment is *to be hanged*, the king (it hath been said) cannot legally order even a peer to be beheaded.

Again: In some cases homicide is justifiable, rather by the *permission*, than by the absolute *command*, of the law: either for the *advancement* of public justice, which without such indemnification would never be carried on with proper vigour;

or, in such instances where it is committed for the *prevention* of some atrocious crime, which cannot otherwise be avoided.

2. Homicides, committed for the *advancement* of public justice, are, 1. Where an officer, in the execution of his office, either in a civil or criminal case, kills a person that assaults and resists him. 2. If an officer, or any private person, attempts to take a man charged with felony, and is resisted; and, in the endeavour to take him, kills him. 3. In case of a riot, or rebellious assembly, the officers endeavouring to disperse the mob are justifiable in killing them, both at common law, and by the riot act, 1 Geo. I. c. 5. 4. Where the prisoners in a gaol, or going to gaol, assault the gaoler or officer, and he in his defence kills any of them, it is justifiable, for the sake of preventing an escape. 5. If trespassers in forests, parks, chases, or warrens, will not surrender themselves to the keepers, they may be slain; by virtue of the statute 21 Edward I. st. 2. *de malefactoribus in parcis*, and 3 & 4 W. & M. c. 10. But, in all these cases, there must be an apparent necessity on the officer's side; *viz.* that the party could not be arrested or apprehended, the riot could not be suppressed, the prisoners could not be kept in hold, the deer-stealers could not but escape, unless such homicide were committed: otherwise, without such absolute necessity, it is not justifiable. 6. If the champions in a trial by battle killed either of them the other, such homicide was justifiable, and was imputed to the just judgment of God, who was thereby presumed to have decided in favour of the truth.

3. In the next place, such homicide as is committed for the *prevention* of any forcible and atrocious crime, is justifiable by the law of nature; and also by the law of England, as it stood so early as the time of Bracton, and as it is since declared by stat. 24 H. VIII. c. 5. If any person attempts a robbery or murder of another, or attempts to break open a house *in the night-time* (which extends also to an attempt to burn it), and shall be killed in such attempt, the slayer shall be acquitted and discharged. This reaches not to any crime unaccompanied with force, as picking of pockets; or to the breaking open of any house *in the day-time*, unless it carries with it an attempt of robbery also. So the Jewish law, which punished no theft with death, makes homicide only justifiable in case of *nocturnal* house-breaking: "if a thief be found breaking up, and he be smitten that he die, no blood shall be shed for him: but if the sun be risen upon him, there shall blood be shed for him; for he should have made full restitution." At Athens, if any theft was committed by night, it was lawful to kill the criminal, if taken in the fact: and, by the Roman law of the twelve tables, a thief might be slain by night with impunity; or even by day, if he armed himself with any dangerous weapon: which amounts very nearly to the same as is permitted by our own constitution.

The Roman law also justifies homicide, when committed in defence of the chastity either of one's self or relations: and so also, according to Selden, stood the law in the Jewish republic. The English law likewise justifies a woman killing one who attempts to ravish her: and so too the husband or father may justify killing a man, who attempts a rape upon his wife or daughter; but not if he takes them in adultery by consent; for the one is forcible and felonious, but not the other. And there is no doubt but the forcibly attempting a crime, of a still more detestable nature, may be equally resisted by the death of the unnatural aggressor. For the one uniform principle that runs through our own, and all other laws, seems to be this: That where a crime, in itself capital, is endeavoured to be committed by force, it is lawful to repel that force by the death of the party attempting. But we must not carry this doctrine to the same visionary length that Mr. Locke does;

who holds, "that all manner of force without right upon a man's person, puts him in a state of war with the aggressor; and, of consequence, that, being in such a state of war, he may lawfully kill him that puts him under this unnatural restraint." However just this conclusion may be in a state of uncivilized nature, yet the law of England, like that of every other well regulated community, is too tender of the public peace, too careful of the lives of the subject, to adopt so contentious a system; nor will suffer with impunity any crime to be prevented by death, unless the same, if committed, would also be punished by death.

In these instances of justifiable homicide, it may be observed, that the slayer is in no kind of fault whatsoever, not even in the minutest degree: and is therefore to be totally acquitted and discharged, with commendation rather than blame. But that is not quite the case in excusable homicide, the very name whereof imports some fault, some error, or omission; so trivial, however, that the law excuses it from the guilt of felony, though in strictness it judges it deserving of some little degree of punishment.

II. Excusable homicide is of two sorts; either *per infortunium*, by misadventure; or *se defendendo*, upon a principle of self-preservation. We will first see wherein these two species of homicide are distinct, and then wherein they agree.

1. Homicide *per infortunium*, or misadventure, is where a man, doing a lawful act, without any intention of hurt, unfortunately kills another: as where a man is at work with a hatchet, and the head thereof flies off and kills a stander-by; or, where a person, qualified to keep a gun, is shooting at a mark, and undesignedly kills a man: for the act is lawful, and the effect is merely accidental. So where a parent is moderately correcting his child, a master his apprentice or scholar, or an officer punishing a criminal, and happens to occasion his death, it is only misadventure; for the act of correction was lawful: but if he exceeds the bounds of moderation, either in the manner, the instrument, or the quantity of punishment, and death ensues, it is manslaughter at least, and in some cases (according to the circumstances) murder; for the act of immoderate correction is unlawful. Thus, by an edict of the emperor Constantine, when the rigour of the Roman law with regard to slaves began to relax and soften, a master was allowed to chastise his slave with rods and imprisonment, and if death accidentally ensued, he was guilty of no crime: but if he struck him with a club or a stone, and thereby occasioned his death, or if in any other yet grosser manner "*immoderatè suo jure utatur, tunc reus homicidii fit.*"

But to proceed. A tilt or tournament, the martial diversion of our ancestors, was however an unlawful act; and so are boxing and sword-playing, the succeeding amusements of their posterity: and therefore, if a knight in the former case, or a gladiator in the latter, be killed, such killing is felony of manslaughter. But if the king command or permit such diversion, it is said to be only misadventure; for then the act is lawful: In like manner as, by the laws both of Athens and Rome, he who killed another in the *pancratium*, or public games, authorized or permitted by the state, was not held to be guilty of homicide. Likewise to whip another's horse, whereby he runs over a child and kills him, is held to be accidental in the rider, for he has done nothing unlawful; but manslaughter in the person who whipped him, for the act was a trespass, and at best a piece of idleness, of inevitably dangerous consequence. And in general, if death ensues in consequence of an idle, dangerous, and unlawful sport, as shooting or casting stones in a town, or the barbarous diversion of cock-throwing; in these and similar cases, the slayer is guilty of manslaughter, and not misadventure only; for these are unlawful acts.

2. Homicide in *self-defence*, or *se defendendo*, upon a sudden

affray, is also excusable rather than justifiable, by the English law. This species of self-defence must be distinguished from that just now mentioned, as calculated to hinder the perpetration of a capital crime; which is not only a matter of excuse, but of justification. But the self-defence which we are now speaking of, is that whereby a man may protect himself from an assault, or the like, in the course of a sudden brawl or quarrel, by killing him who assaults him. And this is what the law expresses by the word *chance-medley*, or (as some rather choose to write it) *chaud-medley*; the former of which in its etymology signifies a casual affray, the latter an affray in the heat of blood or passion: both of them of pretty much the same import; but the former is in common speech too often erroneously applied to any manner of homicide by misadventure; whereas it appears by the statute 24 H. VIII. c. 5. and our ancient books, that it is properly applied to such killing as happens in self-defence upon a sudden rencounter. The right of natural defence does not imply a right of attacking: for, instead of attacking one another for injuries past or impending, men need only have recourse to the proper tribunals of justice. They cannot therefore legally exercise this right of preventive defence, but in sudden and violent cases; when certain and immediate suffering would be the consequence of waiting for the assistance of the law. Wherefore, to excuse homicide by the plea of self-defence, it must appear that the slayer had no other possible means of escaping from his assailant.

In some cases this species of homicide (upon *chance-medley* in self-defence) differs but little from manslaughter, which also happens frequently upon *chance-medley* in the proper legal sense of the word. But the true criterion between them seems to be this: when both parties are actually combating at the time when the mortal stroke is given, the slayer is then guilty of manslaughter; but if the slayer hath not begun to fight, or (having begun) endeavours to decline any farther struggle, and afterwards being closely pressed by his antagonist, kills him to avoid his own destruction, this is homicide excusable by self-defence. For which reason the law requires, that the person, who kills another in his own defence, should have retreated as far as he conveniently or safely can, to avoid the violence of the assault, before he turns upon his assailant; and that not fictitiously, or in order to watch his opportunity, but from a real tenderness of shedding his brother's blood. And though it may be cowardice, in time of war between two independent nations, to flee from an enemy; yet, between two fellow-subjects, the law countenances no such point of honour: because the king and his courts are the *vindices injuriarum*, and will give to the party wronged all the satisfaction he deserves. In this the civil law also agrees with ours, or perhaps goes rather farther; "*qui cum aliter tueri se non possunt, damni culpam dederint, innoxii sunt.*" The party assaulted must therefore flee as far as he conveniently can, either by reason of some wall, ditch, or other impediment; or as far as the fierceness of the assault will permit him; for it may be so fierce as not to allow him to yield a step, with manifest danger of his life, or enormous bodily harm; and then in his defence he may kill his assailant instantly. And this is the doctrine of universal justice, as well as of the municipal law.

And, as the *manner* of the defence, so is also the *time* to be considered: for if the person assaulted does not fall upon the aggressor till the affray is over, or when he is running away, this is revenge and not defence. Neither, under the colour of self-defence, will the law permit a man to screen himself from the guilt of deliberate murder: for if two persons, A and B, agree to fight a duel, and A gives the first onset, and B retreats as far as he safely can, and then kills A, this is murder; because of the previous malice and concerted design. But if A upon a sudden quarrel assaults B first, and, upon B's returning the assault, A really

and *bona fide* flies; and, being driven to the wall, turns again upon B and kills him; this may be *se defendendo*, according to some of our writers; though others have thought this opinion too favourable: inasmuch as the necessity, to which he is at last reduced, originally arose from his own fault. Under this excuse of self-defence, the principal civil and natural relations are comprehended: therefore, master and servant, parent and child, husband and wife, killing an assailant in the necessary defence of each other respectively, are excused; the act of the relation assisting being construed the same as the act of the party himself.

There is one species of homicide *se defendendo*, where the party slain is equally innocent as he who occasions his death: and yet this homicide is also excusable from the great universal principle of self-preservation, which prompts every man to save his own life preferably to that of another, where one of them must inevitably perish. As, among others, in that case mentioned by lord Bacon, where two persons, being shipwrecked, and getting on the same plank, but finding it not able to save them both, one of them thrusts the other from it, whereby he is drowned. He who thus preserves his own life at the expence of another man's, is excusable through unavoidable necessity, and the principle of self-defence; since their both remaining on the same weak plank is a mutual, though innocent, attempt upon, and endangering of, each other's life.

Let us next take a view of the circumstances wherein those two species of homicide, by misadventure and self-defence, agree; and those are in their blame and punishment. For the law sets so high a value upon the life of a man, that it always intends some misbehaviour in the person who takes it away, unless by the command or express permission of the law. In the case of misadventure, it presumes negligence, or at least a want of sufficient caution in him who was so unfortunate as to commit it; who therefore is not altogether faultless. And as to the necessity which excuses a man who kills another *se defendendo*, lord Bacon intitles it *necessitas culpabilis*, and thereby distinguishes it from the former necessity of killing a thief or a malefactor. For the law intends that the quarrel or assault arose from some unknown wrong, or some provocation, either in word or deed: and since in quarrels both parties may be, and usually are, in some fault, and it scarce can be tried who was originally in the wrong; the law will not hold the survivor entirely guiltless. But it is clear, in the other case, that where I kill a thief who breaks into my house, the original default can never be upon my side. The law besides may have a farther view, to make the crime of homicide more odious, and to caution men how they venture to kill another upon their own private judgment; by ordaining, that he who slays his neighbour, without an express warrant from the law so to do, shall in no case be absolutely free from guilt.

Nor is the law of England singular in this respect. Even the slaughter of enemies required a solemn purgation among the Jews; which implies, that the death of a man, however it happens, will leave some stain behind it. And the Mosaiical law appointed certain cities of refuge for him "who killed his neighbour unawares; as if a man goeth into the wood with his neighbour to hew wood, and his hand fetcheth a stroke with the ax to cut down a tree, and the head slippeth from the helve, and lighteth upon his neighbour that he die, he shall flee into one of those cities and live." But it seems he was not held wholly blameless, any more than in the English law; since the avenger of blood might slay him before he reached his asylum, or if he afterwards stirred out of it till the death of the high priest. In the imperial law likewise casual homicide was excused, by the indulgence of the emperor signed with his own sign-manual, "*adnotatione principis*;" otherwise, the death of a man, however committed, was in some degree punishable. Among the

Greeks, homicide by misfortune was expiated by voluntary banishment for a year. In Saxony a fine is paid to the kindred of the slain; which also, among the western Goths, was little inferior to that of voluntary homicide; and in France, no person is ever absolved in cases of this nature, without a largess to the poor, and the charge of certain masses for the soul of the party killed.

The penalty inflicted by our laws is said by Sir Edward Coke to have been anciently no less than death; which, however, is with reason denied by later and more accurate writers. It seems rather to have consisted in a forfeiture, some say of all the goods and chattels, others of only a part of them, by way of fine or *weregild*: which was probably disposed of, as in France, *in pios usus*, according to the humane superstition of the times, for the benefit of his soul who was thus suddenly sent to his account with all his imperfections on his head. But that reason having long ceased, and the penalty (especially if a total forfeiture) growing more severe than was intended, in proportion as personal property has become more considerable, the delinquent has now, and has had as early as our records will reach, a pardon and writ of restitution of his goods as a matter of course and right, only paying for suing out the same. And, indeed, to prevent this expence, in cases where the death has notoriously happened by misadventure or in self-defence, the judges will usually permit (if not direct) a general verdict of acquittal.

III. Felonious homicide is an act of a very different nature from the former, being the killing of a human creature, of any age or sex, without justification or excuse. This may be done either by killing one's self, or another man: for the consideration of which, see the articles *SELF Murder*, *MURDER*, and *MANSLAUGHTER*.

HOMILY, in ecclesiastical writers, a sermon or discourse upon some point of religion, delivered in a plain manner, so as to be easily understood by the common people. The word is Greek, *ὁμιλία*; formed of *ὁμιλεῖν*, *catus*, "assembly or council."

The Greek homily, says M. Fleury, signifies a familiar discourse, like the Latin *sermo*; and discourses delivered in the church took these denominations, to intimate, that they were not harangues or matters of ostentation and flourish, like those of profane orators, but familiar and useful discourses, as of a master to his disciples, or a father to his children.

All the homilies of the Greek and Latin fathers are composed by bishops. We have none of Tertullian, Clemens Alexandrinus, and many other learned persons; because, in the first ages, none but bishops were admitted to preach. The privilege was not ordinarily allowed to priests till toward the fifth century. St. Chrysostom was the first presbyter that preached stately. Origen and St. Augustine also preached; but it was by a peculiar licence or privilege.

Photius distinguishes *homily* from *sermon*; in that the homily was performed in a more familiar manner, the prelate interrogating and talking to the people, and they in their turn answering and interrogating him, so that it was properly a conversation; whereas the sermon was delivered with more form, and in the pulpit, after the manner of the orators.

The practice of compiling homilies, which were to be committed to memory, and recited by ignorant or indolent priests, commenced towards the close of the 8th century; when Charlemagne ordered Paul Deacon and Alcuin to form homilies or discourses upon the Gospels and Epistles, from the ancient doctors of the church. This gave rise to that famous collection intitled the *Homiliarium of Charlemagne*, and which being followed as a model by many productions of the same kind, composed by private persons, from a principle of pious zeal, contributed much (says Mosheim) to nourish the indolence, and to perpetuate the ignorance of a worthless clergy.

There are still extant several fine homilies, composed by the ancient fathers, particularly St. Chrysostom and St. Gregory.

Clementine HOMILIES, in ecclesiastical history, are nineteen homilies in Greek, published by Cotelerius, with two letters prefixed; one of them written in the name of Peter, the other in the name of Clement, to James bishop of Jerusalem; in which last letter they are intitled Clement's Epitome of the Preaching and Travels of Peter. According to Le Clerc, these homilies were composed by an Ebionite in the second century; but Montfaucon supposes that they were forged long after the age of St. Athanasius. Dr. Lardner apprehends, that the Clementine homilies were the original or first edition of the Recognitions; and that they are the same with the work censured by Eusebius under the title of Dialogues of Peter and Appion.

HOMINE REPLEGIANDO, a writ for the bailing of a man out of prison when he is confined without commandment of the king or his judges, or for any cause that is repleviable. But this writ is now seldom used; a writ of *babeas corpus* being sued out on the necessary occasions.

HOMMOC, a name given by mariners to a hillock or small eminence of land, resembling the figure of a cone, and appearing on the sea-coast of any country.

HOMO, MAN, is ranked by Linnæus under the order of primates; and characterised by having four parallel foreteeth both in the upper and lower jaw, and two mammæ on the breast. The species, according to this author, are two, *viz.* the homo sapiens, and the homo troglodytes.

He subdivides the homo sapiens into five varieties, *viz.* the American, the European, the Asiatic, the African, and what he calls the *monstrous*. See **MAN**.

The troglodytes, or orang-outang, is a native of Ethiopia, Java, and Amboina. His body is white; he walks erect; and is about one-half the ordinary human size. He generally lives about 25 years. He conceals himself in caves during the day, and searches for his prey in the night. He is said to be exceedingly sagacious, but is not endowed with the faculty of speech. See **TROGLODYTES**, **SIMIA**, and **COMPARATIVE ANATOMY**, page 641.

HOMOGENEOUS, or **HOMOGENEAL** (composed of the Greek *ὁμος* like, and *γενος* kind), is a term applied to various subjects, to denote that they consist of similar parts, or of parts of the same nature and kind: in contradistinction to *heterogeneous*, where the parts are of different natures, &c.

HOMOLOGATION, in the civil law, the act of confirming or rendering a thing more valid and solemn, by publication, repetition, or recognition thereof. The word comes from the Greek *ὁμολογια* "consent, assent;" formed of *ὁμος* *similis*, "like," and *λογος*, of *λογειν* *dicere*, "to say;" *q. d.* to say the same thing, to consent, agree.

HOMOLOGOUS, in geometry, an appellation given to the corresponding sides and angles of similar figures, as being proportional to each other.

HONAN, a province of China, bounded on the north by that of Ptecheli and Chanfi, on the west by Chanfi, on the south by Houquang, and on the east by Chantong. Every thing that can contribute to render a country delightful is found united in this province; the Chinese therefore call it *Tong-hoa*, or *the middle flower*: it is indeed situated almost in the centre of China. The ancient emperors, invited by the mildness of the climate and the beauty of the country, fixed their residence here for some time. The abundance of its fruits, pastures, and corn, the effeminacy of its inhabitants (who are accounted extremely voluptuous), and lastly, the cheapness of provisions, have no doubt prevented trade from being so flourishing here as in the other provinces of the empire. The whole country is flat, excepting towards the west, where there

arises a long chain of mountains, covered with thick forests; and the land is in such a high state of cultivation, that those who travel through it imagine they are walking in an immense garden. Besides the river Hoangho, which traverses this province, it is watered by a great number of springs and fountains; it has also a valuable lake, which invites to its banks a prodigious number of workmen, because its water has the property of communicating a lustre to silk, which cannot be imitated. Exclusive of forts, castles, and places of strength, this province contains eight *fou* or cities of the first class, and 102 of the second and third. In one of these cities named *Nanyang*, is found a kind of serpent, the skin of which is marked with small white spots: the Chinese physicians steep it in wine, and use it afterwards as an excellent remedy against the palsy.

HONAN-Fou, a city of the above province, situated amidst mountains and between three rivers. The Chinese formerly believed this city to be the centre of the earth, because it was in the middle of their empire. Its jurisdiction is very extensive; for it comprehends one city of the second class and thirteen of the third: one of these cities named *Teng-fong-bien*, is famous on account of the tower erected by the celebrated Tcheoukong for an observatory; there is still to be seen in it an instrument which he made use of to find the shadow at noon, in order to determine the latitude. This astronomer lived above a thousand years before the Christian era, and the Chinese pretend that he invented the mariner's compass.

HONDEKOOTER (MELCHIOR), a famous Dutch painter, born at Utrecht, excelled in painting animals, and especially birds. His father and grandfather were of the same profession, and their subjects the same. He was trained up to the art by his father; but surpassed not only him, but even the best of his cotemporaries in a very high degree. Till he was seventeen years of age, he continued under the direction of his father, and accustomed himself to paint several sorts of birds; but particularly he was pleased to represent cocks, hens, ducks, chickens, and peacocks, which he described in an elegant variety of actions and attitudes. After his father's death, which happened in 1653, he received some instructions from his uncle John Baptist Weenix; but his principal and best instructor was nature, which he studied with intense application. His pencil was wonderfully neat and delicate; his touch light; his colouring exceedingly natural, lively, and remarkably transparent; and the feathers of his fowls were expressed with such a swelling softness, as might readily and agreeably deceive the eye of any spectator. It is reported that he had trained up a cock to stand in any attitude he wanted to describe, and that it was his custom to place that creature near his easel; so that at the motion of his hand the bird would fix itself in the proper posture, and would continue in that particular position without the smallest perceptible alteration for several hours at a time. The landscapes which he introduces as the back grounds of his pictures, are adapted with peculiar judgment and skill, and admirably finished; they harmonize with his subject, and always increase the force and the beauty of his principal objects. His touch was very singular, in imitating the natural plumage of the fowls he painted; which not only produced a charming effect, but also may prove serviceable to an intelligent observer, to assist him in determining which are the genuine works of this master, and which are impositions. His pictures sell at a high price, and are much sought after. He died at Utrecht in 1695, aged 59.

HONDURAS, a large province of North America, bounded on the N. by the bay of the same name, on the E. by the Mosquito Shore, on the S. by Nicaragua, and on the W. by Chiapa and Guatemala. It is comprehended in the government of New Spain, although of this province, and the peninsula of

Yucatan, on the other side of the bay of Honduras, it has been observed, that anciently they can hardly be said to have formed a part of the Mexican empire. Honduras and Yucatan do not, like the other territories of Spain in the New World, derive their value either from the fertility of their soil, or the richness of their mines; but they produce, in greater abundance than any part of America, the logwood tree, which, in dyeing some colours, is so far preferable to any other material, that the consumption of it in Europe is considerable, and it is become an article in commerce of great value. During a long period, no European nation intruded upon the Spaniards in these provinces, or attempted to obtain any share in this branch of trade. But, after the conquest of Jamaica by the English, one of the first objects of the settlers on that island, was the great profit arising from the logwood trade, and the facility of wresting some portion of it from the Spaniards. Their first attempt was made at Cape Catoche, the S. E. promontory of Yucatan. When most of the trees near this cape were felled, they removed to the island of Trist, in the bay of Campeachy; and, in later times, their principal station has been in the bay of Honduras. The Spaniards, alarmed at this encroachment, endeavoured by negotiation, remonstrances, and open force, to prevent the English from obtaining any footing on that part of the American continent. But, after struggling against it for more than a century, the disasters of an unfortunate war extorted from the court of Madrid, in 1763, a reluctant consent to tolerate this settlement of foreigners in the heart of its territories. This privilege was confirmed by the definitive treaty of 1783; by which, however, it was stipulated, that nothing in this concession should be considered as derogating, in any respect, from the sovereignty of his catholic majesty; that if the English had erected any fortifications in the country, they should be demolished, and none erected in future; and that they should confine themselves within a certain district, lying between the rivers Wallis, or Bellize, and Rio Hondo, taking the course of the said two rivers for unalterable boundaries, so as that the navigation of them be common to both nations; to wit, by the river Wallis, from the sea, ascending as far as opposite to a lake, which runs into the land, and forms an isthmus, with another similar inlet, which comes from the side of Rio Nuevo, or New River; so that the line of separation pass straight across the said isthmus, and meet another lake formed by the water of Rio Nuevo, at its current; the said line to continue with the course of Rio Nuevo, descending as far as opposite to a river, which enters Rio Hondo, and thence descending by Rio Hondo to the sea. But, by a convention signed in 1786, these limits were extended; the English line, beginning from the sea, was to take the centre of the river Sibun, or Jabon, and continue up to the source of the said river; thence to cross, in a straight line, the intermediate land, till it intersected the river Wallis; and by the centre of the same river, the said line was to descend to the point where it would meet the line already settled in 1783. By this convention, moreover, the English were not only permitted to cut logwood, but mahogany, or any other kind of wood, and to carry away any other produce of the country; with certain exceptions, however, against the establishing of any plantations of sugar, coffee, &c. and they were likewise permitted, with certain restrictions, to occupy the small island called Casina, St. George's Key, or Cayo Casina. The English settlement in this country had formerly been considered as foreign; but in 1790, by an act of parliament, they were allowed the same advantages, in their exports and imports, as a British colony. The capital of Honduras is Valladolid. See MOSQUITO SHORE.

HONE, a fine kind of white stone, used for setting razors, pen-knives, and the like.

HONEY, a sweet vegetable juice, collected by the bees from the flowers of various plants, and deposited in the cells of the comb; from which it is extracted either by spontaneous percolation through a sieve in a warm place, the comb being separated and laid thereon, or by expression. That which runs spontaneously is purer than that which is expressed, a quantity of the wax and other matters being forced out along with it by the pressure. The best sort of honey is of a thick consistence, a whitish colour inclining to yellow, an agreeable smell, and pleasant taste: both the colour and flavour are said to differ in some degree, according to the plants which the bees collect it from. It is supposed that honey is merely the juice of the flower perspiring, and becoming inspissated thereon; and that the bee takes it up with its proboscis, and carries it to be deposited in its waxen cells, with which the young bees are to be fed in summer, and the old ones in winter: but it is certain, that honey can be procured by no other method of collecting this juice than by the bees. The honey wrought by the young bees, and that which is permitted to run from the comb without heat or pressure, is white and pure, and called *virgin's honey*. The honey of old bees, and that which is forced from the comb by heat or pressure, is yellow, from the wax. Honey produced where the air is clear and hot, is better than that where the air is variable and cold. The honey of Narbonne in France, where rosemary abounds, is said to have a very manifest flavour of that plant, and to be imitable by adding to other honey an infusion of rosemary flowers.

Honey, considered as a medicine, is a very useful detergent and aperient, powerfully dissolving viscid juices, and promoting the expectoration of tough phlegm. In some particular constitutions it has an inconvenience of griping, or of proving purgative; which is said to be in some measure prevented by previously boiling the honey. This, however, with all constitutions, is by no means effectual; and the circumstance mentioned has had so much weight with the Edinburgh college, that they do not now employ it in any preparation, and have entirely rejected the *mella medicata*, substituting syrups in their place: but there can be no doubt that honey is very useful in giving form to different articles, although there be some individuals with whom it may disagree. In order, however, to obtain the good effects of the honey itself, it must be used to a considerable extent, and as an article of diet. The following remarkable instances of the good effects of honey in some asthmatic cases given by Dr. Monro in his *Medical and Pharmaceutical Chemistry*, deserve to be here inserted. "The late Dr. John Hume, one of the Commissioners of the Sick and Hurt of the Royal Navy, was for many years violently afflicted with the asthma. Having taken many medicines without receiving relief, he at last resolved to try the effects of honey, having long had a great opinion of its virtues as a pectoral. For two or three years he ate some ounces of it daily, and got entirely free of his asthma, and likewise of a gravelly complaint which he had long been afflicted with. About two years after he had recovered his health, when he was sitting one day in the Office for the Sick and Hurt, a person labouring under a great difficulty of breathing, who looked as if he could not live many days, came to him, and asked him by what means he had been cured of his asthma? Dr. Hume told him the particulars of his own case, and mentioned to him the means by which he had found relief. For two years after he heard nothing of this person, who was a stranger to him, and had seemed so bad that he did not imagine that he could have lived many days, and therefore had not even asked him who he was; but at the end of that period, a man seemingly in good health, and decently dressed, came to the Sick and Hurt Office, and returned him thanks for his cure, which he assured him had been entirely brought about by the free use of honey."

HONEY-Dew, a sweet saccharine substance found on the leaves of certain trees, of which bees are very fond, by the husbandmen supposed to fall from the heavens like common dew. This opinion hath been refuted, and the true origin of this and other saccharine dews shown by the Abbe Boissier de Sauvages, in a memoir read before the Society of Sciences at Montpellier. "Chance (says the Abbe) afforded me an opportunity of seeing this juice in its primitive form on the leaves of the holm oak: these leaves were covered with thousands of small round globules or drops, which, without touching one another, seemed to point out the pore from whence each of them had proceeded. My taste informed me that they were as sweet as honey: the honey-dew on a neighbouring bramble did not resemble the former, the drops having run together; owing either to the moisture of the air which had diluted them, or to the heat which had expanded them. The dew was become more viscous, and lay in large drops, covering the leaves; in this form it is usually seen.

"The oak had at this time two sorts of leaves; the old, which were strong and firm; and the new, which were tender, and newly come forth. The honey-dew was found only on the old leaves; though these were covered by the new ones, and by that means sheltered from any moisture that could fall from above. I observed the same on the old leaves of the bramble, while the new leaves were quite free from it. Another proof that this dew proceeds from the leaves is, that other neighbouring trees not furnished with a juice of this kind had no moisture on them; and particularly the mulberry, which is a very particular circumstance, for this juice is a deadly poison to silk-worms. If this juice fell in the form of a dew, mist, or fog, it would wet all the leaves without distinction, and every part of the leaves, under as well as upper. Heat may have some share in its production: for though the common heat promotes only the transpiration of the more volatile and fluid juices, a sultry heat, especially if reflected by clouds, may so far dilate the vessel as to produce a more viscous juice, such as the honey-dew.

"The second kind of honey-dew, which is the chief resource of bees after the spring-flowers and dew by transpiration on leaves are past, owes its origin to a small insect called a *vine-fretter*; the excrement ejected with some force by this insect makes a part of the most delicate honey known in nature (see *APHIS*). These vine-fretters rest during several months on the barks of particular trees, and extract their food by piercing that bark, without hurting or deforming the tree. These insects also cause the leaves of some trees to curl up, and produce galls upon others. They settle on branches that are a year old. The juice, at first perhaps hard and crabbed, becomes, in the bowels of this insect, equal in sweetness to the honey obtained from the flowers and leaves of vegetables; excepting that the flowers may communicate some of their essential oil to the honey, and this may give it a peculiar flavour, as happened to myself by planting a hedge of rosemary near my bees at Sauvages: the honey has tasted of it ever since, that shrub continuing long in flower.

"I have observed two species of vine-fretters, which live unsheltered on the bark of young branches; a larger and a lesser. The lesser species is of the colour of the bark upon which it feeds, generally green. It is chiefly distinguished by two horns, or straight, immovable, fleshy substances, which rise perpendicularly from the lower sides of the belly, one on each side. This is the species which live on the young branches of bramble and elder. The larger species is double the size of the other; is of a blackish colour; and instead of the horns which distinguish the other, have in the same part of the skin a small button, black and shining like jet.

"The buzzing of bees in a tuft of holm-oak, made me

suspect that something very interesting brought so many of them thither. I knew that it was not the season for expecting honey-dew, nor was it the place where it is usually found; and was surprised to find the tuft of leaves and branches covered with drops which the bees collected with a humming noise. The form of the drops drew my attention, and led me to the following discovery. Instead of being round like drops which had fallen, each formed a small longish oval. I soon perceived from whence they proceeded. The leaves covered with these drops of honey were situated beneath a swarm of the larger black vine-fretters; and on observing these insects, I perceived them from time to time raise their bellies, at the extremity of which there then appeared a small drop of an amber colour, which they instantly ejected from them to the distance of some inches. I found by tasting some of these drops which I had caught on my hand, that it had the same flavour with what had before fallen on the leaves. I afterwards saw the smaller species of vine-fretters eject their drops in the same manner. This ejection is so far from being a matter of indifference to these insects themselves, that it seems to have been wisely instituted to procure cleanliness in each individual, as well as to preserve the whole swarm from destruction; for pressing as they do one upon another, they would otherwise soon be glued together, and rendered incapable of stirring. The drops thus spurted out fall upon the ground, if not intercepted by leaves or branches; and the spots they make on stones remain some time, unless washed off by rain. This is the only honey-dew that falls; and this never falls from a greater height than a branch where these insects can cluster.

"It is now easy to account for a phenomenon which formerly puzzled me greatly. Walking under a lime-tree in the king's garden at Paris, I felt my hand wetted with little drops, which I at first took for small rain. The tree indeed should have sheltered me from the rain, but I escaped it by going from under the tree. A seat placed near the tree shone with these drops. And being then unacquainted with any thing of this kind, except the honey-dew found on the leaves of some particular trees, I was at a loss to conceive how so glutinous a substance could fall from the leaves in such small drops: for I knew that rain could not overcome its natural attraction to the leaves till it became pretty large drops; but I have since found, that the lime-tree is very subject to these vine-fretters.

"Bees are not the only insects that feast upon this honey; ants are equally fond of it. Led into this opinion by what naturalists have said, I at first believed that the horns in the lesser species of these vine-fretters had in their extremity a liquor which the ants went in search of: but I soon discovered that what drew the ants after them came from elsewhere, both in the larger and lesser species, and that no liquor is discharged by the horns. There are two species of ants which search for these insects. The large black ants follow those which live on the oak and chestnut; the lesser ants attend those on the elder. But as the ants are not, like the bees, provided with the means of sucking up fluids; they place themselves near the vine-fretters, in order to seize the drop the moment they see it appear upon the anus; and as the drop remains some time on the small vine-fretters before they can cast it off, the ants have leisure to catch it, and thereby prevent the bees from having any share: but the vine-fretters of the oak and chestnut being stronger, and perhaps more plentifully supplied with juice, dart the drop instantly, so that the larger ants get very little of it.

"The vine-fretters finding the greatest plenty of juice in trees about the middle of summer, afford also at that time the greatest quantity of honey; and this lessens as the season advances, so that in the autumn the bees prefer it to the flowers then in season. Though these insects pierce the tree to the sap in a thousand places, yet the trees do not seem to suffer at

all from them, nor do the leaves lose the least of their verdure. The husbandman therefore acts injudiciously when he destroys them."

HONEY *Guide*, a curious species of cuckow. See **CUCULUS**.

HONEY-Locust, or *Three-thorned Acacia*. See **GLEDITSIA**.

HONEY-Suckle. See **LONICERA**.

HONFLEUR, a considerable seaport of France, in the department of Calvados and late province of Normandy. It has a very capacious and safe harbour, at the mouth of the Seine: and its principal trade is in lace. It is eight miles N. of Pont l'Eveque, and 110 N. W. of Paris.

HONI SOIT QUI MAL Y PENSE, q. d. "Evil to him that thinks evil;" the motto of the most noble order of the knights of the Garter. See **GARTER**.

HONITON, a borough of Devonshire, with a market on Saturday. A dreadful fire happened there in July 1747, which consumed three parts of the town, and the damage was computed at 43,000*l*. It has one church, half a mile from the town, and a chapel within it. Here is a large manufactory of bonelace. Just before the entrance into the town, from London, is a hill, which commands one of the most beautiful prospects in the kingdom. Honiton is seated on the river Otter, 16 miles E. of Exeter, and 156 W. by S. of London. W. lon. 3. 12. N. lat. 50. 45.

HONORIACI, in antiquity, an order of soldiery under the eastern empire, who introduced the Goths, Vandals, Alani, Suevi, &c. into Spain. Didymus and Verinianus, two brothers, had, with great vigilance and valour, defended the passages of the Pyreneans against the Barbarians for some time, at their own expence; but being at length killed, the emperor Constantius appointed the *honoriaci* to defend those passages, who, not contented to lay them open to all the nations of the north then ravaging the Gauls, joined themselves to them.

HONOUR, a testimony of esteem or submission, expressed by words, actions, and an exterior behaviour, by which we make known the veneration and respect we entertain for any one on account of his dignity or merit. The word *honour* is also used in general for the esteem due to virtue, glory, and reputation. It is also used for *virtue* and *probity* themselves, and for an exactness in performing whatever we have promised; and in this last sense we use the term *a man of honour*. But *honour* is more particularly applied to two different kinds of virtue; bravery in men, and chastity in women.—Virtue and Honour were deified among the ancient Greeks and Romans, and had a joint temple consecrated to them at Rome: but afterwards each of them had separate temples, which were so placed, that no one could enter the temple of Honour without passing through that of Virtue; by which the Romans were continually put in mind, that virtue is the only direct path to true glory. Plutarch tells us, that the Romans, contrary to their usual custom, sacrificed to Honour uncovered; perhaps to denote, that wherever honour is, it wants no covering, but shows itself openly to the world.

The Spanish historians relate a memorable instance of honour and regard to truth. A Spanish cavalier in a sudden quarrel slew a Moorish gentleman, and fled. His pursuers soon lost sight of him, for he had unperceived thrown himself over a garden wall. The owner, a Moor, happening to be in his garden, was addressed by the Spaniard on his knees, who acquainted him with his case, and implored concealment. "Eat this," said the Moor (giving him half a peach),—"you now know that you may confide in my protection." He then locked him up in his garden apartment, telling him as soon as it was night he would provide for his escape to a place of greater safety. The Moor then went into his house, where he had but just seated himself, when a great crowd, with loud

lamentations, came to his gate, bringing the corpse of his son, who had just been killed by a Spaniard. When the first shock of surprise was a little over, he learnt from the description given, that the fatal deed was done by the very person then in his power. He mentioned this to no one; but, as soon as it was dark, retired to his garden, as if to grieve alone, giving orders that none should follow him. Then accosting the Spaniard, he said, "Christian, the person you have killed is my son, his body is now in my house. You ought to suffer; but you have eaten with me, and I have given you my faith, which must not be broken." He then led the astonished Spaniard to his stables, mounted him on one of his fleetest horses, and said, "Fly far while the night can cover you; you will be safe in the morning. You are indeed guilty of my son's blood: but God is just and good; and I thank him I am innocent of yours, and that my faith given is preserved."

This point of honour is most religiously observed by the Arabs and Saracens, from whom it was adopted by the Moors of Africa, and by them was brought into Spain. The following instance of Spanish honour may still dwell in the memory of many living, and deserves to be handed down to the latest posterity. In the year 1746, when we were in hot war with Spain, the Elizabeth of London, captain William Edwards, coming through the Gulph from Jamaica, richly laden, met with a most violent storm, in which the ship sprung a leak, that obliged them, for the saving of their lives, to run into the Havannah, a Spanish port. The captain went on shore, and directly waited on the governor, told the occasion of his putting in, and that he surrendered the ship as a prize, and himself and his men as prisoners of war, only requesting good quarter. "No, Sir," replied the Spanish governor, "if we had taken you in fair war at sea, or approaching our coast with hostile intentions, your ship would then have been a prize, and your people prisoners; but when, distressed by a tempest, you come into our ports for the safety of your lives, we, the enemies, being men, are bound as such by the laws of humanity to afford relief to distressed men who ask it of us. We cannot even against our enemies take advantage of an act of God. You have leave therefore to unload your ship, if that be necessary, to stop the leak; you may refit her here, and traffic so far as shall be necessary to pay the charges; you may then depart, and I will give you a pass to be in force till you are beyond Bermuda: if after that you are taken, you will then be a lawful prize; but now you are only a stranger, and have a stranger's right to safety and protection." The ship accordingly departed, and arrived safe in London.

A remarkable instance of the like honour is recorded of a poor unenlightened African negro, in Captain Snelgrave's account of his voyage to Guinea. A New England sloop, trading there in 1752, left a second mate, William Murray, sick on shore, and sailed without him. Murray was at the house of a black named Cudjoe, with whom he had contracted an acquaintance during their trade. He recovered; and the sloop being gone, he continued with his black friend till some other opportunity should offer of his getting home. In the meantime a Dutch ship came into the road, and some of the blacks coming on board her, were treacherously seized and carried off as their slaves. The relations and friends, transported with sudden rage, ran into the house of Cudjoe, to take revenge by killing Murray. Cudjoe stopped them at the door, and demanded what they wanted. "The white men," said they, "have carried away our brothers and sons, and we will kill all white men. Give us the white man you have in your house, for we will kill him." "Nay," said Cudjoe, "the white men that carried away your relations are bad men, kill them when you can take them; but this white man is a good man,

and you must not kill him."—"But he is a white man," they cried; "and the white men are all bad men, we will kill them all." "Nay," says he, "you must not kill a man that has done no harm, only for being white. This man is my friend, my house is his post, I am his soldier, and must fight for him; you must kill me before you can kill him. What good man will ever come again under my roof, if I let my floor be stained with a good man's blood?" The negroes seeing his resolution, and being convinced by his discourse that they were wrong, went away ashamed. In a few days Murray ventured abroad again with his friend Cudjoe, when several of them took him by the hand, and told him, "They were glad they had not killed him; for as he was a good (meaning innocent) man, their God would have been very angry, and would have spoiled their fishing."

HONOUR, in the *beau monde*, has a meaning materially different from the above, and which it is easier to illustrate than define. It is, however, subject to a system of rules, called the *law of honour*, constructed by people of fashion, calculated to facilitate their intercourse with one another, and for no other purpose. Consequently nothing is considered as inconsistent with honour, but what tends to incommode this intercourse. Hence, as Archdeacon Paley states the matter, profaneness, neglect of public worship or private devotion, cruelty to servants, rigorous treatment of tenants or other dependants, want of charity to the poor, injuries done to tradesmen by insolvency or delay of payment, with numberless examples of the same kind, are accounted no breaches of honour; because a man is not a less agreeable companion for these vices, nor the worst to deal with in those concerns which are usually transacted between one gentleman and another.—Again, the *law of honour* being constituted by men occupied in the pursuit of pleasure, and for the mutual convenience of such men, will be found, as might be expected from the character and design of the law-makers, to be, in most instances, favourable to the licentious indulgence of the natural passions. Thus it allows of fornication, adultery, drunkenness, prodigality, duelling, and revenge in the extreme; and lays no stress upon the opposite virtues.

HONOUR or *Rank*. The degrees of honour which are observed in Britain may be comprehended under these two heads, viz. *nobiles majores* and *nobiles minores*. Those included under the first rank are, archbishops, dukes, marquises, earls, viscounts, barons, and bishops; which are all distinguished by the respective ornaments of their escutcheons: and those of the last are baronets, knights, esquires, and gentlemen. There are some authors who will have baronets to be the last under the first rank; and their reason is, because their honour is hereditary, and by patent, like that of the nobility. See COMMONALTY and NOBILITY.

HONOURS of *War*, in a siege, is, when a governor, having made a long and vigorous defence, is at last obliged to surrender the place to the enemy for want of men and provisions, and makes it one of his principal articles to march out with the *honours of war*; that is, with shouldered arms, drums beating, colours flying, and all their baggage, &c.

Military HONOURS. All armies salute crowned heads in the most respectful manner, drums beating a march, colours and standards dropping, and officers saluting. Their guards pay no compliment, except to the princes of the blood; and even that by courtesy, in the absence of the crowned head. To the commander in chief the whole line turns out without arms, and the camp-guards beat a march, and salute. To generals of horse and foot, they beat a march, and salute. Lieutenant-generals of ditto, three ruffs, and salute. Major-generals of ditto, two ruffs, and salute. Brigadiers of ditto, rested arms, one ruff, and salute. Colonels of ditto, rested

arms, and no beating. Sentinels rest their arms to all field-officers, and shoulder to every officer. All governors, that are not general officers, shall, in all places where they are governors, have one ruff, with rested arms; but for those who have no commission as governors, no drum shall beat. Lieutenant-governors shall have the main-guard turned out to them with shouldered arms.

Prussian HONOURS of War, chiefly imitated by most powers in Europe, are, To the king, all-guards beat the march, and all officers salute. Field-marsals received with the march, and saluted in the king's absence. General of horse or foot, four ruffs; but if he commands in chief, a march and salute. Lieutenant-generals of horse or foot, commanding or not, guards beat three ruffs. Major-generals of horse and foot, two ruffs. Officers, when their guards are under arms, and a general makes a signal, must rest to him, but not beat; when not got under arms, and a signal made, only stand by their arms. Village-guards go under arms only to the king, field-marsals, generals of horse and foot, and to the general of the day. Generals' guards go under arms only to the king, field-marsals, and the general over whom they mount. Commanding officers of regiments and battalions, their own quarter and rear guards to turn out; but not to other field-officers, unless they are of the day. Generals in foreign service, the same.

HONOURS paid by *Sentinels*. Field-marsals; two sentinels with ordered fire-locks, at their tent or quarters. Generals of horse or foot; two sentinels, one with his firelock shouldered, the other ordered. Lieutenant-generals; one, with firelock ordered. Major-generals; one, with firelock shouldered. The first battalion of guards go under arms to the king only; not to stand by, nor draw up in the rear of their arms to any other; nor to give sentinels to foreigners. Second and third battalions draw up behind their arms to the princes, and to field-marsals; but when on grenadier guards or out-posts, they turn out, as other guards do, to the officers of the day. They give one sentinel with shouldered arms to the princes of the blood, and to field-marsals when they lie alone in garrison.

Court of HONOUR. See *Court of CHIVALRY*.

Fountain of HONOUR. The king is so styled, as being the source of honours, dignities, &c. See PREROGATIVE. Although the origin of all sovereignty is in the people, yet it is absolutely impossible that government can be maintained without a due subordination of rank. The British Constitution has therefore entrusted the king with the sole power of conferring dignities and honours, in confidence that he will bestow them only upon such as deserve them. Hence it is that all degrees of nobility, of knighthood, and other titles, are received by immediate grant from the crown: either expressed in writing, by writs or letters patent, as in the creation of peers and baronets; or by corporeal investiture, as in the creation of a simple knight.

From the same principle also arises the prerogative of erecting and disposing of offices: for honours and offices are in their nature convertible and synonymous. All offices under the crown carry in the eye of the law an honour along with them; because they imply a superiority of parts and abilities, being supposed to be always filled with those that are most able to execute them. In fact, all honours, in their original, had duties or offices annexed to them: an earl, *comes*, was the conservator or governor of a county; and a knight, *miles*, was bound to attend the king in his wars. For the same reason therefore that honours are in the disposal of the king, offices ought to be so likewise; and as the king may create new titles, so may he create new offices: but with this restriction, that he cannot create new offices with new fees annexed to them, nor annex

new fees to old offices; for this would be a tax upon the subject, which cannot be imposed but by act of parliament. Wherefore, in 13 Hen. IV. a new office being created by the king's letters patent for measuring cloths, with a new fee for the same, the letters patent were, on account of the new fee, revoked and declared void in parliament.

Upon the same or a like ground, the king has also the prerogative of conferring privileges upon private persons. Such as granting place or precedence to any of his subjects, as shall seem good to his royal wisdom: or such as converting aliens, or persons born out of the king's dominions, into denizens; whereby some very considerable privileges of natural-born subjects are conferred upon them. Such also is the prerogative of erecting corporations; whereby a number of private persons are united and knit together, and enjoy many liberties, powers, and immunities in their politic capacity, which they were utterly incapable of in their natural.

*Maid*s of Honour, are young ladies in the queen's household, whose office is to attend the queen when she goes abroad, &c. In England they are six in number, and their salary 300*l.* per annum each.

HONOUR is particularly applied in our customs to the more noble kind of feignories or lordships, whereof other inferior lordships or manors hold or depend. As a manor consists of several tenements, services, customs, &c. so an honour contains divers manors, knights-fees, &c. It was also formerly called *beneficium* or *royal fee*, being always held of the king *in capite*.

HONOUR-Point, in heraldry, is that next above the centre of the escutcheon, dividing the upper part into two equal portions.

HONOURABLE, a title conferred on the younger sons of earls, the sons of viscounts and barons; as also on such persons as have the king's commission, and upon those who enjoy places of trust and honour. Members of the king's privy council are styled "Right Honourable."

HONOURARY, something done or conferred upon any one, to do him honour. See the article HONOUR. This is sometimes understood of a person who bears or possesses some post or title, only for the name's sake, without doing any thing of the functions belonging to it, or receiving any advantage from it: thus we say honourary counsellors, honourary fellows, &c. Honourary is also used for a lawyer's fee, or a salary given to public professors in any art or science.

HOOD (ROBIN), a famous outlaw and deer-stealer, who chiefly harboured in Sherwood forest in Nottinghamshire. He was a man of family, which by his pedigree appears to have had some title to the earldom of Huntingdon; and played his pranks about the latter end of the 12th century. He was famous for archery, and for his treatment of all travellers who came in his way; levying contributions on the rich, and relieving the poor. Falling sick at last, and requiring to be blooded, he is said to have been betrayed and bled to death. He died in 1247; and was buried at Kirklees in Yorkshire, then a Benedictine monastery, where his gravestone is still shown.

HOOD. See CHAPERON and COWL.

HOOD, in falconry, is a piece of leather wherewith the head of a hawk, falcon, or the like is covered.

HOOD Island, one of the *Marquesas Islands*, in the South Sea. It was discovered in April 1774 by Captain Cook, which gave it that name from the person who first saw the land. It is the most northerly of the cluster, and lies in S. lat. 9. 26. W. long. 139. 13.

HOOF, the horny substance that covers the feet of some animals, as oxen, horses, &c.

HOOF-bound, in farriery. See FARRIERY p. 445.

HOOF (PETER CORNELIUS VAN), an eminent historian and poet, born at Amsterdam in 1581. He was lord of Muiden,

judge of Goyland, and knight of the order of St. Michael. He died at the Hague in 1647. He wrote, 1. An excellent History of the Netherlands, from the abdication of Charles V. to the year 1588. 2. Several Comedies, and other works. By these he acquired such reputation, that the Flemings considered him as the Homer and Tacitus of the Netherlands.

HOOGLY, a small but ancient city of Hindoostan in Bengal. It is now nearly in ruins, but possesses many vestiges of its former greatness. In the beginning of this century, it was the great mart of the export trade of Bengal to Europe. It is seated on an arm of the Ganges, which is called the Hoogly, 26 miles N. of Calcutta. E. lon. 88. 28. N. lat. 32. 30.

HOOGLY River, an arm of the Ganges, formed by the union of its two westernmost branches, named the Cossimbuzar and Yellinghy rivers. It is the port of Calcutta, and the only branch of the Ganges that is commonly navigated by ships.

HOOGSTRATTEN, a town of Dutch Brabant, capital of a county of the same name, 10 miles S. of Breda. E. long. 4. 41. N. lat. 51. 25.

HOOK, in angling, &c. See FISHING-book.

HOOKS, in building, &c. are of various sorts; some of iron, and others of brass, viz. 1. Armour-hooks, which are generally of brass, and are to lay up arms upon, as guns, muskets, half-pikes, pikes, javelins, &c. 2. Casement-hooks. 3. Chimney-hooks, which are made both of brass and iron, and of different fashions: their use is to set the tongs and fire-shovel against. 4. Curtain-hooks. 5. Hooks for doors, gates, &c. 6. Double line-hooks, large and small. 7. Single line-hooks, large and small. 8. Tenter-hooks of various sorts. See TENTER.

HOOKS of a ship, are all those forked timbers which are placed directly upon the keel, as well in her run as in her rake.

Can-HOOKS, those which being made fast to the end of a rope with a noose (like that which brewers use to sling or carry their barrels on), are made use of for slings.

Foot-HOOKS, in a ship, the same with FURLOCKS.

Loof-HOOKS, a tackle with two hooks; one to hitch into a cringle of the main or fore-sail, in the bolt-rope at the leech of the sail by the clew; and the other is to hitch into a strap, which is spliced to the chefs tree. Their use is to pull down the sail, and succour the tackles in a large sail and stiff gale, that all the strefs may not bear upon the tack. It is also used when the tack is to be seized more secure, and to take off or put on a bonnet or drabler.

Hook Pins, in architecture, are taper iron pins, only with a hook-head, to pin the frame of a roof or floor together.

HOOHAH, among the Arabs and other nations of the East, is a pipe of a singular and complicated construction, through which tobacco is smoked: out of a small vessel of a bell or globular form, and nearly full of water, issue two tubes, one perpendicularly, on which is placed the tobacco; the other obliquely from the side of the vessel, and to that the person who smokes applies his mouth; the smoke by this means being drawn through water, is cooled in its passage and rendered more grateful: one takes a whiff, draws up a large quantity of smoke, puffs it out of his nose and mouth in an immense cloud, and passes the hookah to his neighbour; and thus it goes round the whole circle.—The hookah is known and used throughout the East; but in those parts of it where the refinements of life prevail greatly, every one has his hookah sacred to himself; and it is frequently an implement of a very costly nature, being of silver, and set with precious stones: in the better kind, that tube which is applied to the mouth is very long and pliant; and for that reason is termed the snake: people who use it in a luxurious manner, fill the vessel through which the smoke is drawn with rose water, and it thereby receives some of the fragrant quality of that fluid. See pl. 4.

HOOKER (ROBERT); a very eminent English mathematician

and philosopher, was the son of Mr. John Hooke minister of Freshwater, in the isle of Wight, where he was born in 1635. He very early discovered a genius for mechanics, by making curious toys with great art and dexterity. He was educated under Dr. Busby in Westminster-school; where he not only acquired a competent share of Greek and Latin, together with an insight into Hebrew and some other Oriental languages, but also made himself master of a good part of Euclid's elements. About the year 1653 he went to Christ-church in Oxford, and in 1655 was introduced to the Philosophical Society there; where, discovering his mechanic genius, he was first employed to assist Dr. Willis in his operations in chemistry, and afterwards recommended to the honourable Robert Boyle, Esq. whom he served several years in the same capacity. He was also instructed in astronomy about this time by Dr. Seth Ward, Savilian professor of that science; and from henceforward distinguished himself by many noble inventions and improvements of the mechanic kind. He invented several astronomical instruments, for making observations both at sea and land; and was particularly serviceable to Mr. Boyle in completing the invention of the air-pump. Sir John Cutler having founded a mechanic school in 1664, he settled an annual stipend on Mr. Hooke for life, intrusting the president, council, and fellows, of the Royal Society to direct him with respect to the number and subject of his lectures; and on the 11th of January 1664-5, he was elected by that society curator of experiments for life, with an additional salary. In 1666 he produced to the Royal Society a model for rebuilding the city of London destroyed by fire, with which the society was well pleased; and the lord mayor and aldermen preferred it to that of the city surveyor, though it happened not to be carried into execution. It is said, by one part of this model of Mr. Hooke's, it was designed to have all the chief streets, as from Leadenhall to Newgate, and the like, to lie in exact straight lines, and all the other cross streets turning out of them at right angles, with all the churches, public buildings, markets, &c. in proper and convenient places. The rebuilding of the city according to the act of parliament requiring an able person to set out the ground to the proprietors, Mr. Hooke was appointed one of the surveyors; in which employment he got most part of his estate, as appeared pretty evident from a large iron chest of money found after his death, locked down with a key in it, and a date of the time, which showed it to have been so shut up above 30 years.—Mr. Oldenburgh, secretary to the Royal Society, dying in 1677, Mr. Hooke was appointed to supply his place, and began to take minutes at the meeting in October, but did not publish the Transactions. In the beginning of the year 1687, his brother's daughter, Mrs. Grace Hooke, who had lived with him several years, died; and he was so affected with grief at her death, that he hardly ever recovered it, but was observed from that time to become less active, more melancholy, and, if that could be, more cynical than ever. At the same time, a chancery suit in which he was concerned with Sir John Cutler, on account of his salary for reading the Cutlerian lectures, made him very uneasy, and increased his disorder. In 1691 he was employed in forming the plan of the hospital near Hoxton, founded by Robert Ask alderman of London, who appointed archbishop Tillotson one of his executors; and in December the same year, Hooke was created doctor of physic by a warrant from that prelate. In July 1696 the chancery suit with Sir John Cutler was determined in his favour, to his inexpressible satisfaction. His joy on that occasion was found in his diary thus expressed: DOMS H L G I S S A; that is, *Deo, Optimo, Maximo, sit honor, laus, gloria, in secula seculorum, Amen.* "I was born on this day of July 1635, and God hath given me a new birth: may I never forget his mercies to me! while he gives me breath may I praise him!"—In the same year 1696, an order was

granted to him for repeating most of his experiments at the expence of the Royal Society, upon a promise of his finishing the accounts, observations, and deductions from them, and of perfecting the description of all the instruments contrived by him; but his increasing illness and general decay rendered him unable to perform it. He continued some years in this wasting condition; and thus languishing till he was quite emaciated, he died March 3d, 1702, at his lodgings in Gresham college, and was buried in St. Helen's church, Bishopsgate-street; his corpse being attended by all the members of the Royal Society then in London.

As to Mr. Hooke's character, it is not in all respects one of the most amiable. He made but a despicable figure as to his person, being short of stature, very crooked, pale, lean, and of a meagre aspect, with dark brown hair, very long, and hanging over his face uncut and lank. Suitable to his person, his temper was penurious, melancholy, mistrustful: and, though possessed of great philosophical knowledge, he had so much ambition, that he would be thought the only man who could invent or discover; and thus frequently laid claims to the inventions and discoveries of others, while he boasted of many of his own which he never communicated. In the religious part of his character he was so far exemplary, that he always expressed a great veneration for the Deity; and seldom received any remarkable benefit in life, or made any considerable discovery in nature, or invented any useful contrivance, or found out any difficult problem, without setting down his acknowledgment to God, as many places in his diary plainly show. He frequently studied the sacred writings in the original; for he was acquainted with the ancient languages, as well as with all parts of the mathematics.

He wrote, 1. *Lectiões Cutlerianæ.* 2. *Micrographia*, or Descriptions of minute bodies made by magnifying glasses. 3. A description of helioscopes. 4. A description of some mechanical improvements of lamps and water-pipes, quarto. 5. Philosophical collections. After his death were published, 6. Posthumous work collected from his papers by Richard Waller, Secretary to the Royal Society.

HOOKÉ (Nathaniel), author of an esteemed Roman history and other performances. Of this learned gentleman the earliest particulars to be met with are furnished by himself, in the following modest but manly address to the Earl of Oxford, dated Oct. 7, 1722, and published in Nichols's Anecdotes of Bowyer: "My lord, the first time I had the honour to wait upon your lordship since your coming to London, your lordship had the goodness to ask me, what way of life I was then engaged in? A certain *mauvaise honte* hindered me at that time from giving a direct answer. The truth is, my lord, I cannot be said at present to be in any form of life, but rather to live extempore. The late epidemical distemper seized me, I endeavoured to be rich, imagined for a while that I was, and am in some measure happy to find myself at this instant but just worth nothing. If your lordship, or any of your numerous friends, have need of a servant, with the bare qualifications of being able to read and write, and to be honest, I shall gladly undertake any employments your lordship shall not think me unworthy of. I have been taught, my lord, that neither a man's natural pride, nor his self-love, is an equal judge of what is fit for him; and I shall endeavour to remember, that it is not the short part we act, but the manner of our performance, which gains or loses us the applause of Him who is finally to decide of all human actions. My lord, I am just now employed in translating from the French, a History of the Life of the late Archbishop of Cambrai; and I was thinking to beg the honour of your lordship's name to protect a work which will have so much need of it. The original is not yet published. 'Tis written by the author of the 'Discourse upon Epic Poetry,' in the new edition of Telemaque.

As there are some passages in the book of a particular nature, I dare not solicit your lordship to grant me the favour I have mentioned, till you first have perused it. The whole is short, and pretty fairly transcribed. If your lordship could find a spare hour to look it over, I would wait upon your lordship with it, as it may possibly be no unpleasing entertainment. I should humbly ask your lordship's pardon for so long an address in a season of so much business. But when should I be able to find a time in which your lordship's goodness is not employed? I am, with perfect respect and duty, my lord, your lordship's most obliged, most faithful, and most obedient humble servant, NATHANIEL HOOKE." The translation here spoken of was afterwards printed in 12mo, 1723. From this period till his death, Mr. Hooke enjoyed the confidence and patronage of men not less distinguished by virtue than by titles. In 17.. he published a translation of Ramsay's Travels of Cyrus, in 4to; in 1733 he revised a translation of "The History of the Conquest of Mexico by the Spaniards, by Thomas Townsend, Esq;" printed in 2 vols. 8vo; and in the same year he published, in 4to, the first volume of "The Roman History, from the building of Rome to the ruin of the Commonwealth; illustrated with maps and other plates." In the dedication to this volume, Mr. Hooke took the opportunity of "publicly testifying his just esteem for a worthy friend, to whom he had been long and much obliged," by telling Mr. Pope, that the displaying of his name at the head of those sheets was "like the hanging out a splendid sign, to catch the traveller's eye, and entice him to make trial of the entertainment the place affords. But," he proceeds, "when I can write under my sign, that Mr. Pope has been here, and was content, who will question the goodness of the house?" The volume is introduced by "Remarks on the History of the Seven Roman Kings, occasioned by Sir Isaac Newton's objections to the supposed 244 years duration of the royal state of Rome." His nervous pen was next employed in digesting "An Account of the conduct of the Dowager-duchess of Marlborough, from her first coming to Court to the year 1710, in a Letter from herself to Lord —, in 1742," 8vo. His reward on this occasion was considerable; and the reputation he acquired by the performance much greater. The circumstances of this transaction are thus related by Dr. Maty, in his Memoirs of Lord Chesterfield, vol. i. p. 116. The relict of the great duke of Marlborough, being desirous of submitting to posterity her political conduct, as well as her lord's, applied to the earl of Chesterfield for a proper person to receive her information, and put the memoirs of her life into a proper dress. Mr. Hooke was recommended by him for that purpose. He accordingly waited upon the duchess, while she was still in bed, oppressed by the infirmities of age. But, knowing who he was, she immediately got herself lifted up, and continued speaking during six hours. She delivered to him, without any notes, her account, in the most lively as well as the most connected manner. As she was not tired herself, she would have continued longer the business of this first sitting, had not she perceived that Mr. Hooke was quite exhausted, and wanted refreshment as well as rest. So eager was she for the completion of the work, that she insisted upon Mr. Hooke's not leaving her house till he had finished it. This was done in a short time; and her Grace was so well pleased with the performance, that she complimented the author with a present of 5000l. a sum which far exceeded his expectations. As soon as he was free, and permitted to quit the house of his benefactress, he hastened to the earl, to thank him for his favour, and communicated to him his good fortune. The perturbation of mind he was under, occasioned by the strong sense of his obligation, plainly appeared in his stammering out his acknowledgments: and he, who had succeeded so well as the interpreter of her Grace's sentiments, could scarcely

utter his own." The second volume of his Roman History appeared in 1745; when Mr. Hooke embraced the fair occasion of congratulating his worthy friend the earl of Marchmont, on "that true glory, the consenting praise of the honest and the wife," which his lordship had so early acquired. To the second volume Mr. Hooke added "The Capitoline Marbles, or Consular Calendars, an ancient Monument accidentally discovered at Rome in the year 1545, during the Pontificate of Paul III." In 1758 Mr. Hooke published "Observations on, I. The Answer of M. l'Abbe de Vertot to the late Earl of Stanhope's Inquiry concerning the Senate of ancient Rome: dated December 1719. II. A Dissertation upon the Constitution of the Roman Senate, by a Gentleman: published in 1743. III. A Treatise on the Roman Senate, by Dr. Conyers Middleton: published in 1747. IV. An Essay on the Roman Senate, by Dr. Thomas Chapman: published in 1750;" which he with great propriety inscribed to Mr. Speaker Onslow. The third volume of Mr. Hooke's Roman History, to the end of the Gallic war, was printed under his inspection before his last illness; but did not appear till after his death, which happened in 1764. The fourth and last volume was published in 1771. Mr. Hooke left two sons; of whom one was a divine of the church of England; the other, a doctor of the Sorbonne, and professor of astronomy in that formerly illustrious seminary.

HOOKE (JOHN), *alias* VOWELL, was born in Exeter, about the year 1524, the second son of Robert Hooker, who in 1529 was mayor of that city. He was instructed in grammar learning by Dr. Moreman, vicar of Menhinit in Cornwall, and thence removed to Oxford; but to what college is uncertain. Having left the university, he travelled to Germany, and resided some time at Cologne, where he kept exercises in law, and probably graduated. Thence he went to Strasburg, where he studied divinity under the famous Peter Martyr. He now returned to England, and soon after visited France, intending to proceed to Spain and Italy; but was prevented by a declaration of war. Returning therefore again to England, he fixed his residence in his native city, where, having married, he was in 1554 elected chamberlain, being the first person who held that office, and in 1571 represented his fellow-citizens in parliament. He died in the year 1601, and was buried in the cathedral church at Exeter. He wrote, among other works, 1. Order and usage of keeping of parliaments in Ireland. 2. The events of comets or blazing stars, made upon the sight of the comet Pagonia, which appeared in November and December 1577. 3. An addition to the chronicles of Ireland from 1546 to 1568; in the second volume of Holinshed's Chronicle. 4. A description of the city of Exeter, and of the sondrie assaults given to the same; Holinsh. Chron. vol. iii. 5. A book of ensigns. 6. Translation of the history of the conquest of Ireland from the Latin of Giraldus Cambrensis; in Holinsh. Chron. vol. ii. 7. *Synopsis chorographica*, or an historical record of the province of Devon; never printed.

HOOKE (Richard), a learned divine, was born at Heavytree, near Exeter, in the year 1553. Some of his ancestors were mayors of that city, and he was nephew to John HOOKE the historian. By this uncle he was first supported at the university of Oxford, with the addition of a small pension from Dr. Jewel, bishop of Salisbury, who in 1561 got him admitted one of the clerks of Corpus-Christi college. In 1573 he was elected scholar. In 1577 he took the degree of master of arts, and was admitted fellow the same year. In July 1579 he was appointed deputy professor of the Hebrew language. In October, in the same year, he was for some trivial misdemeanor expelled the college, but was immediately restored. In 1581 he took orders; and, being appointed to preach at St. Paul's cross, he came to London, where he was unfortunately drawn into a marriage with Joan Churchman, the termagant daugh-

ter of his hostels. Having thus lost his fellowship, he continued in the utmost distress till the year 1584, when he was presented by John Cheny, Esq. to the rectory of Drayton-Beauchamp, in Buckinghamshire. In this retirement he was visited by Mr. Edwin Sandys, and Mr. George Cranmer, his former pupils. They found him, with a Horace in his hand, tending some sheep in the common field, his servant having been ordered home by his sweet Xantippe. They attended him to his house; but were soon deprived of his company by an order from his wife Joan, for him to come and rock the cradle. Mr. Sandys's representation to his father, of his tutor's situation, procured him the mastership of the Temple. In this situation he met with considerable molestation from one Travers, lecturer of the Temple, and a bigoted Puritan, who in the afternoon endeavoured to confute the doctrine delivered in the morning. From this disagreeable situation he solicited Archbishop Whitgift to remove him to some country retirement, where he might prosecute his studies in tranquillity. Accordingly in 1591 he obtained the rectory of Boscomb in Wiltshire, together with a prebend in the church of Salisbury, of which he was also made sub-dean. In 1594 he was presented to the rectory of Bishopsbourne in Kent, where he died in the year 1600. He was buried in his own parish-church, where a monument was erected to his memory by William Cooper, Esq. He was a meek, pious, and learned divine. He wrote, 1. Ecclesiastical Politie, in eight books, fol. 2. A discourse of justification, &c. with two other sermons, Oxford 1612, 4to. Also several other sermons printed with the Ecclesiastical Politie.

HOOKER, in naval architecture, a vessel much used by the Dutch, built like a pink, but rigged and masted like a hoy. Hookers will lie nearer a wind than vessels with cross-sails can do. They are from 50 to 200 tons burden, and with a few hands will sail to the East Indies.

HOOP, a piece of pliant wood, or iron, bent into a circular form, commonly used for securing casks, &c. Driving a hoop is a boyish exercise, of good effect in rendering the limbs pliable, and for strengthening the system.

HOOPER (JOHN), bishop of Worcester, and a martyr in the Protestant cause, was born in Somersetshire, and educated at Oxford, probably in Merton-college. In 1518 he took the degree of bachelor of arts, and afterwards became a Cistercian monk; but at length, disliking his fraternity, he returned to Oxford, and there became infected with Lutheranism. In 1539 he was made chaplain and house-steward to Sir John Arundel, who afterwards suffered with the protector in the reign of Edward VI. But *that very catholic knight*, as Wood calls him, discovering his chaplain to be a heretic, Hooper was obliged to leave the kingdom. After continuing some time in France, he returned to England, and lived with a gentleman called *Seintlow*: but being again discovered, he escaped in the habit of a sailor to Ireland; thence embarked for the continent, and fixed his abode in Switzerland.—When king Edward came to the crown, Mr. Hooper returned once more to his native country. In 1550, by his old patron Sir John Arundel's interest with the earl of Warwick, he was consecrated bishop of Gloucester; and in 1552 was nominated to the see of Worcester, which he held in *commendam* with the former. But queen Mary had scarce ascended the throne, before his lordship was imprisoned, tried, and, not choosing to recant, condemned to the flames. He suffered this terrible death at Gloucester, on the 9th of February 1554, being then near 60 years of age. He was an avowed enemy to the church of Rome, and not perfectly reconciled to what he thought remnants of Popery in the church of England. In the former reign he had been one of Bonner's accusers, which sufficiently accounts for his being one of queen Mary's first sacrifices to the holy see. He was a person of good parts and learning, as may be found in Fox's Book of Martyrs.

HOOPER (George), a very learned writer, bishop of Bath and Wells, was well skilled in mathematics, and in the eastern learning and languages. He sat in those sees above 24 years, often refused a seat in the privy council, and could not be prevailed upon to accept of the bishopric of London on the death of bishop Compton. He wrote, 1. The church of England free from the imputation of Popery. 2. A discourse concerning Lent. 3. New danger of Presbytery. 4. An inquiry into the state of the ancient measures. 5. *De Valentinianorum hæresi conjecturæ*. 6. Several sermons; and other works.

HOOPING-COUGH. See MEDICINE.

HOOPOE. See UPUPA.

HOORNBECK (JOHN), professor of divinity in the universities of Leyden and Utrecht, was born at Haerlem in 1617. He understood the Latin, Hebrew, Chaldaic, Syriac, Rabbinical, Dutch, German, English, French, and Italian languages, and published many works, among which are, 1. A refutation of Socinianism, in 3 vols 4to. 2. A treatise for the conviction of the Jews. 3. Of the conversion of the Heathens. 4. Theological institutions, &c. which are written in Latin. Mr. Bayle represents him as a complete model of a good pastor and divinity professor.

HOP, in botany. See HUMULUS. Hops were first brought into England from the Netherlands in the year 1524. They are first mentioned in the English statute-book in the year 1552, viz. in the 5 and 6 of Edw. VI. cap. 5. And by an act of parliament of the first year of king James I. *anno* 1603, cap. 18. it appears that hops were then produced in abundance in England. The hop being a plant of great importance in this country, we shall consider what relates to the culture and management of it, under distinct heads:

Of Soil. As for the choice of soil, the hop-planters esteem the richest and strongest ground the most proper; and if it be rocky within two or three feet of the surface, the hops will prosper well; but they will by no means thrive on a stiff clay or spongy wet land.

The Kentish planters account new land best for hops; they plant their hop gardens with apple-trees at a large distance, and with cherry-trees between; and when the land hath done its best for hops, which they reckon it will in about 10 years, the trees may begin to bear. The cherry-trees last about 30 years, and by that time the apple-trees are large, they cut down the cherry-trees. The Essex planters account a moory land the most proper for hops.

As to the *situation* of a hop-ground, one that inclines to the south or west is the most eligible; but if it be exposed to the north-east or south-west winds, there should be a shelter of some trees at a distance, because the north-east winds are apt to nip the tender shoots in the spring; and the south-west winds frequently break and blow down the poles at the latter end of the summer, and very much endanger the hops.

In the winter-time provide your soil and manure for the hop-ground against the following spring. If the dung be rotten, mix it with two or three parts of common earth, and let it incorporate together till you have occasion to make use of it in making your hop hills; but if it be new dung, then let it be mixed as before till the spring in the next year, for new dung is very injurious to hops. Dung of all sorts was formerly more commonly made use of than it is now, especially when rotted and turned to mould, and they who have no other manure must use it; which if they do, cows or hogs dung, or human ordure mixed with mud, may be a proper compost, because hops delight most in a manure that is cool and moist.

Planting. Hops require to be planted in a situation so open as that the air may freely pass round and between them, to dry up and dissipate the moisture, whereby they will not be so subject to fire-blasts, which often destroy the middles of large plantations, while the outsides remain unhurt.

As for the preparation of the ground for planting, it should

in the preceding winter, be ploughed and harrowed even; and then lay upon it in heaps a good quantity of fresh rich earth, or well rotted dung and earth mixed together, sufficient to put half a bushel in every hole to plant the hops in, unless the natural ground be very fresh and good.

The hills where the hops are to be planted should be eight or nine feet asunder, that the air may freely pass between them; for, in close plantations, they are very subject to what the hop-planters call the *fire blast*. If the ground is intended to be ploughed with horses between the hills, it will be best to plant them in squares chequerwise; but if the ground is so small that it may be done with the breast plough or spade, the holes should be ranged in a quincunx form. Which way soever you make use of, a stake should be stuck down at all the places where the hills are to be made.

Persons ought to be very curious in the choice of the plants as to the kind of hop; for if the hop-garden be planted with a mixture of several sorts of hops that ripen at several times, it will cause a great deal of trouble, and be a great detriment to the owner. The two best sorts are the white and the grey bind; the latter is a large square hop, more hardy, and is the more plentiful bearer, and ripens later than the former. There is another sort of the white bind, which ripens a week or ten days before the common; but this is tenderer, and a less plentiful bearer; but it has this advantage, that it comes first to market. But if three grounds, or three distant parts of one ground, be planted with these three sorts, there will be this convenience, that they may be picked successively as they become ripe. The sets should be five or six inches long; with three or more joints or buds on them.

If there be a sort of hop you value, and would increase plants and sets from, the superfluous binds may be laid down when the hops are tied, cutting off the tops, and burying them in the hill; or when the hops are dressed, all the cuttings may be saved; for almost every part will grow, and become a good set the next spring.

As to the seasons of planting hops, the Kentish planters best approve the months of October and March, both which sometimes succeed very well; but the sets are not to be had in October, unless from some ground that is to be destroyed; and likewise there is some danger that the sets may be rotted, if the winter prove very wet; therefore the most usual time of procuring them is in March, when the hops are cut and dressed.

As to the manner of planting the sets, there should be five good sets planted in every hill, one in the middle, and the rest round about sloping, the tops meeting at the centre; they must stand even with the surface of the ground; let them be pressed close with the hand, and covered with fine earth, and a stick should be placed on each side the hill to secure it.

The ground being thus planted, all that is to be done more during that summer, is to keep the hills clear from weeds, and to dig up the ground about the month of May, and to raise a small hill round about the plants. In June you must twist the young binds or branches together into a bunch or knot; for if they are tied up to small poles the first year, in order to have a few hops from them, it will not countervail the weakening of the plants.

A mixture of compost or dung being prepared for your hop-ground, the best time for laying it on, if the weather prove dry, is about Michaelmas, that the wheels of the dung-cart may not injure the hops, nor furrow the ground: if this be not done then, you must be obliged to wait till the frost has hardened the ground, so as to bear the dung-cart; and this is also the time to carry on your new poles, to recruit those that are decayed, and to be cast out every year. If you have good store of dung, the best way will be to spread it in the alleys all over the ground, and to dig it in the winter following. The quantity they will require will be 40 loads to an acre, reckoning about 30

bushels to the load. If you have not dung enough to cover all the ground in one year, you may lay it on one part one year, and on the rest in another, or a third; for there is no occasion to dung the ground after this manner oftener than once in three years. Those who have but a small quantity of dung, usually content themselves with laying on about twenty loads upon an acre every year; this they lay only on the hills, either about November, or in the spring; which last some account the best time, when the hops are dressed, to cover them after they are cut; but if it be done at this time, the compost or dung ought to be very well rotted and fine.

Dressing. As to the dressing of the hops, when the hop-ground is dug in January or February, the earth about the hills, and very near them, ought to be taken away with a spade, that you may come the more conveniently at the stock to cut it. About the end of February, if the hops were planted the spring before, or if the ground be weak, they ought to be dressed in dry weather; but else, if the ground be strong and in perfection, the middle of March will be a good time; and the latter end of March, if it be apt to produce over-rank binds, or the beginning of April may be soon enough. Then having with an iron picker cleared away all the earth out of the hills, so as to clear the stock to the principal roots, with a sharp knife you must cut off all the shoots which grew up with the binds the last year; and also all the young suckers, that none be left to run in the alley, and weaken the hill. It will be proper to cut one part of the stock lower than the other, and also to cut that part low that was left highest the preceding year. By pursuing this method you may expect to have stronger buds, and also keep the hill in good order. In dressing those hops that have been planted the year before, you ought to cut off both the dead tops and the young suckers which have sprung up from the sets, and also to cover the stocks with fine earth a finger's length in thickness.

The poling. About the middle of April the hops are to be poled, when the shoots begin to sprout up; the poles must be set to the hills deep into the ground, with a square iron picker or crow, that they may the better endure the winds; three poles are sufficient for one hill. These should be placed as near the hill as may be, with their bending tops turned outwards from the hill to prevent the binds from entangling; and a space between two poles ought to be left open to the south to admit the sun-beams.

The poles ought to be in length 16 or 20 feet, more or less according as the ground is in strength; and great care must be taken not to overpole a young or weak ground, for that will draw the stock too much, and weaken it. If a ground be overpoled, you are not to expect a good crop from it; for the branches which bear the hops will grow very little till the binds have overreached the poles, which they cannot do when the poles are too long. Two small poles are sufficient for a ground that is young.

If you wait till the sprouts or young binds are grown to the length of a foot, you will be able to make a better judgment where to place the largest poles; but if you stay till they are so long as to fall into the alleys, it will be injurious to them, because they will entangle one with another, and will not clasp about the pole readily. Maple or aspen poles are accounted the best for hops, on which they are thought to prosper best, because of their warmth; or else, because the climbing of the hop is promoted by means of the roughness of the bark. But for durability, aspen or willow poles are preferable; but chestnut poles are the most durable of all. If after the hops are grown up you find any of them have been under-poled, taller poles may be placed near those that are too short to receive the binds from them.

The tying. As to the tying of hops, the buds that do not

clasp of themselves to the nearest pole when they are grown to three or four feet high, must be guided to it by the hand, turning them to the sun, whose course they will always follow. They must be bound with withered rushes, but not so close as to hinder them from climbing up the pole. This you must continue to do till all the poles are furnished with binds, of which two or three are enough for a pole; and all the sprouts and binds that you have no occasion for, are to be plucked up; but if the ground be young, then none of these useless binds should be plucked up, but should be wrapped up together in the middle of the hill. When the binds are grown beyond the reach of your hands, if they forsake the poles, you should make use of a stand-ladder in tying them up.

Towards the latter end of May, when you have made an end of tying them, the ground must have the summer dressing: this is done by casting up with the spade some fine earth into every hill; and a month after this is done, you must hoe the alleys with a Dutch hoe, and make the hills up to a convenient bigness.

Gathering. About the middle of July hops begin to blow, and will be ready to gather about Bartholomew-tide. A judgment may be made of their ripeness by their strong scent, their hardness, and the brownish colour of their seed. When by these tokens they appear to be ripe, they must be picked with all the expedition possible; for if at this time a storm of wind should come, it would do them great damage by breaking the branches, and bruising and discolouring the hops; and it is very well known that hops, being picked green and bright, will sell for a third more than those which are discoloured and brown.

The most convenient way of picking them is into a long square frame of wood, called a *bin*, with a cloth hanging on tenter-hooks within it, to receive the hops as they are picked. The frame is composed of four pieces of wood joined together, supported by four legs, with a prop at each end to bear up another long piece of wood, placed at a convenient height over the middle of the bin; this serves to lay the poles upon, which are to be picked. This bin is commonly eight feet long, and three feet broad; two poles may be laid on it at a time, and six or eight persons may work at it, three or four on each side. It will be best to begin to pick the hops on the east or north side of your ground, if you can do it conveniently; this will prevent the south-west wind from breaking into the garden.

Having made choice of a plot of the ground containing 11 hills square, place the bin upon the hill which is in the centre, having five hills on each side; and when these hills are picked, remove the bin into another piece of ground of the same extent, and so proceed till the whole hop ground is finished. When the poles are drawn up to be picked, you must take great care not to cut the binds too near the hills, especially when the hops are green, because it will make the sap to flow excessively.

The hops must be picked very clean, *i. e.* free from leaves and stalks; and, as there shall be occasion, two or three times in a day the bin must be emptied into a hop-bag made of coarse linen cloth, and carried immediately to the oast or kiln in order to be dried; for if they should be long in the bin or bag, they will be apt to heat and be discoloured. If the weather be hot, there should no more poles be drawn than can be picked in an hour, and they should be gathered in fair weather, if it can be, and when the hops are dry; this will save some expence in firing, and preserve their colour better when they are dried.

The crop of hops being thus bestowed, you are to take care of the poles against another year, which are best to be laid up in a shed, having first stripped off the haulm from them; but if you have not that conveniency, set up three poles in the form of a triangle, or six poles (as you please) wide at bottom;

and having set them into the ground, with an iron picker, and bound them together at the top, set the rest of your poles about them; and being thus disposed, none but those on the outside will be subject to the injuries of the weather, for all the inner poles will be kept dry, unless at the top; whereas, if they were on the ground, they would receive more damage in a fortnight than by their standing all the rest of the year.

Drying. The best method of drying hops is with charcoal on an oast or kiln, covered with hair-cloth, of the same form and fashion that is used for drying malt. There is no need to give any particular directions for making these, since every carpenter or bricklayer in those countries where hops grow, or malt is made, knows how to build them. The kiln ought to be square; and may be of 10, 12, 14, or 16 feet over at the top, where the hops are laid, as your plantation requires, and your room will allow. There ought to be a due proportion between the height and breadth of the kiln and the be-guels of the steddle where the fire is kept, *viz.* if the kiln be 12 feet square on the top, it ought to be nine feet high from the fire, and the steddle ought to be six feet and a half square, and so proportionable in other dimensions.

The hops must be spread even upon the oast a foot thick or more, if the depth of the curb will allow it; but care is to be taken not to overload the oast if the hops be green or wet. The oast ought to be first warmed with a fire before the hops are laid on, and then an even steady fire must be kept under them; it must not be too fierce at first, lest it scorch the hops, nor must it be suffered to sink or slacken, but rather be increased till the hops be nearly dried, lest the moisture or sweat which the fire has raised fall back or discolour them. When they have lain about nine hours they must be turned, and in two or three hours more they may be taken off the oast. It may be known when they are well dried by the brittleness of the stalks and the easy falling off of the hop leaves.

It is found by experience that the turning of hops, though it be after the most easy and best manner, is not only an injury or waste to the hops, but also an expence of fuel and time, because they require as much fuel and as long a time to dry a small quantity, by turning them, as a large one. Now this may be prevented by having a cover (to be let down and raised at pleasure) to the upper bed whereon the hops lie. This cover may also be tinned, by nailing single tin plates over the face of it; so that when the hops begin to dry, and are ready to burn, *i. e.* when the greatest part of their moisture is evaporated, then the cover may be let down within a foot or less of the hops (like a reverberatory), which will reflect the heat upon them, so that the top will soon be as dry as the lowermost, and every hop be equally dried.

Bagging. As soon as the hops are taken off the kiln, lay them in a room for three weeks or a month to cool, give, and toughen; for if they are bagged immediately they will powder, but if they lie a while (and the longer they lie the better, provided they be covered close with blankets to secure them from the air) they may be bagged with more safety, as not being liable to be broken to powder in treading; and this will make them bear treading the better, and the harder they are trodden the better they will keep.

The common method of bagging is as follows: they have a hole made in an upper floor, either round or square, large enough to receive a hop bag, which consists of four ells and a half of ell-wide cloth, and also contains ordinarily two hundred and a half of hops; they tie a handful of hops in each lower corner of the bag to serve as handles to it; and they fasten the mouth of the bag, so placed that the hoop may rest upon the edges of the hole. Then he that is to tread the hops down into the bag, treads the hops on every side, another person continually putting them in as he treads them till

the bag is full; which being well filled and trodden, they unrip the fastening of the bag to the hoops, and let it down, and close up the mouth of the bag, tying up a handful of hops in each corner of the mouth, as was done in the lower part.

Hops being thus packed, if they have been well dried, and laid up in a dry place, will keep good several years; but care must be taken that they be neither destroyed nor spoiled by the mice making their nests in them.

Produce. The charge of an acre of hop-ground, in most parts of England where hops are cultivated, is computed thus: Three pounds for the husbandry, four pounds for the wear of the poles, five pounds for picking and drying, one pound ten shillings for dung, one pound for rent, though in some places they pay four or five pounds an acre yearly for the rent of the land, and ten shillings for tythe; in all 15l. a year. The hop-planters in England reckon that they have but a moderate return, when the produce of an acre of hops does not sell for more than 30l. They frequently have fifty, sixty, eighty, or a hundred pounds; and in a time of general scarcity considerably more: so that, upon the whole, if the total charge of an acre of hops is computed at fifteen pounds a year, and its average produce at thirty pounds, the clear profit from an acre will be fifteen pounds a year. But the plantation of hops has lately so much increased, and the average produce so much exceeded the consumption, that hops have been with many planters rather a losing than a very profitable article.

Uses. In the spring-time, while the bud is yet tender, the tops of the plant being cut off, and boiled, are eaten like asparagus, and found very wholesome, and of service to loosen the body. The heads and tendrils are good to purify the blood in the scurvy, and most cutaneous diseases; decoctions of the flowers, and syrups thereof, are of use against pestilential fevers; juleps and apozems were formerly made with hops for hypochondriacal and hysterical affections, and to promote the menses.

A pillow stuffed with hops and laid under the head, is said to procure sleep in fevers attended with a delirium. But the principal use of hops is in the brewery, for the preservation of malt liquors; which, by the superaddition of this balsamic, aperient, and diuretic bitter, become less viscid, less apt to turn sour, more palatable, more disposed to pass off by urine, and in general more salubrious. They are said to contain an agreeable odoriferous principle, which promotes the vinous fermentation. When slightly boiled or infused in warm water, they increase its spirituality.

Laws relating to Hops. By 9 Anne, cap. 121. an additional duty of 3d. a pound is laid on all hops imported, over and above all other duties; and hops landed before entry and payment of duty, or without warrant for landing, shall be forfeited and burnt; the ship also shall be forfeited, and the person concerned in importing or landing shall forfeit 5l. a hundred weight, 7 Geo. II. cap. 19. By 9 Anne, cap. 12. there shall be paid a duty of 1d. for every pound of hops grown in Great Britain, and made fit for use, within six months after they are cured and bagged; and hop-grounds are required to be entered on pain of 40s. an acre. Places of curing and keeping are also to be entered, on pain of 50l. which may be visited by an officer at any time without obstruction, under the penalty of 20l. All hops shall, within six weeks after gathering, be brought to such places to be cured and bagged, on pain of 5s. a pound. The re-bagging of foreign hops in British bagging for sale or exportation, incurs a forfeiture of 10l. a hundred weight; and defrauding the king of his duty by using twice or oftener the same bag, with the officer's mark upon it, is liable to a penalty of 40l. The removal of hops before they have been bagged and weighed, incurs a

penalty of 50l. Concealment of hops subjects to the forfeiture of 20l. and the concealed hops; and any person who shall privately convey away any hops with intent to defraud the king and owner, shall forfeit 5s. a pound. And the duties are required to be paid within six months after curing, bagging, and weighing, on pain of double duty, two-thirds to the king, and one-third to the informer. No common brewer, &c. shall use any bitter ingredient instead of hops, on pain of 20l. Hops which have paid the duty may be exported to Ireland; but by 6 Geo. II. cap. 11. there shall be no drawback; and by 7 Geo. II. cap. 19. no foreign hops shall be landed in Ireland. Notice of bagging and weighing shall be sent in writing to the officer, on pain of 50l. 6 Geo. cap. 21. And by 14 Geo. III. cap. 68. the officer shall, on pain of 5l. weigh the bags or pockets, and mark on them the true weight or tare, the planter's name, and place of abode, and the date of the year in which such hops were grown; and the altering or forging, or obliterating such mark, incurs a forfeiture of 10l.—The owners of hops shall keep at their oasts, &c. just weights and scales, and permit the officer to use them, on pain of 20l. 6 Geo. cap. 21. And by 10 Geo. III. cap. 44. a penalty of 100l. is inflicted for false scales and weights. The owners are allowed to use casks instead of bags, under the same regulations, 6 Geo. cap. 21. If any person shall mix with hops any drug to alter the colour or scent, he shall forfeit 5l. a hundred weight. If any person shall unlawfully and maliciously cut hop-binds growing on poles in any plantation, he shall be guilty of felony without benefit of clergy. 6 Geo. II. cap. 37. By a late act, five per cent. is added to the duties on hops.

HOPE (DR. JOHN), professor of botany in the university of Edinburgh, was born at Edinburgh on the 10th of May 1725. He was the son of Mr. Robert Hope a respectable surgeon, whose father, Lord Rankeilar, made a distinguished figure as one of the senators of the college of justice in the kingdom of Scotland. By his mother he was descended from the ancient family of Glas of Sauchie in Stirlingshire. After finishing the usual course of school education, he entered at the university of Edinburgh; and having, as it were, an hereditary predilection for the healing art, his attention was soon particularly directed to that branch of science. Having finished his academical education at Edinburgh, he visited other medical schools; and upon his return to his native country, he obtained the degree of Doctor of Medicine from the university of Glasgow in the beginning of the year 1750. A few months after that, he was admitted a member of the royal college of physicians in Edinburgh, and entered upon the practice of medicine in that city. After he had continued about ten years in practice, discharging the duties of his profession with a degree of judgment, attention, and humanity, which did him great honour; by the death of Dr. Alston the botanical chair in the university became vacant; when Dr. Hope, by a commission from his sovereign, dated the 13th of April 1761, was appointed king's botanist for Scotland, and superintendant of the royal garden at Edinburgh. A few weeks after this he was elected by the town council of Edinburgh as the successor of Dr. Alston in the professorships both of botany and materia medica; and thus he became one of the members of the faculty of medicine in the university. After he had continued for about six years to give regular courses of lectures on these subjects, with no less credit to himself than benefit to his hearers, teaching the one branch during the summer, and the other during the winter months, he found that his health was considerably impaired; which induced him to form the resolution of resigning the materia medica, and of afterwards solely confining his labours as a teacher to his favourite science of botany. This resolution

he carried into effect in the year 1768; and by a new commission from his majesty, dated the 6th of May, he was nominated regius professor of medicine and botany in the university, and had the offices of king's botanist and superintendent of the royal garden conferred upon him for life, which till that time had been granted during pleasure only.

Dr. Hope's predecessor, although a learned and worthy man, could never obtain sufficient public funds for the establishment of a proper botanical garden at Edinburgh; and from the situation as well as the extent of the garden at that time, joined to the smallness of its conservatories for plants, it could boast of no riches in the way of exotics. The only field for improvement, therefore, to the botanical student, was the environs of Edinburgh, to which it must indeed be allowed that nature has been uncommonly liberal, in affording a very great variety of indigenous vegetables. In this situation, the establishment of a new garden naturally suggested itself as a grand and important object; and it was accomplished by the zeal and industry of Dr. Hope, aided by the munificence of his present majesty. The first assistance given to the undertaking was under the administration of Lord Bute; and afterwards, under that of the duke of Portland, a permanent fund for the support of the botanical garden at this place was established, which may render it not inferior to any in Europe. Dr. Hope's unwearied exertions in procuring for the garden the vegetable productions of every climate, could not be exceeded. His endeavours were constantly directed in adding not to the show, but to the riches of the garden; and they were employed with such success, that in a very short time the intelligent botanist might gratify his curiosity, in contemplating the rarest plants of every country which has yet been explored. Nor were his industrious exertions more assiduously bestowed in forming and enriching the garden, than in cherishing and promoting a zeal for botanical studies. From but a very small number of lectures, which were all that his predecessor ever gave, he gradually prolonged the course till it became as complete as any one delivered at this place; and during all this extended course, he taught in such a manner as clearly demonstrated a degree of ardour and enthusiasm in himself, which could hardly fail to inspire similar emotions in others. But even such precept, and such example, were not the only means he employed for directing the attention of the industrious, ingenious, and laudably ambitious student, to this branch of science. By bestowing, entirely at his own expence, an annual gold medal, as a testimony of superior merit, he gave a spur to exertion, from which the toils of study were alleviated by the love of fame, and the labours of industry converted into the pleasures of emulation.

Dr. Hope married the daughter of Dr. Stevenson, an eminent physician in Edinburgh; by whom he had four sons and one daughter. He died in November 1786. He was a member not only of the Royal Society of London, but also of several foreign societies; and at the time of his death he held the distinguished office of President of the royal college of physicians.

HOPE, in ethics, is the desire of some good, attended with a belief of the possibility, at least, of obtaining it, and enlivened with joy, greater or less, according to the greater or less probability of our possessing the object of our hope. Alexander, preparing for his Asian expedition, distributed his hereditary dominions among his friends; allotting to some villages, to others boroughs, to others cities; and being asked what he had reserved for himself, replied, Hope.

HOPE, a small river of Essex, which rises near Laindon Hills, waters Stanford-le-Hope, and, entering the Thames below Mucking, gives name to a noted reach of that river.

Good-Hope. See GOOD-Hope.

HOPEA, in botany; a genus of the polyandria order, be-

longing to the polydelphia class of plants. The calyx is quinquefid, superior; the corolla pentapetalous; the stamina are many, and coalited into five pencils; there is one style; the fruit is a plum with a trilocular kernel. There is only one species, the tinctora, a native of Carolina.

HOPKINS (EZEKIEL), bishop of Derry in Ireland, was the son of an obscure clergyman in Devonshire; and was for some time a chorister of Magdalen college, Oxford, and usher of the adjoining school. He was afterwards a Presbyterian minister, and was extolled as an excellent preacher. John, lord Roberts, happening to hear him preach, was so pleased with his person, his discourse, and his manner, that he retained him as his chaplain when he was sent in quality of lord lieutenant into Ireland, and preferred him to the deanery of Raphoe; and on his being recalled, so strongly recommended him to his successor, that he was soon preferred to the bishopric at Raphoe, whence he was translated to Derry. During the war under the earl of Tyrconnel at the revolution, he withdrew into England; and was chosen minister of St. Mary, Aldermanbury, in London, where he died in 1690. His sermons, his exposition of the ten commandments, and that of the Lord's prayer, are much esteemed. His works were printed together in 1710, folio. He was the father of Mr. Charles Hopkins, several of whose poetical pieces are in Dryden's Miscellanies.

HOPLITES, HOPLITÆ, formed of ὅπλον *armour*, in antiquity, were such of the candidates at the Olympic and other sacred games as ran races in armour. One of the finest pieces of the famous Parrhasius was a painting which represented two hoplites; the one running, and seeming to sweat large drops; the other laying his arms down, as quite spent and out of breath.

HOPLITODROMOS, formed of ὅπλον *armour*, and δρεμις *I run*, in the ancient gymnastic sports, a term applied to such persons as went through those toilsome and robust exercises in complete armour; by which the exercise became much more violent, and the wearing of armour in the time of battle much more easy.

HOPLOMACHI, Ὀπλομαχοί, composed of ὅπλον *armour*, and μάχουαι *I fight*, in antiquity, were a species of gladiators who fought in armour; either completely armed from head to foot, or only with a casque and cuirass.

HOPPER, a vessel wherein feed-corn is carried at the time of sowing. The word is also used for that wooden trough in a mill, into which the corn is put to be ground.

HOR, a mountain, or mountainous tract of Arabia Petraea, situated in that circuit which the Israelites took to the south and south-east of Edom in their way to the borders of Moab: on this mountain Aaron died. The inhabitants were called *Horites*. This tract was also called *Seir*, either from a native Horite, or from Esau, by way of anticipation from his hairy habit of body; whose posterity drove out the Horites.

HORÆ. See HOURS.

HORÆA, in antiquity, solemn sacrifices, consisting of fruits, &c. offered in spring, summer, autumn, and winter; that Heaven might grant mild and temperate weather. These, according to Meursius, were offered to the goddesses called Ὅραι, i. e. *Hours*, who were three in number, attended upon the Sun, presided over the four seasons of the year, and had divine worship paid them at Athens.

HORAPOLLO, or HORUS APOLLO, a grammarian of Panopolis in Egypt, according to Suidas, who first taught at Alexandria, and then at Constantinople under the reign of Theodosius. There are extant under his name, two books on the hieroglyphics of the Egyptians; which Aldus first published in Greek in 1505, in folio; and they have often been published since, with a Latin version and notes. It is

not certain, however, that the grammarian of Alexandria was the author of these books; they being rather thought to belong to another Horapollon of more ancient date: on which head, see *Fabricius's Bibliotheca Græca*.

HORATII, three Roman brothers, who, under the reign of Tullus Hostilius, fought against the three Curiatii, who belonged to the Albanian army. Two of the Horatii were first killed; but the third, by his address, successively slew the three Curiatii, and by this victory rendered the city of Alba subject to the Romans.

HORATIUS, surnamed **COELES** from his losing an eye in combat, was nephew to the consul Horatius Pulvillus, and descended from one of the three brothers who fought against the Curiatii. Porfenna, laying siege to Rome, drove the Romans from Janiculum; and pursued them to the wooden bridge over the Tiber, which joined the city to Janiculum. Largius, Herminius, and Horatius Cocles, sustained the shock of the enemy on the bridge, and prevented their entering the city with the Romans; but Largius and Herminius having passed the bridge, Horatius Cocles was left alone, and repulsed the enemy till the bridge was broken under him; he then threw himself armed into the Tiber, swam across the river, and entered Rome in triumph.

HORATIUS (Quintus Flaccus), the most excellent of the Latin poets of the lyric and satirical kind, and the most judicious critic in the reign of Augustus, was the grandson of a freedman, and was born at Venusium 64 B. C. He had the best masters in Rome, after which he completed his education at Athens. Having taken up arms, he embraced the party of Brutus and Cassius, but left his shield at the battle of Philippi. Some time after, he gave himself up entirely to the study of polite literature and poetry. His talents soon made him known to Augustus and Mæcenas, who had a particular esteem for him, and loaded him with favours. Horace also contracted a strict friendship with Agrippa, Pollio, Virgil, and all the other great men of his time. He lived without ambition, and led a tranquil and agreeable life with his friends; but was subject to a defluxion in his eyes. He died at the age of 57. There are still extant his Odes, Epistles, Satires, and Art of Poetry; of which there have been a great number of editions. The best are those of the Louvre, in 1642, folio; of Paris, 1691, quarto; of Cambridge, 1699; and that with Bentley's emendations, printed at Cambridge in 1711.

HORD, in geography, is used for a company of wandering people, which have no settled habitation, but stroll about, dwelling in waggons or under tents, to be ready to shift as soon as the herbage, fruit, and the present province is eaten bare: such are several tribes of the Tartars, particularly those who inhabit beyond the Wolga, in the kingdom of Altraean and Bulgaria. A hord consists of 50 or 60 tents, ranged in a circle, and leaving an open place in the middle. The inhabitants in each hord usually form a military company or troop, the eldest whereof is commonly the captain, and depends on the general or prince of the whole nation.

HORDEUM, **BARLEY**, in botany. See **BARLEY**.

HORDICALIA, or **HORDICIDIA**, in antiquity, a religious feast held among the Romans, wherein they sacrificed cattle big with young. This feast fell on April 15, on which day they sacrificed 30 cows with calf to the goddesses Tellus or the Earth; part of them were sacrificed in the temple of Jupiter. The calves taken out of their bellies were burnt to ashes at first by the pontifices, afterwards by the eldest of the vestal virgins.

HOREB, a mountain of Asia, in Arabia Petrea, at the foot of which is a monastery, where a bishop of the Greek church resides. There are two or three fine springs, and a great number of fruit-trees.

HORESTI, a people of Britain, beyond Solway Frith (Tacitus), now *Esksdale* (Camden).

HORITES, an ancient people, who at the beginning dwelt in the mountains of Seir beyond Jordan (Gen. xiv. 6.). They had princes, and were powerful, even before Esau made a conquest of their country, (*id.* xxxvi. 20—30.). The Horites, the descendants of Seir, and the Edomites, seem afterwards to have been confounded, and to have composed but one people. (Deut. ii. 2. xxxiii. 2. and Judg. v. 4.) They dwelt in Arabia Petrea, and Arabia Deserta, to the south-east of the promised land. We find the Hebrew word חֹרִימִים *Chorim*, which in the book of Genesis is translated *Horites*, to be used in an appellative sense in several other passages of scripture, and to signify nobles, or great and powerful men (1 Kings xxi. 8. 11. and Neh. ii. 16. iv. 14. v. 7. vi. 17. vii. 5. xii. 17. Eccl. x. 17. Isa. xxxiv. 12. Jer. xxvii. 20. xxxix. 6.); and it is very probable that the Greeks derived from hence their *heroes* in like manner as they derived *Anax* "a king," from the sons of Anak, the famous giant in Palestine.

HOREHOUND, **BALLOTA**, or *Stachys*, in botany. See **MARRUBIUM**.

HORIZON, in geography and astronomy, a great circle of the sphere, dividing the world into two parts or hemispheres; the one upper and visible, the other lower and hid. The word is pure Greek, ὁρίζων, which literally signifies "bounding or terminating the sight;" being formed of ὁρίζω, *termino, definio*, "I bound, I limit;" whence it is also called *finitor*, "finisher." See **ASTRONOMY** and **GEOGRAPHY**.

The horizon is either *rational* or *sensible*. 1. The *rational, true, or astronomical HORIZON*, which is also called simply and absolutely *the horizon*, is a great circle, whose plane passes through the centre of the earth, and whose poles are the zenith and nadir. It divides the sphere into two equal parts or hemispheres.

2. The *sensible, visible, or apparent HORIZON*, is a lesser circle of the sphere, which divides the visible part of the sphere from the invisible. Its poles, too, are the zenith and nadir: and consequently the *sensible horizon* is parallel to the *rational*; and it is cut at right angles, and into two equal parts, by the verticals. The *sensible horizon* is divided into *eastern* and *western*. The *eastern* or *ortive horizon*, is that part of the horizon wherein the heavenly bodies rise. The *western* or *occidial horizon* is that wherein the stars set. The altitude or elevation of any point of the sphere, is an arch of a vertical circle intercepted between it and the sensible horizon. By *sensible horizon* is also frequently meant a circle; which determines the segment of the surface of the earth, over which the eye can reach; called also the *physical horizon*. In this sense we say, a spacious *horizon*, a narrow scanty *horizon*.

HORIZONTAL, something that relates to the horizon, is taken in the horizon, or on a level with the horizon. Thus, we say, a *horizontal plane, horizontal line, &c.*

HORIZONTAL Dial, is that drawn on a parallel to the horizon: having its gnomon, or style, elevated according to the altitude of the pole of the place it is designed for. Horizontal dials are, of all others, the most simple and easy. See the article **DIAL**.

HORIZONTAL Line, in perspective, is a right line drawn through the principal point, parallel to the horizon: or, it is the intersection of the horizontal and perspective planes. See **PERSPECTIVE**.

HORIZONTAL Plane, is that which is parallel to the horizon of the place, or any thing inclined thereto. The business of levelling is to find whether two points be in the horizontal plane; or how much the deviation is. See **LEVELLING**.

HORIZONTAL Plane, in perspective, is a plane parallel to the

horizon, passing through the eye, and cutting the perspective plane at right angles.

HORIZONTAL Projection. See GEOGRAPHY, p. 739.

HORIZONTAL Range, of a piece of ordnance, is the distance at which it falls on or strikes the horizon, or on a horizontal plane, whatever be the angle of elevation or direction of the piece. When the piece is pointed parallel to the horizon, the range is then called the point-blank or point-blanc range.

The greatest horizontal range, in the parabolic theory, or in a vacuum, is that made with the piece elevated to 45 degrees, and is equal to double the height from which a heavy body must freely fall to acquire the velocity with which the shot is discharged. Thus, a shot being discharged with the velocity of v feet per second; because gravity generates the velocity $2g$ or $32\frac{1}{2}$ feet in the first second of time, by falling $16\frac{1}{2}$ or g feet, and because the spaces descended are as the squares of the velocities, therefore as $4g^2 : v^2 :: g : \frac{v^2}{4g}$ the space a body must

descend to acquire the velocity v of the shot or the space due to the velocity v ; consequently the double of this, or $\frac{v^2}{2g} = \frac{v^2}{32\frac{1}{2}}$

is the greatest horizontal range with the velocity v , or at an elevation of 45 degrees; which is nearly half the square of a quarter of the velocity.

In other elevations, the horizontal range is as the sine of double the angle of elevation; so that, any other elevation being e ,

it will be, as radius 1 : sin. $2e :: \frac{v^2}{32\frac{1}{2}} : \frac{v^2}{32\frac{1}{2}} \times \sin. 2e$, the range

at the elevation e , with the velocity v .

But in a resisting medium, like the atmosphere, the actual ranges fall far short of the above theorems, in so much that with the great velocities, the actual or real ranges may be less than the 10th part of the potential ranges; so that some balls, which actually range but a mile or two, would in vacuo range 20 or 30 miles. And hence also it happens that the elevation of the piece, to shoot farthest in the resisting medium, is always below 45°, and gradually the more below it as the velocity is greater, so that the greater velocities with which balls are discharged from cannon with gunpowder, require an elevation of the gun equal to but about 30°, or even less. And the less the size of the balls is too, the less must this angle of elevation be, to shoot the farthest with a given velocity. See PROJECTILE, and GUNNERY.

HORIZONTAL Moon. See ASTRONOMY, p. 393.

HORIZONTAL Speculum. See SPECULUM.

HORMINUM, CLARY, in botany; a genus of the gymnospermia order, belonging to the didynamia class of plants; and in the natural method ranking under the 42d order, *Ferri-cillatæ*. The calyx is campanulated, with four segments nearly equal, the fourth larger, and emarginated; the upper lip of the corolla concave. There are several species; the most remarkable of which is the verbenaceum, or common wild clary. It grows naturally on sandy and gravelly ground in many parts of Britain. It has sometimes been called *oculus Christi*, from the supposed virtues of its seeds in clearing the sight, which it does by its viscous covering; for when any thing happens to fall into the eye, if one of the seeds is put in at one corner, and the eyelid kept close over it, moving the seed gently along the eye, whatever happens to be there will stick to it, and so be brought out. The virtues of this are supposed to be the same as those of the garden clary, but not quite so powerful.

HORN, in physiology, a hard substance growing on the heads of divers animals, particularly the cloven-footed quadrupeds; and serving them both as weapons of offence and defence. The horn of animals is of the same nature as their gelatinous

matter; and is only that matter charged with a less quantity of water, and a larger quantity of earth, and sufficiently condensed to have a firm and solid consistence. By digesting horn with water in Papin's digester, it may be entirely converted into jelly.

Horn is a perfectly animalised matter, and furnishes in distillation the same principles as all animal matters; that is, at first a pure phlegm, with a degree of heat not exceeding that of boiling water; then a volatile alkaline spirit, which becomes more and more penetrating and strong; a fetid, light, and thin oil; a concrete volatile salt, which forms ramifications upon the sides of the receiver; much air; fetid oil, which becomes more and more black and thick; and lastly, it leaves in the retort a considerable quantity of almost incombustible coal, from which, after its incineration, scarcely any fixed alkali can be obtained.

Animal oil, and particularly that which is drawn first in the distillation of horn, is susceptible of acquiring great thinness and volatility by repeated distillations, and is then called the *oil of dippel*. The horns of stags, and of other animals of that kind, are the most proper to furnish the animal oil to be rectified in the manner of dippel; because they yield the largest quantity. These horns also differ from the horns of other animals in this, that they contain a larger quantity of the same kind of earth which is in bones; hence they seem to possess an intermediate nature betwixt horns and bones.

Hart's-HORN. See HART'S-Horn.

HORNS make a considerable article in the arts and manufactures. Bullocks horns, softened by the fire, serve to make lanthorns, combs, knives, ink-horns, tobacco-boxes, &c.

Dyeing of HORN.—Black is performed by steeping brags in aqua-fortis till it be returned green: with this the horn is to be washed once or twice, and then put into a warmed decoction of logwood and water. Green is begun by boiling it, &c. in alum-water; then with verdigrise, ammoniac, and white-wine vinegar; keeping it hot therein till sufficiently green. Red is begun by boiling it in alum-water, and finished by decoction in a liquor compounded of quicklime steeped in rain water, strained, and to every pint an ounce of Brazil-wood added. In this decoction the bone, &c. is to be boiled till sufficiently red.

Dr. Lewis informs us that horns receive a deep black stain from solution of silver. It ought to be diluted to such a degree as not sensibly to corrode the subject; and applied two or three times, if necessary, at considerable intervals, the matter being exposed as much as possible to the sun, to hasten the appearance and deepening of the colour.

Dyeing or staining HORN to imitate Tortoise-shell. The horn to be dyed must be first pressed into proper plates, scales, or other flat form; and the following mixture prepared. Take of quick-lime two parts, and of litharge one part; temper them together to the consistence of a soft paste with soap-ley. Put this paste over all the parts of the horn, except such as are proper to be left transparent, in order to give it a nearer resemblance of the tortoise-shell. The horn must remain in this manner covered with the paste till it be thoroughly dry; when, the the paste being brushed off, the horn will be found partly opaque and partly transparent, in the manner of tortoise-shell; and when put over a foil, of the kind of latten called *assidue*, will be scarcely distinguishable from it. It requires some degree of fancy and judgment to dispose of the paste in such a manner as to form a variety of transparent parts, of different magnitudes and figures, to look like the effect of nature: and it will be an improvement to add semitransparent parts; which may be done by mixing whitening with some of the paste to weaken its operation in particular places; by which spots of a reddish brown will be produced, which if properly interspersed, especially on the edges of the dark parts, will greatly increase both

the beauty of the work, and its similitude with the real tortoise-shell.

Human-Horns. In Dr. Charles Leigh's natural history of Lancashire, Cheshire, and the Peak in Derbyshire, is the print of a woman with two horns on her head. When she was 28 years of age an excrescence grew upon her head like a wen, which continued 30 years, and then grew into two horns. After four years she cast them, and in their place grew two others. After four years she cast these also; and the horns which were on her head in 1668 (the time when the account was written) were then loose. Her picture, and one of her horns, are in Ashmole's museum. In the university library at Edinburgh is preserved a horn which was cut from the head of Elizabeth Love, in the 50th year of her age. It grew three inches above the ear, and was growing seven years.

HORN-Distemper, a disease incident to horned cattle, affecting the internal substance of the horn commonly called the pith, which it insensibly wastes, and leaves the horn hollow. The pith is a spongy bone, the cells of which are filled with an unctuous matter. It is furnished with a great number of small blood-vessels, is overspread with a thin membrane, and appears to be united by sutures with the bones of the head. According to an account of this distemper, published by Dr. Tofts in the *Memoirs of the American Academy*, vol. i. the said spongy bone is sometimes partly, and sometimes entirely, wasted. The horn loses its natural heat, and a degree of coldness is felt upon handling it. The distemper, however, is seldom suspected without a particular acquaintance with the other symptoms, which are a dulness in the countenance of the beast, a sluggishness in moving, a failure of appetite, an inclination to lie down, and, when accompanied with an inflammation of the brain, a giddiness and frequent tossing of the head. The limbs are sometimes affected with stiffness, as in a rheumatism; in cows the milk often fails, the udder is hard, and in almost all cases there is a sudden wasting of the flesh. As soon as the distemper is discovered, an opening into the diseased horn should be immediately made: which may be done with a gimlet of a moderate size, in such a part of the horn as is most favourable for the discharge. It is recommended as most prudent to bore at first two or three inches above the head. If it is found hollow, and the gimlet passes through to the opposite side, and no blood discharges from the aperture, it may be best to bore still lower, and as near the head as it shall be judged that the hollowness extends. This opening is affirmed to be a necessary measure, and often gives immediate relief. Care must be taken to keep it clear, as it is apt to be clogged by a thin fluid that gradually oozes out and fills up the passage. Some have practised sawing off the horn; but, according to the best observations, it does not succeed better than boring. From the cases Dr. Tofts has seen, he is led to conclude that injections are in general unnecessary; that, when the distemper is early discovered, no more is required than a proper opening into the horn, keeping it sufficiently clear for the admission of fresh air, the removal of the compression, and the discharge of floating matter. But when the distemper has communicated its effects to the brain, so as to produce a high degree of inflammation, it is much to be doubted whether any method of cure will succeed.

HORN is also a sort of musical instrument of the wind kind; chiefly used in hunting, to animate and bring together the dogs and the hunters. The term anciently was, *wind a horn*, all horns being in those times compassed; but since straight horns are come into use, people say *blow a horn*, and sometimes *sound a horn*. There are various lessons on a horn; as the recheat, double recheat, royal recheat, running or farewell recheat, &c. See *RECHEAT*.

The *French horn* is no other than a wreathed or contorted trumpet. It labours under the same defects as the trumpet it-

self; but these have of late been so palliated, as to require no particular selection of keys for this instrument. In the beginning of the year 1773, a foreigner, named Spandau, played in a concert at the opera-house a concerto, part whereof was in the key of C, with the minor-third; in the performance of which all the intervals seemed to be as perfect as in any wind-instrument. This improvement was effected by putting his right-hand into the bottom or bell of the instrument, and tempering the sounds by the application of his fingers to different parts of the tube. The Hebrews made use of horns, formed of rams horns, to proclaim the jubilee; whence the name *JUBILEE*.

HORN-Beam, in botany. See *CARPINUS*.

HORN-Bill, in ornithology. See *BUCCERUS*.

HORN-Blend, is a black or green indurated bole or clay, consisting of scaly particles, which are distinguishable from those of mica, by being less shining, thicker, and rectangular. It is generally found amongst iron ores, and sometimes intermixed with mica, forming a compact stone.

HORN-Fish, Gar-Fish, or Sea-Needle. See *ESOX*.

HORN-Work, in fortification, an outwork composed of two demi-bastions joined by a curtain. See *FORTIFICATION*.

HORN, a considerable town of the United Provinces, in Friesland, with a good harbour. Here they fatten cattle that come from Denmark and Holstein. It is seated on the east side of the *Zuider-Zee*, 13 miles N. E. of Amsterdam.

HORN, a town of the Austrian Netherlands, capital of a county of the same name, in the bishopric of Liege. E. lon. 5. 55. N. lat. 51. 12.

Cape-HORN, the most southern part of *Tierra-del-Fuego*, in South America, round which all ships now pass that sail into the South Sea. W. lon. 67. 26. N. lat. 55. 58.

HORN-BACH, a town of Germany, in the duchy of Deux-Ponts, seated on the river Horn, with a Benedictine abbey, five miles S. E. of Deux-Ponts. E. lon. 7. 36. N. lat. 49. 10.

HORNBERG, an ancient town of Germany, in the Black Forest, and in the duchy of Wirtemberg, with a fortress upon a mountain. It is seated on the river Gutlach, 21 miles N. E. of Friburg. E. lon. 8. 27. N. lat. 48. 12.

HORNBY, a town of Lancashire in England, seated on a branch of the river Lune, and beautified with a handsome parochial chapel. At this place a considerable manufacture of cotton is carried on. The ruins of a decayed castle are still to be seen. W. lon. 2. 20. N. lat. 54. 6.

HORNCastle, a town of Lincolnshire in England. It had a castle, as the name imports; from the architecture of which, and the Roman coins that are sometimes dug up here, it is thought to have been a camp or station of the Romans. The town is well built, and is almost surrounded with water. It is a signiory of 13 lordships. In these lordships there are several chapels for the convenience of the inhabitants, who are at too great a distance from the mother church, and pretty numerous. It has a market on Saturdays, and fairs in June and August. It is 20 miles E. of Lincoln, and 136 N. of London. W. lon. 0. 2. N. lat. 53. 14.

HORNCHURCH, a village in Essex, the only parish in the liberty of Havering. A large pair of horns is affixed to the east end of the church, for which tradition assigns a reason too idle to be repeated. It is two miles E. by S. of Rufford, of which it is the mother church, and 14 E. by N. of London.

HORNDON, a town of Essex, in England. It stands near a rivulet, that at a small distance from hence falls into the Thames, which is there called the *Hope*. The hill on which it is situated commands a beautiful prospect. It is 16 miles S. by W. of Chelmsford, 5 N. by E. of Tilbury Fort, and 19 E. of London. E. lon. 0. 35. N. lat. 51. 32.

HORNECK (*DR. ANTHONY*), a learned and pious divine, was born at Baccharach, in the lower Palatinate, in 1641. He

studied divinity under Dr. Spanheim at Heidelberg; and afterwards coming to England, completed his studies at Oxford, and became vicar of Allhallows in that city. In 1665 he removed into the family of the duke of Albemarle; and was tutor to his grace's son, then lord Torrington. The duke presented him to the rectory of Doulton in Devonshire, and procured for him a prebend in Exeter. He was afterwards chosen preacher of the Savoy. In 1693 he was collated to a prebend in Westminster, and the same year admitted to a prebend in the cathedral of Wells. He published, 1. *The Great Law of Consideration.* 2. *The Happy Affectick.* 3. *Delight and Judgment.* 4. *The Fire of the Altar.* 5. *The Exercise of Prayer.* 6. *The Crucified Jesus.* 7. Several sermons and other works. He died in 1696, and was interred in Westminster-abbey, where a monument is erected to his memory.

HORNERS, those people whose business it is to prepare various utensils of the horns of cattle. The horners were a very ancient and considerable fraternity in the city of London some hundred years ago. In the reign of Edward II. they complained to parliament, that by foreigners buying up the horns in England, they were in danger of being ruined, and this business lost to the nation. For this reason was made the statute 6 Edw. IV. by which the sale of horns to foreigners (except such as the said horners refused) was prohibited; and the wardens had power granted them to search all the markets in London and 24 miles round, and to inspect Stourbridge and Ely fairs, to prevent such practices, and to purchase horns at stated prices. But on plausible pretences this law was repealed in the reign of James I. and thereupon the old evil revived. The horners again applied to parliament, and king Edward's statute was renewed (excepting as to the inspection of the fairs), and still remains in force. The importation of unwrought horns into this country is also prohibited. In 1750 there were exported to Holland 514,500 lantern leaves, besides powder flasks. There was formerly a duty of 20 shillings a thousand, under which in 1682 were exported 76,650; but in the reign of George I. this duty was taken off, and these and all other manufactures made of horns may be exported free. The present company of horners were incorporated January 12, 1638; and consist of a master, two wardens, and nine assistants, without livery or hall. They have a warehouse in Spitalfields, to which the horns are sent as brought from town and country markets, and thence regularly divided, the widows and orphans of deceased members having equal shares.

HORNET, in zoology, a species of wasp. See **VESPA**.

HORNIUS (GEORGE), professor of history at Leyden, was born in the Palatinate, and died at Leyden in 1670. He was a little maniacal towards the end of his life; which disorder was supposed to be occasioned by the loss of 6000 florins he had entrusted with an alchemist at the Hague. His works are, 1. *Historia Ecclesiastica ad ann. 1666.* This has been well esteemed. 2. *De Originibus Americanis*, 1652, 8vo. 3. *Geographia Vetus & Nova.* 4. *Orbis Politicus.* He was a man of deep reading rather than great parts.

HORNSEA, a town in Yorkshire, 188 miles from London. It is almost surrounded by a small arm of the sea; and the church having a high steeple, is a noted sea-mark. Not many years ago there was a street here called *Hornsea-beck*, which was washed away by the sea, except a house or two. E. lon. o. 6. N. lat. 54. o.

HORNSEY, a town of Middlesex, five miles north of London. It is a long straggling place, situated in a low valley, but extremely pleasant, having the new river winding through it. Its church, of which Highgate is a hamlet, is supposed to be built with the stones that came from Lodge-hill, the bishop of London's hunting seat in his park here; it having been his manor from the most ancient times. About a mile nearer this is

a coppice of young trees, called *Hornsey-wood*, at the entrance of which is a public-house, to which great numbers of persons resort from the city. This house being situated on the top of a hill, affords a delightful prospect of the neighbouring country.

HORNSPIPE, a common instrument of music in Wales, consisting of a wooden pipe, with holes at stated distances, and a horn at each end; the one to collect the wind blown into it by the mouth, and the other to carry off the sounds as modulated by the performer.

HORNSPIPE is also the name of an English air, probably derived from the above instrument. The measure of this air is triple time, with six crotchets in a bar; four of which are to be beat with the hand down and two up. The dance which is accompanied with this lively tune, is also called a hornpipe.

HOROLOGIUM, Ὠρολογιον, composed of ὥρα *hora*, "time, hour," and λογος "speech, discourse," a common name among ancient writers for any instrument or machine for measuring the hours; (see **CHRONOMETER**).—Such are our clocks, watches, sun-dials, &c. See **CLOCK**, **WATCH**, **DIAL**, and **CLEPSYDRA**.

Modern inventions, and gradual improvements, have given birth to some new terms that come properly under this head, and annexed new meanings to others totally different from what they had originally. All chronometers that announced the hour by striking on a bell, were called *clocks*: thus, we read of pocket-clocks, though nothing could seem more absurd than to suppose that a clock, according to the modern idea, should be carried in the pocket. In like manner, all clocks that did not strike the hour were called *watches* or *time-pieces*; and the different parts of a striking-clock were distinguished by the watch-part and the clock-part; the former meaning that part which measures the time, and the latter the part which proclaims the hours. In the report of Sir Isaac Newton to the house of commons, anno 1713, relative to the longitude act, he states the difficulties of ascertaining the longitude by means of a watch: yet it is obvious, from several circumstances, that his remarks were directly to be understood of a time-piece regulated by a pendulum; for his objections are founded on the known properties of the pendulum, some of which differ essentially from the properties of the balance and spring. It is also to be remembered, that all the attempts of Huygens for finding the longitude were by means of pendulum-clocks that did not strike the hour, and consequently, according to the language of the times, were called *watches*. At this time such machines for measuring time as are fixed in their place are called *clocks*, if they strike the hour: if they do not strike the hour, they are called *time-pieces*; and when constructed with more care, for a more accurate measure of time, they are called *regulators*. Some artists of late have affected to call such watches as were constructed for astronomical and nautical observations by the name of *time-pieces*, probably to intimate that they possess the advantages of those constructed with a pendulum.

Mr. John Harrison first gave the name of *time-keeper* to his watch, for the performance of which he received from parliament the sum of 20,000*l.* See **LONGITUDE**. For the account of the principles of this machine, see **TIME-KEEPER**. And for the chief improvements that have been made for the more accurate measure of time, see **PALLETS**, **PENDULUM**, and **SCAPEMENT**.

HOROSCOPE, in astrology, the degree or point of the heavens rising above the eastern point of the horizon at any given time when a prediction is to be made of a future event: as, the fortune of a person then born, the success of a design then laid, the weather, &c. The word is composed of ὥρα *hora*, "hour," and the verb σκοπεῖσθαι, *speleto, considero*, "I consider." They were formerly so infatuated with horoscopes, that Albertus Magnus, Cardan, and others, are said to have had the temerity to draw that of Jesus Christ.

HOROSCOPE is also used for a scheme or figure of the twelve houses; i. e. the twelve signs of the zodiac, wherein is marked the disposition of the heavens for any given time. Thus we say, to draw a horoscope, construct a horoscope, &c. We call it, more peculiarly, *calculating a nativity*, when the life and fortune of a person are the subject of the prediction; for they draw horoscopes of cities, great enterprises, &c. See HOUSE.

HOROSCOPY. See DIVINATION.

HORREA, in Roman antiquity, were public magazines of corn and salt meat, out of which the soldiers were furnished on their march in the military roads of the empire. *Horrea* was also the name which they gave to their granaries.

HORROX (JEREMIAH), an eminent English astronomer in the 17th century, was born at Toxteth near Liverpool in Lancashire in 1619. He died, to the great loss of that science and of the world, in the 23d year of his age, after he had just finished his *Venus in sole visa*; which, with some other works, were published by Dr. Wallis, in quarto.

HORROR, in the common acceptation of the word, signifies such an excess of fear as makes a person tremble. In medicine, it denotes a shivering and shaking of the whole body, coming by fits. It is common at the beginning of all fevers, but is particularly remarkable in those of the intermittent kind.

HORROR of a Vacuum, was an imaginary principle among the ancient philosophers, to which they ascribed the ascent of water in pumps, and other similar phenomena, which are now known to be occasioned by the weight of the air.

HORSE, in zoology. See the article BARB. Horses were very rare in Judæa till Solomon's time. Before him we find no horsemen mentioned in the armies of Israel. David having won a great battle against Hadadezer king of Shobah (2 Sam. viii. 4, 5.), took 1700 horses, and lamed all belonging to the chariots of war, reserving only 100 chariots. The judges and princes of Israel used generally to ride on mules or asses. After David's time, horses were more common in the country of Judah, &c. Solomon is the first king of Judah who had a great number of horses, and he kept them rather for pomp than for war; for we do not read that he made any military expeditions. He had, says the Scripture (1 Kings iv. 26.) 40,000 stalls of horses for his chariots, and 12,000 horsemen distributed in his fortified places (1 Kings x. 25). He had his horses from Egypt (*ibid.* ver. 28, 29.); and there was not a set which did not cost him more than 600 shekels, which make of our money about 90l. Moses had forbidden the king of the Hebrews to keep a great number of horses (Deut. xvii. 16.), lest at any time he should be inclined to carry the people back into Egypt.

We read in the second book of Kings (xxiii. 17.), that Josiah took away the horses which the kings of Judah his predecessors had consecrated to the Sun. We know the Sun was worshipped over all the east, and that the horse, the swiftest of tame beasts, was consecrated to this deity, who was represented as riding in a chariot drawn by the most beautiful and swiftest horses in the world, and performing every day his journey from east to west, in order to communicate his light to mankind. Xenophon describes a solemn sacrifice of horses, which was made with ceremony to the Sun: they were all the finest steeds, and were led with a white chariot, crowned, and consecrated to the same god. We may believe that the horses which Josiah removed out of the court of the temple, were appointed for the like sacrifices. The rabbins inform us, that these horses were every morning put to the chariots dedicated to the Sun, whereof there is mention made in the same book; and that the king, or some of his officers, got up and rode to meet the Sun in its rising, as far as from the eastern gate of the temple to the suburbs of Jerusalem. Others are of opinion, that the horses mentioned in the book of Kings were of wood, stone, or metal,

erected in the temple in honour of the Sun. Others, say they were horses which none were permitted to ride or fasten to the yoke, but were free, and left to themselves, like those which Julius Cæsar let loose and set at liberty after his passage of the Rubicon.

Horses were used both amongst the Greeks and Romans in war, but were not originally very numerous; for, as each horseman provided his own horse, few would be able to bear the expense. Horses for a considerable time were managed by the voice alone, or by a switch, without bridle, saddle, or stirrups. Their harness was skins of beasts, or sometimes cloth. Both horses and men amongst the Greeks underwent a severe probation before their admission into the cavalry. Horse-races were common amongst the Greeks and Romans, and the place where they ran or breathed their couriers was called *hippodromus*.

Management of a HORSE upon and after a Journey. On this subject the following directions are given in the Sportsman's Dictionary. See that his shoes be not too strait, or press his feet, but be exactly shaped; and let him be shod some days before you begin a journey, that they may be settled to his feet.

Observe that he is furnished with a bit proper for him, and by no means too heavy, which may incline him to carry low, or to rest upon the hand when he grows weary, which horsemen call *making use of his fifth leg*. The mouth of the bit should rest upon his bars about half a finger's-breadth from his tusches, so as not to make him frumple his lips; the curb should rest in the hollow of his beard a little above the chin; and if it gall him, you must defend the place with a piece of buff or other soft leather. Be careful that the saddle do not rest upon his withers, loins, or back-bone, and that one part of it do not press his back more than another. Some riders gall a horse's sides below the saddle with their stirrup-leathers, especially if he be lean; to hinder it, you fix a leather-strap between the points of the fore and hind-bows of the saddle, and make the stirrup leather pass over them.

Begin your journey with short stages, especially if the horse has not been exercised for a long time. Suffer him to stale as often as you find him inclined; and not only so, but invite him to it.

It is advisable to ride very softly, for a quarter or half an hour before you arrive at the inn, that the horse not being too warm, nor out of breadth, when put into the stable, you may unbridle him: but if your business obliges you to put on sharply, you must then (the weather being warm) let him be walked in a man's hand, that he may cool by degrees; otherwise, if it be very cold, let him be covered with cloths, and walked up and down in some place free from wind; but in case you have not the conveniency of a sheltered walk, stable him forthwith, and let his whole body be rubbed and dried with straw.

As soon as the horse is partly dried, and ceases to beat in the flanks, let him be unbridled, his bit washed, cleansed, and wiped, and let him eat his hay at pleasure. If he be very dry, and you have not given him water on the road, give him oats washed in mild ale. The dust and sand will sometimes so dry the tongues and mouths of horses, that they lose their appetites: in such case, give them bran well moistened with water to cool and refresh their mouths; or-wash their mouths and tongues with a wet sponge, to oblige them to eat.

The foregoing directions are to be observed after moderate riding; but if you have rode excessively hard, unsaddle your horse, and scrape off the sweat with a scraper, holding it with both hands, and going always with the hair; then rub his head and ears with a large hair-cloth, wipe him also between the fore-legs and hind-legs; in the mean while, his body should be rubbed all over with straw, especially under his belly and

benath the saddle, till he is thoroughly dry. That done, set on the saddle again, cover him; and if you have a warm place, let him be gently led up and down in it, for a quarter of an hour; but if not, let him dry where he stands. Or you may unsaddle him immediately; scrape off the sweat; let the ostler take a little vinegar in his mouth, and squirt it into the horse's; then rub his head, between the fore and hind-legs, and his whole body, till he is pretty dry. Let him not drink till thoroughly cool and has eaten a few oats; for many, by drinking too soon, have been injured. Set the saddle in the sun or by a fire, in order to dry the pannels.

When horses are arrived at an inn, a man should, before they are unbridled, lift up their feet, to see whether they want any of their shoes, or if those they have do not rest upon the quarters; afterwards he should pick and clear them of the earth and gravel, which may be got betwixt their shoes and soles.

If you water them abroad, upon their return from the river cause their feet to be stopped with cow-dung, which will ease the pain therein; and if it be in the evening, let the dung continue in their feet all night, to keep them soft and in good condition: but if your horse have brittle feet, it will be requisite to anoint the fore feet, at the on-setting of the hoofs, with butter, oil, or hog's grease, before you water him in the morning, and in dry weather they should be also greased at noon.

Many horses, as soon as unbridled, instead of eating, lay themselves down to rest, by reason of the great pain they have in their feet, so that a man is apt to think them sick: but if he looks at their eyes, he will see they are lively and good; and if he offers them meat as they are lying, they will eat it very willingly; yet if he handles their feet, he will find them extremely hot, which discovers their suffering in that part. You must therefore see if their shoes do not rest upon their soles, which is somewhat difficult to be certainly known without unshoeing them; but if you take off their shoes, then look to the inside of them, and you may perceive that those parts which rest upon the soles are more smooth and shining than the others: in this case you are to pare their feet in those parts, and fix on their shoes again, anointing the hoofs, and stopping the soles with hog's lard.

After a long day's journey, at night feel your horse's back if he be pinched, galled, or swelled; if you do not immediately discover it, perhaps you may after supper: there is nothing better than to rub it with good brandy, or with lead-water. If the galls are between the legs, use the same remedy; but if the ostler rubs him well between the legs, he will seldom be galled in that part.

In order to preserve horses after travelling, take these few useful instructions. When you are arrived from a journey, immediately draw the two heel-nails of the fore feet; and, if it be a large shoe, then four. Two or three days after, you may bleed him in the neck, and feed him for 10 or 12 days only with wet bran, without giving him any oats; but keep him well littered. The reason why you are to draw the heel nails, is because the heels are apt to swell, and if they are not thus eased, the shoes will press and straighten them too much: it is also adviseable to stop them with cow-dung for a while; but do not take the shoes off, nor pare the feet, which is a bad practice.

The following bath will be very serviceable for preserving your horse's legs. Take the dung of a cow or ox, and make it thin with vinegar, so as to be of the consistence of thick broth; and having added a handful of small salt, rub his fore-legs from the knees, and the hind-legs from the gambrels, chafing them well with and against the hair, that the remedy may sink in and stick to those parts, that they may be all covered over with it. Thus leave the horse until morning, not wetting his legs, but giving him his water that evening in a pail: next morning

lead him to the river, or wash his legs in well-water, which is very good, and will keep them from swelling.

Those persons who, to recover their horses' feet, make a hole in them, which they fill with moistened cow-dung, and keep it in their fore-feet during the space of a month, do very ill; because, though the continual moisture that issues from the dung occasions the growing of the hoof, yet it dries and shrinks it so excessively when out of that place, that it splits and breaks like glass, and the foot immediately straitens. For it is certain, that cow dung (contrary to the opinion of many people) spoils a horse's hoof: it does indeed moisten the sole; but it dries up the hoof, which is of a different nature from it. In order, therefore, to recover a horse's feet, instead of cow-dung, fill a hole with wet clay, and make him keep his fore-feet in it for a month.

Most horses that are fatigued, or over-ridden and made lean by long journeys, have their flanks altered without being purisy, especially vigorous horses that have worked too violently. There is no better method to recover them, than to give each of them in the morning half a pound of honey very well mingled with scalded bran; and when they readily eat the half pound, give them the next time a whole one, and afterwards two pounds, every day continuing this course till your horses are empty, and purge kindly with it; but as soon as you perceive that their purging ceases, forbear to give them any more honey. You may administer powder of liquorice in the scalded bran for a considerable time; and to cool the blood, it will not be improper to let them have three or four glisters. In case the horse be very lean, it is expedient to give him some wet bran, over and above his proportion of oats; and grass is also beneficial, if he be not purisy.

Sometimes excessive feeding may do horses more harm than good, by rendering them subject to the farcy. You should therefore be cautious in giving them too great a quantity at a time, and take a little blood from them now and then. When a horse begins to drink water heartily, it is a certain sign that he will recover in a short time. As to the method of giving him water during a journey, observe the following rules:

All the while you are upon a journey, let your horse drink of the first good water you come to, after seven o'clock in the morning if it be in summer-time, and after nine or ten in winter. That is accounted good water which is neither too clear and pellucid, nor too muddy and stinking. This is to be done, unless you would have him gallop a long time after drinking; for if so, you must forbear. Though it is the custom of England to run and gallop horses after drinking, which we call *watering-courses*, to bring them (as they say) *in'o wind*; yet, says M. de Solleyfel, it is the most pernicious practice that can be imagined for horses, by which many are rendered purisy and broken-winded.

Notwithstanding a horse be warm, and sweat very much, yet if he is not quite out of breath, and you have still four or five miles to ride, he will be better after drinking a little, than if he had drank none at all.

If when you happen to bait he be hot or sweaty, you must not let him drink for a long time, as it would endanger his life; and when his bridle is taken off, his excessive thirst will hinder him greatly from eating, so that he will not offer to touch his meat for an hour or two, which perhaps your occasions will not allow you for a baiting time, and not to have any food will render him unfit to proceed.

If you meet with any ford before you come to your inn, it has been advised to ride the horse through it two or three times, but not up to his belly. This, it is true, cleanses his legs; but the coldness of the water may do him a mischief, and it is on the whole a bad practice.

If your horse has been very warm, and you have not had the

means of watering him upon the road, he will, when unbridled, eat but very little; therefore he should have his oats given him washed in ale or beer, or only a part of them, if you intend to feed him again after he has drank.

Some are of opinion, that horses are often hurt by giving them oats before their water; because they say the water makes the oats pass too soon, and leave the stomach undigested. But M. de Solleyfel affirms, that though it be the common custom not to do it till after, yet it is proper to feed with oats both before and after, especially if the horse be warm, and has been hard rode.

Breeding of Horses. On this subject M. Buffon makes the following remarks. When the stallion is chosen, and all the mares intended for him are collected together, there must be another stone-horse, to discover which of the mares are in heat; and, at the same time, contribute to inflame them. All the mares are to be brought successively to this stone-horse; which should also be inflamed, and suffered frequently to neigh. As he is for leaping every one, such as are not in heat keep him off, whilst those which are so suffer him to approach them. But instead of being allowed to satisfy his impulse, he must be led away, and the real stallion substituted in his stead. This trial is necessary for ascertaining the true time of the mare's heat, especially of those which have not yet had a colt; for with regard to such as have recently foaled, the heat usually begins nine days after their delivery; and on that very day they may be led to the stallion to be covered; and, nine days after, by the experiment above mentioned, it may be known whether they are still in heat. If they are, they must be covered a second time; and thus successively every ninth day while their heat continues: for when they are impregnated, their heat abates, and in a few days ceases entirely.

But that every thing may be done easily and conveniently, and at the same time with success and advantage, great attention, expence, and precaution are requisite. The stud must be fixed in a good soil, and in a suitable place, proportioned to the number of mares and stallions intended to be used. This spot must be divided into several parts, inclosed with rails or ditches well fenced; in the part where the pasture is the richest, the mares in foal, and those with colts by their sides, are to be kept. Those which are not impregnated, or have not yet been covered, are to be separated and kept with the fillies in another close, where the pasture is less rich, that they may not grow too fat, which would obstruct the progress of generation. Lastly, the young stone colts or geldings are to be kept in the driest part of the fields, and where the ground is most unequal; that by running over the uneven surface they may acquire a freedom in the motion of their legs and shoulders. This close, where the stone-colts are kept, must be very carefully separated from the others, lest the young horses break their bounds, and enervate themselves with the mares. If the tract be so large as to allow of dividing each of these closes into two parts, for putting oxen and horses into them alternately, the pasture will last much longer than if continually eaten by horses; the ox improving the fertility, whereas the horse lessens it. In each of these closes should be a pond; standing water being better than running, which often gripes them: and if there are any trees in the ground, they should be left standing, their shade being very agreeable to the horses in great heats; but all stems or stumps should be grubbed up, and all holes levelled, to prevent accidents. In these pastures your horses should feed during the summer; but in the winter the mares should be kept in the stable and fed with hay. The colts also must be housed, and never suffered to feed abroad in winter, except in very fine weather. Stallions that stand in the stable should be fed more with straw than hay; and moderately exercised till covering time, which generally lasts from the be-

ginning of April to the end of June. But during this season they should have no other exercise, and be plentifully fed, but with the same food as usual. Before the stallion is brought to the mare, he should be dressed, as that will greatly increase his ardour. The mare must also be curried, and have no shoes on her hind feet, some of them being ticklish, and will kick the stallion. A person holds the mare by the halter, and two others lead the stallion by long reins; when he is in a proper situation, another assistant carefully directs the yard, pulling aside the mare's tail, as a single hair might hurt him dangerously. It sometimes happens that the stallion does not complete the work of generation, coming from the mare without making any injection: it should therefore be attentively observed, whether, in the last moments of the copulation, the dock of the stallion's tail has a vibrating motion; for such a motion always accompanies the emission of the seminal liquor. If he has performed the act, he must on no consideration be suffered to repeat it; but be led away directly to the stable, and there kept two days. For, however able a good stallion may be for covering every day during the three months, it is much better to let him be led to a mare only every other day: his produce will be greater and he himself less exhausted. During the first seven days, let four different mares be successively brought to him; and the ninth day let the first be again brought, and so successively while they continue in heat: but as soon as the heat of any one is over, a fresh mare is to be put in her place, and covered in her turn every nine days; and as several retain even at the first, second, or third time, it is computed that a stallion, by such management, may, during the three months, cover 15 or 18 mares, and beget 10 or 12 colts. These animals have a very large quantity of the seminal liquor: so that a considerable portion of it is shed during the emission. In the mares likewise is an emission, or rather distillation of the seminal lymph, during the whole time they are horsing; ejecting a viscid whitish lymph, called the *beats*, which cease on conception. This ichor the Greeks called *hippomanes*; and pretended that philtres might be made of it, one remarkable effect of which was, to render a horse frantic with lust. This hippomanes is very different from that found in the secundines of the foal, which M. Daubenton first discovered, and has so accurately described its nature, origin, and situation. The ejection of this liquor is the most certain sign of the mare's heat; but it is also known by the inflation of the lower part of the vulva, by her frequent neighings, and attempts to get to the horses. After being covered, nothing more is requisite than to lead her away to the field. The first foal of a mare is never so strongly formed as the succeeding; so that care should be taken to procure for her, the first time, a larger stallion, that the defect of the growth may be compensated by the largeness of the size. Particular regard should also be had to the difference or congruity of the fashion of the stallion and the mare, in order to correct the faults of the one by the perfections of the other: especially never to make any disproportionate copulations, as of a small horse with a large mare, or a large horse with a small mare; as the produce of such copulation would be small, or badly proportioned. It is by gradations that we must endeavour to arrive at natural beauty: for instance, to give to a mare a little too clumsy, a well-made horse and finely shaped; to a small mare, a horse a little higher; to a mare which is faulty in her fore-hand, a horse with an elegant head and noble chest, &c.

It has been observed, that horses fed in dry and light grounds, produce temperate, swift, and vigorous foals, with muscular legs and a hard hoof; while the same bred in marshes and moist pastures have produced foals with a large heavy head, a thick carcase, clumsy legs, bad hoofs, and broad feet. These differences proceed from the air and food, which is easily understood; but what is more difficult to be accounted for, and

still more essential than what we have hitherto observed, is, to be continually crossing the breed to prevent a degeneracy.

In couplng of horses the colour and size should be suited to each other, the shape contrasted, and the breed crossed by an opposition of climates: but horses and mares foaled in the same stud should never be joined. These are essential articles: but there are others which should by no means be neglected; as that no short-docked mares be suffered in a stud, because from their being unable to keep off the flies, they are much more tormented by them than others which have a long sweeping tail; and their continual agitations from the stings of these insects, occasions a diminution in the quantity of their milk, and has a great influence on the constitution and size of the colt, which will be vigorous in proportion as its dam is a good nurse. Care must also be taken that the stud mares be such as have been always brought up in pastures, and never overworked. Mares which have always been brought up in the stable on dry food, and afterwards turned to grass, do not breed at first: some time is required for accustoming them to this new aliment.

Though the usual season for the heat of mares be from the beginning of April to the end of June, yet it is not uncommon to find some among a large number that are in heat before that time: but it is advisable to let this heat pass over without giving them to the stallion, because they would foal in winter; and the colts, besides the inclemency of the season, would have bad milk for their nourishment. Again, if the mares are not in heat till after the end of June, they should not be covered that season, because the colts being foaled in summer, have not time for acquiring strength sufficient to repel the injuries of the following winter.

Many, instead of bringing the stallion to the mare, turn him loose into the close where all the mares are brought together; and there leave him to choose such as will stand to him. This is a very advantageous method for the mares: they will always take horse more certainly than in the other; but the stallion, in six weeks, will do himself more damage than in several years by moderate exercise, conducted in the manner we have already mentioned.

When the mares are pregnant, and their bellies begin to swell, they must be separated from those that are not, lest they hurt them. They usually go 11 months and some days; and foal standing, whereas most other quadrupeds lie down. Those that cannot foal without great difficulty, must be assisted; the foal must be placed in a proper situation; and sometimes, if dead, drawn out with cords. The head of the colt usually presents itself first, as in all other animals: at its coming out of the matrix, it breaks the secundines or integuments that inclose it, which is accompanied with a great flux of the lymph contained in them; and at the same time one or more solid lumps are discharged, formed by the sediment of the inspissated liquor of the allantoides. This lump, which the ancients called the *hippomanes of the colt*, is so far from being, as they imagined, a mass of flesh adhering to the head of the colt, that it is separated from it by a membrane called *amnios*. As soon as the colt is fallen, the mare licks it, but without touching the hippomanes; which points out another error of the ancients, who affirmed that she instantly devours it.

The general custom is to have a mare covered nine days after her foaling, that no time may be lost; but it is certain, that the mare having, by this means, both her present and future foal to nourish, her ability is divided, and she cannot supply both so largely as she might one only. It would therefore be better, in order to have excellent horses, to let the mares be covered only every other year: they would last the longer, and bring foals more certainly: for, in common studs, it is so far from being true that all mares which have been covered bring

colts every year, that it is considered as a fortunate circumstance if half or at most two thirds of them foal.

Mares, when pregnant, will admit of copulation; but it is never attended with any superfœtation. They usually breed till they are 14 or 15 years of age; and the most vigorous till they are above 18. Stallions, when well managed, will engender till the age of 20, and even beyond; but it must be observed, that such horses as are soonest made stallions, are also the soonest incapable of generation: thus the large horses, which acquire strength sooner than the slender, and are therefore often used as stallions as soon as they are four years old, are incapable of generation before they are sixteen.

Gelding of HORSES. See GELDING.

Rearing of HORSES. After the colts have been foaled, you may suffer them to run with the mare till about Michaelmas, sooner or later, according as the cold weather comes in; then they must be weaned; though some persons are for having them weaned after Martinmas, or the middle of November. The author of the *Complete Horseman* is of opinion, that the reason why most foals advance so slowly, and are not capable of service till they are six or seven years old, is because they have not sucked long enough; whereas, if they had sucked the whole winter over, they would be as good at four or five years old as they are now at eight.

They ought now to be kept in a convenient house, with a low rack and manger for their hay and oats, which must be sweet and good; with a little wheaten bran mixed with the oats to cause them to drink, and to keep their bodies open. But, since there are some who allege that oats make foals become blind, or their teeth crooked, the same author is of opinion, that oats will wear their teeth, and make them the sooner to change, and also to raze; therefore he judges it to be the best way to break them in a mill, because that by endeavouring with their jaws to bruise and chew them, they stretch and swell their eye and nether-jaw veins, which so attract the blood and humours that they fall down upon the eyes, and frequently occasion the loss of them: so that it is not the heating quality of the oats, but the difficulty in chewing, that is the cause of their blindness.

Further, colts thus fed with grain do not grow thickish upon their legs, but grow broader and better knit than if they had eaten nothing but hay and bran, and will endure fatigue the better. But above all they must be kept from wet and cold, which are hurtful to them, nothing being more tender than they are. For proof of this, take a Spanish stallion, and let him cover two mares, which for age, beauty, and comeliness, may admit of no difference between them; and if they produce both horse colts, or both fillies, which is one and the same thing, let one run abroad, and the other be housed every winter, kept warm, and ordinarily attended; and that colt that has been kept abroad shall have large fleshy shoulders, flabby and gouty legs, weak pasterns, and ill hoofs; and shall be a dull heavy jade, in comparison to the other which is housed and orderly kept; and which will have a fine forehead, be fine shaped, and have good legs and hoofs, and be of good strength and spirit: by which you may know, that to have the finest stallion, and the beautifullest mare, is nothing if they are spoiled in the breeding up. It is worth observation, that some foals under six months old, though their dams yield plenty of milk, yet decay daily, and have a cough, proceeding from certain pellicles or skins that breed in their stomachs, which obstruct their breathing, and at last destroy them entirely. To remedy this malady, take the bag wherein the colt was foaled, dry it, and give him as much of it in milk as you can take up with three fingers: but if you have not preserved the bag, procure the lungs of a young fox, and use it instead of the foresaid powder.

It will be proper to let the colts play an hour or two in some

court-yard, &c. when it is fair weather, provided you put them up again carefully, and see that they take no harm. When the winter is spent, turn them into some dry ground, where the grass is short and sweet, and where there is good water, that they may drink at pleasure: for it is not necessary that a colt should fill his belly immediately, like a horse that labours hard. The next winter you may take them into the house, and use them just as you do your other horses; but let not your horse colts and fillies be kept together after the first year. This method may be observed every summer and winter till you break them, which you may do after they have been three years old; and it will be a very easy thing, if you observe the aforesaid method of housing them: for, ordering them the second year as you do your other horses, they will be so tame and gentle, that you need not fear their leaping, plunging, kicking, or the like; for they will take the saddle quietly. As for all those ridiculous methods of beating and cowing them, they are in effect spoiling them, whatever they call it, in ploughed fields, deep ways, or the like; instead of which, let the rider strive to win them by gentle usage, never correcting them but when it is necessary, and then with judgment and moderation. You will not need a cavesson of cord, which is a head strain, nor a pad of straw; but only a common saddle, and a common cavesson on his nose, such as other horses are ridden with; but it ought to be well lined with double leather; and if you please you may put on his mouth a watering-bit, but without reins, only the head stall, and this but for a few days; and then put on such a bit as he should be always ridden with; and be sure not to use spurs for some time after backing. Take notice, that as yearlings must be kept abroad together, so those of two years old together: the like for those of three yearlings: which ordering is most agreeable to them.

In order to make him endure the saddle the better, the way to make it familiar to him will be by clapping the saddle with your hand as it stands upon his back, by striking it, and swaying upon it, dangling the stirrups by his sides, rubbing them against his sides, and making much of them, and bringing him to be familiar with all things about him; as straining the crupper, fastening and loosening the girths, and taking up and letting out the stirrups. Then as to the motion of him, when he will trot with the saddle obediently, you may wash a trench of a full mouth, and put the same into his mouth, throwing the reins over the forepart of the saddle, so that he may have a full feeling of it; then put on a martingale, buckled at such a length that he may but just feel it when he jerks up his head; then take a broad piece of leather, and put it about his neck, and make the ends of it fast by plaiting of it, or some other way, at the withers, and the middle part before his weasand, about two handfuls below the throple, betwixt the leather and his neck; let the martingale pass so, that when at any time he offers to duck, or throw down his head, the cavesson being placed upon the tender gristle of his nose, may correct and punish him; which will make him bring his head to, and form him to an absolute rein: trot him abroad; and if you find the reins or martingale grow slack, straiten them, for when there is no feeling there is no effect produced.

Draught-Horse, in farming, a sort of coarse-made horse destined for the service of the cart or plough. In the choice of these horses for what is called the *slow draught*, they are to be chosen of an ordinary height; for otherwise, when put into the cart, one draws unequally with the other. The draught-horse should be large bodied and strong loined, and of such a disposition as rather to be too dull than too brisk, and rather to crave the whip than to draw more than is needful. Mares are the fittest for this use with the farmer, as they will be kept cheap, and not only do the work, but be kept breeding, and give a yearly increase of a foal. They should have a good head,

neck, breast, and shoulders; for the rest of the shape, it is not of much consequence. Only, for breeding, the mare should have a large belly; for the more room a foal has in the dam, the better proportioned it will be. Draught horses should be always kept to that employ. Some put them to the saddle on occasion; but it does them great harm, alters their pace, and spoils them for labour. The draught-horse ought to have a large broad head, because horses of this shaped head are less subject than others to diseases of the eyes. The ears should be small, straight and upright; the nostrils large and open, that he may breathe with the more freedom. A horse with a full and bold eye always promises well. On the other hand, a sunk eye and an elevated brow are bad signs. The horse is esteemed fittest for this purpose also, that has a large and round buttock, which neither sinks down nor cuts. He must have a firm and strong tail, and the dock must be thick and well furnished with hair, and placed neither very high nor very low. The legs should be rather flat and broad than round: the roundness of the leg being a fault in a horse destined to labour that will soon ruin him. As to the hinder legs, the thighs should be fleshy and long, and the whole muscle which shows itself on the outside of the thigh should be large and very thick. No country can bring a parallel to the size and strength of our horses destined for the draught. In London there are instances of single horses that are able to draw on a plain, for a small space, the weight of 3 tons, and which can with ease, and for continuance, draw half that weight. The pack-horses of Yorkshire usually carry a burden of 420lb. over the highest hills of the north, as well as the most level roads: but the most remarkable proof of the strength of our British horses is derived from that of our mill horses; some of which will at one load carry 13 measures, which at a moderate computation of 70lb. each, will amount to 910lb. Nothing is so essential to the health of these serviceable creatures as cleanliness: if they are fed ever so well, and not kept clean, they will be subject to numerous diseases.

The servant who has the care of them ought to be up very early, and to clean the racks and mangers from all filth. The currying of them ought to be carefully performed every morning, but not in the stable, for the dust to fall upon the other horses, as it is too often done. After the horses are dusted, he should daily twist a whisp of straw hard up, and, wetting it in water, rub the legs, shoulders, and body with it. Many of the diseases of draught-horses, which are not owing to nastiness, are owing to bad water; such as are too raw, too muddy, or too cold, being all improper. If there be any running stream in the neighbourhood, they should always be led to that to water every day in summer; but in winter, well-water is warmest, and is better for them. If there be a necessity for giving them well-water in summer, it must be drawn up some hours before the time, and exposed to the sun-beams in tubs or troughs; marsh-water or that of lowland ditches is worst of all. When the labouring horse has drank his water, he should have his oats given him, and these should be carefully sifted, and the manger dusted first. It is a common practice, as soon as a horse is come in from his work, to rub down his legs with a hard whisp of hay; but the best judges of horses absolutely condemn this, and observe, that this rubbing of the legs after hard labour brings down humours into them, and makes them stiff.

The rubbing itself is wholesome, but the doing it when the creature is hot is the mischief; while a horse is in a sweat, it is a great relief and refreshment to him to have his body rubbed down, but when he is cold is the proper time to rub his legs. The racks are to be well supplied with hay, and the horses should be left to rest and eat, about two hours, and then led to water; after this their oats should be given them, and they should then go to work again.

In the evening, when the labour of the day is over, the first thing to be done is to examine the feet, and see if any thing is amiss about the shoes, and what earth or gravel is lodged in the foot, between the shoe and the sole, is to be picked out, and some fresh cow-dung put in its place, which will cool and refresh the part. A very material thing for the preservation of all sorts of cattle, but of none so much as draught-horses, is fresh and clean litter.

HORSE-Chestnut. See *ÆSCULUS*, and *HIPPOCASTANUM*.

HORSE-Guards. See *GUARDS*.

HORSE-Measure is a rod of box to slide out of a cane, with a square at the end, being divided into hands and inches to measure the height of horses.

HORSE-Muscle. See *MYTULUS*.

Race-HORSE. See *RACING*.

HORSE-Radish. See *COCHLEARIA*.

Horse-Shoe, a cover or defence for the sole of a horse's foot. See *FARRIERY*, p. 450. A patent has been lately obtained by Mr. Moorcroft for a mode of constructing horse-shoes by the assistance of a kind of die. This method may undoubtedly have a tendency to bring into more general use any particular description of shoe which may be thought advantageous; but it is liable, nevertheless, to some objections, particularly as shoes must not only vary in size, but must be adapted also to each minute peculiarity in the feet of different horses that have had their hoofs incurably injured by the mismanagement of ignorant farriers. Mr. Moorcroft describes his invention in the patent in these words: "First," says he, "I take bars of iron, or steel, or a composition of metals, of a breadth and thickness suitable to the horse-shoes I intend to make. Having heated these bars red-hot, (as is usual in the process of rolling and slitting iron,) I run them betwixt and through a pair of grooved rolls, turned by a horse-mill, or other power. The grooves in these rolls are various, according to the surfaces of the shoes intended to be made, and form the groove, and impressions for the heads of the nails, and regulate the thickness of the shoes; or simply regulate the thickness of the shoes, without making the groove, or impressions for the nails. Secondly, after the bars have been run betwixt and through the rolls, I cut them into different lengths, according to the size of the shoes intended to be made. Thirdly, I bend or turn them into the proper shape, either by hammer and anvil, or otherwise. Fourthly, when the shoes have been so turned, I heat them again red-hot, and strike them between dies fixed in a common fly-press, (such as is used for coining money,) or in stamps, such as are used for the same operation, or for giving impressions to other pieces of metal. These dies are engraved and formed in such a manner as to confirm to the shoe the proper thickness in the usual parts, and also to form the groove, and impressions for the nails, when not formed by the operation of rolling, as above-mentioned, or by any other operation; or they give the groove, without the impressions for the nails; or they give the impressions for the nails, without the groove. The rolls and dies respectively are to be cut with projecting parts, adapted to give the impressions for the nails or groove, if such impressions, or groove, are intended to be made; or plain, if those impressions or groove are not to be made by the rolls and dies respectively. The dies for these shoes must be formed in such a manner as to correspond with those parts of a horse's foot to which shoes are usually affixed; and, in consequence of the dies being so formed, the shoes struck by them are more perfect in their shape, and afford a truer and better support to the foot of the horse than the shoes in common use, and prevent many of the diseases incident to that part, from the manner of manufacturing horse-shoes now in common use."

HORSE-shoe head, a disease in infants, wherein the sutures of the skull are too open, or too great a vacuity is left between

them; so that the aperture shall not be totally closed up, or the cranium in that part not become so hard as the rest for some years after. This openness is thought to be increased upon the child's catching cold. When the disease continues long, it is reputed a sign of weakness and short life. In this case, it is usual to rub the head now and then with warm rum or brandy, mixed with the white of an egg and palm-oil. Sometimes the disorder arises from a collection of waters in the head called an *hydrocephalus*.

Stone-HORSE. See *STALLION*.

HORSE-Tail. See *EQUISETUM* and *EPHEDRA*.

HORSE-Vetch. See *HIPPOCREPIS*.

War-HORSE. The proper rules for choosing a horse for service in war, are these: he should be tall in stature, with a comely head, and out-swelling forehead. His eye should be bright and sparkling, and the white part of it covered by the eye-brow. The ears should be small, thin, short, and pricking; or if long, they should be moveable with ease, and well carried. The neck should be deep, and the breast large and swelling. The ribs bending, the chine broad and straight, and the buttocks round and full. The tail should be high and broad, neither too thick nor too thin; the thigh swelling; the leg broad and flat, and the pastern short. When such a horse is chosen, he must be kept high during the time of his teaching, that he may be full of vigour. His food must be sweet hay, and good clean oats, or two parts of oats and one part of beans or pease, well dried and hardened. The quantity should be half a peck in the morning, and the same quantity at noon and in the evening. Upon his resting days he is to be dressed between five and six in the morning, and watered at seven or eight. In the evening he is to be dressed at four, and watered about five, and he must always have provender given him after watering; he must be littered about eight, and then must have food given him for all night. The night before he is ridden, all his hay is to be taken away about nine o'clock, and he must have a handful or two of oats about four in the morning; when he has eaten these, he is to be turned upon the snaffle, and rubbed very well with dry cloths; then saddled, and made fit for his exercise. When he has performed this, he is to be brought sweating into the stable, and rubbed down with dry wisps. When this has been done, the saddle is to be taken off, and he is to be rubbed down with dry cloths; the housing cloth is then to be laid on; and the saddle being again laid on, he is to be walked gently about till thoroughly cool. After this, he must stand without meat two or three hours, then he must be fed; and in the afternoon he is to be rubbed and dressed as before, and watered in the usual manner.

HORSE-Worm, in natural history, a species of fly-worm called also *bott*, produced of eggs deposited by a two-winged fly, of the shape and size of the humble bee, in the anus of the horse. See *BOTTS*.

River-HORSE, in zoology. See *HIPPOPOTAMUS*.

HORSE is also used in the military language, to express the cavalry; or the body of soldiers who serve on horseback. The horse includes horse-guards, horse-grenadiers, and troopers. Dragoons are also frequently comprehended under this name, though they fight on foot: of these there are now 18 regiments; besides three regiments of dragoon-guards raised in 1685. See *GRANADIER*, *DRAGOONS*, and *GUARDS*.

Master of the HORSE. See *MASTER*.

Light-HORSE, are regiments of cavalry, mounted on light swift horses, whose men are small and lightly accoutred. They were first raised in 1757. The denomination arose hence, that anciently they were lightly armed, in comparison of the royal-guards, which were armed at all points.

HORSE is also a term used in various arts and manufactories, for something that helps to sustain their work from the ground,

for the more commodious working at it. The horse used by tanners and skinners, also called the *leg*, is a piece of wood cut hollow and roundish, four or five feet long, and placed aslope; upon which they pare their skins to get off the dirt, hair, flesh, &c.

HORSE is also used in carpentry, for a piece of wood jointed across two other perpendicular pieces, to sustain the boards, planks, &c. which make bridges over small rivers; and on various other occasions.

HORSE, in sea language, is the name of a rope reaching from the middle of a yard to its extremity, or what is called the *yard-arm*, and depending about two or three feet under the yard, for the sailors to tread upon whilst they are loosing, reefing, or furling the sails, rigging out the studding-sail booms, &c. In order, therefore, to keep the horse more parallel to the yard, it is usually suspended to it at proper distances, by certain ropes called stirrups, which hang about two feet under the yard, having an eye in their lower ends through which the horse passes.

HORSE is also a thick rope, extended in a perpendicular direction near the fore or after-side of a mast, for the purpose of hoisting or extending some sail upon it. When it is fixed before a mast, it is calculated for the use of a sail called the *square-sail*, whose yard being attached to the horse, by means of a traveller or bull's eye, which slides up and down occasionally, is retained in a steady position; either when the sail is set, or whilst it is hoisting or lowering. When the horse is placed abaft or behind a mast, it is intended for the try-sail of a snow, and is accordingly very rarely fixed in this position, except in those sloops of war which occasionally assume the form of snows, in order to deceive the enemy.

HORSE is also a cant name introduced into the management

of lotteries, for the chance or benefit of a ticket or number for one or more days, upon condition, if it be drawn a prize within the time covenanted for, of returning to the seller an undrawn ticket. To determine the value of a horse; multiply the amount of the prizes in the lottery by the time the horse is hired for; and from the product subtract the amount of the number of prizes by the value of an undrawn ticket into the time of the horse: the remainder being divided by the number of tickets into the whole time of drawing, the quotient is the value of the horse. See LOTTERY.

HORSE-Dung, in gardening, is of great use in making hot-beds, for the raising all sorts of early crops; as fallading, cucumbers, melons, asparagus, &c. for which purposes no other kinds of dung will do so well. Horse dung ferments the strongest; and if mixed with litter and sea-coal ashes in a due proportion, will continue its heat much longer than any other sort of dung whatsoever: and afterward, when rotted, becomes an excellent manure for most sorts of land; more especially for such as are of a cold nature. For stiff clayey land, horse-dung mixed with sea-coal ashes, and the cleansing of streets, will cause the parts to separate much sooner than any other compost: so that where it can be obtained in plenty, it is always to be recommended for such lands. See DUNG and HUSBANDRY.

Animated Horse-Hairs, a description applied to a sort of long and slender water-worm, of a blackish colour, and so much resembling a horse-hair, that it is generally, by the vulgar, supposed to be the hair fallen from a horse's mane into the water when drinking, and there animated by some strange power. Dr. Lister has at large confuted this absurd opinion in the *Philosophical Transactions*.

HORSE-Hair-Worms. See AMPHIBIENA.

HORSE-Hoeing Husbandry. See the article HUSBANDRY.

H O R S E M A N S H I P,

THE art of breaking, disciplining, and managing horses. This term, in its utmost latitude, includes what relates to the knowledge of the make, colour, age, temper and qualities, of horses; their respective countries and climates, with the manner of breeding, propagating, &c. the discovery of the uses or services they are fitted for; whether for war, the race, the saddle, or labour; and forwarding and accommodating them for these purposes.

In this general sense, it also includes the knowledge of the defects and diseases of horses, and the remedies proper for the same, with the several operations requisite thereto, as DOCKING, GELDING, SHOING, &c. and thus takes in the farrier's province.

But the word is in a more peculiar manner understood of the art of riding, or of directing a horse to advantage; not only in the ordinary motions, but more especially in the maneging, or making him work upon volts, airs, &c. and in this view chiefly we propose to consider it.

SECT. I. *The Method of preparing Horses to be mounted.*

THOUGH most horses are bought at an age when they have already been backed, they should be begun and prepared for the rider with the same care, gentleness, and caution, as if they had never been handled or backed, in order to prevent accidents, which might else arise from skittishness or other causes: and as it is proper that they should be taught the figure of the ground they are to go upon when they are at first mount-

ed, they should be previously trotted in a *longe* on circles, without any rider.

The earl of Pembroke's directions on this subject are these: Put an easy *caveçon* upon the horse's nose, and make him go forwards round you, standing quiet and holding the *longe*; and let another man, if you find it necessary, follow him with a whip. All this must be done very gently, and but a little at a time: for more horses are spoiled by overmuch work, than by any other treatment whatever; and that by very contrary effects; for sometimes it drives them into vice, madness, and despair, and often stupefies and totally dispirits them.

The first obedience required in a horse is going forwards; till he perform this duty freely, never even think of making him rein back, which would inevitably make him restive: as soon as he goes forwards readily, stop and caress him. You must remember in this, and likewise in every other exercise, to use him to go equally well to the right and left; and when he obeys, caress him and dismiss him immediately. If a horse that is very young takes fright and stands still, lead on another horse before him, which probably will induce him instantly to follow. Put a snaffle in his mouth; and when he goes freely, saddle him, girding him at first very loose. Let the cord, which you hold, be long and loose; but not so much so as to endanger the horse's entangling his legs in it. It must be observed, that small circles, in the beginning, would constrain the horse too much, and put him upon defending himself. No bend must be required at first: never suffer him to gallop false; but whenever he at-

tempts it, stop him without delay, and then let him off afresh. If he gallops of his own accord, and true, permit him to continue it; but if he does it not voluntarily, do not demand it of him at first. Should he fly and jump, shake the cord gently upon his nose without jerking it, and he will fall into his trot again. If he stands still, plunges, or rears, let the man who holds the whip make a noise with it; but never touch him till it be absolutely necessary to make him go on. When you change hands, stop and caress him, and entice him by fair means to come up to you: for by presenting yourself, as some do, on a sudden before horses, and frightening them to the other side, you run a great risk of giving them a shyness. If he keeps his head too low, shake the *cavesson* to make him raise it; and in whatever the horse does, whether he walks, trots, or gallops, let it be a constant rule, that the motion be determined, and really such as is intended, without the least shuffling, pacing, or any other irregular gait.

SECT. II. *The Method of placing the Rider and rendering him firm on Horseback, with some occasional Instructions for Riders and their Horses.*

IT is necessary that the greatest attention, and the same gentleness that is used in teaching a horse, be observed likewise in teaching his rider, especially at the beginning. Every method and art must be practised to create and preserve, both in man and horse, all possible feeling and sensibility; contrary to the usage of most riding-masters, who seem industriously to labour at abolishing these principles both in the one and the other. As so many essential points depend upon the manner in which a man is at first placed on horseback, it ought to be considered and attended to with the strictest care and exactness.

The absurdity of putting a man, who perhaps has never before been upon a horse, on a rough trotting horse, on which he is obliged to stick with all the force of his arms and legs, is too obvious to need mentioning. This rough work, all at once, is plainly as detrimental at first, as it is excellent afterwards in proper time. No man can be either well or firmly seated on horseback, unless he be master of the balance of his body, quite unconstrained, with a full possession of himself, and at his ease; none of which requisites can he enjoy, if his attention be otherwise engaged; as it must wholly be in a raw, unsuppled, and unprepared lad, who is put at once upon a rough horse: in such a distressful state, he is forced to keep himself on at any rate, by holding to the bridle (at the expence of the sensibility both of his own hand and the horse's mouth), and by clinging with his legs, in danger of his life, and to the certain depravation of a right feeling in the horse.

The first time a man is put on horseback, it ought to be upon a very gentle one. He never should be made to trot, till he is quite easy in the walk; nor gallop, till he is able to trot properly. The same must be observed in regard to horses; they should never be made to trot till they are obedient, and their mouths are well formed on a walk; nor be made to gallop, till the same be effected on a trot. When he is arrived at such a degree of firmness in his seat, the more he trots, and the more he rides rough horses, the better. This is not only the best method, but also the easiest and the shortest: by it a man is soon made sufficiently an horseman for a soldier: but by the other detestable methods that are commonly used, a man, instead of improving, contracts all sorts of bad habits, and rides worse and worse every day; the horse too becomes daily more and more unfit for use. In proceeding according to the manner proposed, a man is rendered firm and easy upon the horse, both his own and the horse's sensibility is preserved, and each in a situation fit to receive and practise all lessons effectually.

Among the various methods that are used of placing people on horseback, few are directed by reason. Before you let the

man mount, teach him to know, and always to examine, if the curb be well placed, (that is, when the horse has a bit in his mouth, which at first he should not; but only a snaffle, till the rider is firm in his seat, and the horse also somewhat taught): likewise to know if the nose-band be properly tight; the throat-band loose; and the mouth-piece neither too high nor too low in the horse's mouth, but rightly put so as not to wrinkle the skin nor to hang lax; the girths drawn moderately, but not too tight; and the crupper and the breast-plate properly adjusted. A very good and careful hand may venture on a bit at first, and succeed with it full as well as by beginning with a snaffle alone; only with colts, indeed, it is better, in all schools whatsoever, to avoid any pressure on the bars just at first, which a curb, though ever so delicately used, must in some degree occasion. When the bridle, &c. have been well looked to, let the man approach the horse gently near the shoulder; then taking the reins and an handful of the mane in his left hand, let him put his foot softly in the left stirrup, by pulling it towards him, lest he touch the horse with his toe; then raising himself up, let him rest a moment on it with his body upright, but not stiff; and after that, passing his right leg clear over the saddle without rubbing against any thing, let him seat himself gently down. He must be cautious not to take the reins too short, for fear of making the horse rear, run, or fall back, or throw up his head; but let him hold them of an equal length, neither tight nor slack, and with the little finger betwixt them. It is fit that horses should be accustomed to stand still to be mounted, and not to stir till the rider pleases. All soldiers should be instructed to mount and dismount equally well on both sides, which may be of great use in times of hurry and confusion. Then place the man in his saddle, with his body rather back, and his head held up with ease, without stiffness; seated neither forwards, nor very backwards; with the breast pushed out a little, and the lower part of the body likewise a little forwards; the thighs and legs turned in without constraint, and the feet in a straight line, neither turned in nor out. By this position, the natural weight of the thighs has a proper and sufficient pressure of itself, and the legs are in readiness to act when called upon: they must hang down easy and naturally; and be so placed, as not to be wriggling about, touching, and tickling, the horse's sides, but always near them in case they should be wanted, as well as the heels.

The body must be carefully kept easy and firm, and without any rocking when in motion; which is a bad habit very easily contracted, especially in galloping. The left elbow must be gently leant against the body, a little forwards: unless it be so relied, the hand cannot be steady, but will always be checking, and consequently have pernicious effects on the horse's mouth. And the hand ought to be of equal height with the elbow; if it were lower, it would constrain and confine the motion of the horse's shoulders: but, as the mouths of horses are different, the place of the hand also must occasionally differ: a leaning, low, heavy, fore-hand requires a high hand; and a horse that pokes out his nose, a low one. The right-hand arm must be placed in symmetry with the left; only let the right-hand be a little forwarder or backwarder, higher or lower, as occasion may require, in order that both hands may be free; both arms must be a little bent at the elbow, to prevent stiffness.

A soldier's right-hand should be kept unemployed in riding; it carries the sword, which is a sufficient business for it.

There remains one farther observation, that ought not to be omitted, about the hand, that it must be kept clear of the body; *i. e.* about two inches and a half forwards from it, with the nails turned opposite to the belly, and the wrist a little rounded downwards; a position not less graceful than ready for slackening, tightening, and moving the reins from one side to the other, as may be found necessary.

When the men are well placed, the more rough trotting they have without stirrups the better; but with a strict care always that their position be preserved very exactly. In all cases, great care must be taken to hinder their clinging with their legs: in short, no sticking by hands or legs is ever to be allowed of at any time. If the motion of the horse be too rough, slacken it, till the rider grows by degrees more firm; and when he is quite firm and easy on his horse in every kind of motion, stirrups may be given him; but he must never leave off trotting often without any.

The stirrups must be neither short nor long; but of such a length, that when the rider, being well placed, puts his feet into them (about one third of the length of each foot from the point of it), the points may be between two and three inches higher than the heels. The rider must not bear upon his stirrups, but only let the natural weight of his legs rest on them: for if he bears upon them, he will be raised above and out of his saddle; which should never be, except in charging sword in hand, with the body inclined forwards at the very instant of attacking. Spurs may be given as soon as the rider is grown familiar with stirrups; or even long before, if his legs are well placed.

A hand should always be firm, but delicate: a horse's mouth should never be surprised by any sudden transition of it, either from slack to tight, or from tight to slack. Every thing in horsemanship must be effected by degrees, but at the same time with spirit and resolution. That hand which, by giving and taking properly, gains its point with the least force, is the best; and the horse's mouth, under this same hand's directions, will also consequently be the best, supposing equal advantages in both from nature. This principle of gentleness should be observed upon all occasions in every branch of horsemanship. Sometimes the right-hand may be necessary, upon some troublesome horses, to assist the left: but the seldomer this is done, the better; especially in a soldier, who has a sword to carry, and to make use of.

The snaffle must on all occasions be uppermost; that is to say, the reins of it must be above those of the bridle, whether the snaffle or the bit be used separately, or whether they be both used together. When the rider knows enough, and the horse is sufficiently prepared and settled to begin any work towards suppling, one rein must be shortened according to the side worked to; but it must never be so much shortened as to make the whole strength rest on that rein alone: for, not to mention that the work would be false and bad, one side of the horse's mouth would by that means be always deadened; whereas, on the contrary, it should always be kept fresh by its own play, and by the help of the opposite rein's acting delicately in a somewhat smaller degree of tension; the joint effect of which produces in a horse's mouth the proper, gentle, and easy degree of *appui* or bearing.

A coward and a madman make alike bad riders, and are both alike discovered and confounded by the superior sense of the creature they are mounted upon, who is equally spoiled by both, though in very different ways. The coward, by suffering the animal to have his own way, not only confirms him in his bad habits, but creates new ones in him: and the madman, by false and violent motions and corrections, drives the horse, through despair, into every bad and vicious trick that rage can suggest.

It is very requisite in horsemanship, that the hand and legs should act in correspondence with each other in every thing; the latter always subservient and assistant to the former. Upon circles, in walking, trotting, or galloping, the outward leg is the only one to be used, and that only for a moment at a time, in order to set off the horse true, or put him right if he be false; and as soon as that is done, it must be taken away again

immediately: but if the horse be lazy, or otherwise retains himself, both legs must be used and pressed to his sides at the same time together. The less the legs are used in general, the better. Very delicate good riders, with horses they have dressed themselves, will scarcely ever want their help. By the term *outward* is understood the side which is more remote from the centre; and by *inward* is meant the side next to the centre. In reining back, the rider should be careful not to use his legs, unless the horse backeth on his shoulders; in which case they must be both applied gently at the same time, and correspond with the hand. If the horse refuse to back at all, the rider's legs must be gently approached, till the horse lifts up a leg, as if to go forwards; at which time, when that leg is in the air, the rein of the same side with that leg which is lifted up, will easily bring that same leg backwards, and accordingly oblige the horse to back; but if the horse offers to rear, the legs must be instantly removed away. The inward rein must be tighter on circles, so that the horse may bend and look inwards; and the outward one crossed over a little towards it; and both held in the left hand.

Let the man and horse begin on very slow motions, that they may have time to understand and reflect on what is taught them; and in proportion as the effects of the reins are better comprehended, and the manner of working becomes more familiar, the quickness of motion must be increased. Every rider must learn to feel, without the help of the eye, when a horse goes false, and remedy the fault accordingly: this is an intelligence, which nothing but practice, application, and attention, can give, in the beginning on slow motions. A horse may not only gallop false, but also trot and walk false. If a horse gallops false, that is to say, if going to the right he leads with the left leg, or if going to the left he leads with the right; or in case he is disunited, i. e. if he leads with the opposite leg behind to that which he leads with before; stop him immediately, and put him off again properly. The method of effecting this, is by approaching your outward leg, and putting your hand outwards; still keeping the inward rein the shorter, and the horse's head inwards, if possible: and if he should still resist, then bend and pull his head outwards also; but replace it again, bent properly inwards, the moment he goes off true. A horse is said to be disunited to the right, when going to the right, and consequently leading with the right leg before, he leads with the left behind; and is said to be disunited to the left, when going to the left, and consequently leading with the left leg before, he leads with the right behind. A horse may at the same time be both false and disunited; in correcting both which faults, the same method must be used. He is both false and disunited to the right, when in going to the right he leads with the left leg before, and the right behind; notwithstanding that hinder leg be with propriety more forward under his belly than the left, because the horse is working to the right: and he is false and disunited to the left, when in going to the left he leads with the right leg before and the left behind; notwithstanding, as above, that hinder leg be with propriety more forward under his belly than the right, because the horse is working to the left.

In teaching men a right seat on horseback, the greatest attention must be given to prevent stiffness, and sticking by force in any manner upon any occasion: stiffness disgraces every right work; and sticking serves only to throw a man (when displaced) a great distance from his horse by the spring he must go off with: whereas, by a proper equilibrating position of the body, and by the natural weight only of the thighs, he cannot but be firm and secure in his seat.

As the men become more firm, and the horses more supple, it is proper to make the circles less; but not too much so, for fear of throwing the horses forwards upon their shoulders.

Some horses, when first the bit is put into their mouths, if great care be not taken, will put their heads very low. With such horses, raise your right hand with the *bridoon* in it, and play at the same time with the bit in the left hand, giving and taking.

On circles, the rider must lean his body inwards; unless great attention be given to make him do it, he will be perpetually losing his seat outwards. It is scarce possible for him to be displaced, if he leans his body properly inwards.

SECT. III. *The Method of suppling Horses with Men upon them, by the EPAULE en dedans, &c. with and without a Longe, on Circles and on straight Lines.*

WHEN a horse is well prepared and settled in all his motions, and the rider firm, it will be proper then to proceed on towards a farther suppling and teaching of both.

In setting out upon this new work, begin by bringing the horse's head a little more inwards than before, pulling the inward rein gently to you by degrees. When this is done, try to gain a little on the shoulders, by keeping the inward rein the shorter, as before, and the outer one crossed over towards the inward one. The intention of these operations is this: The inward rein serves to bring in the head, and procures the bend; whilst the outward one, that is a little crossed, tends to make that bend perpendicular, and as it should be, that is to say, to reduce the nose and the forehead to be in a perpendicular line with each other: it also serves, if put forwards, as well as also crossed, to put the horse forwards, if found necessary; which is often requisite, many horses being apt in this and other works rather to lose their ground backwards than otherwise, when they should rather advance; if the nose were drawn in towards the breast beyond the perpendicular, it would confine the motion of the shoulders, and have other bad effects. All other bends, besides what are above specified, are false. The outward rein, being crossed, not in a forward sense, but rather a little backwards, serves also to prevent the outward shoulder from getting too forwards, and makes it approach the inward one; which facilitates the inward leg's crossing over the outward one, which is the motion that so admirably supples the shoulders. Care must be taken that the inward leg pass over the outward one, without touching it: this inward leg's crossing over must be helped also by the inward rein, which you must cross towards and over the outward rein every time the outward leg comes to the ground, in order to lift and help the inward leg over it: at any other time, but just when the outer leg comes to the ground, it would be wrong to cross the inward rein, or to attempt to lift up the inward leg by it; nay, it would be demanding an absolute impossibility, and lugging about the reins and horse to no purpose: because in this case, a very great part of the horse's weight resting then upon that leg, would render such an attempt not only fruitless, but also prejudicial to the sensibility of the mouth, and probably oblige him to defend himself: and, moreover, it would put the horse under a necessity of straddling before, and also of leading with the wrong leg, without being productive of any suppling motion whatsoever.

When the horse is thus far familiarly accustomed to what you have required of him, then proceed to effect by degrees the same crossing in his hinder legs. By bringing in the fore-legs more, you will of course engage the hinder ones in the same work: if they resist, the rider must bring both reins more inwards; and, if necessary, put back also, and approach his inward leg to the horse; and if the horse throws out his croup too far, the rider must bring both reins outwards, and, if absolutely necessary, he must also make use of his outward leg, in order to replace the horse properly: observing that the croup should always be considerably behind the shoulders, which in

all actions must go first; and the moment that the horse obeys, the rider must put his hand and leg again in their usual position.

Nothing is more ungraceful in itself, more detrimental to a man's seat, or more destructive of the sensibility of a horse's sides, than a continual wriggling unsettledness in a horseman's legs, which prevents the horse from ever going a moment together true, steady, or determined.

A horse should never be turned, without first moving a step forwards: and when it is doing, the rider must not lift his elbow, and displace himself; a motion only of the hand from the one side to the other being sufficient for that purpose. It must also be a constant rule, never to suffer a horse to be stopped, mounted, or dismounted, but when he is well placed. The slower the motions are when a man or horse is taught any thing, the better.

At first, the figures worked upon must be great, and afterwards made less by degrees, according to the improvement which the man and horse make; and the cadenced pace also, which they work in, must be accordingly augmented. The changes from one side to the other, must be in a bold determined trot, and at first quite straight forwards, without demanding any side-motion on two *pistes*, which is very necessary to require afterwards when the horse is sufficiently suppled. By two *pistes* is meant, when the fore-parts and hinder parts do not follow, but describe two different lines.

In the beginning, a *longe* is useful on circles, and also on straight lines, to help both the rider and the horse; but afterwards, when they are grown more intelligent, they should go alone. At the end of the lesson, rein back; then put the horse, by a little at a time, forwards, by approaching both legs gently to his sides, and playing with the bridle: if he rears, push him out immediately into a full trot. Shaking the *carrieffion* on the horse's nose, and also putting yourself before him and rather near to him, will generally make him back, though he otherwise refuse to do it: and moreover a slight use and approaching of the rider's legs, will sometimes be necessary in backing, in order to prevent the horse from doing it too much upon his shoulders; but the pressure of the legs ought to be very small, and taken quite away the moment that he puts himself upon his haunches. If the horse does not back upon a straight line properly, the rider must not be permitted to have recourse immediately to his leg, and so distort himself by it; but first try, if crossing over his hand and reins to whichever side may be necessary, will not be alone sufficient: which most frequently it will; if not, then employ the leg.

After a horse is well prepared and settled, and goes freely on in all his several paces, he ought to be in all his works kept, to a proper degree, upon his haunches, with his hinder legs well placed under him; whereby he will be always pleasant to himself and his rider, will be light in hand, and ready to execute whatever may be demanded of him, with facility, vigour, and quickness.

The common method that is used, of forcing a horse sideways, is a most glaring absurdity, and very hurtful to the animal in its consequences; for instead of suppling him, it obliges him to stiffen and defend himself, and often makes a creature that is naturally benevolent, restive, frightened, and vicious.

For horses, who have very long and high fore-hands, and who poke out their noses, a running snaffle is of excellent use; but for such as bore and keep their heads low, a common one is preferable; though any horse's head indeed may be kept up also with a running one, by the rider's keeping his hands very high and forwards: but whenever either is used alone without a bridle upon horses that carry their heads low and that bore, it must be sawed about from one side to the other.

This lesson of the *epaule en dedans* should be taught to such people as are likely to become useful in helping to teach men and to break horses; and the more of such that can be found the better: none others should ever be suffered upon any occasion to let their horses look any way besides the way they are going. But all horses whatever, as likewise all men who are designed for the teaching others, must go thoroughly and perfectly through this excellent lesson, under the directions of intelligent instructors, and often practise it too afterwards; and when that is done, proceed to, and be finished by, the lessons of head and tail to the wall.

SECT. IV. *Of the Head to the Wall, and of the Croup to the Wall.*

THIS lesson should be practised immediately after that of the *epaule en dedans*, in order to place the horse properly the way he goes, &c. The difference between the head to the wall, and the croup to the wall, consists in this: In the former, the fore-parts are more remote from the centre, and go over more ground; in the latter, the hinder parts are more remote from the centre, and consequently go over more ground: in both, as likewise in all other lessons, the shoulders must go first. In riding-horses, the head to the wall is the easier lesson of the two at first, the line to be worked upon being marked by the wall, not far from his head.

The motion of the legs to the right, is the same as that of the *epaule en dedans* to the left, and so *vice versa*; but the head is always bent and turned differently: in the *epaule en dedans*, the horse looks the contrary way to that which he goes; in this, he looks the way he is going.

In the beginning, very little bend must be required: too much at once would astonish the horse, and make him defend himself: it is to be augmented by degrees. If the horse absolutely refuses to obey, it is a sign that either he or his rider has not been sufficiently prepared by previous lessons. It may happen that weakness or a hurt in some part of the body, or sometimes temper, though seldom, may be the cause of the horse's defending himself: it is the rider's business to find out from whence the obstacle arises; and if he finds it to be from the first-mentioned cause, the previous lessons must be resumed again for some time; if from the second, proper remedies must be applied; and if from the last cause, when all fair means that can be tried have failed, proper corrections with coolness and judgment must be used.

In practising this lesson to the right, bend the horse to the right with the right rein; helping the left leg over the right (at the time when the right leg is just come to the ground), with the left rein crossed towards the right, and keeping the right shoulder back with the right rein towards your body, in order to facilitate the left leg's crossing over the right; and so likewise *vice versa* to the left, each rein helping the other by their properly mixed effects. In working to the right, the rider's left leg helps the hinder-parts on to the right, and his right leg stops them if they get too forwards; and so *vice versa* to the left: but neither ought to be used, till the hand being employed in a proper manner has failed, or finds that a greater force is necessary to bring about what is required than it can effect alone: for the legs should not only be corresponding with, but also subservient to, the hand; and all unnecessary aids, as well as all force, ought always to be avoided as much as possible.

In the execution of all lessons the equilibrium of the rider's body is of great use to the horse: it ought always to go with and accompany every motion of the animal; when to the right, to the right; and when to the left, to the left.

Upon all horses, in every lesson and action, it must be observed, that there is no horse but has his own peculiar appui or degree of bearing, and also a sensibility of mouth, as likewise a

rate of his own, which it is absolutely necessary for the rider to discover, and make himself acquainted with. A bad rider always takes off at least the delicacy of both, if not absolutely destroys it. The horse will inform his rider when he has got his proper bearing in the mouth, by playing pleasantly and steadily with his bit, and by the spray about his chaps. A delicate and good hand will not only always preserve a light appui or bearing in its sensibility; but also of a heavy one, whether naturally so or acquired, make a light one. The lighter this appui can be made, the better; provided that the rider's hand corresponds with it: if it does not, the more the horse is properly prepared, so much the worse. Instances of this inconvenience of the best of appuis, when the rider is not equally taught with the horse, may be seen every day in some gentlemen, who try to get their horses *bitted*, as they call it, without being suitably prepared themselves for riding them: the consequence of which is, that they ride in danger of breaking their necks; till at length, after much hauling about, and by the joint insensibility and ignorance of themselves and their grooms, the poor animals gradually become mere senseless unfeeling posts; and thereby grow what they call *settled*. When the proper appui is found, and made of course as light as possible, it must not be kept duly fixed without any variation, but be played with; otherwise one equally continued tension of reins would render both the rider's hand and the horse's mouth very dull. The slightest and frequent giving and taking is therefore necessary to keep both perfect.

Whatever pace or degree of quickness you work in, be it ever so fast, or ever so slow, it must be cadenced; time is as necessary for an horseman as for a musician.

This lesson of the head and of the tail to the wall, must be taught every soldier: scarce any manœuvre can be performed without it. In closing and opening of files, it is almost every moment wanted.

SECT. V. *The Method of making Horses stand Fire, and endure Noises, Alarms, Sights, &c.*

IN order to make horses stand fire, the sound of drums, and all sorts of different noises, you must use them to it by degrees in the stable at feeding-time; and instead of being frightened at it, they will soon come to like it as a signal for eating.

With regard to such horses as are afraid of burning objects, begin by keeping them still at a certain distance from some lighted straw: caress the horse; and in proportion as his fright diminishes, approach gradually the burning straw very gently, and increase the size of it. By this means he will very quickly be brought to be so familiar with it, as to walk undaunted even through it.

As to horses that are apt to lie down in the water, if animating them, and attacking them vigorously, should fail of the desired effect, then break a straw-bottle full of water upon their heads, and let the water run into their ears, which is a thing they apprehend very much.

All troop-horses must be taught to stand quiet and still when they are shot off from, to stop the moment you present, and not to move after firing till they are required to do it; this lesson ought especially to be observed in light troops: in short, the horses must be taught to be so cool and undisturbed, as to suffer the rider to act upon him with the same freedom as if he was on foot. Patience, coolness, and temper, are the only means requisite for accomplishing this end. Begin by walking the horse gently, then stop and keep him from stirring for some time, so as to accustom him by degrees not to have the least idea of moving without orders: if he does, then back him; and when you stop him, and he is quite still, leave the reins quite loose.

To use a horse to fire-arms, first put a pistol or a carbine in the manger with his feed; then use him to the sound of the

lock and the pan; after which, when you are upon him, show the piece to him, presenting it forwards, sometimes on one side, sometimes on the other: when he is thus far reconciled, proceed to flash in the pan; after which, put a small charge into the piece, and so continue augmenting it by degrees to the quantity which is commonly used: if he seems uneasy, walk him forward a few steps slowly; and then stop, back and caress him. Horses are often also disquieted and unsteady at the flash, and drawing, and returning of swords; all which they must be familiarised to by little and little, by frequency and gentleness.

It is very expedient for all cavalry in general, but particularly for light cavalry, that their horses should be very ready and expert in leaping over ditches, hedges, gates, &c. The leaps, of whatever sort they are, which the horses are brought to in the beginning, ought to be very small ones; the riders must keep their bodies back, raise their hands a little in order to help the fore-parts of the horse up, and be very attentive to their equilibrium. It is best to begin at a low bar covered with furze, which pricking the horse's legs, if he does not raise himself sufficiently, prevents his contracting a sluggish and dangerous habit of touching, as he goes over, which any thing yielding and not pricking would give him a custom of doing. Let the ditches you first bring horses to be narrow; and in this, as in every thing else, let the increase be made by degrees. Accustom them to come up to every thing which they are to leap over, and to stand coolly at it for some time; and then to raise themselves gently up in order to form to themselves an idea of the distance. When they leap well standing, then use them to walk gently up to the leap, and to go over it without first halting at it; and after that practice is familiar to them, repeat the like in a gentle trot, and so by degrees faster and faster, till at length it is as familiar to them to leap flying on a full gallop as any other way: all which is to be acquired with great facility by calm and soft means, without any hurry.

As horses are naturally apt to be frightened at the sight and smell of dead horses, it is advisable to habituate them to walk over and leap over carcasses of dead horses: and as they are particularly terrified at this sight, the greater gentleness ought consequently to be used.

Horses should also be accustomed to swim, which often may be necessary upon service; and if the men and horses both are not used to it, both may be frequently liable to perish in the water. A very small portion of strength is sufficient to guide a horse, any where indeed, but particularly in the water, where they must be permitted to have their heads, and be no-ways constrained in any shape.

The unreasonable rage in Britain of cutting off all extremities from horses, is in all cases a very pernicious custom. It is particularly so in regard to a troop-horse's tail. It is almost incredible, how much they suffer at the picket for want of it; constantly fretting and sweating, kicking about and laming one another, tormented and stung off their meat, miserable and helpless; whilst other horses, with their tails on, brush off all flies, are cool and at their ease, and mend daily; whilst the docked ones grow every hour more and more out of condition.

SECT. VI. *The Method of reining back, and of moving forwards immediately after. Of Piafing, Pillars, &c.*

NEVER finish your work by reining back with horses that have any disposition towards retaining themselves; but always move them forwards, and a little upon the haunches also, after it, before you dismount (unless they retain themselves very much indeed, in which case nothing at all must be demanded from the haunches): This lesson of reining back, and piafing, is excellent to conclude with, and puts an horse well and

properly on the haunches: It may be done, according as horses are more or less suppled, either going forward, backing, or in the same place: if it is done well advancing, or at most on the same spot, it is full sufficient for a soldier's horse. For to piafe in backing, is rather too much to be expected in the hurry which cannot but attend such numbers both of men and horses as must be taught together in regiments. This lesson must never be attempted at all, till horses are very well suppled, and somewhat accustomed to be put together; otherwise it will have very bad consequences, and create restiveness. If they refuse to back, and stand motionless, the rider's legs must be approached with the greatest gentleness to the horse's sides; at the same time that the hand is acting on the reins to solicit the horse's backing. This seldom fails of procuring the desired effect, by raising one of the horse's fore legs, which being in the air, has no weight upon it, and is consequently very easily brought backwards by a small degree of tension in the reins. When this lesson is well performed, it is very noble and useful, and has a pleasing air; it is an excellent one to begin teaching scholars with.

The lesson is particularly serviceable in the pillars, for placing scholars well at first. Very few regimental riding houses have pillars, and it is fortunate they have not: for though, when properly made use of with skill, they are one of the greatest and best discoveries in horsemanship; they must be allowed to be very dangerous and pernicious, when they are not under the direction of a very knowing person.

SECT. VII. *The Method of curing Restiveness, Vice, Defences, Starting, &c.*

WHENEVER a horse makes resistance, one ought, before remedy or correction is thought of, to examine very minutely all the tackle about him, if any thing hurts or tickles him, whether he has any natural or accidental weakness, or in short any the least impediment in any part. For want of this precaution, many fatal disasters happen: the poor dumb animal is frequently accused falsely of being restive and vicious; is used ill without reason; and, being forced into despair, is in a manner obliged to act accordingly, be his temper and inclination ever so well disposed. It is very seldom the case, that a horse is really and by nature vicious; but if such be found, he will despise all carcases, and then chastisements become necessary.

Correction, according as you use it, throws a horse into more or less violent action, which, if he be weak, he cannot support: but a vicious strong horse is to be considered in a very different light, being able both to undergo and consequently to profit by all lessons; and is far preferable to the best-natured weak one upon earth. Patience and attention are never-failing means to reclaim such a horse: in whatsoever manner he defends himself, bring him back frequently with gentleness (not however without having given him proper chastisement if necessary) to the lesson which he seems most averse to. Horses are by degrees made obedient, through the hope of recompense and the fear of punishment. How to mix these two motives judiciously together, is a very difficult matter; it requires much thought and practice; and not only a good head, but a good heart likewise. The coolest and best-natured rider will always succeed best. By a dexterous use of the incitements above mentioned, you will gradually bring the horse to temper and obedience; mere force, and want of skill and coolness, would only tend to confirm him in bad tricks. If he be impatient or choleric, never strike him, unless he absolutely refuse to go forwards; which you must resolutely oblige him to do, and which will be of itself a correction, by preventing his having time to meditate and put in execution any defence by retaining himself. Resistance in horses, you must consider, is sometimes a mark of strength and vigour, and proceeds from spirit, as well as some-

times from vice and weakness. Weakness frequently drives horses into viciousness, when any thing wherein strength is necessary is demanded from them; nay, it inevitably must: great care therefore should always be taken to distinguish from which of these two causes any remedy or punishment is thought of. It may sometimes be a bad sign when horses do not at all defend themselves, and proceed from a sluggish disposition, a want of spirit, and of a proper sensibility. Whenever one is so fortunate as to meet with a horse of just the right spirit, activity, delicacy of feeling, with strength and good nature, he cannot be cherished too much; for such a one is a rare and inestimable jewel, and, if properly treated, will in a manner do every thing of himself. Horses are oftener spoiled by having too much done to them, and by attempts to dress them in too great an hurry, than by any other treatment.

If after a horse has been well supplied, and there are no impediments, either natural or accidental, if he still persists to defend himself, chastisements then become necessary: but whenever this is the case, they must not be frequent, but always firm, though always as little violent as possible; for they are both dangerous and very prejudicial when frequently or slightly played with, and still more so when used too violently.

It is impossible, in general, to be too circumspect in lessons of all kinds, in aids, chastisements, or caresses. Some have quicker parts and more cunning than others. Many will imperceptibly gain a little every day on the rider. Various, in short, are their dispositions and capacities. It is the rider's business to find out their different qualities, and to make them sensible how much he loves them, and desires to be loved by them; but at the same time that he does not fear them, and will be master.

Plunging is a very common defence among restive and vicious horses: if they do it in the same place, or backing, they must, by the rider's legs and spurs firmly applied, be obliged to go forwards, and their heads kept up high. But if they do it flying forwards, keep them back, and ride them gently and very slow for a good while together. Of all bad tempers and qualities in horses, those which are occasioned by harsh treatment and ignorant riders are the worst.

Rearing is a bad vice, and, in weak horses especially, a very dangerous one. Whilst the horse is up, the rider must yield his hand; and when the horse is descending, he must vigorously determine him forwards: if this be done at any other time but whilst the horse is coming down, it may add a spring to his rearing, and make him fall backwards. With a good hand on them, horses seldom persist in this vice; for they are themselves naturally much afraid of falling backwards. If this method fails, you must make the horse kick up behind, by getting somebody on foot to strike him behind with a whip; or, if that will not effect it, by pricking him with a goad.

Starting often proceeds from a defect in the sight; which therefore must be carefully looked into. Whatever the horse is afraid of, bring him up to it gently; if you caress him every step he advances, he will go quite up to it by degrees, and soon grow familiar with all sorts of objects. Nothing but great gentleness can correct this fault; for if you inflict punishment, the apprehension of chastisement becomes prevalent, and causes more starting than the fear of the object. If you let him go by the object, without bringing him up to it, you increase the fault, and confirm him in his fear: the consequence of which is, he takes his rider perhaps a quite contrary way from what he was going, becomes his master, and puts himself and the person upon him every moment in great danger.

With such horses as are to a very great degree fearful of any objects, make a quiet horse, by going before them, gradually entice them to approach nearer and nearer to the thing they are afraid of. If the horse, thus alarmed, be undisciplined and

headstrong, he will probably run away with his rider; and if so, his head must be kept up high, and the snaffle sawed backwards and forwards from right to left, taking up and yielding the reins of it, as also the reins of the bit: but this latter must not be sawed backwards and forwards like the snaffle, but only taken up and yielded properly. No man ever yet did, or ever will, stop a horse, or gain any one point over him, by main force, or by pulling a dead weight against him.

SECT. VIII. *Rules for bad Horsemen.*

ON this subject Mr. Thompson has given the following rules.

In the first place, every horse should be accustomed to stand still when he is mounted. One would imagine this might be readily granted; yet we see how much the contrary is practised. When a gentleman mounts at a livery-stable, the groom takes the horse by the bit, which he bends tight round his under jaw: the horse, striving to go on, is forced back; advancing again, he frets, as he is again stopped short, and hurt by the manner of holding him. The rider, in the mean time, mounting without the bridle, or at least holding it but slightly, is helped to it by the groom, who being thoroughly employed by the horse's fluttering, has at the same time both bridle and stirrup to give. This confusion would be prevented, if every horse were taught to stand still when he is mounted. Forbid your groom, therefore, when he rides your horse to water, to throw himself over him from a horse-block, and kick him with his leg even before he is fairly upon him. This wrong manner of mounting is what chiefly teaches your horse the vicious habit against which we are here warning. On the other hand, a constant practice of mounting in the proper manner, is all that is necessary to prevent a horse's going on till the rider is quite adjusted in the saddle.

The next thing necessary therefore is, that the rider should mount properly. The common method is to stand near the croup or hinder part of the horse, with the bridle held very long in the right hand. By this manner of holding the bridle before you mount, you are liable to be kicked; and when you are mounted, your horse may go on some time, or play what gambols he pleases, before the rein is short enough in your hand to prevent him. It is common likewise for an awkward rider, as soon as his foot is in the stirrup, to throw himself with all his force to gain his seat; which he cannot do, till he hath first overbalanced himself on one side or the other: he will then wriggle into it by degrees. The way to mount with ease and safety is, to stand rather before than behind the stirrup. In this posture take the bridle short, and the mane together in your left hand, helping yourself to the stirrup with your right, so that your toe may not touch the horse in mounting. When your left foot is in the stirrup, move on your right, till you face the side of the horse, looking across over the saddle. Then with your right hand grasp the hinder part of the saddle; and with that and your left, which holds the mane and bridle, list yourself upright on your left foot. Remain thus a mere instant on your stirrup, only so as to divide the action into two motions. While you are in this posture, you have a sure hold with both hands, and are at liberty, either to get safely down, or to throw your leg over and gain your seat. By this deliberate motion, likewise, you avoid, what every good horseman would endeavour to avoid, putting your horse into a flutter.

When you dismount, hold the bridle and mane together in your left hand, as when you mounted; put your right hand on the pommel of the saddle, to raise yourself; throw your leg back over the horse, grasp the hinder part of the saddle with your right hand, remain a moment on your stirrup, and in every respect dismount as you mounted; only what was your first motion when you mounted, becomes the last in dismounting. Remember not to bend your right knee in dismounting, lest your spur should rub against the horse.

It may be next recommended to hold your bridle at a convenient length. Sit square, and let not the purchase of the bridle pull forward your shoulder; but keep your body *even*, as it would be if each hand held a rein. Hold your reins with the whole grasp of your hand, dividing them with your little finger. Let your hand be perpendicular; your thumb will then be uppermost, and placed on the bridle. Bend your wrist a little outward; and when you pull the bridle, raise your hand toward your breast, and the lower part of the palm rather more than the upper. Let the bridle be at such a length in your hand, as, if the horse should stumble, you may be able to raise his head, and support it by the strength of your arms, and the weight of your body thrown backward. If you hold the rein too long, you are subject to fall backward as your horse rises.

If, knowing your horse perfectly well, you think a tight rein unnecessary, advance your arm a little (but not your shoulder) towards the horse's head, and keep your usual length of rein. By this means, you have a check upon your horse, while you indulge him.

If you ride with a curb, make it a rule to hook on the chain yourself; the most quiet horse may bring his rider into danger, should the curb hurt him. If, in fixing the curb, you turn the chain to the right, the links will unfold themselves, and then oppose a farther turning. Put on the chain loose enough to hang down on the horse's under lip, so that it may not rise and press his jaw, till the reins of the bridle are moderately pulled.

If your horse has been used to stand still when he is mounted, there will be no occasion for a groom to hold him: but if he does, suffer him not to touch the reins, but that part of the bridle which comes down the cheek of the horse. He cannot then interfere with the management of the reins, which belongs to the rider only; and holding a horse by the curb (which is ever painful to him) is evidently improper when he is to stand still.

Another thing to be remembered is, not to ride with your arms and elbows as high as your shoulders; nor let them shake up and down with the motion of the horse. The posture is unbecoming, and the weight of the arms (and of the body too if the rider does not sit still) acts in continual jerks on the jaw of the horse, which must give him pain, and make him unquiet, if he has a tender mouth or any spirit.

Bad riders wonder why horses are gentle as soon as they are mounted by skilful ones, though their skill seems unemployed: the reason is, the horse goes at his ease, yet finds all his motions watched; which he has sagacity enough to discover. Such a rider hides his whip, if he finds his horse is afraid of it; and keeps his legs from his sides, if he finds he dreads the spur.

Avoid the ungraceful custom of letting your legs shake against the sides of the horse: and as you are not to keep your arms and elbows high, and in motion; so you are not to rivet them to your sides, but let them fall easy. One may, at a distance, distinguish a genteel horseman from an awkward one: the first sits still, and appears of a piece with his horse; the latter seems flying off at all points.

It is often said with emphasis, that such a one has no *seat* on horseback; and it means, not only that he does not ride well, but that he does not sit on the right part of the horse. To have a *good seat*, is to sit on that part of the horse, which, as he springs, is the centre of motion; and from which, of course, any weight would be with most difficulty shaken. As in the rising and falling of a board placed in *æquilibrio*, the centre will be always most at rest; the true seat will be found in that part of your saddle, into which your body would naturally slide, if you rode without stirrups; and is only to be preserved by a proper poise of the body, though the generality of riders imagine it is to be done by the grasp of the thighs and knees. The rider should consider himself as united to his horse in this point; and, when shaken from it, endeavour to restore the balance.

Perhaps the mention of the two extremes of a bad seat may help to describe the true one. The one is, when the rider sits very far back on the saddle, so that his weight presses the loins of the horse; the other, when his body hangs forward over the pommel of the saddle. The first may be seen practised by grooms, when they ride with their stirrups affectedly short; the latter, by fearful horsemen on the least flutter of the horse.

Every *good rider* has, even on the hunting saddle, as *determined* a place for his thighs, as can be determined for him by the bars of a demi-peak. Indeed there is no difference between the seat of either: only, as in the first you ride with shorter stirrups, your body will be consequently more behind your knees.

To have a good seat yourself, your saddle must fit well. To fix a precise rule might be difficult: it may be a *direction*, to have your saddle press as nearly as possible on that part which we have described as the point of union between the man and horse; however, so as not to obstruct the motion of the horse's shoulders. Place yourself in the middle or lowest part of it: sit erect; but with as little constraint as in your ordinary sitting. The ease of action marks the gentleman: you may repose yourself, but not lounge. The set and studied erectness acquired in the riding-house, by those whose deportment is not easy, appears ungenteel and unnatural.

If your horse stops short, or endeavours by rising and kicking to unseat you, bend not your body forward, as many do in those circumstances: that motion throws the breech backward, and you off your fork or twist, and out of your seat; whereas, the advancing the lower part of your body, and bending back the upper part and shoulders, is the method both to keep your seat, and to recover it when lost. The bending your body back, and that in a great degree, is the greatest security in *flying* leaps; it is a security too, when your horse leaps *standing*. The horse's rising does not try the rider's seat; the lash of his hind-legs is what ought chiefly to be guarded against, and is best done by the body's being greatly inclined back. Stiffen not your legs or thighs; and let your body be pliable in the loins, like the coachman's on his box. This loose manner of sitting will elude every rough motion of the horse; whereas the fixture of the knees, so commonly laid a stress on, will in great shocks conduce to the violence of the fall.

Were the cricket-player, when the ball is struck with the greatest velocity, to hold his hand firm and fixed when he receives it, the hand would be bruised, or perhaps the bones fractured by the resistance. To obviate this accident, he therefore gradually yields his hand to the motion of the ball for a certain distance; and thus, by a due mixture of opposition and obedience, catches it without sustaining the least injury. The case is exactly the same in riding: the skilful horseman will recover his poise by giving some way to the motion; and the ignorant horseman will be flung out of his seat by endeavouring to be fixed.

Stretch not out your legs before you; this will push you against the back of the saddle: neither gather up your knees, like a man riding on a pack; this throws your thighs upwards: each practice unseats you. Keep your legs straight down; and sit not on the most fleshy part of the thighs, but turn them inward, so as to bring in your knees and toes: and it is more safe to ride with the ball of the foot pressing on the stirrup, than with the stirrup as far back as the heel; for the pressure of the heel being in that case behind the stirrup, keeps the thighs down.

When you find your thighs thrown upwards, widen your knees to get them and the upper part of your fork lower down on the horse. Grasp the saddle with the hollow or inner part of your thighs, but not more than just to assist the balance of your body: this will also enable you to keep your spurs from the horse's sides, and to bring your toes in, without that affected and

useless manner of bringing them in practised by many. Sink your heels straight down; for while your heels and thighs keep down, you cannot fall: this (aided with the bend of the back) gives the security of a seat, to those who bear themselves up in their stirrups in a swift gallop, or in the alternate rising and falling in a full trot.

Let your seat determine the length of your stirrups, rather than the stirrups your seat. If more precision is requisite, let your stirrups (in the hunting saddle) be of such a length, as that, when you stand in them, there may be the breadth of four fingers between your seat and the saddle.

It would greatly assist a learner, if he would practise riding in a large circle, as directed in sect. ii. without stirrups; keeping his face looking on the outward part of the circle so as not to have a full view of the horse's head, but just of that ear which is on the outward part of the circle; and his shoulder, which is towards the centre of the circle, very forward. By this means you learn to balance your body, and keep a true seat, independent of your stirrups: you may probably likewise escape a fall, should you at any time lose them by being accidentally shaken from your seat.

As the seat in some measure depends on the saddle, it may not be amiss to observe, that because a saddle with a high pommel is thought dangerous, the other extreme prevails, and the pommel is scarce allowed to be higher than the middle of the saddle. The saddle should lie as near the back-bone as can be, without hurting the horse; for the nearer you sit to his back, the better seat you have. If it does so, it is plain the pommel must rise enough to secure the withers from pressure: therefore, a horse whose withers are higher than common, requires a higher pommel. If, to avoid this, you make the saddle of a more straight line, the inconvenience spoken of follows; you sit too much above the horse's back, nor can the saddle form a proper seat. There should be no ridge from the button at the side of the pommel, to the back part of the saddle. That line also should be a little concave, for your thighs to lie at ease. In short, a saddle ought to be, as nearly as possible, as if cut out of the horse.

When you want your horse to move forward, raise his head a little, and touch him gently with your whip; or else, press the calves of your legs against his sides. If he does not move fast enough, press them with more force, and so till the spur just touches him. By this practice he will (if he has any spirit) move upon the least pressure of the leg. Never spur him by a kick; but if it be necessary to spur him briskly, keep your heels close to his sides, and slacken their force as he becomes obedient.

When your horse attempts to be vicious, take each rein separate, one in each hand, and advancing your arms forward, hold him very short. In this case, it is common for the rider to pull him hard, with his arms low. But the horse by this means having his head low too, has it more in his power to throw out his heels: whereas, if his head be raised very high, and his nose thrown out a little, which is consequent, he can neither rise before nor behind; because he can give himself neither of those motions, without having his head at liberty. A plank placed in *æquilibrio*, cannot rise at one end unless it sinks at the other.

If your horse is headstrong, pull not with one continued pull, but stop, and back him often, just shaking the reins, and making little repeated pulls till he obeys. Horses are so accustomed to bear on the bit when they go forward, that they are discouraged if the rider will not let them do so.

If a horse is loose necked, he will throw up his head at a continued pull; in which situation, the rider, seeing the front of his face, can have no power over him. When your horse does thus, drop your hand and give the bridle play, and he will

of course drop his head again into its proper place: while it is coming down, make a second gentle pull, and you will find his mouth. With a little practice, this is done almost instantaneously; and this method will stop, in the distance of a few yards, a horse, which will run away with those who pull at him with all their might. Almost every one must have observed, that when a horse feels himself pulled with the bridle, even when he is going gently, he often mistakes what was designed to stop him, as a direction to bear on the bit and to go faster.

Keep your horse's head high, that he may raise his neck and crest; play a little with the rein, and move the bit in his mouth, that he may not press on it in one constant and continued manner: be not afraid of raising his head too high; he will naturally be too ready to bring it down, and tire your arms with its weight, on the least abatement of his mettle. When you feel him heavy, stop him, and make him go back a few paces: thus you break by degrees his propensity to press on his bridle.

You ought not to be pleased (though many are) with a round neck, and a head drawn-in towards his breast: let your horse carry his head bridling in, provided he carries it high, and his neck arching upwards; but if his neck bends downwards, his figure is bad, his sight is too near his toes, he leans on the bridle, and you have no command over him. If he goes pressing but lightly on the bridle, he is the more sure-footed, and goes pleasanter; as your wrist only may guide him. If he hangs down his head, and makes you support the weight of that and his neck with your arms bearing on his fore legs (which is called *being on his shoulders*), he will strike his toes against the ground, and stumble.

If your horse is heavy upon the bit, tie him every day, for an hour or two, with his tail to the manger, and his head as high as you can make him lift it, by a rein on each post of the stall, tied to each ring of the snaffle bit.

Horse-breakers and grooms have a great propensity to bring a horse's head *down*, and seem to have no seat without a strong hold by the bridle. They know indeed, that the head should yield to the reins, and the neck form an arch; but do not take the proper pains to make it an arch *upward*. A temporary effect of attempting to raise a horse's head, may perhaps be making him push out his nose. They will here tell you, that his head is too high already; whereas it is not the distance from his nose, but from the *top* of his head to the ground, which determines the head to be high or low. Besides, although the fault is said to be in the manner of carrying the head, it should rather be said to be in that of the neck; for if the neck was raised, the head would be more in the position of one set on a well formed neck.

The design therefore of lifting up the head, is to raise the neck, and *thereby* bring in the head; for even while the bridle makes the same line from the rider's hand to the bit, the horse's nose may be either drawn in, or thrust out, according as his neck is raised or depressed. Instead of what has been here recommended, we usually see colts broke with their heads caved down very low, their necks stiff, and not in the least suppled. When the breaking tackle is left off, and they are mounted for the road, having more food and rest, they frequently plunge, and a second breaking becomes necessary. Then, as few gentlemen can manage their own horses, they are put into the hands of grooms, from whom they learn a variety of bad habits.

If, on the other hand, your horse carries his head (or rather his nose) too high, he generally makes some amends by moving his shoulders lightly, and going safely. Attend to the cause of this fault. Some horses have their necks set so low on their shoulders, that they bend first down, then upwards, like a stag's. Some have the upper line of their necks, from their ears to their withers, too short. A head of this sort cannot possibly bend in-

wards and form an arch, because the vertebræ (or neck-bones) are too short to admit of flexure; for in long and short-necked horses the number of the vertebræ is the same. In some, the jaw is so thick, that it meets the neck, and the head by this means has not room to bend. On the other hand, some have the under line from the jaw to the breast so short, that the neck cannot rise.

In all these cases you may gain a *little* by a nice hand with an easy bit; but no curb, martingale, or other forcible method, will *teach* a horse to carry his head or neck in a posture which nature has made uneasy to him. By trying to pull in his nose farther than he can bear, you will add a bad habit to nature. You could not indeed *contrive* a more effectual method to make him continually toss his nose up, and throw his foam over you.

The rule already given to ride a loose-necked horse, will be a proper one for all light-mouthed horses: one caution being added, which is, always to search whether his saddle or girths may not in some way pinch him; and whether the bit may not hurt his lip by being too high in his mouth: because, whenever he frets from either of these causes, his head will not be steady.

It is a common custom to be always pulling at the bridle, as if to set off to advantage either the spirit of the horse, or the skill of the rider. Our horses therefore are taught to hold their heads low, and pull so as to bear up the rider from the saddle, standing in his stirrups, even in the gentlest gallop: how very improper this is, we are experimentally convinced, when we happen to meet with a horse which gallops otherwise: we immediately say, *he canters excellently*, and find the ease and pleasure of his motion. When horses are designed for the race, and swiftness is the only thing considered, the method may be a good one.

It is not to be wondered that *dealers* are always pulling at their horses; that they have the spur constantly in their sides, and are at the same time continually checking the rein: by this means they make them bound, and champ the bit, while their rage has the appearance of spirit. These people ride with their arms spread, and very low on the shoulders of their horses: this method makes them stretch their necks, and gives a better appearance to their forehands; it conceals also a thick jaw, which, if the head was up, would prevent its yielding to the bit; it hides likewise the ewe-neck, which would otherwise show itself. Indeed, if you have a horse unsteady to the bit, formed with a natural heavy head, or one which carries his nose obstinately in the air, you must find his mouth where you can, and make the best of him.

Many horses are taught to start by whipping them for starting. How is it possible they can know it is designed as a punishment? In the riding-house, you teach your horse to rise up before, and to spring and lash out his hinder legs, by whipping him when tied between two pillars, with his head a little at liberty. If he understood this to be a punishment for doing so, he would not by that method learn to do it. He seems to be in the same manner *taught* to spring and fly when he is frightened. Most horses would go quietly past an object they were beginning to fly from, if their riders, instead of gathering up their bridles, and showing themselves so ready, should throw the reins loose upon their necks.

When a horse starts at any thing on one side, most riders turn him out of the road, to make him go up to what he starts at: if he does not get the better of his fear, or readily comply, he generally goes past the object, making with his hinder parts, or croup, a great circle out of the road; whereas, he should learn to keep straight on, without minding objects on either side.

If he starts at any thing on the left, hold his head high, and keep it straight in the road, pulling it *from* looking at the

thing he starts at, and keeping your right leg hard pressed against his side, towards his flank: he will then go straight along the road. By this method, and by turning his head a little more, he may be forced with his croup close up to what frightened him; for, as his head is pulled one way, his croup necessarily turns the other. Always avoid a quarrel with your horse, if you can: if he is apt to start, you will find occasions enough to exercise his obedience, when what he starts at lies directly in his way, and you *must* make him pass; if he is not subject to start, you should not quarrel with him about a trifle.

It must be observed, however, that this rule in going past an object may perhaps be a little irregular in a managed horse, which will always obey the leg: but even such a horse, if he is really afraid, and not restive, it may not be amiss to make look another way; unless the object be something you would particularly accustom him to the sight of.

The case will also be different with a horse whose fear is owing to his not being used to objects; but such a one is not to be rode by any horseman to whom these rules are directed: the starting here meant arises merely from the horse's being unaccustomed, and springing through liveliness.

The notion of the necessity of making a horse go immediately up to every thing he is afraid of, and not suffering him to become master of his rider, seems to be in general carried too far. It is an approved and good method to conquer a horse's fear of the sound of a drum, by beating one near to him at the time of feeding him: this not only familiarizes the noise to him, but makes it pleasant, as a fore-runner of his meat (see sect. v.); whereas, if he was whipped up to it, he might perhaps start at it as long as he lived. Might not this be applied to his starting at other things, and show that it would be better to suffer him (provided he does not turn back) to go a little from and avoid an object he has a dislike to, and to accustom him to it by degrees, convincing him, as it were, that it will not hurt him; than to punish him, quarrel with him, and perhaps submit to his will at last, while you insist on his overcoming his fear in an instant? If he sees a like object again, it is probable he will recollect his dread, and arm himself to be disobedient.

We are apt to suppose that a horse fears nothing so much as his rider: but may he not, in many circumstances, be afraid of instant destruction? of being crushed? of being drowned? of falling down a precipice? Is it a wonder that a horse should be afraid of a loaded waggon? may not the hanging load seem to threaten the falling on him? There cannot be a rule more general, than, in such a case, to show him there is room for him to pass. This is done by turning his head a very little from the carriage, and pressing your leg, which is farthest from it, against his side.

A horse is not to stop without a sign from his rider. Is it not then probable, that, when driven up to a carriage he starts at it, he conceives himself obliged either to attack or run against it? Can he understand the rider's spurring him with his face directed to it, as a sign for him to pass it? That a horse is easily alarmed for his face and eyes (he will even catch back his head from a hand going to caress him); that he will not go with any force, face to face, even to another horse (if in his power to stop); and that he sees perfectly sideways, may be useful hints for the treatment of horses with regard to starting.

Though you ought not to whip a horse for starting, there can be no good effect from clapping his neck with your hand to encourage him. If one took any notice of his starting, it should be rather with some tone of voice which he usually understood as an expression of dislike to what he is doing; for there is *opposition* mixed with his starting, and a horse will ever repeat what he finds has foiled his rider.

Notwithstanding the directions above given, of not pressing a horse up to a carriage he starts at; yet if one which you appre-

end will frighten him meets you at a narrow part of the road, when you have once let him know he is to pass it, be sure you remain determined, and press him on. Do this more especially when part of the carriage has already passed you: for if, when he is frightened, he is accustomed to go back, and turn round, he will certainly do it if he finds, by your hand slackening, and legs not pressing, that you are irresolute; and this at the most dangerous point of time, when the wheels of the carriage take him as he turns. Remember not to touch the curb rein at this time; it will certainly check him. It is not known to every one, that the person who would lead a horse by the bridle, should not turn his face to him when he refuses to follow him: if, besides this, he raises his arms, shows his whip, or pulls the bridle with jerks, he frightens the horse, instead of persuading him to follow; which a little patience may bring about.

Ride with a snaffle; and use your curb, if you have one, only occasionally. Choose your snaffle full and thick in the mouth, especially at the ends to which the reins are fastened. Most of them are made too small and long; they cut the horse's mouth, and bend back over the bars of his jaw, working like pinners.

The management of the curb is too nice a matter to enter on here, farther than to prescribe great caution in the use of it: a turn of the wrist, rather than the weight of your arm, should be applied to it. The elasticity of a rod, when it hath hooked a fish, may give you some idea of the proper play of a horse's head on his bridle; his spirit and his pliability are both marked by it.

A horse should never be put to do any thing in a curb which he is not ready at: you may force him, or pull his head any way with a snaffle; but a curb acts only in a straight line. It is true, that a horse will be turned out of one track into another by a curb, but it is because he knows it as a *signal*. When he is put to draw a chair, and does not understand the necessity he is then under of taking a larger sweep when he turns, you frequently see him *resistive*, as it is then called: but put him on a snaffle, or buckle the rein to that part of the bit which does not curb him; and the horse submits to be pulled about, till he understands what is desired of him. These directions suppose your horse to have spirit, and a good mouth: if he has not, you must take him as he is, and ride him with such a bit as you find most easy to yourself.

When you ride a journey, be not so attentive to your horse's nice carriage of himself, as to your encouragement of him, and keeping him in good humour. Raise his head; but if he flags, you may indulge him with bearing a little more upon the bit than you would suffer in an airing. If a horse is lame, tender-footed, or tired, he naturally hangs upon his bridle. On a journey, therefore, his mouth will depend greatly on his strength and the goodness of his feet. Be then very careful about his feet, and let not a blacksmith spoil them, but attend to the directions given under the article FARRIERY, p. 442 and 450.

Even though practised in riding, very few persons know they have any power over a horse but by the bridle; or any use for the spur, except to make him go forward. A little experience will teach them a farther use. If the left spur touches him (and he is at the same time prevented from going forward), he has a sign, which he will soon understand, to move sideways to the right. In the same manner to the left, if the right spur goads him. He afterwards, through fear of the spur, obeys a touch of the leg; in the same manner as a horse moves his croup from one side of the stall to the other, when any one strikes him with his hand. In short, his croup is guided by the leg, as his head is by the bridle. He will never disobey the leg, unless he becomes resistive. By this means you will have a far greater power over him: he will move sideways, if you close

one leg to him; and straight forward, if both: even when he stands still, your legs held near him will keep him on the watch; and with the slightest, unseen motion of the bridle upwards, he will raise his head, and show his forehead to advantage.

On this use of the legs of the rider, and guidance of the croup of the horse, are founded all the *airs* (as the riding-masters express themselves) which are taught in the manege; the passage, or side-motion of troopers to close or open their files, and indeed all their evolutions. But the convenience of some degree of this discipline for common use is the reason of mentioning it here. It is useful if a horse is apt to stumble or start. If to the first, by pressing your legs to his flank, and keeping up his head, he is made to go light on his fore-legs, which is aiding and supporting him; and the same if he does actually stumble, by helping him at the very instant to exert himself, while as yet any part of him remains not irrecoverably impressed with the precipitate motion. Hence this use of the hand and legs of the rider is called *giving aids* to a horse; for, as to holding up the weight of a heavy inactive horse by mere pulling, it is as impossible as to recover him when falling down a precipice.

A horse is supported and helped by the hands and legs of his rider in every action they require of him; hence he is said to perform his *airs* by the *aids* from his rider.

The same manner is useful if a horse starts. For if when he is beginning to fly to one side, you leg on the side he is flying to, he stops his spring immediately. He goes past what he started at, keeping straight on, or as you choose to direct him; and he will not fly back from any thing if you press him with both legs. You keep his haunches under him going down a hill; help him on the side of a bank; more easily avoid the wheel of a carriage; and approach more gracefully and nearer to the side of a coach or horseman. When a pampered horse curvets irregularly, and twists his body to and fro, turn his head either to the right or left, or both alternately (but without letting him move out of the track), and press your leg to the opposite side: your horse cannot then spring on his hind-legs to one side, because your leg prevents him; nor to the other, because his head looks that way, and a horse does not start and spring to the side on which he looks. Here it may not be amiss to observe the impropriety of the habit which many riders have, of letting their legs shake against the sides of the horse: if a horse is taught, they are then continually pressing him to violent action; and if he is not, they render him insensible and incapable of being taught. The fretting of a hot horse will hence be excessive, as it can no otherwise be moderated than by the utmost stillness of the seat, hands, and legs of the rider.

Colts at first are taught to *bear* a bit, and by degrees to *pull* at it. If they did not press it, they could not be guided by it. By degrees they find their necks stronger than the arms of a man; and that they are capable of making great opposition, and often of foiling their riders. Then is the time to make them supple and pliant in every part. The part which of all others requires most this pliancy is the neck. Hence the metaphor of *stiff-necked* for *disobedient*. A horse cannot move his head but with the muscles of his neck: this may be called his *helm*; it guides his course, changes and directs his motion.

The use of this pliancy in the different parts and limbs of a horse has been already shown in a former section. The present section being directed to the *unexperienced* horseman, it may suffice to add, that *his* idea of suppleness need only be, that of an ability and readiness in a horse to move every limb, on a sign given him by the hands or legs of his rider; as also to bend his body, and move in a short compass, quick and collected within himself, so as instantly to be able to perform any other motion.

HORSHAM, a town of Suffex, seated near St. Leonard's forest, 38 miles from London. It has its name from Horfa, brother to Hengist the Saxon; and is one of the largest towns in the county. It has sent members to parliament ever since the 30th of Edward I. and is the place where the county gaol is held, and often the assizes. It is a borough by prescription, with the title of two bailiffs and burgage-holders within and without the borough, &c. who elect the members of parliament, and they are returned by the bailiffs chosen yearly by a court-leet of the lord of the manor, who return four candidates to the steward, and he nominates two of them for the office. Here is a very fine church, and a well endowed free-school. Great store of poultry is bought up for London at its market on Saturday, and it has a patent also for a monthly market.

HORSTIUS (JAMES), professor of medicine in the university of Helmstadt, in the 16th century. He joined devotion with the knowledge and practice of physic. He carefully prayed to God to bless his prescriptions, and published a form of prayer upon this subject. He also wrote, 1. A Treatise on the Qualities of a good Physician. 2. Another on the Qualities of a good Apothecary. 3. A Treatise of the Plague, in German. 4. A Commentary in *Litros Hippocratis de Corde*, and other works.

HORSTIUS (Gregory), nephew of the former, called *the Æsculapius of Germany*, published several books, which are esteemed.

HORTAGILERS, in the grand signior's court, upholsters, or tapeltry hangers. The grand signior has constantly 400 in his retinue when he is in the camp: these go always a day's journey before him, to fix upon a proper place for his tent, which they prepare first; and afterwards those of the officers, according to their rank.

HORTENSIUS (QUINTUS), a celebrated Roman orator, the cotemporary of Cicero, pleaded with universal applause at 19 years of age, and continued the same profession during 48 years. But being at last eclipsed by Cicero, he quitted the bar, and embraced a military life; became a military tribune, prætor, and afterwards consul, about 70 B. C. Cicero speaks of him in such a manner as makes us regret the loss of his orations. Hortensius had a wonderful memory, and delivered his orations without writing down a single word, or forgetting one particular that had been advanced by his adversaries. He died very rich, a little before the civil war, which he had endeavoured by all possible means to prevent.

HORTUS SICCUS, a DRY GARDEN; an appellation given to a collection of specimens of plants carefully dried and preserved. The value of such a collection is very evident, since a thousand minutæ may be preserved in the well dried specimens of plants, which the most accurate engraver would overlook. We shall therefore give two methods of drying and preserving a *hortus siccus*: the first by Sir Robert Southwell in the Philosophical Transactions, N^o 237; and the other by Dr. Hill, in his review of the works of the Royal Society, with his objections to Sir Robert's method.

According to the former gentleman, the plants are to be laid flat between papers, and then put between two smooth plates of iron, screwed together at the corners; and in this condition committed to a baker's oven for two hours. When taken out, they are to be rubbed over with a mixture of equal parts of aquafortis and brandy; and after this to be fastened down on paper with a solution of the quantity of a walnut of gum tragacanth dissolved in a pint of water. See **HERBAL**. To this the Doctor objects, that the heat of an oven is much too uncertain to be employed in so nice an operation; and that the space of time ordered for continuing the plants in it is of no information, unless the degree of heat, and even the different nature of the plant as to its succu-

lency and the firmness or tenderness of its fibres, be attended to; there being scarcely any two plants alike in these particulars: consequently the degree and duration of heat sufficient for one plant would destroy another. Beside which, the acid used destroys the colour of many plants; and never recovers that of others lost in the drying; and frequently, after the plant is fixed down, rots both the paper it is fixed to, and that which falls over it. Dr. Hill's method is as follows: Take a specimen of a plant in flower, and with it one of its bottom leaves if it have any; bruise the stalk if too rigid, or slit it if too thick: spread out the leaves and flowers on paper, cover it with more paper, and lay a weight over all. At the end of 18 hours take out the plants, now perfectly flattened, and lay them on a bed of dry common sand; sift more dry sand over them to the depth of two inches, and thus let them lie about three weeks: the less succulent dry much sooner, but they take no harm afterward. If the floor of a garret be covered in spring with sand two inches deep, leaving space for walking to the several parts, it will receive the collection of a whole summer; the covering of sand being sifted over every parcel as laid in, they need no farther care from the time of laying them till they are taken up to be stuck on paper. The cement used by the Doctor is thus prepared: Early in the spring, put two ounces of camphor into three quarts of water in a large bottle, shake it from time to time; and when the first collected plants are ready for the fastening down, put into a pint of the water, poured off into an earthen vessel that will bear the fire, two ounces of common glue, such as is used by the carpenters, and the same quantity of ichthyocolla beat to shreds; let them stand 36 hours, then gently boil the whole a few moments, and strain it off through a coarse cloth: this is to be warmed over a gentle heat when it is to be used, and the back of the plants smeared over with a painter's brush: after this lay them on paper, and gently press them for a few minutes, then expose them to the air a little; and finally, lay them under a small weight between quires of paper to be perfectly dried.

It is scarce to be conceived how strongly the water becomes impregnated with the camphor, by this simple process: a part of it indeed flies off in the making of the cement and the using of it: but enough remains with the plants to prevent the breeding of insects in it. He farther observes, that plants may be dried very well without sand, by only putting them frequently into fresh quires of paper, or a few, by only pressing them between the leaves of a book: but the sand method preserves the colour best, and is done with least trouble.

Another method much better than that of the oven is the flattening and drying the plant by passing a common smoothing iron for linen over the papers between which it is laid: but for nice things the most perfect of all methods is that by a common sand heat, such as is used for chemical purposes. The cold sand is to be spread smooth upon this occasion, the plant laid on it carefully flatted, and a thick bed of sand sifted over: the fire is then to be made, and the whole process carefully watched until by a very gentle heat the plant be carefully dried. The colour of the tenderest herb may by this manner be preserved; and flowers that can no way else be preserved, may be managed perfectly well thus.

HORUS, a renowned deity of ancient Egypt. He was an emblem of the sun. Plutarch, in his treatise *de Iside et Osiride*, says, "that virtue which presides over the sun, whilst he is moving through space, the Egyptians called *Horus*, and the Greeks *Apollo*." Job also calls *Ur* or *Orus* the sun—"If I gazed upon the sun (*Ur, Orus*) when he was shining, or on the moon (*Jävêcha*) walking in brightness, and my heart hath been severely enticed (*i. e.* to worship), or my mouth hath

kissed my hand; this also were an iniquity to be punished by the judge, for I should have denied the God who is above." Chap. xxxi. ver. 26, 27, 28.

The interpretation left by Hermapion of the hieroglyphics engraved on the obelisk of Heliopolis (according to Ammianus Marellinus), offers these remarkable words: "Horus is the supreme lord and author of time." These qualities, it is known, were chiefly attributed to Osiris: that they may apply, therefore, to Horus, he must necessarily denote the star of the day in certain circumstances; and this is what is explained to us by the oracle of Apollo of Claros: "*Learn that the first of the gods is Jao. He is called invisible in winter, Jupiter in the spring, the Sun in summer, and towards the end of autumn the tender Jao.*" The star of the day, on attaining the summer solstice, and called *per excellentiam* "The Sun," is the same as Horus. In fact, the Egyptians represented him borne on lions, which signified his entrance into the sign of the lion. They who presided over the divine institutions, then placed sphynxes at the head of the canals and sacred fountains, to warn the people of the approaching inundation. Macrobius (*Saturnal. lib. 1.*), who informs us why the Greeks gave Horus the name of Apollo, confirms this sentiment: "In the mysteries," says he, "they discover as a secret, which ought to be inviolable, that the sun arrived in the upper hemisphere is called Apollo." These testimonies concur in proving, that this emblematical deity was no other than the star of day passing through the signs of summer.

These lights may lead us to the explication of the sacred fable, which the priests published on the subject of Horus; for they enveloped in mystery every point of their religion. Plutarch gives it at length in his treatise of Isis and Osiris: The following are the principal traits. They said that he was the son of Osiris and of Isis; that Typhon, after killing his brother Osiris, took possession of the kingdom; that Horus, leaguering himself with Isis, avenged the death of his father, expelled the tyrant from his throne without depriving him of life, and reigned gloriously in Egypt. A person who has travelled ever so little in Egypt, easily discovers natural phenomena hid under the veil of fable. In the spring, the wind khamsin frequently makes great ravages there. It raises whirlwinds of burning sands, which suffocate travellers, darken the air, and cover the face of the sun in such a manner as to leave the earth in perfect obscurity. Here is the death of Osiris and the reign of Typhon. These hurricanes break loose usually in the months of February, March, and April. When the sun approaches the sign of the lion, he changes the state of the atmosphere, disperses these tempests, and restores the northerly winds, which drive before them the malignant vapours, and preserve in Egypt coolness and salubrity under a burning sky. This is the triumph of Horus over Typhon, and his glorious reign. As the natural philosophers acknowledge the influence of the moon over the state of the atmosphere, they united her with this god, to drive the usurper from the throne. The priests, considering Osiris as the father of time, might bestow the name of his son on Horus, who reigned three months in the year. This, according to Mr. Savary (*Letters on Egypt, ii. 403.*), is the natural explication of this allegory. And all enlightened men, he thinks, must have understood this language, which was familiar to them. The people only, whose feeble sight extends no farther than the exterior, without diving into the true meaning of things, might regard these allegorical personages as real gods, and decree prayers and offerings to them.

Jablonski, who has interpreted the epithet of Arueri, which the Egyptians gave to Horus, pretends that it signifies *effica-*

cious virtue. These expressions perfectly characterise the phenomena which happened during the reign of this god. It is in summer, in fact, that the sun manifests all its power in Egypt. It is then that he swells the waters of the river with rains, exhaled by him in the air, and driven against the summits of the Abyssinian mountains; it is then that the husbandman reckons on the treasures of agriculture. It was natural for them to honour him with the name of *Arueri, or efficacious virtue*, to mark these auspicious effects.

HOSANNA, in the Hebrew ceremonies, a prayer which they rehearsed on the several days of the feast of tabernacles. It was thus called, because there was frequent repetition therein of the word *הושיענו*, *serva nunc*; or *serva, precor*; i. e. save us now; or, save us, we pray. There are many of these hosannahs. The Jews call them *hoschannoth*; i. e. the *hosannahs*. Some are rehearsed on the first day, others on the second, &c. which they call *hosanna* of the first day, *hosanna* of the second day, &c.

HOSANNA *Rabba*, or *Grand Hosanna*, is a name they give to their feast of tabernacles, which lasts eight days; because, during the course thereof, they are frequently calling for the assistance of God, the forgiveness of their sins, and his blessing on the new year; and to that purpose they make great use of the *hoschannoth*, or prayers above mentioned. The Jews also apply the term *hosanna rabba*, in a more peculiar manner, to the seventh day of the feast of tabernacles; because they apply themselves more immediately on that day to invoke the divine blessing, &c.

HOSCHIUS (SIDRONIUS), a jesuit, who was born at Marke, in the diocese of Ypres, in 1596, and died at Tongres in 1653. He wrote some elegies and other poems in Latin with great purity and elegance.

HOSE, from the Saxon *hosa*, a stocking. See STOCKING.

HOSEA, a canonical book of the Old Testament, so called from the prophet of that name, its author, who was the son of Beri, and the first of the lesser prophets. He lived in the kingdom of Samaria, and delivered his prophecies under the reign of Jeroboam II. and his successors, kings of Israel; and under the reigns of Uzziah, Jotham, Ahaz, and Hezekiah, kings of Judah. His principal design is to publish the gross idolatries of the people of Israel and Judah, to denounce the divine vengeance against them, and to foretel the captivity in Assyria.

HOSPINIAN (RODOLPHUS), one of the greatest writers that Switzerland has given birth to. He was born in 1547, at Altorf near Zurich; obtained the freedom of Zurich; and was made provisor of the abbey school. Notwithstanding this employment, he undertook a noble work of vast extent, which was a *History of the Errors of Popery*. Though he could not complete this work according to his plan, he published some considerable parts of it: what he published on the Eucharist, and another work called *Concordia Discors*, exceedingly exasperated the Lutherans. He did not reply to them; but, turning his arms against the Jesuits, published *Historia Jesuitica*, &c. These writings gained him preferment; he being appointed archdeacon of Caroline church, and then minister of the abbey-church. He died in 1626; and there was an edition of his works published at Geneva 1681, in seven volumes in folio.

HOSPITAL, popularly SPITAL, a place or building erected, out of charity, for the reception and support of the poor, aged, infirm, sick, and otherwise helpless. The word is formed of the Latin *hospes*, host, stranger." See HOST. In the ages of the church, the bishop had the immediate charge of all the poor, both sound and diseased, as also of

widows, orphans, strangers, &c. When the churches came to have fixed revenues allotted them, it was decreed, that at least one fourth part thereof should go to the relief of the poor; and to provide for them the more commodiously, many houses of charity were built, which are since denominated *hospitals*. They were governed wholly by the priests and deacons, under the inspection of the bishop. In course of time, separate revenues were assigned for the hospitals; and particular persons, out of motives of piety and charity, gave lands and money for erecting of hospitals. When the church discipline began to relax, the priests, who till then had been the administrators of hospitals, converted them into a sort of benefices, which they held at pleasure, without giving account thereof to any body; reserving the greatest part of the income to their own use; so that the intentions of the founders were frustrated. To remove this abuse, the council of Vienne expressly prohibited the giving any hospital to secular priests in the way of a benefice; and directed the administration thereof to be given to sufficient and responsible laymen, who should take an oath, like that of tutors, for the faithful discharge thereof, and be accountable to the ordinaries. This decree was executed and confirmed by the council of Trent.

In Britain, hospitals are buildings properly endowed, or otherwise supported by charitable contributions, for the reception and support of the poor, aged, infirm, sick, or helpless. A charitable foundation laid thus for the sustenance and relief of the poor, is to continue for ever. Any person seized of an estate in fee, may, by deed enrolled in chancery, erect and found an hospital, and nominate such heads and governors therein as he shall think fit; and this charitable foundation shall be incorporated, and subject to the inspection and guidance of the heads and visitors nominated by the founder. Likewise such corporations shall have, take, and purchase lands, so as not to exceed 200l. a year, provided the same be not held of the king; and to make leases, reserving the accustomed yearly rent. See CORPORATION.

HOSPITAL (MICHAEL DE L'), chancellor of France in the 16th century, was one of the greatest men of his age, and had raised himself by degrees. He agreed to an edict much severer against the Protestants than he could have wished, to prevent the introduction of the Inquisition. It was that of Romorantin. The speeches he made, in order to inspire a spirit of toleration, made him much suspected by the Roman Catholics, and extremely odious to the court of Rome. The maxims of state upon which he regulated himself were of great advantage to France, since he formed some disciples who opposed, in proper time, the pernicious attempts of the leaguers, and rendered them abortive. His pacific views being disliked by Catharine de Medicis, who had contributed to his advancement, she excluded him from the council of war, and occasioned his disgrace. He retired, however, of his own accord, in 1568; and spent the rest of his life at his country-seat at Vignai, where he died in 1573, aged 68. His poems are esteemed. He also published some excellent speeches and memoirs.

HOSPITAL (William-Francis Antony, marquis of), a great mathematician of France, was born of an ancient family in 1661. He was a geometrician almost from his infancy; for one day being at the duke of Rohan's, where some able mathematicians were speaking of a problem of Pascal's which appeared to them extremely difficult, he ventured to say that he believed he could solve it. They were amazed at such presumption in a boy of 15, for he was then no more; nevertheless, in a few days he sent them the solution. He entered early into the army, and was a captain of horse; but being extremely short-sighted, and exposed on that account to perpetual inconveniencies and errors, he at length quitted the

army, and applied himself entirely to his favourite amusement. He contracted a friendship with Malbranche, and took his opinion upon all occasions. In 1693 he was received an honorary member of the academy of sciences at Paris; and he published a work upon Sir Isaac Newton's calculations, intitled, *L'Analyse des infinimens petits*. He was the first in France who wrote upon this subject; and on this account was regarded almost as a prodigy. He engaged afterwards in another work of the mathematical kind, in which he included *Les Sections Coniques, les Lieux Geometriques, la Construction des Equations, et Une Theorie des Courbes Mechaniques*: but a little before he had finished it, he was seized with a fever, of which he died Feb. 2, 1704, aged 43. It was published after his death.

HOSPITALITY, the practice of entertaining strangers. Dr. Robertson, speaking of the middle ages, says, "Among people whose manners are simple, and who are seldom visited by strangers, hospitality is a virtue of the first rank. This duty of hospitality was so necessary in that state of society which took place during the middle ages, that it was not considered as one of those virtues which men may practise or not, according to the temper of their minds and the generosity of their hearts. Hospitality was enforced by statutes, and those who neglected the duty were liable to punishment. The laws of the Slavi ordained that the moveables of an inhospitable person should be confiscated, and his house burnt. They were even so solicitous for the entertainment of strangers, that they permitted the landlord to steal for the support of his guest."

The hospitality of our British ancestors, particularly of the great and opulent barons, hath been much admired. Their castles were capacious palaces, daily crowded with their numerous retainers, who were always welcome to their plentiful tables. They had their privy counsellors, their treasurers, marshals, constables, stewards, secretaries, chaplains, heralds, pursuivants, pages, henchmen or guards, trumpeters, minstrels, and in a word all the officers of a royal court. The etiquette of their families was an exact copy of that of the royal household; and some of them lived in a degree of pomp and splendour little inferior to that of the greatest kings. Richard Neville, earl of Warwick, we are told, "was ever had in great favour of the commons of the land, because of the exceeding household which he daily kept in all countries wherever he sojourned or lay: and when he came to London, he held such an house, that six oxen were eaten at a breakfast; and every tavern was full of his meat." The earls of Douglas in Scotland, before the fall of that great family, rivalled or rather exceeded their sovereigns in pomp and profuse hospitality. But to this manner of living, it is highly probable, these great chieftains were prompted by a desire of increasing the number and attachment of their retainers, on which, in those turbulent times, their dignity, and even their safety, depended, rather than to the innate generosity of their tempers. Those retainers did not constantly reside in the families of their lords; but they wore their liveries and badges, frequently feasted in their halls, swelled their retinues on all great solemnities, attended them in their journeys, and followed them into the field of battle. Some powerful chieftains had so great a number of these retainers constantly at their command, that they set the laws at defiance, were formidable to their sovereigns, and terrible to their fellow-subjects; and several laws were made against giving and receiving liveries. But these laws produced little effect at that period of time.

Hospitality was not confined to the great and opulent, but was practised much more than it is at present by persons in the middle and lower ranks of life. But this was owing to necessity, arising from the scarcity of inns, which obliged travellers and strangers to apply to private persons for lodging and

entertainment; and those who received them hospitably acquired a right to a similar reception. This was evidently the case in Scotland in the first part of this period. James I. A. D. 1424, procured the following act of parliament: "It is ordanit, That in all burrow townis, and throughfairis quhair commoun passages ar, that thair be ordanit hostillaries and refettis, havand stables and chalmers; and that men find with thame bread and aill, and all uther fude, alsweil for horse as men, for resonable price." But travellers had been so long accustomed to lodge in private houses, that these public inns were quite neglected; and those who kept them presented a petition to parliament, complaining, "That the liegis travel-land in the realme, quhen they come to burrowis and through-fairis, herbreis thame not in hostillaries, bot with thair acquaintance and friendis." This produced an act prohibiting travellers to lodge in private houses where there were hostalries, under the penalty of 40s. and subjecting those who lodged them to the same penalty.

HOSPITALLERS, HOSPITALARIU, an order of religious knights, who built an hospital at Jerusalem, wherein pilgrims were received. To these pope Clement V. transferred the effects and revenues of the Templars; whom, by a council held at Vienne, he suppressed for their many and great misdemeanours. These hospitallers were otherwise called *Knights of St. John of Jerusalem*; and are the same with those whom we now call *Knights of Malta*.

HOSPITIUM, a term used in old writers either for an inn or a monastery, built for the reception of strangers and travellers. See **INN** and **MONASTERY**.

HOSPODAR, a title borne by the princes of Walachia and Moldavia, who receive the investiture of their principalities from the grand signior. He gives them a vest and standard; they are under his protection, and obliged to serve him, and he even sometimes deposes them; but in other respects they are absolute sovereigns within their own dominions.

HOST, HOSPEs, a term of mutual relation, applied both to a person who lodges and entertains another, and to the person thus lodged, &c. The word is formed of the Latin *hospes*, which some will have thus called, *quasi hostium* or *ostium petens*; for *ostium* was anciently written with an aspirate. Thus the inn-keeper says, he has a good *host*, in speaking of the traveller who lodges with him: and the traveller again says, he has a kind *host*, in speaking of his landlord. It must be observed then, that it was the custom among the ancients, when any stranger asked for lodging, for the master of the house, and the stranger, each of them to set a foot on their own side of the threshold, and swear they would neither of them do any harm to the other. It was this ceremony that raised so much horror against those who violated the law or right of hospitality on either side; inasmuch as they were looked on as perjured. Instead of *hospes*, the ancient Latins called it *hostis*; as Cicero himself informs us: though, in course of time, *hostis* came to signify an enemy; so much was the notion of hospitality altered.

HOST is also used by way of abbreviation for *hostia*, a victim or sacrifice offered to the Deity. In this sense, *host* is more immediately understood of the person of the Word incarnate, who was offered up an host or *hostia* to the Father on the cross for the sins of mankind. See **HOSTIA**.

HOST, in the church of Rome, a name given to the elements used in the eucharist, or rather to the consecrated wafer, which they pretend to offer up every day as a new host or sacrifice for the sins of mankind. They pay adoration to the host, upon a false presumption that the elements are no longer bread and wine, but transubstantiated into the real body and blood of Christ. See **TRANSUBSTANTIATION**. Pope Gregory IX. first decreed a bell to be rung, as the signal for the people to

betake themselves to the adoration of the host. The vessel wherein the hosts are kept is called the *cibory*; being a large kind of covered chalice.

HOSTAGE, a person given up to an enemy as a security for the performance of the articles of a treaty.

HOSTIA, HOST, in antiquity, a victim offered in sacrifice to a deity. The word is formed from *hostis*, "enemy;" it being customary to offer up a sacrifice before they joined battle, to render the gods propitious; or, after the battle was over, to give them thanks. Some choose to derive the word from *hostio*, q. d. *ferio*, "I strike." Isidore on this word remarks, that the name *hostia* was given to those sacrifices which they offered before they marched to attack an enemy, (*antiquam ad hostem pergerent*); in contradistinction from *viclima*, which were properly those offered after the victory.

Hostia also signified the lesser sorts of sacrifice, and *viclima* the larger. A. Gellius says, that every priest, indifferently, might sacrifice the *hostia*, but that the *viclima* could be offered by none but the conqueror himself. But, after all, we find these two words promiscuously used one for the other by ancient writers. We read of many kinds of *hostiæ*: as *hostiæ pura*, which were pigs or lambs ten days old; *hostiæ prævidanae*, sacrifices offered the day before a solemn feast; *hostiæ bidentes*, sacrifices of sheep or other animals of two years old; *hostiæ esimia*, a sacrifice of the flower of the flock; *hostiæ succedanea*, sacrifices offered after others which had exhibited some ill omen; *hostiæ ambarvales*, victims sacrificed after having been solemnly led round the fields at the *ambarvalia*; *hostiæ ambrubiales*, victims slain after the *ambrubium*; *hostiæ canceares* or *caviaries*, victims sacrificed every fifth year by the college of pontiffs, in which they offered the part of the tail called *caviar*; *hostiæ prodigia*, sacrifices in which the fire consumed all, and left nothing for the priests; *hostiæ piaculares*, expiatory sacrifices; *hostiæ ambegna* or *ambiegna*, sacrifices of cows or sheep that had brought forth twins; *hostiæ haruga*, victims offered to predict future events from; *hostiæ mediales*, black victims offered at noon.

HOT-BEDS, in gardening, beds made with fresh horse-dung, or tanner's bark, and covered with glasses to defend them from cold winds. By the skilful management of hot-beds, we may imitate the temperature of warmer climates; by which means, the seeds of plants brought from any of the countries within the torrid zone may be made to flourish even under the poles.

The hot-beds commonly used in kitchen-gardens, are made with new horse-dung mixed with the litter of a stable, and a few sea-coal-ashes, which last are of service in continuing the heat of the dung. This should remain six or seven days in a heap; and being then turned over, and the parts mixed well together, it should be again cast into a heap; where it may continue five or six days longer, by which time it will have acquired a due heat. These hot-beds are made in the following manner: In some sheltered part of the garden, dig out a trench of a length and width proportionable to the frames you intend it for; and if the ground be dry, about a foot or a foot and a half deep: but if it be wet, not above six inches: then wheel the dung into the opening, observing to stir every part of it with a fork, and to lay it exactly even and smooth on every part of the bed, laying the bottom part of the heap, which is commonly free from litter, upon the surface of the bed: and if it be designed for a bed to plant out cucumbers to remain for good, you must make a hole in the middle of the place designed for each light about ten inches over, and six deep, which should be filled with good fresh earth, thrusting in a stick to show the places where the holes are; then cover the bed all over with the earth that was taken out of the trench, about four inches thick, and put on the frame, letting it remain till the earth be warm, which commonly happens in

three or four days after the bed is made, and then the plants may be placed in it. But if your hot-bed be designed for other plants, there need be no holes made in the dung; but after having smoothed the surface with a spade, you should cover the dung about three or four inches thick with good earth, putting on the frames and glasses as before. In making these beds, care must be taken to settle the dung close with a fork; and if it be pretty full of long litter, it should be trod down equally on every part. During the first week or ten days after the bed is made, you should cover the glasses but slightly in the night, and in the day time carefully raise them, to let out the steam: but as the heat abates, the covering should be increased; and as the bed grows cold, new hot dung should be added round the sides of it.

The hot-bed made with tanner's bark is, however, much preferable to that described above, especially for all tender exotic plants and fruits, which require an even degree of warmth to be continued for several months, which cannot be effected with horse-dung. The manner of making them is as follows: Dig a trench about three feet deep, if the ground be dry; but if wet, it must not be above a foot deep at most, and must be raised two feet above the ground. The length must be proportioned to the frames intended to cover it; but it should never be less than ten or twelve feet, and the width not less than six. The trench should be bricked up round the sides to the abovementioned height of three feet, and filled in the spring with fresh tanner's bark that has been lately drawn out of their vats, and has lain in a round heap, for the moisture to drain out of it, only three or four days: as it is put in, gently beat it down equally with a dung-fork; but it must not be trodden, which would prevent its heating, by settling it too close: then put on the frame, covering it with glasses; and in about ten days or a fortnight it will begin to heat; at which time plunge your pots of plants or seed into it, observing not to tread down the bark in doing it. These beds will continue three or four months in a good temper of heat; and if you stir up the bark pretty deep, and mix a load or two of fresh bark with the old when you find the warmth decline, you will preserve its heat two or three months longer. Many lay some hot horse-dung in the bottom of the trench under the bark; but this ought never to be practised unless the bed is wanted sooner than the bark would heat of itself, and even then there ought only to be a small quantity of dung at the bottom.

The frames which cover these beds, should be proportioned to the several plants they are designed to contain. If they are to cover the ananas or pine-apple, the back part should be three feet high, and the lower part 15 inches: if the bed be intended for taller plants, the frame must be made of a depth proportionable to them: but if it be for sowing of seeds, the frame need not be above 14 inches high at the back, and 7 in the front; by which means the heat will be much greater.

HOT-HOUSE. See STOVE and HYPOCAUSTUM.

HOTEL, a French term, anciently signifying a house or dwelling-place; afterwards used for the palaces or houses of the king, princes, and great lords. In this sense they had the *hotel de Condé*, *hotel de Conti*, *hotel de Louvre*, &c. Since the abolition of monarchy, however, this term has been more commonly applied to public buildings, hospitals, &c. In England, the word *Hotel* signifies a large inn or temporary lodging-house ready furnished.

HOTMAN (FRANCIS), one of the most learned civilians in the 16th century. He professed law at Bourges; but, on account of religion, retired to Geneva, read lectures on civil law there, and published books with so much effect against the persecutors, that great promises were made to him to engage him not to write any more in that manner; but he did not regard their offers. He died at Basil in 1590. His *Franco-*

Gallia is well known, having been done in English by lord Molesworth. Some persons think he was the author of *Vindiciae contra Tyrannos*. All his works were printed at Geneva in 1590, in 3 vols folio.

HOTTENTOTS, a people in the southern part of Africa, whose country surrounds the empire of Monomotapa, in form of a horse-shoe, extending, according to Magin, from the Negroest of Cabo as far as the Cape of Good Hope; and from thence northward to the river Magnica, or Rio de St. Spiritus, including Mattatan a distinct kingdom. According to Sanutus, this coast, beginning at the Mountains of the Moon under the tropic of Capricorn in $23\frac{1}{2}^{\circ}$ S. lat. extends north beyond the Cape to the coast of Zanguebar; having the Indian sea on the east, the Ethiopic on the west, the southern ocean on the south; and on the north the kingdoms of Mattatan, Monomotapa, and the coast of Zanguebar, or rather the Mountains of the Moon, which divide it from the rest of the continent.

The Europeans first became acquainted with this country in the year 1493, when Bartholomew Diaz, a Portuguese admiral, discovered the most southerly point of Africa now called the *Cape of Good Hope*, but by him *Cabo dos totos tormentos*, or Cape of all Plagues, on account of the storms he met with in the neighbourhood; but John, then king of Portugal, having from the account of Diaz concluded that a passage to the East Indies was now discovered, changed the name to that of the *Cape of Good Hope*, which it still retains. In 1497 it was circumnavigated by Gasco de Gama, who made a voyage to India that way: however, it remained useless to Europeans till the year 1650, when Van Riebeck a Dutch surgeon first saw the advantages that would accrue to the East India company in Holland from a settlement at such a convenient distance both from home and from India. The colony which he planted has till lately continued in the hands of the Dutch, has greatly increased in value, and is visited by all the European ships trading to the East Indies. See *GOOD-HOPE*.

The country, now possessed by the British, is of pretty considerable extent, and comprehends that part of the African coast on the west called *Terra de Natal*. It is naturally barren and mountainous; but the industry of its former possessors overcame all natural difficulties, and it now produces not only a sufficiency of all the necessaries of life for the inhabitants, but also for the refreshment of all the Europeans who pass and repass that way.

The coast abounds in capes, bays, and roads. Thirty leagues to the east of the Cape of Good Hope, in S. lat. $34. 21.$ is another Cape which runs out beyond 35° , called by the Portuguese, who first doubled it, *Cabo dos Agulhas*, or the *Cape of Needles*, on account of some strange variations in the magnetical needle observed as they came near it. Near this Cape is a flat shore, with plenty of fish: it begins in the west near a fresh-water river, and, extending 15 leagues in the main sea, ends in the east near *Fish-bay*. Cabo Falso, so called by the Portuguese, who returning from India mistook it for the Cape of Good Hope, lies to the eastward between these two capes, about eight or nine leagues beyond that of Good Hope. Along the coasts, on both sides of the Cape of Good Hope, are many fine bays. Twenty-seven leagues to the north-west is Saldanha Bay, so named from a Portuguese captain shipwrecked on the coast. The largest and most commodious is *Table Bay*, on the south, and near the mountain of that name, six leagues in circumference, with four fathom water close to the beach. Opposite to this bay is *Robu Eilan*, or the Island of Rabbits, in $34. 30.$ S. lat. 67 leagues east from the Cape of Good Hope. Peter Both, in 1651, discovered a bay, which he named *Uelst*, sheltered only from north winds, in which is a small island, and on the west a rivulet of fresh water extremely convenient for European mariners. Twenty-five or thirty leagues farther

east, Both discovered Marhal Bay, afterwards named by the Portuguese *Seno Formoso*. Next to this is *Seno de Lago*, from its resemblance to a lake. There are several roads in this bay, and an island called *Ilha dos Caos*. Cabo de S. Francisco and Cabo das Serras are marked upon charts between these two bays. Near the latter of these capes is Cabo de Arecito, and the island Contento; and something more north-east is St. Christopher's river, called *Sau Christovano* by the Portuguese, and by the Hottentots *Nagod*. The country beyond this river was called by the Portuguese, who discovered it on the day of our Lord's nativity, *Terra de Natal*. Between the Cape of Good Hope and Cabo das Agulhas are the Sweet, Salt, and Jagulina rivers, which run into the sea, and Sweet-water river flows from the Table-mountain.

The most remarkable mountains in this country are, Table-mountain, Devil's Tower, Lion's Head, and the Tiger-hills. The three first lie near Table-bay and surround Table-valley, where the Cape-town stands. (See the article *Good-Hope*.) Mr. Forster, in his voyage, informs us, that "the extremity of Africa towards the south is a mass of high mountains, of which the outermost are craggy, black, and barren, consisting of a coarse granite, which contains no heterogeneous parts, such as petrified shells, &c. nor any volcanic productions. The ground gradually rises on all sides towards the three mountains which lie round the bottom of the bay, keeping low and level only near the sea-side, and growing somewhat marshy in the Isthmus between False and Table Bays, where a salt rivulet falls into the latter. The marshy part has some verdure, but intermixed with a great deal of sand. The higher grounds, which, from the sea-side, have a parched and dreary appearance, are, however, covered with an immense variety of plants, among which are a prodigious number of shrubs, but scarce one or two species that deserve the name of *trees*. There are also a few small plantations wherever a little run of water moistens the ground. The ascent of Table-mount is very steep and difficult, on account of the number of loose stones which roll away under the feet of the traveller. About the middle of the mountain is a bold, grand chasm, whose walls are perpendicular, and often impending rocks piled up in strata. Small rills of water ooze out of crevices, or fall from precipices in drops, giving life to hundreds of plants and low shrubs in the chasm. The summit of the mountain is nearly level, very barren, and bare of soil; several cavities, however, are filled with rain water, or contain a small quantity of vegetable earth, from whence a few odoriferous plants draw their nourishment. Some antelopes, howling baboons, solitary vultures, and toads, are sometimes to be met with on the mountain. The view from thence is very extensive and picturesque. The bay seems a small pond or basin, and the ships in it dwindled to little boats; the town under our feet, and the regular compartments of its gardens, look like the work of children."

Most accounts of this country that have been published, mention a surprising phenomenon which is annually to be seen on the top of Table-hill from September to March; namely, a white cloud hovering on its top, and called by sailors, from its extensive flat surface, *the Devil's table-cloth*. This cloud is said by some to appear at first no bigger than a barley-corn; then increases to the size of a walnut, and soon after covers the whole top of the mount. But, according to Mr. Kolben, it is never less, even on its first appearance, than the size of a large ox, often bigger. It hangs in several fleeces over the Table-hill and the Wind or Devil's Hill; which fleeces, at last uniting, form a large cloud that covers the summits of these two hills. After this has rested for some time without change or motion, the wind bursts out suddenly from it with the utmost fury. The skirts of the cloud are white, but seem much more compact than the matter of common clouds; the upper parts are

of a leaden colour. No rain falls from it, but sometimes it discovers a great deal of humidity; at which times it is of a darker colour, and the wind issuing from it is broken, raging by fits of short continuance. In its usual state, the wind keeps up its first fury unabated for one, two, three, or eight days; and sometimes for a whole month together. The cloud seems all the while undiminished, though little fleeces are from time to time detached from it, and hurried down the sides of the hills, vanishing when they reach the bottom; so that during the storm the cloud seems to be supplied with new matter. When the cloud begins to brighten up, these supplies fail, and the wind proportionally abates. At length the cloud growing transparent the wind ceases. During the continuance of these south-east winds, the Table-valley is torn by furious whirlwinds. If they blow warm, they are generally of short duration; and in this case the cloud soon disappears. This wind rarely blows till after sun-set, and never longer than till towards midnight, though the cloud remains; but then it is thin and clear: but when the wind blows cold, it is a sure sign that it will last for some time, an hour at noon and midnight excepted; when it seems to lie still to recover itself, and then lets loose its fury anew.

The Europeans at the Cape consider the year as divided into two seasons, which they term *monsoons*. The wet monsoon or winter, and the dry one or summer. The first begins with our spring in March; the latter with September, when our summer ends. In the summer monsoon reign the south-east winds already mentioned; which, though they clear and render the air more healthy, yet make it difficult for ships outward bound to enter Table-bay. In the bad season, the Cape is much subject to fogs; and the north-west winds and rain make the inhabitants stay much at home. But there are frequent intermissions and many clear days till June and July; when it rains almost continually, and from thence till summer. The weather in winter, is cold, raw, and unpleasant; but never more rigorous than autumn in Germany. Water never freezes to above the thickness of half a crown; and as soon as the sun appears, the ice is dissolved. The Cape is rarely visited by thunder and lightning, excepting a little near the turn of the seasons, which never does any hurt. During the continuance of the south-east winds which rage in summer, the sky is free of all clouds except that on the Table and Wind Hills already mentioned; but during the north-west winds, the air is thick, and loaded with heavy clouds big with rain. If the south-east winds should cease for any length of time, the air becomes sickly by reason of the sea-weeds driving ashore and rotting; hence the Europeans are at such times affected with headaches and other disorders: but, on the other hand, the violence of those winds subjects them to inflammations of their eyes, &c.

The natives of this country are called *Hottentots*, in their own language; a word of which it is vain to inquire the meaning, since the language of this country can scarce be learned by any other nation. The Hottentot language is indeed said to be a composition of the most strange and disagreeable sounds, deemed by many the disgrace of speech, without human sound or articulation, resembling rather the noise of irritated turkeys, the chattering of magpies, hooting of owls, and depending on extraordinary vibrations, inflexions, and clappings of the tongue against the palate. If this account is true, however, it is obvious, that all the relations we have concerning the religion, &c. of the Hottentots derived from themselves, must fall to the ground, as nobody can pretend to understand a language in itself unintelligible. The manners and customs of these people, however, are easily observable, whether they themselves give the relation or not; and if their language is conformable to them, it is no doubt of a nature sufficiently wonderful.

Many accounts have been published concerning the extreme nastiness and filthy customs of the Hottentots; but from the observations of late travellers it appears, that these have either been exaggerated, or that the Hottentots (which is not improbable) have in some measure laid aside their former manners. Dr. Sparman describes them in much less disgusting terms, and M. Vaillant seems to have been charmed with their innocence and simplicity. According to the Doctor, these people are as tall as the generality of Europeans, though more slender in their persons, which he attributes to their scanty supply of food, and not accustoming themselves to hard labour. The characteristic of the nation, however, and which he thinks has not been observed by any one before, is, that they have small hands and feet in proportion to the other parts of the body. The distance between the eyes appears greater than in Europeans, by reason of the root of the nose being very low. The tip is rather flat, and the iris of the eye has generally a dark-brown cast, sometimes approaching to black. Their skins are of a yellowish brown, something like that of an European who has the jaundice in a high degree; though this colour does not in the least appear in the whites of the eyes. Their lips are thinner than those of their neighbours the *Negroes*, *Caffres*, or *Mozambiques*. "In fine (says our author), their mouths are of a middling size, and generally furnished with a set of the finest teeth that can be seen; and, taken together with the rest of their features, as well as their carriage, shape, and every motion, in short their *tout ensemble*, indicates health and delight, or at least an air of *sans souci*. This careless mien, however, discovers marks at the same time both of alacrity and resolution; qualities which the Hottentots, in fact, can show upon occasion." The hair of the head is black and frizzled, though not very close; and has so much the appearance of wool, that it would be taken for it, were it not for its harshness. They have but seldom any appearance of a beard, or hair upon other parts of their bodies; and when any thing of this kind happens to be visible, it is always very slight.

A general opinion has prevailed, that the Hottentot women have a kind of natural veil which covers the sexual parts; but this is denied by our author. "The women (says he) have no parts uncommon to the rest of their sex: but the clitoris and nymphæ, particularly of those who are past their youth, are pretty much elongated; a peculiarity which has undoubtedly got footing in this nation in consequence of the relaxation necessarily produced by the method they have of besmearing their bodies, their slothfulness, and the warmth of the climate."

The Hottentots besmear all their bodies copiously with fat mixed up with a little soot. "This (says our author) is never wiped off; on the contrary, I never saw them use any thing to clean their skins, excepting that, when in greasing the wheels of their waggons their hands were besmeared with tar and pitch, they used to get it off very easily with cow-dung, at the same time rubbing their arms into the bargain up to the shoulders with this cosmetic; so that as the dust and other filth, together with their sooty ointment, and the sweat of their bodies, must necessarily, notwithstanding it is continually wearing off, in some measure adhere to the skin, it contributes not a little to conceal the natural hue of the latter, and at the same time to change it from a bright amber-brown to a brownish-yellow colour, obscured with filth and nastiness." The Doctor was enabled to discover the natural colour of the Hottentots by means of the nicety of some Dutch farmers' wives, who had made their Hottentot girls wash and scour their skins, that they might be less filthy in looking after the children, or doing any other work that required cleanliness. Many of the colonists, however, are of opinion, that this operation of washing is no improvement to the look of an Hottentot; but that their natural yellow is full as disagreeable as the black or brown

colour of the ointment; and that the washed skin of a native of this country seems to be deficient in dress, like shoes that want blacking. This the Doctor does not pretend to determine; though, whatever may be supposed deficient in look, we should think must be made up in cleanliness.

The Hottentots perfume their bodies by daubing them all over with the powder of an herb, the smell of which is at once rank and aromatic, approaching to that of the poppy mixed with spices. For this purpose they use various species of the diosina, called by them *bucku*, and which they imagine to be very efficacious in the cure of disorders. One species of this plant, growing about *Goud's-rivier*, is said to be so valuable, that no more than a thimble-full of its powder is given in exchange for a lamb.

By the ointment of soot and grease stuck full of the powder of *bucku*, a paste is formed which defends the bodies of the Hottentots in a great measure from the action of the air; so that they require very few clothes, and in fact go almost quite naked. The only covering of the men consists of two leather straps, which generally hang down the back from the chine to the thighs, each of them in the form of an isosceles triangle, their points uppermost, and fastened to a belt which goes round the waist, their bases not being above three fingers broad; so that the covering they form is extremely trifling. These straps have very little dressing bestowed upon them, so that they make a rattling noise as the Hottentot runs along; and our author supposes that they may produce an agreeable coolness by fanning him. Besides this, the men have a bag or flap made of skin which hangs down before, and is fastened to the belt already mentioned. The hollow part of this seems designed to receive that which with us modesty requires to be concealed; but being only fastened by a small part of its upper end to a narrow belt, in other respects hanging quite loose, it is but a very imperfect concealment; and when the wearer is walking, or otherwise in motion, it is none at all. They call this purse by the Dutch name of *jackall*, it being almost always prepared of the skin of that animal, with the hairy side turned outwards.

The women cover themselves much more scrupulously than the men, having always two, and very often three coverings like aprons; though even these seem to be abundantly small for what we should term decency in this country. The outermost of these, which is the largest, measures only from about six inches to a foot in breadth. All of them are made of a skin well prepared and greased, the outermost being adorned with glass beads strung in different figures. The outermost reaches about half-way down the thighs, the middle about a third, or one half less, and the third scarcely exceeds the breadth of the hand. The first is said to be designed for ornament, the second as a defence for modesty, and the third to be useful on certain occasions, which, however, are much less troublesome to the Hottentot than to the European females. Our author with great probability supposes, that it was the sight of this innermost apron which misled the reverend Jesuit Tackard, who, on his return to Europe, first propagated the stories concerning the natural veils or excrescences of the Hottentots. A story was likewise commonly believed, that the men in general had but one testicle, and that such as were not naturally formed in this manner were artificially made so. But this our author likewise denies; and though he says that such an operation might have been formerly performed upon the males, yet it is not so now.

The other garments worn by the Hottentots are formed of a sheep's-skin with the woolly side turned inwards: this forming a kind of cloak, which is tied forwards over the breast: though sometimes, instead of a sheep's-skin, some smaller kind of fur is used as a material. In warm weather they let this

cloak hang carelessly over their shoulders, so that it reaches down to the calves of the legs, leaving the lower part of the breast, stomach, and fore-part of the legs and thighs bare; but in cold weather they wrap it round them; so that the fore-part of the body is likewise pretty well covered by it as far as the knees; but as one sheep-skin is not sufficient for this purpose, they sew on a piece on the top at each side with a thong or catgut. In warm weather they sometimes wear the woolly side outwards, but more frequently take off the cloak altogether, and carry it under the arm. This cloak or *krossi* serves them not only for clothes, but bedding also; and in this they lie on the bare ground, drawing up their bodies so close, that the cloak is abundantly sufficient to cover them.—The cloaks used by the women differ little from those already described, excepting only that they have a long peak on them, which they turn up; forming with it a little hood or pouch, with the hairy side inwards. In this they carry their little children, to which the mother's breasts are now and then thrown over the shoulders; a custom common among some other nations, where the breasts of the females, by continual want of support, grow to an enormous length. The men commonly wear no covering on their heads, though our author says he has seen one or two who wore a greasy nightcap made of skin with the hair taken off. Those who live nearest the colonists have taken a liking to the European hats, and wear them slouched all round, or with only one side turned up. The women also frequently go bare-headed; though they sometimes wear a cap made in the shape of a short truncated cone. This appears to be the section of some animal's stomach, and is perfectly blacked by soot and fat mixed up together. These caps are frequently prepared in such a manner as to look shaggy; others have the appearance of velvet; and, in our author's opinion, are not inelegant. Over this they sometimes wear an oval wreath or kind of crown made of a buffalo's hide, with the hair outermost. It is about four fingers breadth in height, and surrounds the head so as to go a little way down upon the forehead, and the same depth on the neck behind, without covering the upper part of the cap above described. The edges of this wreath, both upper and under, are always smooth and even; each of them set with a row of small shells of the *cyprea* kind, to the number of more than 30, in such a manner that, being placed quite close to one another, their beautiful white enamel, together with their mouths, are turned outwards. Between two rows of these shells run two others parallel, or else waved and indented in various ways. The Hottentots never adorn their ears or noses as other savages do: though the latter are sometimes marked with a black streak of soot; at others, though more rarely, with a large spot of red lead; of which last, on festivals and holidays, they likewise put a little on their cheeks. The necks of the men are bare, but those of the women are ornamented with a thong of undressed leather, upon which are strung eight or ten shells. These, which are about the size of beans, have a white ground, with large black spots of different sizes: but as they are always made use of in a burnished state, the Doctor is uncertain whether they be of that kind which is received in the *Systema Naturæ* under the name of *nerita albicilla*, or *exuvia*. These shells are sold at an enormous price, no less than a sheep for each; as it is said that they come from the most distant coast of Caffraria. Both men and women are very fond of European beads, particularly the blue and white ones of the size of a pea; of which they tie several rows round the middle, and next to the girdles which hold the coverings above mentioned. Besides these ornaments, they use rings on their arms and legs; most of them made of thick leather straps generally cut in a circular shape; which by being beat and held over the fire, are rendered tough enough to retain the curvature that is given them. From these rings it has been almost universally believed, that

the Hottentots wrap guts about their legs in order to eat them occasionally. The men wear from one to five or six of these rings on their arms, just above the wrist, but seldom on their legs. The matrons of a higher rank have frequently a considerable number of them both on their arms and legs, especially on the latter; so that they are covered with them from the feet up to the knees. These rings are of various thicknesses, from that of a goose-quill to two or three times that size. Sometimes they are made of pieces of leather forming one entire ring; so that the arms and feet must be put through them when the wearer wishes to put them on. They are strung upon the legs, small and great, without any nicety; but are so large, that they shake and get twisted when the person walks. Rings of iron or copper, but especially of brass, of the size of a goose-quill, are considered as more genteel than those of leather. However, they are sometimes worn along with the latter, to the number of six or eight at a time, particularly on the arms. The girls are not allowed to use any rings till they are marriageable. The Hottentots seldom wear any shoes; but such as they do make use of are of the same form with those worn by the African peasants, by the Esthonians, and Livonians, as well as by some Finlanders; so that it is impossible to say whether they are the invention of the Dutch or the Hottentots themselves. They are made of undressed leather, with the hairy side outward; without any other preparation than that of being beat and moistened. If it be a thick and stout hide, as that of a buffalo, it is kept for some hours in cow-dung, which renders it besides very soft and pliable. Some kind of grease is afterwards used for the same purpose. The shoes are then made in the following manner. They take a piece of leather, of a rectangular form, something longer and broader than the foot of the person for whom the shoes are intended; the two foremost corners are doubled up together, and sewed down, so as to cover the fore-part of the foot; but this seam may be avoided, and the shoes made much neater at the toes, by fitting immediately over them a cap taken from the membrane in the knee joint of the hind-leg of some animal. In order to make this piece of skin or leather rise up to the height of an inch on both sides of the foot, and close it in neatly, it is pierced with holes at small distances all round the edge, as far as the hind-quarters; and through these holes is passed a thong, by which the rim is drawn up into gathers. In order to make strong hind-quarters, the back part of the piece of leather is doubled inwards, and then raised up and pressed along the heel. The ends of the thong or gathering string are then threaded on both sides through the upper edge of the hind-quarters, to the height of about two inches; they are then carried forwards, in order to be drawn through two of the above-mentioned holes on the inside of each rim. Lastly, they are tied over the instep, or, if it be thought necessary to tie the shoe still faster, they are carried cross-ways over the instep, and so downwards under the thong, which comes out from the hind-quarters; then upwards again over the ankle, and even round the leg itself if the wearer chooses. Shoes of this kind are not without their advantages; they fit as neat upon the foot as a stocking, and at the same time preserve their form. They are easily kept soft and pliable by constantly wearing them; or, if at any time they should become somewhat hard, this is easily remedied by beating and greasing them. They are extremely light and cool, by reason that they do not cover so much of the foot as a common shoe. They wear very well, as they are without any seam, and the soles of the shoes are both tough and yielding. These field shoes, as they are called, being made of almost raw leather, are much more durable than those of tanned leather, which are burnt up by the African sands, and slip and roll about in them; being also very ready to be torn in a rocky soil, which is not the case with the others.

The Doctor is of opinion, that these shoes would be particularly useful to sailors.

The huts of the Hottentots are built exactly alike; and we may readily give credit to our author when he tells us, that they are done in a style of architecture which does not a little contribute to keep envy from insinuating itself under their roofs. Some of these huts are circular, and others of an oblong shape, resembling a round beehive or vault; the ground-plot being from 18 to 24 feet in diameter. The highest are so low, that it is scarce ever possible for a middle-sized man to stand upright even in the centre of the arch; "but (says our author) neither the lowness thereof, nor that of the door, which is but just three feet high, can perhaps be considered as any inconvenience to an Hottentot, who finds no difficulty in stooping and crawling upon all fours, and is at any time more inclined to lie down than to stand. The fire-place is in the middle of each hut, by which means the walls are not so much exposed to danger from fire. From this situation of the fire-place also the Hottentots derive this additional advantage, that they can all sit or lie in a circle round it, enjoying equally the warmth of the fire. The door, low as it is, alone lets in daylight or lets out the smoke: and so much are these people accustomed to live in such smoky mansions, that their eyes are never affected by it in the least, nor even by the mephitic vapour of the fuel, which to Europeans would be certain death.

The frame of the arched roof is composed of slender rods or sprays of trees. These being previously bent into a proper form, are laid, either whole or pieced, some parallel to one another, others crosswise; after which they are strengthened by binding others round them in a circular form with withies. All these are taken principally from the *cliffortia conoides*, which grows plentifully in this country near the rivers. Large mats are then placed very neatly over this lattice work, so as perfectly to cover the whole. The aperture which is left for the door is closed occasionally by a skin or piece of matting. These mats are made of a kind of cane or reed in the following manner: The reeds being laid parallel to one another, are fastened together with sinews or catgut, or some kind of catgut which they have had an opportunity of getting from the Europeans; so that they have it in their power to make them as long as they please, and as broad as the length of the reeds, which is from six to ten feet. The colonists make use of the same kind of matting, next to the tilts of their waggons, to prevent the sail-cloth from being rubbed and worn, and likewise to help to keep out the rain.

In a *craal*, or Hottentot-village, the huts are most commonly disposed in a circle, with the doors inwards; by which means a kind of court-yard is formed, where the cattle are kept at nights. The milk, as soon as taken from the cow, is put to other milk which is curdled, and kept in a leather sack with the hairy side inwards, as being the more cleanly; so that thus the milk is never drunk sweet. In some northern districts, where the land is dry and parched, both Hottentots and colonists are shepherds. When an Hottentot has a mind to shift his dwelling, he lays all the mats, skins, and rods, of which it is composed, on the backs of his cattle, which, to a stranger, makes a monstrous, unwieldy, and even ridiculous appearance.

There is a species of Hottentots named *Boskiesmen*, who dwell in the woody and mountainous parts, and subsist entirely by plunder. They use poisoned arrows, which they shoot from bows about a yard long and an inch in thickness in the middle, very much pointed at both ends. Dr. Sparrman does not know the wood of which they are made, but thinks that it is not very elastic. The strings were made, some of sinews, and others of a kind of hemp, or the inner bark of some vegetable; but most of them in a very slovenly manner. The ar-

rows are about a foot and an half long, headed with bone, and a triangular bit of iron; having also a piece of quill bound on very strongly with sinews, about an inch and an half from the top, in order to prevent it from being easily drawn out of the flesh. The whole is lastly covered over with a very deadly poison of the consistence of an extract. Their quivers are two feet long and four inches in diameter; and are supposed by our author to be made of the branch of a tree hollowed out, or more probably of the bark of one of the branches taken off whole, the bottom and cover being made of leather. It is daubed on the outside with an unctuous substance which grows hard when dry, and is lined about the aperture with the skin of the yellow serpent, supposed to be the most deadly in all that part of the world. The poison they make use of is taken from the most venomous serpents; and, ignorant as the Hottentots are, they all know that the poison of serpents may be swallowed with safety. See the article BOSKIESMEN.

In the year 1779, Lieutenant William Paterfon, who took a long and dangerous excursion from the Cape along the western side of the continent, discovered a new tribe of Hottentots, whose living, he says, is in the highest degree wretched, and who are apparently the dirtiest of all the Hottentot tribes. Their dress is composed of the skins of seals and jackalls, the flesh of which animals they feed upon. If a grampus happen to be cast ashore, they remove their huts to the place, and feed upon the carcase as long as it lasts, though perhaps it may be half rotten by the heat of the weather. They besmear their skins with the oil; by which means they smell so exceedingly rank that their approach may be thus perceived before they come in sight. Their huts, however, are much superior to those of the southern Hottentots already described; being higher, thatched with grass, and furnished with stools made of the back-bones of the grampus. They dry their fish in the sun; as the lieutenant found several kinds of fish near their huts suspended from poles, probably for this purpose. He found also several aromatic plants which they had been drying.

With respect to the religion of the Hottentots, it does not appear that they have any. On being questioned on the subject of a Creator and Governor of the universe, they answer that they know nothing of the matter; nor do they seem willing to receive any instruction. All of them, however, have the most firm belief in the powers of magic; from whence it might be inferred that they believe in an evil being analogous to what we call *the devil*; but they pay no religious worship to him, though from this source they derive all the evil that happens, and among these evils they reckon cold, rain, and thunder. So monstrously ignorant are they, that many of the colonists assured Dr. Sparrman, that their Boskiesmen would abuse the thunder with many opprobrious epithets, and threaten to assault the flashes of lightning with old shoes or any thing that comes first to hand. Even the most intelligent among them could not be convinced by all the arguments our author could use, that rain was not always an evil, and that it would be an unhappy circumstance if it were never to rain. "A maxim (says he), from a race of men in other respects really endowed with some sense, and frequently with no small degree of penetration and cunning, ought, methinks, to be considered as an indelible religious or superstitious notion entertained by them from their infancy, rather than as an idea taken up on due deliberation and consequent conviction."

As the Hottentots have so strong a belief in the powers of magic, it is no wonder that they have abundance of witches and conjurers among them. These will readily undertake any thing, even to put a stop to thunder and rain, provided they be well paid for their pains; and if it happen to thunder or rain longer than the time they promised, they have always for an excuse, that a more powerful conjurer has put a stop to

their incantations. Many of the Hottentots believe that all disorders incident to the human body are cured by magic. The wizards are fond of encouraging this idea; but at the same time take care to employ both external and internal remedies. Among the former may be reckoned a cure performed upon Captain Cook in some of the South-Sea islands, viz. that of pinching, cuffing, and kneading the whole body of the patient. To this, however, the Hottentot physicians add that of pretending to suck out a bone from some part of the patient's body. After this it sometimes happens that the sick person is relieved, and sometimes not. In the latter case the operation is repeated; and, if he dies, his friends lament that he was bewitched beyond the power of any one to assist him. These conjurers appear to be possessed of considerable slight of hand. Our author was informed by a colonist, that when he was a child, and playing with a bone of an ox which he drew as a cart, it appeared to his great astonishment to be sucked out of a sick person's back by a wizard; and as far as he could remember, the patient recovered soon after. These pretensions of the wizards sometimes render them liable to persecutions; and there is an instance of a chief named *Paloo*, who ordered a general massacre among them, in hopes of cutting off the person who he believed had bewitched himself, and afflicted him with sore eyes.

The superstition of the Hottentots never operates in the way of making them afraid in the dark. They seem, however, to have some ideas of a future state, as they reproach their friends, when dead, with leaving them so soon; at the same time admonishing them from henceforth to demean themselves properly: by which they mean that their deceased friends should not come back again and haunt them, nor allow themselves to be made use of by wizards to bring any mischief on those that survive them.

There is a genus of insects (the *mantis*) which, it has been generally thought, the Hottentots worship; but our author is so far from being of this opinion, that he tells us they have more than once caught several of them for him, and assisted him in sticking pins through them as he did through other insects. "There is (says he), however, a diminutive species of this insect, which some think it would be a crime, as well as very dangerous, to do any harm to: but this we have no more reason to look upon as any kind of religious worship, than we have to consider in the same light a certain superstitious notion prevalent among many of the more simple people in our own country (Sweden), who imagine that three pins will be forgiven them, if they set a cock-chaffer on its feet that has happened to fall upon its back. The moon, according to Kolben, receives a kind of adoration from the Hottentots; but the fact is, that they merely take the opportunity of her beams, and at the same time of the coolness of the night, to amuse themselves with dancing; and consequently have no more thoughts of worshipping her than the Christian colonists who are seen at that time strolling in great numbers about the streets, and parading on the stone steps with which their houses are usually encircled." The conjurers themselves, according to our author, are generally freethinkers, who have neither religion nor superstition of any kind.

Lieutenant Paterfon has given the following account of the Caffres, a nation whom no European but himself has ever seen, and who inhabit the country to the north-east of the Cape as far down as 31 South latitude. The men are from five feet ten inches to six feet high, and well proportioned; and in general manifest great courage in attacking lions or other wild beasts. The nation, at the time he visited them, was divided into two parties, one to the northward, commanded by a chief named *Chatha Bea*, or *Tambusbie*, which latter appellation he had obtained from his mother, a woman of an Hottentot tribe

named *Tambukies*. This man was the son of a chief named *Pharao*, who died about three years before, and left two sons *Cha Cha Bea*, and another named *Dfrika*, who claimed the supreme authority on account of his mother being of the Caffre nation. This occasioned a contest between the two brothers, in the course of which *Cha Cha Bea* was driven out of his territories with a great number of his party; after which he took up his residence at a place named *Kbouta*, where he had an opportunity of entering into an alliance with the Boshtiefmen.—The Caffres are of a jet black colour, their eyes large, and their teeth as white as ivory. The clothing of both sexes is nearly the same; consisting entirely of the hides of oxen, which are made as pliant as cloth. The men wear tails of different animals tied round their thighs, pieces of brass in their hair, and large rings of ivory on their arms: they are likewise adorned with the hair of lions, feathers fastened on their heads, &c. They use the ceremony of circumcision, which is usually performed upon them when they are nine years of age. They are very fond of dogs, which they exchange for cattle, and will even give two bullocks in exchange for one dog which pleases them. They are expert in throwing lances, and in time of war use shields made of the hides of oxen. Throughout the day the men occupy themselves in hunting, fighting, or dancing; the women being employed in the cultivation of their gardens and corn. They seem not to be destitute of the knowledge of agriculture, as they cultivate several vegetables which do not naturally grow in their own country, viz. tobacco, water-melons, a small kind of kidney-beans, and hemp. The women also make their baskets and the mats on which they lie. The men are very fond of their cattle, and cut their horns in such a manner as to be able to turn them into any shape they please, and teach them to answer to a whistle. Mr. Paterfon is of opinion that the country they inhabit is greatly superior to any part of Africa.

Of the Dutch settlements and policy at the Cape, Mr. Forster gives the following account. "The income of the governor here is very considerable; for, besides a fixed appointment, and the use of houses, gardens, proper furniture, and every thing that belongs to his table, he receives about 10 dollars for every leagre of wine which the company buy of the farmer in order to be exported to Batavia. The company allows the sum of 40 dollars for each leagre, of which the farmer receives but 24: what remains is shared between the governor and second or deputy; the former taking two-thirds, which sometimes are said to amount to 4000 dollars per annum. The deputy-governor has the direction of the company's whole commerce here, and signs all orders to the different departments under him, as well as the governor to others. He and the fiscal have the rank of *upper koopman*. The fiscal is at the head of the police, and sees the penal laws put in execution: his income consists of fines, and of the duties laid on certain articles of commerce; but if he be strict in exacting them, he is universally detested. The sound policy of the Dutch has likewise found it necessary to place the fiscal as a check, to overawe the other officers of the company, that they may not counteract the interests of their masters, or infringe the laws of the mother-country. He is, to that end, commonly well versed in juridical affairs, and depends solely upon the mother-country. The major (at present Mr. Von Prehn, who received us with great politeness) has the rank of *koopman* or merchant: this circumstance surprises a stranger, who, in all other European states, is used to see military honours confer distinction and precedence; and appears still more singular to one who knows the contrast in this particular between Holland and Russia, where the idea of military rank is annexed to every place, even that of a professor at the university. The number of regular soldiers at this colony amounts to about 700; of which 400 form the garrison of the

fort, near the Cape town. The inhabitants capable of bearing arms form a militia of 4000 men; of whom a considerable part may be assembled in a few hours, by means of signals made from alarm-places in different parts of the country. We may from hence make some estimate of the number of white people in this colony, which is at present so extensive, that the distant settlements are above a month's journey from the Cape: but these remote parts lie sometimes more than a day's journey from each other, are surrounded by various nations of Hottentots, and too frequently feel the want of protection from their own government at that distance. The slaves in this colony are at least in the proportion of five or more to one white person. The principal inhabitants at the Cape have sometimes from 20 to 30 slaves, which are in general treated with great lenity, and sometimes become great favourites with their masters, who give them very good clothing, but oblige them to wear neither shoes nor stockings, reserving these articles to themselves. The slaves are chiefly brought from Madagascar, and a little vessel annually goes from the Cape thither on that trade; there are, however, besides them, a number of Malays and Bengalese, and some negroes. The colonists themselves are for the greatest part Germans, with some families of Dutch, and some of French Protestants. The character of the inhabitants of the town is mixed. They are industrious, but fond of good living, hospitable, and social; though accustomed to hire their apartments to strangers for the time they touch at this settlement, and used to be complimented with rich presents of stuffs, &c. by the officers of merchant ships. They have no great opportunities of acquiring knowledge, there being no public schools of note at the Cape; their young men are therefore commonly sent to Holland for improvement, and their female education is too much neglected. A kind of dislike to reading, and the want of public amusements, make their conversation uninteresting, and too frequently turn it upon scandal, which is commonly carried to a degree of inveteracy peculiar to little towns. The French, English, Portuguese, and Malay languages are very commonly spoken, and many of the ladies have acquired them. This circumstance, together with the accomplishments of singing, dancing, and playing a tune on the lute, frequently united in an agreeable person, make amends for the want of refined manners and delicacy of sentiment. There are, however, among the principal inhabitants, persons of both sexes, whose whole deportment, extensive reading, and well-cultivated understanding, would be admired and distinguished even in Europe. Their circumstances are in general easy, and very often affluent, on account of the cheap rate at which the necessaries of life are to be procured: but they seldom amass such prodigious riches here as at Batavia; and I was told the greatest private fortune at the Cape did not exceed 100,000 dollars, or about 22,500l. sterling.

"The farmers in the country are very plain hospitable people; but those who dwell in the remotest settlements seldom come to town, and are said to be very ignorant: this may easily be conceived, because they have no better company than Hottentots, their dwellings being often several days journey asunder, which must in a great measure preclude all intercourse. The vine is cultivated in plantations within the compass of a few days journey from the town; which were established by the first colonists, and of which the ground was given in perpetual property to them and their heirs. The company at present never part with the property of the ground, but let the surface to the farmer for an annual rent, which, though extremely moderate, being only 25 dollars for 60 acres, yet does not give sufficient encouragement to plant vineyards. The distant settlements, therefore, chiefly raise corn and rear cattle; nay, many of the settlers entirely follow the latter branch of rustic employment, and some have very numerous flocks. We were told there were

two farmers who had each 15,000 sheep, and oxen in proportion; and several who possessed 6000 or 8000 sheep, of which they drive great droves to town every year: but lions and buffaloes, and the fatigue of the journey, destroy numbers of their cattle before they can bring them so far. They commonly take their families with them in large waggon covered with linen or leather, spread over hoops, and drawn by 8, 10, and sometimes 12 pair of oxen. They bring butter, mutton-tallow, the flesh and skins of sea-cows (hippopotamus), together with lion and rhinoceros' skins to sell. They have several slaves, and commonly engage in their service several Hottentots of the poorer sort, and (as we were told) of the tribe called *Boshiesman*, *Boschmans*, or *Bushmen*, who have no cattle of their own, but commonly subsist by hunting, or by committing depredations on their neighbours. The opulent farmers set up a young beginner by intrusting to his care a flock of 400 or 500 sheep, which he leads to a distant spot, where he finds plenty of good grass and water; the one-half of all the lambs which are yearned fall to his share, by which means he soon becomes as rich as his benefactor.

"Though the Dutch company seem evidently to discourage all new settlers, by granting no lands in private property; yet the products of the country have of late years sufficed not only to supply the isles of France and Bourbon with corn, but likewise to furnish the mother-country with several ship-loads. These exports would certainly be made at an easier rate than at present, if the settlements did not extend so far into the country, from whence the products must be brought to the Table-bay by land-carriage, on roads which are almost impassable. The intermediate spaces of uncultivated land between the different settlements are very extensive, and contain many spots fit for agriculture; but one of the chief reasons why the colonists are so much divided and scattered throughout the country, is to be met with in another regulation of the company, which forbids every new settler to establish himself within a mile of another. It is evident, that if this settlement were in the hands of the commonwealth, it would have attained to a great population, and a degree of opulence and splendor of which it has not the least hopes at present: but a private company of East-India merchants find their account much better in keeping all the landed property to themselves, and tying down the colonist, lest he should become too great and powerful.

"The wines made at the Cape are of the greatest variety possible. The best, which is made at M. Vander Spy's plantation of Constantia, is spoken of in Europe, more by report than from real knowledge; 30 leagues (or pipes) at the utmost are annually raised of this kind, and each league sells for about 50l. on the spot. The vines from which it is made were originally brought from Shiraz in Persia. Several other sorts grow in the neighbourhood of that plantation, which produce a sweet rich wine, that generally passes for genuine Constantia in Europe. French plants of burgundy, muscade, and frontignan, have likewise been tried, and have succeeded extremely well, sometimes producing wines superior to those of the original soil. An excellent dry wine, which has a slight agreeable tartness, is commonly drunk in the principal families, and is made of Madeira vines transplanted to the Cape. Several low sorts, not entirely disagreeable, are raised in great plenty, and sold at a very cheap rate; so that the sailors of the East-India ships commonly indulge themselves very plentifully in them whenever they come ashore.

"The products of the country supply with provisions the ships of all nations which touch at the Cape. Corn, flour, biscuit, salted beef, brandy, and wine, are to be had in abundance, and at moderate prices; and their fresh greens, fine fruits, good mutton and beef, are excellent restoratives to seamen who have made a long voyage."

HOTTINGER (JOHN HENRY), born at Zurich in Switzerland in 1620, professed the Oriental languages at Leyden, and was esteemed by all his learned colleagues. He was drowned, with part of his family, in the river Leinit, in the year 1667. He wrote a prodigious number of works; the principal of which are, 1. *Exercitationes Anti-Morinianæ de Pentateucho Samaritano*, 4to; in which he defends the Hebrew text against father Morin. 2. *Histeria Orientalis*, 4to. 3. *Bibliothecarius quadripartitus*. 4. *Thesaurus Philologicus Sacræ Scripturæ*, 4to. 5. *Histeria Ecclesiastica*. 6. *Promptuarium, sive Bibliotheca Orientalis*, 4to. 7. *Dissertationes miscellaneæ*, &c.

HOTTONIA, WATER-VIOLET; a genus of the monogynia order, belonging to the pentandria class of plants; and in the natural method ranking under the 21st order, *Preciæ*. The corolla is salver-shaped; the stamina are placed in the tube of the corolla; and the capsule is unilocular. There is but one species, viz. the palustris, with a naked stalk. It grows naturally in the standing waters in many parts of England. The leaves, which are for the most part immersed in water, are finely winged and flat like most of the sea-plants; and at the bottom have long fibrous roots, which strike into the mud: the flower-stalks rise five or six inches above the water, and toward the top have two or three whorls of purple flowers, terminated by a small cluster of the same. These flowers have the appearance of those of the stock gilliflower, so make a pretty appearance on the surface of the water. It may be propagated in deep standing waters, by procuring its seeds when they are ripe, from the places of their natural growth; which should be immediately dropped into the water in those places where they are designed to grow, and the spring following they will appear; and if they are not disturbed, they will soon propagate themselves in great plenty. Cows eat this plant; swine refuse it.

HOUBRAKEN (JACOB), a celebrated engraver, whose great excellence consisted in the portrait line. His works are distinguished by an admirable softness and delicacy of execution, joined with good drawing, and a fine taste. If his best performances have ever been surpassed, it is in the masterly determination of the features, which we find in the works of Nanteuil, Edelinck, and Drevet: this gives an animation to the countenance, more easily to be felt than described. His works are pretty numerous; and most of them being for English publications, they are sufficiently known in this country. In particular the greater and best part of the collection of portraits of Illustrious men, published in London by I. and P. Knapton, were by his hand.

HOVEDON (ROGER DE), born of an illustrious family in Yorkshire, most probably at the town of that name, now called *Hoveden*, some time in the reign of Henry I. After he had received the first parts of education in his native country, he studied the civil and canon law, which were then become most fashionable and lucrative branches of learning. He became domestic chaplain to Henry II. who employed him to transact several ecclesiastical affairs; in which he acquitted himself with honour. But his most meritorious work was his *Annals of England*, from A. D. 731, when Bede's Ecclesiastical History ends, to A. D. 1202. This work, which is one of the most voluminous of our ancient histories, is more valuable for the sincerity with which it is written, and the great variety of facts which it contains, than for the beauty of its style, or the regularity of its arrangement.

HOUGH, HAM, in the manege, the joint of the hind-leg of a beast, which connects the thigh to the leg. See HAM.

To **HOUGH**, or *cut the Houghs*, is to ham-string, or to disable an animal by cutting the sinews of the ham.

HOULIÈRES (ANTOINETTE DE), a French lady, whose poetry is highly esteemed in France. Her works and those of her daughter have been collected and printed together in two

volumes. Most of the Idyls, particularly those on sheep and birds, surpass every thing of the kind in the French language: the thoughts and expressions are noble; and the style pure, flowing, and chaste. Mademoiselle des Houlières carried the poetic prize in the French academy against Fontenelle. Both of these ladies were members of the academy of Ricovatri; the mother was also a member of the academy of Arles. Those who desire to be more particularly acquainted with the history of Madam des Houlières, may consult her Life prefixed to her works in the Paris edition of 1747, 2 vols. 12mo.

HOULSWORTHY, a large town of Devonshire, seated between two branches of the river Tamer, having a good market for corn and provisions. W. long. 4. 42. N. lat. 50. 50.

HOUND. See the articles CANIS, BLOOD-HOUND, and GRE-HOUND.

Training of HOUNDS. Before we speak of the methods proper to be used for this purpose, it will be necessary to point out the qualities which sportsmen desire to meet with in these animals. It is generally understood, that hounds of the middle size are the most proper, it being remarked, that all animals of that description are stronger than either such as are very small or very large. The shape of the hound ought to be particularly attended to; for if he be not well proportioned, he can neither run fast nor do much work. His legs ought to be straight, his feet round, and not very large; his shoulders back; his breast rather wide than narrow; his chest deep, his back broad, his head small, his neck thin; his tail thick and bushy, and if he carry it well so much the better. None of those young hounds which are *out at the elbow*, or such as are weak from the knee to the foot, should ever be taken into the pack. That the pack may look well, it is proper that the hounds should be as much as possible of a size: and if the animals be handsome at the same time, the pack will then be perfect. It must not, however, be thought, that this contributes any thing to the *goodness* of a pack; for very unhandy packs, consisting of hounds entirely different in size and colour, have been known to afford very good sport. It is only necessary that they should run well together; to which indeed an uniformity in size and shape would seem to contribute in some degree. The pack that can run ten miles, or any other considerable space, in the shortest time, may be said to go fastest, though the hounds taken separately might be considerably inferior to others in swiftness. A pack of hounds, considered in a collective body, go fast in proportion to the excellence of their noses and the head they carry. Packs which are composed of hounds of various kinds seldom run well. When the packs are very large, the hounds are seldom sufficiently hunted to be good; twenty or thirty couple, therefore, or at most forty, will be abundantly sufficient for the keenest sportsman in this country, as thus he may be enabled to hunt three or even four times a-week. The number of hounds to be kept, must, however, in a considerable degree, depend on the strength of the pack and the country in which you hunt. They should be left at home as seldom as possible; and too many old hounds should not be kept. None ought to be kept above five or six seasons, though this also is somewhat uncertain, as we have no rule for judging how long a hound will last.

In breeding of hounds, considerable attention ought to be paid to the dog from whom you breed. All such are to be rejected as have a tender nose, as are *babblers* or *skirters*. An old dog should never be put to an old bitch; nor should any attempts be made to cross the breed unless in a proper and judicious manner. Mr. Beckford, in his Essay on Hunting, informs us, that he has seen fox-hounds bred out of a Newfoundland dog and fox-hound bitch; the whelps were monstrously ugly, and had other bad qualities besides. The cross most likely to be of service to a fox-hound is the beagle. The reason of crossing the breeds sometimes is, that the imperfections of one

may sometimes be remedied by another. The months of January, February, and March, are the best for breeding; late puppies seldom thrive. After the females begin to grow big with young, it will not be proper to let them hunt any more, or indeed to remain for a much longer time in the kennel. Sometimes these animals will have an extraordinary number of whelps. Mr. Beckford informs us, that he has known a bitch have 15 puppies at a litter; and he assures us, that a friend of his informed him, that a hound in his pack brought forth 16, all of them alive. In these cases it is proper to put some of the puppies to another bitch, if you want to keep them all; but if any are destroyed, the best coloured ought to be kept. The bitches should not only have plenty of flesh, but milk also; and the puppies should not be taken from them till they are able to take care of themselves: their mothers will be relieved when they learn to lap milk, which they will do in a short time. After the puppies are taken away from their mothers, the litter should have three purging balls given them, one every other morning, and plenty of whey the intermediate day. If a bitch bring only one or two puppies, and you have another that will take them, by putting the puppies to her the former will soon be fit to hunt again. She should, however, be first physicked, and it will also be of service to anoint her dugs with brandy and water.

Whelps are very liable to the distemper to which dogs in general are subject, and which frequently makes great havoc among them at their walks; and this is supposed by Mr. Beckford to be owing to the little care that is taken of them. "If the distemper (says he) once get among them, they must all have it: yet notwithstanding that, as they will be constantly well fed, and will lie warm (in a kennel built on purpose), I am confident it would be the saving of many lives. If you should adopt this method, you must remember to use them early to go in couples: and when they become of a proper age, they must be walked out often; for, should they remain confined, they would neither have the health, shape, or understanding, which they ought to have. When I kept harriers, I bred up some of the puppies at a distant kennel; but having no servants there to exercise them properly, I found them much inferior to such of their brethren as had the luck to survive the many difficulties and dangers they had undergone at their walks; these were afterwards equal to any thing, and afraid of nothing; whilst those that had been nursed with so much care, were weakly, timid, and had every disadvantage attending private education. I have often heard as an excuse for hounds not hunting a cold scent, that they were too *high-bred*. I confess I know not what that means: but this I know, that hounds are frequently too *ill-bred* to be of any service. It is judgment in the breeder, and patience afterwards in the huntsman, that makes them hunt.

"When young hounds are first taken in, they should be kept separate from the pack; and as it will happen at a time of the year when there is little or no hunting, you may easily give them up one of the kennels and grafs court adjoining. Their play frequently ends in a battle; it therefore is less dangerous where all are equally matched. If you find that they take a dislike to any particular hound, the safest way will be to remove him, or it is probable they will kill him at last. When a feeder hears the hounds quarrel in the kennel, he halloos to them to stop them; he then goes in among them, and flogs every hound he can come near. How much more reasonable, as well as efficacious, would it be, were he to see which were the combatants before he speaks to them! Punishment would then fall, as it ought, on the guilty only. In all packs there are some hounds more quarrelsome than the rest: and it is to them we owe all the mischief that is done. If you find chaf-

tisement cannot quiet them, it may be prudent to break their holders; for, since they are not necessary to them for the meat they have to eat, they are not likely to serve them in any good purpose. Young hounds should be fed twice a day, as they seldom take kindly to the kennel meat at first, and the distemper is most apt to seize them at this time. It is better not to round them till they are thoroughly settled; nor should it be put off till the hot weather, for then they would bleed too much. It may be better, perhaps, to round them at their quarters, when about six months old; should it be done sooner, it would make their ears tuck up. The tailing of them is usually done before they are put out; it might be better, perhaps, to leave it till they are taken in. Dogs must not be rounded at the time they have the distemper upon them, as the loss of blood would weaken them too much.

"If any of the dogs be thin over the back, or any more quarrelsome than the rest, it will be of use to cut them: I also spay such bitches as I shall not want to breed from; they are more useful, are stouter, and are always in better order; besides, it is absolutely necessary if you hunt late in the spring, or your pack will be very short for want of it. The latter operation, however, does not always succeed; it will be necessary therefore to employ a skilful person, one on whom you can depend; for if it be ill done, though they cannot have puppies, they will go to heat notwithstanding. They should be kept low for several days before the operation is performed, and must be fed on thin meat for some time after."

It is impossible to determine how many young hounds ought to be bred in order to keep up the pack, as this depends altogether on contingencies. The deficiencies of one year must be supplied by the next; but it is probable, that from 30 to 35 couple of old hounds, and from eight to twelve couple of young ones, will answer the purpose where no more than 40 couple are to be kept. A considerable number, however, ought always to be bred; for it is undoubtedly and evidently true, that those who breed the greatest number of hounds must expect the best pack.

After the hounds have been rounded, become acquainted with the huntsman, and answer to their names, they ought to be coupled together, and walked out among sheep. Such as are particularly ill-natured ought to have their couples loose about their necks in the kennel till they become reconciled to them. The most stubborn ought to be coupled to old hounds rather than to young ones; and two dogs should not be coupled together when you can avoid it. As young hounds are awkward at first, a few ought only to be set out at a time with people on foot, and they will soon afterwards follow a horse. When they have been walked out often in this manner amongst the sheep, they should be uncoupled by a few at a time, and those chastised who offer to run after the sheep; but it will be difficult to reclaim them after they have once been allowed to taste blood. Some are accustomed to couple the dogs with a ram in order to break them from sheep; but this is very dangerous for both parties. Mr. Beckford relates a story of a nobleman who put a large ram into his kennel in order to break his hounds from sheep: but when he came some time after to see how nobly the ram defended himself, he found him entirely eaten up, and the hounds gone to sleep after having filled their bellies.

When hounds are to be aired, it is best to take them out separately, the old ones one day, and the young another; though, if they are to have whey from a distant dairy, both old and young may be taken out together, observing only to take the young hounds in couples, when the old ones are along with them. Young hounds are always apt to fall into mischief, and even old ones when idle will be apt to join them. Mr. Beck-

ford mentions a whole pack running after a flock of sheep through the mere accident of a horse's falling, and then running away.

With regard to the first entering of hounds to a scent, our author gives such directions as have subjected him to a severe charge of inhumanity. We shall give them in his own words. "You had better enter them at their own game; it will save you much trouble afterwards. Many dogs, I believe, like that scent best which they were first blooded to: but be this as it may, it is most certainly reasonable to use them to that which it is intended they should hunt. It may not be amiss first when they begin to hunt to put light collars on them. Young hounds may easily get out of their knowledge; and shy ones, after they have been much beaten, may not choose to return home. Collars, in that case, may prevent their being lost.—You say you like to see your young hounds run a trail-scent.—I have no doubt that you would be glad to see them run over an open down, where you could so easily observe their action and their speed. I cannot think the doing of it once or twice could hurt your hounds; and yet as a sportsman I dare not recommend it to you. All that I can say is, that it would be less bad than entering them at hare. A cat is as good a trail as any; but on no account should any trail be used after your hounds are stooped to a scent. I know an old sportsman who enters his young hounds first at a cat, which he drags along the ground for a mile or two, at the end of which he turns out a badger, first taking care to break his teeth: he takes out about a couple of old hounds along with the young ones to hold them on. He never enters his young hounds but at vermin; for he says, "Train up a child in the way he should go, and when he is old he will not depart from it!"

Hounds ought to be entered as soon as possible, though the time must be uncertain, as it depends on the nature of the country in which they are. In corn countries hunting may not be practicable till the corn is cut down; but you may begin sooner in grass countries, and at any time in woodlands. "If (says Mr. Beckford) you have plenty of foxes, and *can afford to make a sacrifice of some of them* for the sake of making your young hounds steady, take them first where you have least riot, putting some of the steadiest of your old hounds among them. If in such a place you are fortunate enough to find a litter of foxes, you may assure yourself you will have but little trouble with your young hounds afterwards.—If, owing to a scarcity of foxes, you should stoop your hounds at hare, let them by no means have the blood of her; nor, for the sake of consistency, give them much encouragement. Hare-hunting has one advantage: the hounds are chiefly in open ground, where you can easily command them; but notwithstanding that, if foxes be in tolerable plenty, keep them to their own game.—Frequent hallooing is of use with young hounds; it keeps them forward, prevents their being lost, and hinders them from hunting after the rest. The oftener therefore that a fox is seen and hallooed, the better. I by no means, however, approve of much hallooing to old hounds; though it is true that there is a time when hallooing is of use, a time when it does hurt, and a time when it is perfectly indifferent: but long practice and great attention to hunting can only teach the application.

"Hounds at their first entrance cannot be encouraged too much. When they are become handy, love a scent, and begin to know what is right, it will then be soon enough to chastise them for what is wrong; in which case one severe beating will save a great deal of trouble. When a hound is flogged, the whipper-in should make use of his voice as well as his whip. If any be very unsteady, it will not be amiss to send them out by themselves when the men go out to exercise their horses. If you have hares in plenty, let some be found sitting, and turned

out before them; and you will find that the most riotous will not run after them. If you intend them to be steady from deer, they should often see deer, and then they will not regard them; and if after a probation of this kind you turn out a cub before them, with some old hounds to lead them on, you may assure yourself they will not be unsteady long."

It is proper to put the young hounds into the pack when they stoop to a scent, become handy, know a rate, and stop easily. A few only are to be put to the pack at a time; and it is not advisable even to begin this till the pack have been out a few times by themselves, and "are gotten well in blood." They should be low in flesh when you begin to hunt; the ground being generally hard at that time, so that they are liable to be shaken.—By hounds being *bandy*, our author means their being ready to do whatever is required of them; and particularly, when cast, to turn easily which way the huntsman pleases.

Mr. Beckford begins to hunt with his young hounds in August. The huntsman in the preceding months keeps his old hounds healthy by giving them proper exercise, and gets his young hounds forward; and for this purpose nothing answers so well as taking them frequently out. The huntsman should go along with them, get frequently off his horse, and encourage them to come to him:—too much restraint will frequently incline the hounds to be riotous. Our author frequently walks out his hounds among sheep, hares and deer. Sometimes he turns down a cat before them, which they kill; and when the time of hunting approaches, he turns out young foxes or badgers; taking out some of the most steady of his old hounds to lead on the young ones. Small covers and furze-brakes are drawn with them to use them to a halloo, and to teach them obedience. If they find improper game and hunt it, they are stopped and brought back; and as long as they will stop at a rate, they are not chastised. At such times as they are taken out to air, the huntsman leads them into the country in which they are designed to hunt; by which means they acquire a knowledge of the country, and cannot miss their way home at any time afterwards. When they begin to hunt, they are first brought into a large cover of his own, which has many ridings cut in it; and where young foxes are turned out every year on purpose for them. After they have been hunted for some days in this manner, they are sent to more distant covers, and more old hounds added to them. There they continue to hunt till they are taken into the pack, which is seldom later than the beginning of September; for by that time they will have learned what is required of them, and seldom give much trouble afterwards. In September he begins to hunt in earnest; and after the old hounds have killed a few foxes, the young ones are put into the pack, two or three couple at a time, till all have hunted. They are then divided; and as he seldom has occasion to take in more than nine or ten couple, one half are taken out one day, and the other the next, till they are steady.

To render fox-hunting complete, no young hounds should be taken into the pack the first season;—a requisite too expensive for most sportsmen. The pack should consist of about 40 couple of hounds, that have hunted one, two, three, four, or five seasons. The young pack should consist of about 20 couple of young hounds, and an equal number of old ones. They should have a separate establishment, and the two kennels should not be too near one another. When the season is over, the best of the young hounds should be taken into the pack, and the draught of old ones exchanged for them. Many must be bred to enable a sportsman to take in 20 couple of young hounds every season. It will always be easy to keep up the number of old hounds; for when your own draft is not sufficient, drafts from other packs may be obtained, and at a small expence.

When young hounds are hunted together for the first season, and have not a sufficient number of old ones along with them, it does more harm than good.

Kennel for HOUNDS. SEE KENNEL.

HOUNSLOW, a town of Middlesex, with a market on Thursday. It belongs to two parishes; the N. side of the street to Heston, and the S. side to Isleworth. It is situated on the edge of the heath of the same name, on which are some powder-mills, on a branch of the river Coln. On this heath James II. formed an encampment, after the suppression of the duke of Monmouth's rebellion, in order the more effectually to enslave his subjects; and here he first perceived the little dependence he could place on his army, by their rejoicings on receiving the news of the acquittal of the seven bishops. Hounslow is 10 miles W. by S. of London.

HOU-QUANG, a province of China, occupying nearly the centre of the empire: the river Yang-tsekiang traverses it from west to east; and divides it into two parts, the northern and southern. This province (the greater part of which is level, and watered by lakes, canals, and rivers) is celebrated for its fertility; the Chinese call it the store-house of the empire; and it is a common saying among them, that "the abundance of Kiang-si could furnish all China with a breakfast; but the province of Hou-quang alone could supply enough to maintain all its inhabitants." Some princes of the race of Hong-vou formerly resided in this province; but that family was entirely destroyed by the Tartars when they conquered China. The people here boast much of their cotton cloths, simples, gold-mines, wax, and paper made of the bamboo-reed. The northern part of the province contains eight *fou*, or cities of the first class, and sixty of the second and third. The southern comprehends seven of the first class, and fifty-four of the second and third, exclusive of forts, towns, and villages, which are every where to be found.

HOUR, in chronology, an aliquot part of a natural day, usually a 24th, but sometimes a 12th. The origin of the word *bora*, or *ώρα*, comes, according to some authors, from a surname of the sun, the father of hours, whom the Egyptians call *Horus*. Others derive it from the Greek *ὀρίζειν*, to *terminate, distinguish*, &c. Others from the word *ουρον* *urine*; holding, that *Trifonegistus* was the first that settled the division of hours, which he did from observation of an animal consecrated to Serapis, named *cynocephalus*, which makes water 12 times a day, and as often in the night, at equal intervals. An hour, with us, is a measure or quantity of time, equal to a 24th part of the natural day, or *nycthemeron*; or the duration of the 24th part of the earth's diurnal rotation. Fifteen degrees of the equator answer to an hour; though not precisely, but near enough for common use. It is divided into 60 minutes; the minute into 60 seconds, &c. The division of the day into hours is very ancient: as is shown by Kircher, *Oedipt. Egypt.* tom. ii. parts ii. class. vii. c. 8.: though the passages he quotes from Scripture do not prove it. The most ancient hour is that of the 12th part of the day. Herodotus, lib. ii. observes, that the Greeks learned from the Egyptians, among other things, the method of dividing the day into twelve parts. The astronomers of Cathaya, &c. bishop Beveridge observes, still retain this division. They call the hour *chag*; and to each *chag* give a peculiar name, taken from some animal: The first is called *zetb*, "mouse;" the second, *chin*, "bullock;" the third, *zem*, "leopard;" the fourth, *mau*, "hare;" the fifth, *chin*, "crocodile, &c. The division of the day into 24 hours, was not known to the Romans before the first Punic war.—Till that time they only regulated their days by the rising and setting of the sun. They divided the 12 hours of their day into four, viz. *prime*, which commenced at six o'clock; *third*, at nine; *sixth*,

at twelve; and *none*, at three. They also divided the night into four watches, each containing three hours.

HOURS, HORÆ, in the ancient mythology, were certain goddesses, the daughters of Jupiter and Themis; at first only three in number, Eunomia, Dice, and Irene; to which were afterwards added two more, Carpo and Thallote. Homer makes them the door-keepers of heaven. Ovid allots them the employment of harnessing the sun's horses; "*Jungere equos Titan velocibus imperat Horis:*" and speaks of them as standing, at equal distances, about the throne of Sol; "*—et, positæ spatiis equalibus, Horæ.*" The poets represent them as dressed in fine coloured or embroidered robes, and gliding on with a quick and easy motion.

HOURS, Horæ, in the Romish church, are certain prayers performed at stated times of the day; as matins, vespers, lauds, &c. The lesser hours are, *prime, tierce, sixth, and none*. They are called *hours*, or *canonical hours*, as being to be rehearsed at certain hours prescribed by the canons of that church, in commemoration of the mysteries accomplished at those hours. These hours were anciently also called *course, cursus*; F. Mabillon has a dissertation on them, intitled, *De Cursu Gallicano*. The first constitution enjoining the observation of the canonical *hours*, is of the ninth century, being found in a capitular of Heito bishop of Basil directed to his curates, importing that the priests shall never be absent at the canonical hours either by day or night.

Hour-Glass, a popular kind of chronometer or clepsydra, serving to measure the flux of time by the descent or running of sand out of one glass vessel into another. The best hour-glasses are those which, instead of sand, have egg-shells well dried in the oven, then beaten fine and sifted. Hour-glasses are much used at sea for reckoning, &c.

HOURIS, in modern history, is a name given by the Mahometans to those females that are designed for the faithful in paradise. These are not the same with whom they have lived on earth, but formed for this purpose with singular beauty and undecaying charms.

HOUSE, a habitation, or place built with conveniences for dwelling in. See ARCHITECTURE. Houses, amongst the Jews, Greeks, and Romans, were flat on the top for them to walk upon, and had usually stairs on the outside, by which they might ascend and descend without coming into the house. Each house, in fact, was so laid out, that it inclosed a quadrangular area or court. This court was exposed to the weather, and being open to the sky, gave light to the house. This was the place where company was received, and for that purpose it was strewn with mats or carpets for their better accommodation. It was paved with marble or other materials, according to the owner's ability, and provided with an umbrella of vellum to shelter them from the heat and inclemencies of the weather. This part of their houses, called by the Romans *impluvium*, or *cava ædium*, was provided with channels to carry off the water into the common sewers. The top of the house was level, and covered with a strong plaster by way of terrace. Hither, especially amongst the Jews, it was customary to retire for meditation, private converse, devotion, or the enjoyment of the evening breezes.

The Grecian houses were usually divided into two parts, in which the men and women had distinct mansions assigned them. That assigned to the men was towards the gate, and called *Ανδρωνίτις*; the apartment of the women was the farthest part of the house, and called *Γυναικωνίτις*. Jews, Greeks, and Romans supposed their houses to be polluted by dead bodies, and to stand in need of purification.

A cheap, easy, and expeditious method of constructing houses fit for the recovery of the sick, has been described in the follow-

ing terms: The first thing to be done is to choose a dry and airy situation, on a gravelly or chalky soil if possible; upon this lay down the plan of your building, make one end of it face that quarter from whence the purest and healthiest winds may be expected to blow, of a breadth that can be conveniently roofed. Then, if boarding does not come so cheap, drive stakes, at about six feet distance from each other, into the ground, so as to stand about six feet above it; and, interlacing them with wattles, coat the wattles on the side next the weather with fresh straw; and make the roof in the same manner, but thicker, or of thatch in the usual way, with a hole at the very top of it, to open occasionally. Let the end of the building facing the wholesomest quarter lie open some feet back, so as to form a porch, where the convalescents may take the air without danger of any injury from the weather. A large chimney and kitchen grate may be erected at the other end. If the soil happens to be chalky or gravelly, you may hollow it four or five feet deep, within a foot or eighteen inches of the walls; but let the steps into this hollow lie far enough within the porch, that no water may get into it, and, if of chalk, that the steps may not grow slippery in wet weather. From time to time open the vent-hole at the roof; by means of which all the unwholesome infectious air, as being warmer, and consequently lighter, than that which is pure and wholesome, will be driven out by the rushing in of the fresh air: a purpose which the little openings, that may be left in the sides and roofs of such rude and hasty buildings, will, even of themselves, answer so well, as sufficiently to compensate any cold they may let in, even in the coldest months. Let the floor likewise be scraped three or four inches deep every five or six days, and what comes off removed to some distance. Halls of this kind, 50 feet long and 20 broad, cost but a trifle to build; yet, with these precautions (even without the addition of clean straw for every new patient to lie on, inclosed in clean washed sacks fit for the purpose, which come infinitely cheaper than the bare cleaning of flock or even feather beds, supposing it possible to wash such beds), proved of infinitely more advantage in the recovery of sick soldiers, than the low-roofed rooms of the farm-houses of the Isle of Wight, or even the better accommodations of Carisbrooke-cattle in the same island, in which there perished four times the number of sick that there did in these temporary receptacles; which were first thought of by doctor Brocklesby, in consequence of some terrible infectious complaints arising from confined animal effluvia.

Is it not surprising, that we have not availed ourselves more of the above discovery in natural history, being, perhaps, the most important the moderns can boast of, in the most useful science, viz. the superior lightness of unwholesome and infectious air! The upper sashes in most houses, even of those who pretend to some knowledge in these matters, are generally immovable, by means of which no part of the foul air above the level of the lowest rail of the other sash's greatest rise can escape by the window; and, if it escapes by the doors, it is generally for want of a vent in the highest part of the roof, merely to accumulate in the upper story of the house, and add to the infection, which the great quantities of old furniture usually stored up there are of themselves but too apt to create, when care is not frequently taken to open the windows of it. Thus, the chief benefit to be expected from lofty rooms is in a great measure lost. Whereas, were the upper sashes contrived to come down, all the air might be easily changed, and that almost insensibly, by letting them down an inch or two. Nay, the upper sash might be often let entirely down with less danger or inconvenience from cold, than the lower thrown up the tenth part of an inch, though the doing of the former would be attended with infinitely more advantage to the health of the inhabitants than the latter. It is perhaps on this principle

that we are to account for the good health enjoyed by the poor who live crowded in damp cellars, and often with great numbers of rabbits, poultry, and even swine about them. These cellars are open to the street, with doors reaching from the floor to the very ceiling, but never so close at bottom or at top as to prevent a free circulation of air; in consequence of which, that all-vivifying fluid, as fast as it is spoiled by passing through the lungs of the inhabitants and their stock, or is infected by their insensible perspiration, excrements, &c. is driven out and replaced by the fresh air.

A patent was granted in July 1796, to Mr. Henry Walker, of Thurmaston in Leicestershire, for a curious invention of a method by which houses and other buildings of any description or dimensions may be erected in one entire mass or body, equally durable, and at a much less expence, especially in the articles of timber, lime, and workmanship, than houses on the usual construction. This invention is described by Mr. Walker in the following way: "In the first place I take an argillaceous earth or natural clay, which I select, examine, and purify, by the usual well-known methods, and compound the same with sand, or broken or pounded pottery, or brick, or coal-ashes, or charcoal, or, in short, with any other of those substances which experience has shewn to be adapted to form a good, firm, and durable brick, when properly baked; and I vary my composition according to the nature of the component parts themselves, and the purposes which they are intended to answer; but, for common constructions, I use the same proportions as brickmakers in general do. I then proceed to mix, knead, and incorporate the said materials, until the same are brought to the requisite firmness and tenacity for building; which is nearly such that the parts of any lump or mass of the same may be readily incorporated with, or joined to, any other similar mass, by moderate blows with a wooden mallet, and the occasional addition of a very small portion of water: I call this composition the prepared material.

"Secondly, I construct floors, walls, and all other buildings, after my said new invention, in such a manner that I can apply the power of fire, from wood, coal, charcoal, coak, or other combustible matters, not only to the external surfaces of the said floors, walls, and other parts, but also to the interior parts of such floors, walls, and other parts, by means of fires maintained in certain cavities left within the same: I call these cavities by the name of furnaces.

"Thirdly, with regard to the particular forms, dimensions, and relative positions of the said floors, walls, and other parts of buildings, and the furnaces left or formed within the same, together with the apertures or communications, for the purposes of ventilating the fires therein, of suffering the volatile matters to escape, and of converting the whole into one entire mass of brick by a due communication and continuance of heat, I do here proceed to explain the general principles and practice relating thereto, by describing the particular operations of constructing and baking a portion of a straight perpendicular wall, as follows; that is to say, the ground must be rendered solid, and the foundation laid in the usual manner; after which, I lay thereon a quantity of my prepared material herein before described, and do beat, ram, or otherwise press down the same to the thickness of about six inches; and in width corresponding with the intended dimensions of the wall, regulated by boards, or framing, or other suitable application to the outer surfaces. I then plant upright, at the distance of about thirty inches asunder, in the said layer or bed of prepared material, a number of cylindrical pieces of wood, of about nine inches in diameter each, and eighteen or more inches in length, to serve as moulds for the cavities of the furnaces; and between each of the said moulds I place, in the longitudinal direction of the wall, and parallel

to the horizon, a number of pipes, of wood or other materials, or rods, or other proper masses, of combustible or incombustible matter, for the purpose of forming communications between all the several furnaces, or as many of them as I think proper. In the next place, I proceed to form another layer or bed of the material to the same height, namely, about six inches, and dispose a number of pipes of wood or other materials, or rods, or other proper masses, of combustible or incombustible matter, for the purpose of forming communications between the furnaces as before. In this manner I construct the whole, or so much of the wall as I apprehend at the time may be conveniently formed, in the raw or unburned state; taking care, as the work advances, to raise the wooden cylinders or moulds of the cavities or furnaces, in order that a sufficient portion thereof shall remain above the surface of the work, to admit of the reception and proper fashioning of each subsequent bed or layer. Or otherwise, I form the communications between the furnaces by perforating the wooden moulds, in various places, at right angles to their respective axes; and through the said perforations I pass a bar of iron, or other material, which serves to connect three or more of the said furnace-moulds together, and, being afterwards withdrawn as the work proceeds, doth leave a cavity or cavities of communication, similar to those formed in the methods herein before described, by pipes, or rods, or other masses. And moreover I do, with a carpenter's auger, or other fit boring-tools, open such a number of horizontal or oblique apertures or flues into all the furnaces, and also into all the communication pipes, or rods, or masses, or cavities, as aforesaid, as may be requisite for admitting a good communication on all sides with the open air. Or otherwise, in some instances, I form the said horizontal or oblique apertures or flues, by disposing a suitable number of taper rods in the work, along with the pipes, which rods I afterwards draw out.

"Fourthly, when the said wall, or so much thereof as may conveniently be constructed at one time in the raw material, is builded, I suffer the same to dry spontaneously. Or otherwise, I dry the same by moderate fires in the furnaces, which draw in the air by the lower apertures, and emit the heated air, vapour, flame, and other volatile matters, through the upper apertures; and afterwards, by stronger fires in the said furnaces, or by suitable applications of fire externally, or by both at the same time, I convert the whole into one entire mass of brick: and I must also observe, that, by occasional closing of the furnaces at top, or any of the other apertures, or by opening of the same or others of the said furnaces or apertures, in various parts, according to circumstances which the intelligent operator will readily apprehend, I do in such manner regulate the progress, communication, and effect of the heat, that the conversion into brick is regularly and uniformly made through the entire mass.

"Fifthly, I do farther state and declare, that the dimensions of the furnaces, the positions and relative distances of the pipes of communication and lateral apertures, and the thickness of the layers of the prepared material, are each and all susceptible of great variations, according to the nature of the said material, the activity of the fuel, the proposed solidity or figure of the work, and numerous other obvious circumstances; and that, accordingly, I do by no means confine myself to the dimensions here given by way of elucidation.

"Sixthly, I proceed to form the remaining or subsequent part or parts of such wall or other edifice, to be constructed as aforesaid, by applying additional portions of the prepared material in contact with that which hath been already baked; and, in this and every other part of my work, I place and dispose proper and suitable external and internal moulds, supports, frames, and other occasional contrivances, well known to builders, for sustaining works, or forming arches, or determining the figure

and positions of soft plastic substances. The explanation hereby given is sufficient to enable any builder, of moderate skill, to carry my said invention into full effect, as far as relates to walls, buttresses, arches, and other perpendicular or oblique parts of edifices; I therefore do proceed to describe the methods of forming floors and roofs, in the same strong, durable, and uniformly consistent material, forming one mass with the rest of the building, as follows; that is to say,

"Seventhly, I form the ground-floor of the prepared material, leaving hollow spaces between the supports beneath, for making fires to burn the same: these fires are ventilated by side apertures, and the flame and volatile products issue therefrom through numerous holes, previously made in the said floor, or otherwise. When the said floor is of considerable thickness I make furnaces therein, as before described with regard to walls constructed in this my new method, together with pipes of communication, and horizontal apertures and flues, as aforesaid.

"Eighthly, I form the first floor above the ground-floor, in such a manner, upon suitable temporary framing, that the upper surface shall be plane, and the lower surface thereof shall be concave; that is to say, either cylindrical, spherical, elliptical, or otherwise curved, with regard to the lower bounding-line of one or more of its vertical sections, that it may, when baked, support itself upon the principle of a low arch; and I do convert the said floor into brick, by means of fire in the apartments beneath, of which the flame and volatile products issue through numerous small apertures, designedly made in the said floor.

"Ninthly, I do construct and bake or burn the other floors above the first floor, and also the roof, in the same manner as the said first floor; and, in all and every case and cases of floors, roofs, platforms, staircases, and other horizontal or oblique parts of edifices, I do occasionally make use of, and dispose upon the surface, or within the mass of the prepared materials of which the same are made, such and so many bars of wood, or metal, or masses of stone, or baked earth, duly figured and disposed, as may be needful, either for preserving and sustaining the same in their proper figures respectively, until perfectly baked, or for giving stability and permanency to the same afterwards.

"Tenthly, and lastly, I do close the apertures, fill up the furnaces, amend the deficiencies or imperfections, adorn the walls, floors, ceilings, or other parts, internally and externally, by requisite applications of my prepared material, or otherwise, according to the taste and direction of the proprietor of such building or buildings as I may construct according to this my said new invention."

HOUSE is also used for one of the estates of the kingdom of Britain assembled in parliament. Thus we say, the house of lords, the house of commons, &c. See PEERS, COMMONS, &c.

HOUSE is also used for a noble family, or a race of illustrious persons issued from the same stock. In this sense we say, the house or family of the Stuarts, the Bourbons, the house of Hanover, of Austria, of Lorraine, of Savoy, &c.

HOUSE, in astrology, denotes the twelfth part of the heavens. The division of the heavens into houses, is founded upon the pretended influence of the stars, when meeting in them, on all sublunary bodies. These influences are supposed to be good or bad; and to each of these houses particular virtues are assigned, on which astrologers prepare and form a judgment of their horoscopes. The horizon and meridian are two circles of the celestial houses, which divide the heavens into four equal parts, each containing three houses; six of which are above the horizon and six below it; and six of these are called *eastern* and six *western houses*.

A scheme or figure of the heavens is composed of 12 triangles, all called *houses*, in which are marked the stars, signs,

and planets, so included in each of these circles. Every planet has likewise two particular houses, in which it is pretended that they exert their influence in the strongest manner; but the sun and moon have only one, the house of the former being Leo, and that of the latter Cancer.

The houses in astrology have also names given them according to their qualities. The first is the house of life: this is the ascendant, which extends five degrees above the horizon, and the rest below it. The second is the house of riches: the third, the house of brothers: the fourth, in the lowest part of the heavens, is the house of relations, and the angle of the earth: the fifth, the house of children: the sixth, the house of health: the seventh, the house of marriage, and the angle of the west: the eighth, the house of death: the ninth, the house of piety: the tenth, the house of offices: the eleventh, the house of friends: and the twelfth, the house of enemies.

Country-HOUSE is the *villa* of the ancient Romans (See *VILLA*), the *quinta* of the Spaniards and Portuguese, the *closerie* and *caffine* of the French, and the *vigna* of the Italians. 1. It ought always to have wood and water near it; these being the principal beauties of a rural seat. The trees make a far better defence than hills, as they yield a cooling and healthy air, shade during the heat of summer, and very much break the severities of the winter season. 2. It should not be situated too low, on account of the moisture of the air; and, on the other hand, those built on places exposed to the winds are expensive to keep in repair. In houses not above two stories high, and upon a good foundation, the length of two bricks, or 18 inches, for the heading course, will be sufficient for the ground-work of any common structure; and six or seven courses above the earth, to a water-table, where the thickness of the walls is abated or taken in, on either side the thickness of a brick, *viz.* two inches and a quarter. But for large and high houses of three, four, or five stories, with garrets, their walls ought to be three heading courses of bricks, or 28 inches at least, from the foundation to the first water-table; and at every story a water-table, or taking in, on the inside, for the summers, girders, and joists to rest upon, laid into the middle, or one quarter of the wall at least, for the better bond. But as for the partition-wall, a brick and half will be sufficiently thick; and for the upper stories, a brick length or nine inch brick will suffice.

Hot-HOUSE. See *STOVE* and *HYPOCAUSTUM*.

HOUSE-Breaking, or *Robbing*, is the breaking into and robbing a house in the day-time; the same crime being termed *BURGLARY* when done by night: both are felony without benefit of clergy.

HOUSEHOLD, the whole of a family considered collectively, including the mistress, children, and servants. But the household of a sovereign prince includes only the officers and domestics belonging to his palace. The principal officers of his majesty's household are, the lord steward, lord chamberlain of the household, the groom of the stole, the master of the great wardrobe, and the master of the horse.

The civil government of the king's house is under the care of the lord steward of the king's household; who being the chief officer, all his commands are observed and obeyed. His authority extends over all the other officers and servants, except those of his majesty's chapel, chamber, and stable, and he is the judge of all crimes committed either within the court or the verge. Under him are the treasurer of the household, the comptroller, cofferer, the master of the household, the clerks of the green cloth, and the officers and servants belonging to the accounting-house, the marshalsea, the verge, the king's kitchen, the household kitchen, the acatery, the bake-house, pantry, buttery, cellar, pastry, &c. Next to the lord steward is the lord chamberlain of the household, who has under him the vice-chamberlain, the treasurer,

and comptroller of the chamber; 48 gentlemen of the privy chamber, 12 of whom wait quarterly, and two of them lie every night in the privy-chamber; the gentleman-usher, the grooms of the great chamber, the pages of the presence-chamber; the mace-bearers, cup-bearers, carvers, musicians, &c. See *Lord Chamberlain of the Household*.

The groom of the stole has under him the eleven other lords of the bed-chamber, who wait weekly in the bed-chamber, and by turns lie there a-nights on a pallet-bed; and also the grooms of the bed-chamber, the pages of the bed-chamber and back-stairs, &c. See *Groom of the Stole*. The master or keeper of the great wardrobe has under him a deputy, comptroller, clerk of the robes, brusher, &c. and a number of tradesmen and artificers, who are all sworn servants to the king. The master of the horse has under his command the equerries, pages, footmen, grooms, coachmen, farriers, saddlers, and all the other officers and tradesmen employed in his majesty's stables.

Next to the civil list of the king's court, is the military, consisting of the band of gentlemen pensioners, the yeomen of the guard, and the troops of the household; of which the two first guard the king above stairs.

When the king dines in public, he is waited upon at table by his majesty's cup-bearers, carvers, and gentlemen sewers; the musicians playing all the time. The dinner is brought up by the yeomen of the guard, and the gentlemen sewers set the dishes in order. The carvers cut for the king, and the cup-bearers serve him the drink with one knee on the ground, after he has first tasted it in the cover.

HOUSE and Window Duty, a branch of the king's extraordinary revenue. See *REVENUE*. As early as the Conquest mention is made in Domesday book of fumage or fusage, vulgarly called *smoke-farthings*; which were paid by custom to the king for every chimney in the house. And we read that Edward the Black Prince (soon after his successes in France), in imitation of the English custom, imposed a tax of a florin upon every hearth in his French dominions. But the first parliamentary establishment of it in England was by statute 13 and 14 Car. II. c. 10. whereby an hereditary revenue of 2s. for every hearth, in all houses paying to church and poor, was granted to the king for ever. And, by subsequent statutes, for the more regular assessment of this tax, the constable and two other substantial inhabitants of the parish, to be appointed yearly (or the surveyor appointed by the crown, together with such constable or other public officer), were, once in every year, empowered to view the inside of every house in the parish. But, upon the Revolution, by stat. 1 W. and M. c. 10. hearth-money was declared to be "not only a great oppression to the poorer sort, but a badge of slavery upon the whole people, exposing every man's house to be entered into and searched at pleasure, by persons unknown to him; and therefore, to erect a lasting monument of their majesties' goodness, in every house in the kingdom the duty of hearth-money was taken away and abolished." This monument of goodness remains among us to this day: but the prospect of it was somewhat darkened, when in six years afterwards, by statute 7 W. III. c. 18. a tax was laid upon all houses (except cottages) of 2s. now advanced to a larger sum, and a tax also upon all windows, if they exceeded nine, in such house. These rates have been from time to time varied, being now extended to all windows exceeding six; and power is given to surveyors, appointed by the crown, to inspect the outside of houses, and also to pass through any house, two days in the year, into any court or yard, to inspect the windows there. The following convenient Table of the different rates of duty upon houses (exclusive of *windows*, which form a separate article of revenue) appears in *Kearseley's Tax-Tables*, which are published yearly in London.

Rent.	At per Pound.	Total per Yr.	Rent.	At per Pound.	Total per Yr.
l.	s. d.	l. s. d.	l.	s. d.	l. s. d.
5	0 6	0 2 6	23	0 9	0 17 3
6	—	0 3 0	24	—	0 18 0
7	—	0 3 6	25	—	0 18 9
8	—	0 4 0	26	—	0 19 6
9	—	0 4 6	27	—	1 0 3
10	—	0 5 0	28	—	1 1 0
11	—	0 5 6	29	—	1 1 9
12	—	0 6 0	30	—	1 2 6
13	—	0 6 6	31	—	1 3 3
14	—	0 7 0	32	—	1 4 0
15	—	0 7 6	33	—	1 4 9
16	—	0 8 0	34	—	1 5 0
17	—	0 8 6	35	—	1 6 3
18	—	0 9 0	36	—	1 7 0
19	—	0 9 6	37	—	1 7 9
20	0 9	0 15 0	38	—	1 8 6
21	—	0 15 9	39	—	1 9 3
22	—	0 16 6	40	1 0	2 0 0

And so on at the same rate of 1s. in the pound for a rent of any amount.

The clauses relative to the house-tax are, 1. That offices, yards, gardens, coach-houses, brew-houses, wood-houses, wash-houses, &c. provided they all stand within the compass of one acre, belonging to the dwelling-house, must be valued with the dwelling-house, and be liable to the same duties. 2. Shops and warehouses are also liable, if attached to the dwelling-houses, except those of wharfingers. 3. No warehouse that is a distinct building is liable. 4. No house to be deemed occupied where one person is only left in charge of it. 5. Where houses are let in tenements, the landlords must pay the duty. 6. Halls and offices that pay other taxes are liable to this. 7. Farm-houses used only for husbandry, under 10l. per annum, are not chargeable; nor are houses for the reception of poor, or if not occupied by the owner, or rented by a tenant. 19 Geo. 3. c. 15.

HOUSE-*Leck*, in botany. See SEDUM and SEMPERVIVUM.

HOUSING, or HOUSE-*Line*, in the sea-language, a small line, formed of three fine strands or twills of hemp, smaller than rope-yarn. It is chiefly used to seize blocks into their strops, to bind the corners of the sails, or to fallen the bottom of a sail to its bolt-rope, &c. See BOLT-*Rope*.

HOUSING, or *H-usee*, a cover laid over the saddle of a horse, in order to save it from the weather, dirt, &c. The word is formed of the French *houffe*, which signifies the same thing; though it anciently denoted a kind of hood worn by country people. The cavaliers appeared with their embroidered housings.

HOUSING, among bricklayers, a term used for a brick which is warped, or is cast crooked or hollow in burning; in such a case, they say, it is *housing*.

HOUSTONIA, in botany; a genus of the monogynia order, belonging to the tetrandria class of plants; and in the natural method ranking under the 47th order, *Stellata*. The corolla is monopetalous and funnel-shaped; the capsule bilocular, dispermous, superior.

HOU-TCHOU-FOU, a city of China, in the province of Tche-kiang. It is a city of the first class; and is situated on a lake, from which it takes its name. The quantity of silk manufactured here is almost incredible. To give some idea of it, we shall only say, that the tribute paid by a city under its jurisdiction, named *Ts-tsin bian*, amounts to more than 500,000

taels or ounces of silver. Its district contains seven cities, one of which is of the second, and six of the third, class.

HOWARD (HENRY), earl of Surry, a soldier and a poet, the son and grandson of two lord treasurers, dukes of Norfolk, was born probably about the year 1520, and educated in Windsor-castle, with young Fitzroy earl of Richmond, natural son to king Hen. VIII. Wood says, from tradition, that he was some time a student at Cardinal College, Oxford. In his youth he became enamoured of the Fair Geraldine, whom his sonnets have immortalized. He fell a victim, as our English history relates, to the jealousy of the Seymours, who being rivals of the Norfolk family, and in favour with king Hen. VIII. accused him of aspiring to the crown. Surry, and his father the duke of Norfolk, were committed to the Tower, in December 1546; and on the 13th of January following, the former was tried at Guildhall by a common jury, and beheaded on Tower-hill on the 19th, nine days before the death of the king himself; who thus, that the measure of his crimes might be full, finished his life with the murder of his best subject. The accusations brought against this amiable and innocent young nobleman on his trial, were so extremely ridiculous, that one is astonished how it was possible, even in the most despotic reign, to find a judge and jury so pusillanimously villainous as to carry on the farce of justice on the occasion. Lord Surry was first interred in the church of All-hallows, Barking, near Tower-hill; and afterwards, in the reign of king James I. his body was removed to Farningham in Suffolk, by his son Henry, earl of Northampton.

As to the character of this unfortunate earl, all our poets have sung his praise. Mr. Walpole begins his anecdotes of Surry with these words: "We now emerge from the twilight of learning to an almost classic author, that ornament of a boisterous, yet not unpolished court, the earl of Surry, celebrated by Drayton, Dryden, Fenton, Pope, illustrated by his own muse, and lamented for his unhappy death: a man (as Sir Walter Raleigh says) no less valiant than learned, and of excellent hopes." Leland calls him the conscript enrolled heir of Sir Thomas Wyatt, the elder, in his learning and other excellent qualities; and the author of *The Art of English Poetry* says, that the earl of Surry, and Sir Thomas Wyatt, may be justly called the reformers of our poetry and style. His poems were published in 1557, 12mo; and in 1565, 1574, 1585, 1587, 8vo. Several of the sonnets are by Sir Thomas Wyatt and others.

HOWARD (John), Esq. a man remarkable for philanthropy and humanity, was the son of a reputable tradesman in St. Paul's church-yard. He was born about the year 1725 or 1726; and at a proper age was put apprentice to Mr. Nathaniel Newnham, a wholesale grocer in Watling-street. His father died, leaving only this son and a daughter, to both of whom he bequeathed handsome fortunes; and by his will directed that his son should not be considered of age till he was five-and-twenty. His constitution was thought very weak, and his health appeared to have been injured by the necessary duties of his apprenticeship; and therefore, at the expiration of it, he took an apartment in a lodging-house in Church-street, Stoke Newington, Middlesex; but not meeting with the tenderest treatment there, he removed to another lodging house in the same street, which was kept by a widow lady, Mrs. Sarah Lardeau, a worthy sensible woman, but an invalid. Here he was nursed with so much care and attention, that he resolved to marry his landlady out of gratitude for her kindness. In vain she expostulated with him upon the extravagance of such a proceeding, he being about 28 and she about 51 years of age, and 20 years older in constitution: but nothing could alter his resolution, and they were privately married about the year 1752. She was possessed a small fortune, which he presented to her sister. During

his residence at Newington, the minister of the dissenting meeting-house there resigned his office, and a successor was elected; and Mr. Howard, who was bred a dissenter, and steadfastly adhered all his life to that profession, proposed to purchase the lease of a house near the meeting-house, and to appropriate it as a parsonage-house for the use of the minister for the time being, and contributed 50*l.* for that purpose. His wife died November 10, 1755, aged 54; and he was a sincere and affectionate mourner for her death. About this time, it is believed, he was elected F. R. S. In the year 1756 he had the fortune to experience some of the evils which it afterwards became the business of his life to redress. He embarked that year in a Lisbon packet, the Hanover, in order to make the tour of Portugal; when the vessel was taken by a French privateer. "Before we reached Brest (says he in his publication *On Prisons*, p. 11.) I suffered the extremity of thirst, not having for above 40 hours one drop of water, nor hardly a morsel of food. In the castle at Brest I lay six nights upon straw; and observing how cruelly my countrymen were used there and at Morlaix, whither I was carried next, during the two months' I was at Carhaix upon parole, I corresponded with the English prisoners at Brett, Morlaix, and Dinnan: at the last of those towns were several of our ship's crew, and my servant. I had sufficient evidence of their being treated with such barbarity, that many hundreds had perished, and that 36 were buried in a hole at Dinnan in one day. When I came to England, still on parole, I made known to the commissioners of sick and wounded seamen the sundry particulars, which gained their attention and thanks. Remonstrance was made to the French court: our sailors had redress; and those that were in the three prisons mentioned above, were brought home in the first cartel ships. Perhaps (adds Mr. Howard) what I suffered on this occasion increased my sympathy with the unhappy people whose case is the subject of this book."

He afterwards, it is said, made the tour of Italy; and at his return settled at Brokenhurst, a retired and pleasant villa in the New Forest, near Lymington in Hampshire, having, April 25, 1758, married a daughter of Edward Leeds, Esq. of Croxton, Cambridgeshire, king's serjeant. This lady died in 1765, in child-bed, of her only child, a son, who unfortunately became lunatic. After her death, Mr. Howard left Lymington, and purchased an estate at Cardington, near Bedford.

"While he lived here in retirement (says Mr. Palmer, in his funeral discourse), it was his meat and drink to make his neighbours happy. His neat but humble mansion was ever hospitable to a few select friends, but was never the scene of riot or luxurious banqueting. Though polite to all, he neither sought nor admitted the company of the profligate, however distinguished by rank or fortune. His charity had no bounds, except those of prudence; and was not more commendable for the extent of it, than for the manner in which it was exercised. He gave not his bounty to countenance vice and idleness, but to encourage virtue and industry. He was singularly useful in furnishing employment for the labouring poor of both sexes, at those seasons when a scarcity of work rendered their situation most compassionate. And at other times, though never inattentive to the tale of woe, he was not easily imposed upon by it, but made himself acquainted with the case. He had indeed a general acquaintance with the cases and characters of the poor around him, and made it his business to visit the abodes of affliction. In circumstances of bodily disorder he often acted the part of a physician as well as a friend. But his kindness was not confined to the bodies of his fellow-creatures, it extended to their spiritual and immortal part. He carefully watched over the morals of his neighbourhood, and used his advice, his admonitions, and influence, to discountenance immorality of all kinds, and to promote the knowledge

and practice of religion. As a most effectual means to this great end, he provided for the instruction of poor children, by erecting and supporting schools, which he carefully superintended. In short, he was a universal blessing to the village where he resided, in every part of which are to be seen the pleasing monuments of his munificence and taste. His liberality extended also to adjacent places, in which there are many who will call him blessed. Nor was it confined to persons of his own religious persuasion, but comprehended the necessitous and deserving of all parties; while he was particularly useful in serving the interest of the Christian society to which he belonged. What wonder if such a man were universally beloved? Was it possible he should have an enemy? One however he had (and I never heard of more), an idle and dissolute wretch, who, having been often reproved by him for his vices, formed the desperate resolution to murder him as he was going to public worship, which he almost always did on foot. But Providence remarkably interposed to preserve so valuable a life, by inclining him that morning to go on horseback a different road."

But the sphere in which he had hitherto moved was too narrow for his enlarged mind. Being named in 1773 to the office of sheriff of Bedfordshire, from that time his scene of usefulness was extended. His office, as he himself observes, brought the distress of prisoners more immediately under his notice. A sense of duty induced him personally to visit the county-jail, where he observed such abuses; and such scenes of calamity, as he had before no conception of; and he soon exerted himself to procure a reform. With a view to obtain precedents for certain regulations which he purposed, he went to inspect the prisons in some neighbouring counties. But finding in them equal room for complaint and commiseration, he determined to visit the principal prisons in England. The farther he proceeded, the more shocking were the scenes presented to his view; which induced him to resolve upon exerting himself to the utmost, to accomplish a general reform in these horrid places of confinement; considering it as of the highest importance, not only to the wretched objects themselves, but to the community at large. Upon this subject he was examined in the house of commons in March 1774, when he had the honour of their thanks. This encouraged him to proceed in his design. He revisited all the prisons in the kingdom, together with the principal houses of correction. He, also in 1775 enlarged his circuit by going into Wales, Scotland, and Ireland, where he found the same need of reformation.

One grand object which he had in view was, to put a stop to the *jail fever*; which raged so dreadfully in many of the prisons, as to render them to the last degree offensive and dangerous; a disease by which more had been taken off than by the hands of the executioner; and which, in several instances, had been communicated from the prisoners into the courts of justice, and had proved fatal to the magistrates and judges, and to multitudes of persons who attended the trials, as well as to the families of discharged felons and debtors. Another end he proposed was, to procure the immediate release of prisoners, who, upon trial, were acquitted, but who often continued long to be unjustly detained for want of being able to pay the accustomed fees; as also to abolish many other absurd and cruel usages which had long prevailed. But the great object of all was, to introduce a thorough reform of morals into our prisons; where he had found the most flagrant vices to prevail in such a degree, that they were become seminaries of wickedness and villainy, and the most formidable nuisances to the community; in consequence of the promiscuous intercourse of prisoners of both sexes, and of all ages and descriptions; whereby the young and less experienced were ini-

tiated, by old and hardened sinners, into all the arts of villainy and the mysteries of iniquity; so that, instead of being reformed by their confinement (which should be the chief end of punishment), those that were discharged became more injurious to society than before.

In order to the attainment of these great objects, Mr. Howard spared no pains nor expence, and cheerfully exposed himself to much inconvenience and hazard; particularly from that malignant distemper, of which he saw many dying in the most loathsome dungeons, into which none, who were not obliged, besides himself, would venture. "I have been frequently (says Mr. Howard) asked what precautions I used to preserve myself from infection in the prisons and hospitals which I visit. I here answer, next to the free goodness and mercy of the Author of my being, temperance and cleanliness are my preservatives. Trusting in divine Providence, and believing myself in the way of my duty, I visit the most noxious cells; and while thus employed, I fear no evil. I never enter an hospital or prison before breakfast; and in an offensive room, I seldom draw my breath deeply."

His laudable endeavours he had the pleasure to see, in some instances, crowned with success; particularly in regard to the healthiness of prisons, some of which were rebuilt under his inspection. Through his interposition also, better provision has been made for the instruction of prisoners, by the introduction of bibles and other pious books into their cells, and a more constant attendance of clergymen. The gaolers likewise have, by act of parliament, been rendered incapable of selling strong liquors, which had been the source of much drunkenness and disorder. But a minute detail of particulars is not to be expected here; for these the reader is referred to Mr. Howard's publications, which show that much is yet wanting.

But in order to a more general and happy regulation, and the reformation of criminals, he determined to visit other countries, to see the plans there adopted; in hope of collecting some information which might be useful in his own country. For this purpose he travelled into France, Flanders, Holland, Germany, and Switzerland: afterwards through the Prussian and Austrian dominions. He visited also the capitals of Denmark, Sweden, Russia, and Poland, and some cities in Portugal and Spain. In all these expensive and hazardous journeys, he denied himself the usual gratifications of travellers, and declined the honours which were offered him by persons of the first distinction, applying himself solely to his one grand object. To him the inspection of a jail, or hospital, was more grateful than all the entertainments of a palace. With what astonishment and gratitude he was received by their miserable inhabitants may easily be imagined, since while he made observations on their situation, he meditated their relief; and many distressed prisoners abroad, as well as at home, partook of his bounty, and some were liberated by it; for he considered all of every nation, and people, and tongue, as brethren. Nor was he sparing of advice, or of reproof, as he saw occasion, to persons of rank and influence, whereby the miseries of their countrymen might be relieved. As he courted the favour of none, neither did he fear the frowns of any; but, with a manly freedom and a christian fortitude, spoke his mind to crowned heads (particularly the late emperor of Germany) in a manner to which they were not accustomed; which, however, in a person of such disinterested views, procured him reverence and esteem, and in some instances proved effectual for relieving the miserable and oppressed. On his return, he published in 1777, "The State of the Prisons in England and Wales, with Preliminary Observations, and an Account of some Foreign Prisons," 4to. And in 1778 he took a third journey through the Prussian and Austrian domi-

nions, and the free cities of Germany, and likewise extended his tour through Italy, and revisited some of the countries he had before seen. The observations he made in this tour were published in an Appendix, 1780; containing also some remarks respecting the management of prisoners of war, and the hulks on the Thames. But wishing to acquire some further knowledge on the subject, he in 1781 again visited Holland and some cities in Germany. He visited also the capitals of Denmark, Sweden, Russia, and Poland; and in 1783 some cities in Portugal and Spain, and returned through France, Flanders, and Holland. The substance of all these travels was afterwards thrown into one narrative, which was published in 1784. He also published a curious account of the Bastile, in 8vo. that infamous French prison happily now no more.

His travels and exertions, however, were not yet at an end. He conceived a further design, which was to visit the principal lazarettos in France and Italy, in order to obtain information concerning the best methods to prevent the spreading of the plague, with a view to apply them with respect to other infectious disorders. Not gaining all the satisfaction here which he wished for, he proceeded to Smyrna and Constantinople, where that most dreadful of human distempers actually prevailed, "pleasing himself (as he said) with the idea of not only learning, but of being able to communicate somewhat to the inhabitants of those distant regions." In the execution of this design, though he was so much exposed to danger, and actually caught the plague, "that merciful Providence (as he himself piously remarks) which had hitherto preserved him, was pleased to extend his protection to him in this journey also, and to bring him home once more in safety." In his return he revisited the chief prisons and hospitals in the countries through which he passed; and afterwards went again to Scotland, and then to Ireland, where he proposed a new and very important object; namely, to inspect the Protestant Charter Schools, in some of which he had before observed shameful abuses, which he had reported to a committee of the Irish house of commons. In this more extensive tour, he took a particular account of what he observed amiss in the conduct of this noble charity, with a view to a reformation, and not without considerable success. In the course of these journeys, particular cities and communities were not unmindful to pay him proper respect. At Dublin, he was created by the university a Doctor of Laws; and the city of Glasgow and the town of Liverpool did honour to themselves by enrolling him among their members. Upon his return home, having again inspected the prisons in England, and the hulks on the Thames, to see what alterations had been made for the better (which he found to be very considerable, though yet imperfect), he published the result of his last laborious investigations, in "An Account of the principal Lazarettos in Europe, with various Papers relative to the Plague, together with further Observations on some Foreign Prisons and Hospitals, and Additional Remarks on the present State of those in Great-Britain and Ireland," with a great number of curious plates. The work likewise contained Observations on Penitentiary Houses, which had been encouraged by act of parliament, for the correction and reformation of criminals, of which he and Dr. Fothergill had been nominated by the king to be superintendants. Beside these, he published the Grand Duke of Tuscany's "New Code of Criminal Law, with an English Translation:" and of all his publications he gave away a vast number of copies among his acquaintance, in the most liberal manner. His laying open the horrors of despotism in a neighbouring country had very nearly exposed him to the sufferings of them; and had it not been for the timely notice of our ambassador, he had ended his days in the Bastile.

Not satisfied, however, with what he had already done, he

concludes his "Account of Lazarettos" with announcing his intention again to quit his country, for the purpose of revisiting Russia, Turkey, and some other countries, and extending this our in the East. "I am not insensible (says he) of the dangers that must attend such a journey. Trusting, however, in the protection of that kind Providence which has hitherto preserved me, I calmly and cheerfully commit myself to the disposal of unerring wisdom. Should it please God to cut off my life in the prosecution of this design, let not my conduct be uncandidly imputed to rashness or enthusiasm, but to a serious deliberate conviction that I am pursuing the path of duty, and to a sincere desire of being made an instrument of more extensive usefulness to my fellow-creatures than could be expected in the narrower circle of a retired life." Accordingly, to the great concern of his friends, he set out in summer 1789 on this hazardous enterprise; the principal object of which was to administer Dr. James's Powder, a medicine in high repute at home, in malignant fevers, under a strong persuasion that it would be equally efficacious in the plague. In this second tour in the East "it *did* please God to cut off his life:" for, having spent some time at Cherson, a new settlement of the empress of Russia, in the mouth of the Dnieper or Borysthenes, toward the northern extremity of the Black Sea, near Oczakow, he caught, in visiting the Russian hospital of that place, or as some say a young lady who was ill of the same complaint, a malignant fever, which carried him off on the 20th of January, after an illness of about twelve days: and after having been kept, according to his express directions to his servant, five days, he was buried, by his own desire, in the garden of a villa in the neighbourhood, belonging to a French gentleman from whom he had received great civilities, by his faithful servant who had attended him on his former journeyings, and whom he expressly enjoined not to return home till five weeks from his death. While absent on his first tour to Turkey, &c. his character for active benevolence had so much attracted the public attention, that a subscription was set on foot to erect a statue to his honour in St. Paul's Cathedral, and 1500 l. was quickly subscribed for that purpose. But some of those who knew Mr. Howard best, never concurred in the scheme being well assured that he would neither countenance nor accede to it; and in consequence of two letters from Mr. Howard himself to the subscribers, the design was laid aside. It has, however, been effected since his death: and surely, of all the statues or monuments ever erected by public gratitude to illustrious characters either in ancient or modern times, none was ever erected in honour of worth so genuine and admirable as his—who devoted his time, his strength, his fortune, and finally sacrificed his life, in the pursuits of humanity:—who, to adopt the expressive words of Mr. Burke, in his speech at Guildhall in Bristol, in 1780, "visited all Europe [and the East], not to survey the sumptuousness of palaces, or the statefulness of temples; not to make accurate measurements of the remains of ancient grandeur, nor to form a scale of the curiosity of modern art: not to collect medals, or to collate manuscripts; but to dive into the depth of dungeons; to plunge into the infection of hospitals; to survey the mansions of sorrow and of pain; to take the gauge and dimensions of misery, depression, and contempt; to remember the forgotten; to attend to the neglected; to visit the forsaken; and to compare and collate the distresses of all men in all countries. His plan is original; and it is as full of genius as it is of humanity. It is a voyage of discovery, a circumnavigation of charity; and already the benefit of his labour is felt more or less in every country."

HOWDEN, a town in the East Riding of Yorkshire, 180 miles from London, stands on the north side of the Ouse, has a market on Saturdays, and four fairs in the year. Here was

formerly a collegiate church of five prebendaries, erected in the last century but one; adjacent to which the bishops of Durham, who possess many estates hereabouts with a temporal jurisdiction, have a palace. One of them built a very tall steeple to the church here, whither the inhabitants might retire in case of inundations; to which it is very liable from the great freshes that come down the Ouse sometimes at ebb. This part of the county is from hence called Howdenshire, and is watered by a conflux of several large rivers that fall into the Humber. At Howdendike is a ferry over the Ouse.

Lord HOWE's Island, a small island in the neighbourhood of New South Wales, discovered on February 17, 1788, S. lat. 31. 36. E. long. 159. 04. It is of an arched figure, lying from north-west to south-east, the two extremities including a space of about six miles, though, by reason of the curved figure of the island itself, it is near seven in length. It is deeply indented on the middle of the eastern part by a bay named Ross's Bay, and on the opposite and western part has another named Prince William Henry's Bay; so that the whole has the appearance of two islands joined together by an isthmus, which in some places is not above half a mile broad. On the southern part of that division which lies most to the northward are two considerable bays, named Callam's and Hunter's Bay; and on the south-western part of the other are two high mountains, the most southerly named Mount Gower, and the other Mount Lidgbird. The convex part of the island lying towards the north-east, and the concave side towards the opposite quarter, is terminated by two points named Point King and Point Philip. No fresh water was found on the island; but it abounds with cabbage-palms, mangrove, and maunched trees, even up to the summits of the mountains. There are plenty of ganets, and a land fowl of a dusky brown colour, with a bill about four inches long, and feet like those of a chicken. These were found to be remarkably fine meat, and were very fat. There are many large pigeons, and the white birds found in Norfolk Island were also met with in this place. The bill of this bird is red, and very strong, thick, and sharp pointed. Great numbers of fine turtle frequent this island in summer, but go to the northward in winter. These, it was imagined, would prove of great service to the colony at Port Jackson; but, from some cause or other, it appears they have hitherto been disappointed. Plenty of fish were caught by a hook and line. At the distance of about four leagues from Lord Howe's Island is a very remarkable and high rock, to which the name of Ball's Pyramid has been given. This island may be approached without danger; but about four miles from the south-west part of the pyramid there is a very dangerous rock, which shows itself above the surface of the water, and appears not to be larger than a boat. The southern part of the island is lined with a sandy beach, which is guarded against the sea by a reef of coral rock, at the distance of half a mile from the beach, through which there are several small openings for boats; but there is nowhere a greater depth of water within the reef than four feet. By the account of Mr. Watts, who visited this island in his return from Port Jackson, the isthmus which joins the two parts has evidently been overflowed, and the island disjoined, as in the very centre the men saw large beds of coral rocks and great quantities of shells; and on the east, which seems in general to be the weather-side, the sea has thrown up a bank of sand from 25 to 30 feet high, which serves as a barrier against future inundations. The island also appears to have suffered by volcanic eruptions, as great quantities of pumice-stones and other matters of that kind were found upon it. Mr. Austin also found the whole reef which shelters the west bay a burnt-up mass. The time he visited the island was that of the incubation of the ganets, of which there were then prodigious numbers,

their nests being only hollows made in the sand, there not being any quadrupeds on the island to disturb them. Besides the large pigeons already mentioned, they met with beautiful parrots and parroquets; a new species of the coot, as well as of the rail and magpie. They found likewise a very beautiful small bird of a brown colour with a yellow breast, and yellow on the wing, which seemed to be a species of humming-bird. They found also a black bird like a sheerwater, having a hooked bill; and which burrows in the ground. The only insects met with here were the common earth-worm and ants; which last were in great plenty. Besides the trees already mentioned, they found several esculent vegetables, as scurvy-grass, celery, spinach, endive, and samphire.

HOVELL (JAMES), a voluminous writer of the 17th century, supported himself many years by writing and translating of books. Though he had been a zealous loyalist, he afterwards flattered Cromwell; yet on the restoration he was made historiographer to the king, being the first in England who enjoyed that title. He died in 1666.

HOWITZ, or HOWITZER, a kind of mortar, mounted upon a field-carriage like a gun. The difference between a mortar and a howitz is, that the trunnions of the first are at the end, and at the middle in the last. The invention of howitzers is of much later date than mortars, for they really had their origin from them. The constructions of howitzes are as various and uncertain as those of mortars, excepting the chambers, which are all cylindrical. They are distinguished by the diameter of the bore; for instance, a ten inch howitz is that the diameter of which is 10 inches; and so of the smaller ones.

HOWTH, a promontory which forms the northern entrance of the bay of Dublin, having a small village about seven miles north-east from that city in the province of Leinster. It gives title of earl to the family of St. Lawrence, who were so called from a victory obtained by them over the Irish on St. Lawrence's day 1177, their former name being Tristram; and this place has continued in possession of the family above 600 years. N. lat. 53. 21. W. long. 6. 22. The shores off this hill are rocky and precipitous, affording, however, a few harbours for small craft. It was formerly called Ben-hedar, i. e. "the Birds promontory;" and celebrated for having Dun Criomthan, or the rath or royal palace of Criomthan erected on it, he having been chief or king of that district, and memorable for making several successful descents on the coast of Britain against the Romans in the time of Agricola. Howth, though now stripped of trees, was formerly covered with venerable oaks, and was a seat of the Druids; one of their altars still remains in a sequestered valley on the east side of the hill. The mansion-house is built in form of a castle, and was probably erected by Sir Armoricus Tristram. Near the house stands the family chapel, and on the western shore are the ruins of St. Mary's church, with some ancient monuments of lord Howth's ancestors. Due west of Howth house are the ruins of St. Fenton's church.

HOXTER, a town of Germany, in Westphalia, seated on the river Weser, 27 miles N. E. of Paderborn. E. long. 9. 39. N. lat. 51. 50.

HOY, a small vessel, chiefly used in coasting, or carrying goods to or from a ship, in a road or bay, where the ordinary lighters cannot be managed with safety or convenience. It would be very difficult to describe, precisely, the marks of distinction between this vessel and some others of the same size, which are also rigged in the same manner; because what is called a *boy* in one place, would assume the name of a *sloop* or *smack* in another; and even the people who navigate these vessels, have, upon examination, very vague ideas of the marks by which they are distinguished from those above mentioned.

In Holland, the hoy has two masts; in England, it has but one, where the main-sail is sometimes extended by a boom, and sometimes without it. Upon the whole, it may be defined a small vessel, usually rigged as a sloop, and employed for carrying passengers and luggage from one place to another, particularly on the sea-coast.

Hoy, one of the Orkney islands, situated between the island of Pomona and the north coast of Caithnessshire. It is about 10 miles long. On this island, beside the great conic hill of Hoyhead, which is a sea-mark, there is a stupendous rock, called the Beary, where a bird, here named the layer, supposed to be a species of penguin, is found. It is about the size of a small duck, remarkably fat, and esteemed by many a great delicacy. These birds burrow in the rabbit-holes. The person employed in taking the young is usually let down by a rope from the top of the precipice. In this island too, in a gloomy valley, is an entire stone, 36 feet long, and 18 broad, called the Dwarfie stone. It is hollow within, having the form of a bed and pillow cut in the stone. It is supposed to have been once the habitation of a hermit. W. long. 3. 20. N. lat. 58. 56.

HOYE, a town of Germany, in Westphalia, capital of a county of the same name, and subject to the elector of Hanover. It is seated on the river Weser, 43 miles N. W. of Zell. E. long. 9. 6. N. lat. 52. 57.

HRADISCH, a town of Germany, in Moravia, seated on an island in the river Morava, 30 miles S. E. of Olmutz, and 30 E. of Brinn. E. long. 17. 53. N. lat. 49. 0.

HUA, or КАHУА, a large town of Asia, capital of Cochinchina, with a handsome palace, where the king commonly resides. It is seated in a beautiful plain, and divided into two parts by a large river. The inhabitants are sincere, good-natured, and civil to strangers, and their religion is like that of China. They all blacken their teeth, thinking it a shame to have them white, like dogs; and they wear their nails very long. There is also a garrison kept here, and there are a few Christians. E. lon. 105. 5. N. lat. 17. 40.

HUAHINE, one of the SOCIETY-ISLANDS, in the South Sea, situated in S lat. 16. 43. W. long. 150. 52. and is about seven or eight leagues in compass. Its surface is hilly and uneven, and it has a safe and convenient harbour. It was first discovered by Captain Cook in 1769. It is divided by a deep inlet into two peninsulas connected by an isthmus, which is entirely overflowed at high water. From the appearance of its hills it may be concluded, that the country has at some period or other been the seat of a volcano. The summit of one of them had much the appearance of a crater, and a blackish spongy earth was seen upon one of its sides, which seemed to be lava; and the rocks and clay every where had a burnt appearance. The island is plentifully supplied with water by many rivulets which descend from the mountains and broken rocks. The inhabitants are nearly as fair as Europeans; and their conduct is bolder than that of the inhabitants of the other Society-Islands. They are a stout large-made people, some of the tallest being six feet three inches in height; they are extremely indolent, and seem to have as little curiosity as fear. The dogs are in great favour with all their women, "who could not have caressed them (says Mr. Forster) with a more ridiculous affection if they had been European ladies of fashion." Here was seen a middle-aged woman, whose breasts were full of milk, offering them to a little puppy who had been trained up to suck them. The sight disgusted those who saw it so much, that they could not forbear expressing their dislike to it: but the woman smiled, and told them that she allowed young pigs to do the same. It appeared afterwards that this woman had lost her child. Some of the gentlemen were present at a dramatic entertainment on this island: the piece represented a girl running away from her parents;

and seemed to be levelled at a female passenger who had come in Captain Cook's ship from Otaheite, and who happened to be present at the representation. It made such an impression on the girl, that the gentlemen could scarce prevail upon her to see the piece out, or to refrain from tears while it was acting. It concluded with the reception she was supposed to meet with from her friends, which was made out not to be a very agreeable one.—These people introduce extempore pieces upon occasion; and it is most probable that this was meant as a satire upon the girl above mentioned, and to discourage others from acting in the same manner.

HUBER (ULRIC), one of the greatest civilians in the 17th century, was born at Dockum in 1636. He became professor of law at Franeker; and wrote, 1. A treatise *De jure civitatis*. 2. *Jurisprudentia Frisica*. 3. *Specimen philosophiæ civilis*. 4. *Institutiones historiæ civilis*; and several other works, which are esteemed. He died in 1694.

HUBERT ST. a town of the Austrian Netherlands, in Luxemburg, with a handsome abbey. It is 20 miles N. E. of Bouillon, and 150 N. E. of Paris. Lon. 5. 12. E. Lat. 50. 0. N.

HUBNER (JOHN), a learned geographer of Germany, taught geography at Leipzig and Hamburg with extraordinary reputation; and died at Hamburg in 1732, aged 63. His principal work is a Geographical treatise, printed at Basil in 1746, in 6 vols. 12mo.

HUDSON (HENRY), an eminent English navigator, who, about the beginning of the last century, undertook to find out a passage by the north-east or north-west to Japan and China. For this purpose he was four times fitted out: he returned three times unsuccessful; but in the last voyage, in 1610, being persuaded that the great bay to which his name has been since given, must lead to the passage he sought, he wintered there, to prosecute his discovery in the spring. But their distresses during the winter producing a mutiny among his men, when the spring arrived, they turned him, with his son and seven sick men, adrift in his own shallop, and proceeded home with the ship. As Hudson and his unhappy companions were never heard of afterward, it is to be supposed they all perished.

HUDSON (JOHN), a very learned English critic, born in 1662. He distinguished himself by several valuable editions of Greek and Latin authors, and in 1701 was elected head keeper of the Bodleian library at Oxford. In 1712 he was appointed principal of St. Mary's Hall, through the interest of the famous Dr. Ratchiffe; and it is said that the university of Oxford is indebted for the most ample benefactions of that physician to Dr. Hudson's solicitations. He died in 1719, while he was preparing for publication a catalogue of the Bodleian library, which he had caused to be fairly transcribed in six folio volumes.

HUDSON'S BAY, a large bay of N. America, lying between 51° and 69° N. latitude, and discovered, in 1610, by Mr. Henry Hudson. This intrepid mariner, in searching after a N. W. passage to the S. Sea, discovered three straits, through which he hoped to find out a new way to Asia by America. He had made two voyages before on the same adventure; the first in 1607, and the second in 1608. In his third and last, in 1610, he entered the straits that lead into this new Mediterranean, the bay known by his name; coasted a great part of it, and penetrated to 80 degrees and a half to the heart of the frozen zone. His ardour for the discovery not being abated by the difficulties he struggled with in this empire of winter, and world of frost and snow, he staid here till the ensuing spring, and prepared, in the beginning of 1611, to pursue his discoveries; but his crew, who suffered equal hardships, without

the same spirit to support them, mutinied, seized him and seven of those who were most faithful to him, and committed them to the fury of the icy seas in an open boat. Hudson and his companions were either swallowed up by the waves, or, gaining the inhospitable coast, were destroyed by the savages; but the ship and the rest of the men returned home. Other attempts toward a discovery were made in 1612 and 1667; and a patent for planting the country, with a charter for a company, was obtained in 1670. In 1746, captain Ellis wintered as far north as 57 degrees and a half: and captain Christopher attempted farther discoveries in 1761. But beside these, and the late voyages, which satisfy us that we must not look for a passage on this side of the latitude 67 degrees north we are indebted to the Hudson's Bay company for a journey by land, which throws much additional light on this matter, by affording what may be called demonstration, how much farther north, at least in some parts of their voyage, ships must go, before they can pass from one side of America to the other. The northern Indians, who come down to the company's factories to trade, had brought to the knowledge of our people a river, which, on account of much copper being found near it, had obtained the name of Coppermine River. The company, being desirous of examining into this matter with precision, directed Mr. Hearne, a young gentleman in their service, to proceed over land, under the convoy of those Indians, for that river; which he had orders to survey, if possible, quite down to its exit into the sea, to make observations for fixing the latitudes and longitudes, and to bring home maps and drawings both of it and the countries through which he should pass. Accordingly, Mr. Hearne set out from Prince of Wales' Fort, or Churchill River, lat. 58. 47. N. and lon. 94. 7. W. on the 7th of December 1770. On the 13th of June he reached the Coppermine River, and found it all the way, even to its exit into the sea, encumbered with shoals and falls, and entering it over a dry flat of the shore, the tide being then out, which seemed, by the edges of the ice, to rise about 12 or 14 feet. This rise, on account of the falls, could carry the tide but a little way within the river's mouth, so that the water in it had not the least brackish taste. Mr. Hearne was, nevertheless, sure of the place it emptied itself into, being the sea, or a branch of it, by the quantity of whale and seal skins which the Eskimaux had at their tents; and also by the number of seals which he saw upon the ice. The sea, at the river's mouth, was full of islands and shoals, as far as he could see by the assistance of a pocket telescope; and the ice was not yet (July 17th) broken up, but thawed away only for about three quarters of a mile from the shore, and for a little way round the islands and shoals which lay off the river's mouth. But he had the most extensive view of the sea when he was about eight miles up the river; from which station, the extreme parts of it bore N. W. by W. and N. E. It appears from the map which Mr. Hearne constructed of this singular journey, that the mouth of the Coppermine River lies in lat. 72° N. and lon. 25° W. from Churchill River; that is about 119° W. of Greenwich. Mr. Hearne's journey back from the Coppermine River to Churchill River, lasted till June 30, 1772; so that he was absent almost a year and seven months. The country lying round Hudson's Bay is called New Britain, including Labrador, now New N. and S. Wales. The entrance of the bay, from the ocean, after leaving to the N. Cape Farewell and Davis' Straits, is between Resolution Isles on the N. and Button's Isles on the Labrador coast to the S. forming the eastern extremity of the strait, distinguished by the name of its great discoverer. The vast countries that surround Hudson's Bay, abound with animals whose skins and furs are far superior in quality to those found in less northerly regions.

In 1670 a charter was granted to a company, which does not consist of above ten persons, for the exclusive trade to this bay; and they have acted under it, ever since, with great benefit to themselves. They employ four ships and 130 seamen, and have several forts; namely, Prince of Wales' Fort, Churchill River; Nelson, New Severn, and Albany, which are all seated on the west side of the bay. The French, commanded by the late unfortunate navigator, M. de la Peyroufe, destroyed these forts, and the settlements, &c. valued at 500,000*l.* But the damage has been since repaired, and the commerce in a flourishing situation. See *New BRITAIN, ESKIMAUX, and LABRADOR.*

HUDSON'S Bay Company. See *COMPANY.*

HUDSON'S-River, one of the finest rivers in North America, rising in the mountainous country between the Lakes Ontario and Champlain. It waters Albany and Hudson, and proceeds in a southerly direction to New York, where it enters the Atlantic Ocean, at York Bay, after a course of 250 miles. The tide flows a few miles above Albany, which is 160 miles from New York. It is navigable for floops to Albany, and for ships to Hudson.

HUDSONIA, in botany; a genus of the monogynia order, belonging to the dodecandria class of plants. There is no corolla; the calyx is pentaphyllous and tubular: there are 15 stamina; the capsule is unilocular, trivalvular, and trispermous.

HUE and CRY, in law, the pursuit of a person who has committed felony on the high-way. Of this custom, which is of British origin, the following deduction is given by Mr. Whitaker. "When it was requisite for the Britons to call out their warriors into the field, they used a method that was particularly marked by its expeditiousness and decisiveness, and remains partially among us to this moment. They raised a cry, which was immediately caught up by others, and in an instant transmitted from mouth to mouth through all the region. And, as the notice passed along, the warriors snatched their arms, and hurried away to the rendezvous. We have a remarkable description of the fact in Cæsar, and there see the alarm propagated in 16 or 17 hours through 160 miles in a line. And the same practice has been retained by the Highlanders to our own time. When the lord of a clan received intelligence of an enemy's approach, he immediately killed a goat with his own sword, dipped the end of a half-burnt stick in the blood, and then gave it and the notice of the rendezvous to be carried to the next hamlet. The former symbolically threatened fire and sword to all his followers that did not instantly repair to the latter. The notice was dispatched from hamlet to hamlet with the utmost expedition. And in three or four hours the whole clan was in arms, and assembled at the place appointed. This was within these few years the ordinary mode by which the chieftains assembled their followers for war. The first person that received the notice, set out with it at full speed, delivered it to the next that he met, who instantly set out on the same speed, and handed it to a third. And, in the late rebellion of 1745, it was sent by an unknown hand through the region of Breadalbane; and, flying as expeditiously as the Gallic signal in Cæsar, traversed a tract of 32 miles in three hours. This quick method of giving a diffusive alarm is even preserved among ourselves to the present day; but is applied, as it seems from Cæsar's account above to have been equally applied among the Celtæ, to the better purposes of civil polity. The *butesium* and *clamour* of our ancient laws, and the *hue and cry* of our own times, is a well-known and powerful process for spreading the notice and continuing the pursuit of any fugitive felons. The cry, like the clamour of the Gauls or the summons of the Highlanders, is taken from town to town and from county to county; and a chain of communication is speedily carried from one end of the kingdom to the other."

HUER, a name given to certain fountains in ICELAND, of a most extraordinary nature; forming at times *jets d'eau* of scalding water ninety-four feet high and thirty in diameter, creating the most magnificent gerbes that can be imagined, especially when backed by the setting sun. They arise out of cylindrical tubes of unknown depths: near the surface they expand into apertures of a funnel shape, and the mouths spread into a large extent of stalactitical matter, formed of successive scaly concentric undulations. The playing of these stupendous spouts is foretold by noises roaring like the cataract of Niagara. The cylinder begins to fill: it rises gradually to the surface, and as gradually increases its height, smoking amazingly, and flinging up great stones. After attaining its greatest height it gradually sinks till it totally disappears. Boiling *jets d'eau* and boiling springs are frequent in most parts of the island; and in many parts they are applied to the culinary uses of the natives, see plate 4. The most capital is that which is called *Geyser* or *Geyser*, in a plain rising into small hills, and in the midst of an amphitheatre, bounded by the most magnificent and various-shaped icy mountains; among which the three-headed Heckla soars pre-eminent. These huers are not confined to the land; they rise in the very sea, and form scalding fountains amidst the waves. Their distance from the land is unknown; but the new volcanic isle, twelve miles off the point of Reickenes, emitting fire and smoke, proves that the subterraneous fires and waters extend to that space; for those awful effects arise from the united fury of these two elements.

In the "Habitable World described," we find the following account. "Hot springs are found in many parts of Iceland; from some, the water flows gently as from other springs, and it is then called *laug*, that is, a bath; from others it spouts boiling water with a great noise, and is then called *buer* or *kittel*, (kettle). I have visited, says Horrebow, many of these warm baths, but never found the least appearance of sulphur near them, (though Von Troil says he tasted sulphur in them), nor do the waters taste of any mineral. Though the degree of heat in these springs is unequal, I do not remember, says Von Troil, ever to have observed it under 188 of Fahrenheit's thermometer; in some places we found it 193, at another, where the most remarkable boiling fountain is, 213 degrees. If you fill a bottle at one of these spouting springs, says Horrebow, the water contained in the bottle will boil up two or three times, at the same time with the water in the well; and if the bottles are corked up as soon as filled, they will burst. This water when cold is pleasant to drink, and cows that drink of it yield a greater proportion of milk. The inhabitants use these waters for various purposes; some use it for dyeing, others boil their meat in it, by putting the meat in a vessel of cold water, and setting it in the hot spring; others bend hoops of great thickness with it, and others bathe in it and wash with it.

"Among the many hot springs in Iceland, is one worth the attention of the curious, and we have given a plate, the better to describe it. It is about two days journey from Heckla, and makes its appearance in a large field, where, on one side, the eye is awfully surpris'd with high mountains seen at a great distance covered with ice, whose summits are lost in the clouds, so that their sharp unequal points become invisible. Sometimes, by particular winds, the clouds shall sink and enwrap the mountains, leaving their summits only to view, appearing as it were to rest upon the clouds. On the other side, the sight is dreadful, awakened by the volcano Heckla, with its three points covered with ice, rising above the clouds, and with the smoke ascending from it, forming other clouds at some distance from the real ones: in one place is a ridge of high rocks, at the foot of which boiling water gushes forth, and further on, a marsh extends about half a mile in circumference, where are forty or fifty boiling springs, from which a vapour ascends

to a prodigious height, and from some, water four or five feet in height.

“ In the midst of these spouts, an enormous fountain of boiling water rises by starts, at certain intervals, from 20 to 60 feet in height, attended with a stupendous roar. The depth of the opening from whence this water issued could not be ascertained, for sometimes the water sunk down several fathoms, and some seconds passed before a stone, that was thrown in, reached its surface. The opening itself is perfectly round, nineteen feet in diameter, and forming above, on the surface of the ground, a basin 59 feet in diameter, whose edge is 9 feet above the orifice or hole.

“ The strength of the vapour that throws up this water is excessive; it not only prevents the stones thrown in from sinking, but even casts them up with the water to a very great height.”

HUENS, an island of the Baltic, six miles from the coast of Zealand, and three from that of Sweden. It is subject to the Swedes, to whom it was ceded by the Danes in 1658. It has one scattered village, and produces hay and every species of corn, more than sufficient for its own consumption. In this island was the observatory of the celebrated Tycho Brahe. Huens is six miles in circumference, nine miles S. by E. of Elsinore, and 14 N. by E. of Copenhagen. E. lon. 12. 38. N. lat. 55. 54.

HUESCA, an ancient and considerable town of Spain, in Arragon, with a bishop's see, and a university. It is seated on the Illuela, 35 miles N. E. of Saragossa. W. lon. 0. 2. N. lat. 42. 18.

HUESCAR, a town of Spain, in Granada, with a castle, 60 miles N. E. of Granada. W. lon. 2. 20. N. lat. 37. 45.

HUET (PETER DANIEL), a very learned French writer, born at Caen in Normandy, February 8, 1630. He discovered from his infancy a great inclination to the study of polite literature and the sciences, and at first applied himself to the law; but Des Cartes's principles, and Bochart's sacred geography, made him change his studies for those of philosophy, mathematics, the languages, and antiquities. His admiration for Bochart made him desirous of knowing him. He contracted a very strict friendship with him, and accompanied that learned man to Sweden. Here Christina would have engaged him in her service; but he, sensible of her inconstant temper, returned to France. All he brought with him was a copy of a MS. of Origen, which he transcribed at Stockholm. He refused several offers from Christina after she abdicated and went to Rome, and from Gustavus her successor. In 1670, Mr. Bossuet being appointed by the king preceptor to the dauphin, his majesty chose Mr. Huet for his colleague, with the title of *sub-preceptor to the prince*. It was he that formed the plan of the commentaries in *usum Delphini*, and directed the execution. His sentiments of piety determined him to enter into holy orders, which he did at the age of 46. Soon after this, he was presented by the king to the abbey of Amay; and in 1685 was nominated to the bishopric of Soissons, which he exchanged for the see of Avranches. After governing that diocese ten years, he resigned, and was made abbot of Fontenay near Caen. His love for his native place determined him to fix there. But law-suits coming upon him, he retired to Paris, and lodged among the Jesuits in the *Maison Professe*, whom he had made heirs to his library. A severe distemper weakened his body extremely, but not the vigour of his genius: he wrote his own life in a very elegant style; and died in 1721, aged 91. He was a man of very agreeable conversation; and of great probity, as well as immense erudition. The following are the titles of his principal works. 1. *De claris interpretibus, et de optimo genere interpretandi*. 2. An edition of Origen's Commentaries on the holy Scriptures, in Greek and Latin. 3. A Treatise on the Origin of the Romans. 4. *Demonstratio Evangelica*, folio. 5. *Quaestiones Ahetane de concordia rationis et fidei*. 6. Of

the situation of the terrestrial paradise, in French. 7. A History of the commerce and navigation of the Ancients, which has been translated into English. 8. *Commentarius de rebus ad eum pertinentibus*. 9. *Huetiana*. 10. Latin and Greek verses, &c.

HUGHES (JOHN), an ingenious and polite writer, was born in 1677. In the earliest parts of his youth, he cultivated the filter-arts, poetry, drawing and music, in each of which he by turns made a considerable progress; but followed those and his other studies only as agreeable amusements, under frequent confinement on account of his ill state of health. The lord chancellor Cowper made him secretary for the commissions of the peace without his knowledge, and distinguished him with singular marks of his esteem. He continued in the same employment under the earl of Macclesfield, and held it to the day of his death; which happened in 1719, the very night in which his tragedy, intitled *The Siege of Damascus*, was first acted. He was then 42. He translated Pontenelle's Dialogues of the Dead, Vertot's Revolutions of Portugal, and the Letters of Abelard and Eloisa. He gave a very accurate edition of Spenser's works, with his life, a glossary, and remarks; and wrote several papers in the Tatler, Spectator, and Guardian. Mr. Duncombe, who married his sister, collected his poems and essays in 2 vols. 12mo, in 1735.

HUGHLY, a town of Asia, in the kingdom of Bengal, seated on the most westerly branch of the river Ganges. It is of large extent, reaching about two miles along the river side, and drives a great trade in all the commodities of that country; affording rich cargoes for 50 or 60 ships annually, besides what is brought on carriages to the neighbouring towns. Saltpetre is brought hither from Patna in vessels above 50 yards long and five broad. The inhabitants are chiefly Indians; but there are also Portuguese, English, and other Europeans. E. long. 87. 55. N. lat. 22. 0.

HUGO CAPET, chief of the third race of the kings of France. Being count of Paris and Orleans, he was raised to the throne for his military valour and public virtues in 987.

HUGONIA, in botany; a genus of the decandria order, belonging to the monadelphia class of plants; and in the natural method ranking with those of which the order is doubtful. The corolla is pentapetalous; the fruit is a plum with a striated kernel.

HUGUENOTS, an appellation given by way of contempt to the Reformed or Protestant Calvinists of France. The name had its first rise in 1560; but authors are not agreed as to the origin and occasion thereof: but one of the two following seems to be the least forced derivation.

One of the gates of the city of Tours is called the gate Fourgon, by corruption from *feu Hugon*, i. e. the late Hugon. This Hugon was once count of Tours, according to Eginhardus, in his Life of Charles the Great, and to some other historians. He was it seems a very wicked man, who by his fierce and cruel temper made himself dreadful; so that after his death he was supposed to walk about in the night-time, beating all those he met with: this tradition the judicious Thuanus has not scrupled to mention in his History. Davila and other historians pretend, that the nickname of *Huguenots* was first given to the French Protestants, because they used to meet in the night-time in subterraneous vaults near this gate of Hugon; and what seems to countenance this opinion is, that they were first called by the name of *Huguenots* at this city of Tours. Others assign a more illustrious origin to that name; and say that the Leaguers gave it to the Reformed, because they were for keeping the crown upon the head of the royal line descended from Hugh Capet; whereas they were for giving it to the house of Guise, as descended from Charles the Great. Others again derive it from a French and faulty pronunciation of the German word

édignés, signifying confederates, and originally applied to that valiant part of the city of Geneva, which entered into an alliance with the Swiss cantons, in order to maintain their liberties against the tyrannical attempts of Charles III. duke of Savoy. These confederates were called *Eignots*, whence Huguenots.

The persecution which they underwent has scarce its parallel in the history of religion: though they obtained a peace from Henry III. in 1576, it was only of short continuance; and their sufferings, mitigated by the famous edict of Nantes, granted to them in 1598 by Henry IV. were again renewed, after the revocation of this edict, by Louis XIV. in 1685.

HULHEN, a town of the Austrian Netherlands, nine miles S. E. of Brussels. E. lon. 4. 37. N. lat. 51. 44.

HULK, an old ship of war, fitted with an apparatus to fix or take out the masts of his majesty's ships as occasion requires. The mast of this vessel is extremely high, and withal properly strengthened by *shrouds and stays*, in order to secure what are called the *sheers*, which serve, as the arm of a crane, to hoist out or in the masts of any ship lying alongside. The sheers are composed of several long masts, whose heels rest upon the side of the hulk, and having their heads declining outward from the perpendicular, so as to hang over the vessel whose masts are to be fixed or displaced. The tackles, which extend from the head of the mast to the sheer-heads, are intended to pull in the latter towards the mast head, particularly when they are charged with the weight of a mast after it is raised out of any ship, which is performed by strong tackles depending from the sheer-heads. The effort of these tackles is produced by two capsterns, fixed on the deck for this purpose.

HULK is also a name bestowed on any old vessel laid by as unfit for further service. It is probably derived from the *κλάδες*, or vessels of burthen, of the ancient Grecians.

HULL, or KINGSTON-UPON-HULL, a town in the E. riding of Yorkshire, with a market on Tuesday and Saturday. It is seated on a river called the Hull, on the N. side of the river Humber, and is a handsome large town, with two parish churches. It is fortified, and is the first town that shut its gates against Charles I.; but its fortifications are now inconsiderable, while its commerce has increased so much, that it is probably the fourth port in the kingdom. Its situation is extremely advantageous; for, beside its communication with the Yorkshire rivers and canals, it has access also, by the Humber, to the Trent and all its branches and communications. Hence it has the import and export trade of many of the northern and midland counties. The foreign trade is chiefly to the Baltic; but it has also regular traffic with the southern parts of Europe, and with America. More ships are sent hence to Greenland than from any other port, that of London excepted. The coasting trade for coal, corn, wool, manufactured goods, &c. is very extensive. The harbour is artificial, consisting of a dock, said to be the largest in the kingdom, with which the river communicates. Among the public buildings, are the Trinity House, for the relief of seamen and their widows; an exchange, and a town-hall. The noble stone bridge, over the river, to Holderness, was rebuilt in 1787, and consists of 14 arches. Hull sends two members to parliament, and is 41 miles N. of Lincoln, 36 S. E. of York, and 173 N. of London. W. lon. 0. 14. N. lat. 53. 45.

HULL, in the sea-language, is the main body of a ship, without either masts, yards, sails, or rigging. Thus *to strike a bull* in a storm, is to take in her sails, and to lash the helm on the lee-side of the ship; and *to hull*, or *lie a bull*, is said of a ship whose sails are thus taken in, and helm lashed a-lee.

HULST, a strong town of Dutch Flanders, capital of a bailiwick of the same name. It was taken by the French in 1747. It has a very fine town-house, and the palace of the com-

mander is the handsomest in all Flanders. It is seated on a plain, which may be overflowed, 15 miles N. W. of Antwerp, and 17 N. E. of Ghent. E. lon. 4. 6. N. lat. 51. 18.

HUMANITIES, signify grammar, rhetoric, and poetry, known by the name of *literæ humaniores*; for teaching of which, there are professors in the universities of Scotland, called *humanists*.

HUMBER, a river formed by the Trent, Ouse, Derwent, and several other streams. By the late inland navigation, it has a communication with the rivers Mersey, Dec, Ribble, Severn, Thames, Avon, &c.; which navigation, including its windings, extends above 500 miles, in the counties of Lincoln, Nottingham, York, Lancaster, Westmoreland, Chester, Stafford, Warwick, Leicester, Oxford, Worcester. It divides Yorkshire from Lincolnshire, and falls into the German ocean near Holderness.

HUME (DAVID, Esq.) a late celebrated philosopher and historian, was born in the south part of Scotland, on the 26th of April O. S. in the year 1711. Being the younger son of a country gentleman of good family, but no great fortune, his patrimony was of consequence insufficient to support him. For this reason he was destined for the bar, and passed through his academical courses in the university of Edinburgh; but being more inclined to studies of a different nature, he never put on the gown, nor even took the introductory steps necessary for that purpose. The writings of Locke and Berkeley had directed the attention of the generality of learned men towards metaphysics; and Mr. Hume having early applied himself to studies of this kind, published in 1739 the two first volumes of his *Treatise of human nature*, and the third the following year. He had the mortification, however, to find his book generally decried, and to perceive that the taste for systematic writing was now on the decline. He therefore divided this treatise into separate Essays and Dissertations, which he afterwards published at different times with alterations and improvements.

In 1742 Mr. Hume published two small volumes, consisting of Essays moral, political, and literary. These were better received than his former publication; but contributed little to his reputation as an author, and still less to his profit; and his small patrimony being now almost spent, he accepted an invitation from the marquis of Annandale to come and live with him in England. With this nobleman he staid a twelvemonth; during which time his small fortune was considerably increased. He then received an invitation from General St. Clair, to attend him as a secretary to his expedition, which was at first meant against Canada, but afterwards ended in an excursion against the coast of France. In 1747 he received an invitation from the general to attend him in the same station in his military embassy to the courts of Vienna and Turin. He then wore the uniform of an officer; and was introduced at these courts as aid-de camp to the general, along with Sir Harry Erskine and Captain Grant, afterwards General Grant. In 1749 he returned to Scotland, and lived two years with his brother at his country-house; where he composed the second part of his Essays, called *Political Discourses*. And now the general approbation of his performances was indicated by a more extensive sale than formerly, and likewise by the numerous answers published by different persons in order to counteract their supposed pernicious tendency. In 1752 were published, at Edinburgh, his *Political Discourses*, the only work of his which was well received on its first appearance; and the same year, at London, his *Inquiry concerning the Principles of Morals*, which in his own opinion was incomparably the best of all his performances. This year also he was appointed librarian to the Faculty of Advocates at Edinburgh; the principal advantage resulting from which employment was, that he had by that means the command of a large library. He then formed

the plan of writing the History of England: but deeming the whole to be too extensive, he confined his history to that of Britain under the house of Stuart. The book was almost universally decried on its first appearance, and soon after seemed to sink in oblivion. Dr. Herring primate of England, and Dr. Stone primate of Ireland, were the only literati of the author's acquaintance who approved of the work, and sent him messages not to be discouraged.

Notwithstanding the approbation of these eminent men, however, Mr. Hume's spirits were so much sunk by his bad success, that he had some thoughts of retiring to France, changing his name, and bidding adieu to his own country for ever; but his design was rendered impracticable by the breaking out of the war of 1755 between France and Britain. He then published his Natural History of Religion; to which an answer was published, soon after its appearance, in the name of Dr. Hurd bishop of Lichfield and Coventry; of which, however, he hath since disclaimed being the sole author. In 1756 the second volume of the History of the Stuarts was published, two years after the appearance of the first. This was better received, and helped to retrieve the character of the former volume. Three years after, his History of the House of Tudor made its appearance; which was almost as ill received as the History of the Stuarts had been, the reign of Elizabeth being particularly obnoxious. The author, however, had now learned to despise popular clamours; and continued to finish at his leisure the more early part of the English history, which was published in 1761, and was received with tolerable success.

Mr. Hume being now turned of fifty, and having obtained by the sale of his books a competent and independent fortune, retired into his native country of Scotland, determined never more to set his foot out of it. From this resolution, however, he was diverted by the earl of Hertford; whom he attended as secretary on his embassy to Paris in 1763. In 1765, the earl being appointed lord lieutenant of Ireland, Mr. Hume was intrusted with the sole management of the business of the state till the arrival of the duke of Richmond towards the latter end of the year. In 1767 he returned to Edinburgh, with a much larger income, procured to him by the earl of Hertford, than he formerly had; and now formed the same design he had formerly entertained, namely, of burying himself in his philosophical retreat. In this, however, he was again disappointed, by receiving an invitation from General Conway to be undersecretary; and this invitation he was prevented from declining, both by the character of the person, and his connections with lord Hertford. In 1769 he returned to Edinburgh, possessed of 1000*l.* a-year, healthy, and though somewhat stricken in years, yet having a prospect of long enjoying his ease, and of seeing the increase of his reputation. Of his last illness and character, he himself gives the following account: "In spring 1775 I was struck with a disorder in my bowels; which at first gave me no alarm, but has since, as I apprehend it, become mortal and incurable. I now reckon upon a speedy dissolution. I have suffered very little pain from my disorder; and what is more strange, have, notwithstanding the great decline of my person, never suffered a moment's abatement of my spirits; insomuch that, were I to name the period of my life which I should most choose to pass over again, I might be tempted to point to this latter period. I possess the same ardour as ever in study, and the same gaiety in company. I consider, besides, that a man of sixty-five, by dying, cuts off only a few years of infirmities; and though I see many symptoms of my literary reputation breaking out at last with additional lustre, I know that I could have but few years to enjoy it. It is difficult to be more detached from life than I am at present.

"To conclude, historically, with my own character, I am, or rather was (for that is the style I must now use in speaking

of myself; which emboldens me the more to speak my sentiments); I was, I say, a man of mild dispositions, of command of temper, of an open, social, and cheerful humour, capable of attachment, but little susceptible of enmity, and of great moderation in all my passions. Even my love of literary fame, my ruling passion, never soured my temper, notwithstanding my frequent disappointments. My company was not unacceptable to the young and careless, as well as to the studious and literary; and as I took a particular pleasure in the company of modest women, I had no reason to be displeas'd with the reception I met with from them. In a word, though most men any wise eminent have found reason to complain of calumny, I never was touch'd, or even attacked, by her baleful tooth: and though I wantonly expos'd myself to the rage of both civil and religious factions, they seem'd to be disarm'd, in my behalf, of their wonted fury. My friends never had occasion to vindicate any one circumstance of my character and conduct: not but that the zealots, we may well suppose, would have been glad to invent and propagate any story to my disadvantage, but they could never find any which they thought would wear the face of probability. I cannot say there is no vanity in making this funeral oration of myself, but I hope it is not a misplaced one; and this is a matter of fact which is easily cleared and ascertained."

His fears concerning the incurableness of his disorder proved too true. He died on the 25th of August 1776; and was interred in the Calton burying-ground, Edinburgh, where a monument is erected to his memory.

HUMECTATION, formed of humour, moisture, moistening, in pharmacy, the preparing of a medicine, by steeping it a while in water, in order to soften and moisten it when too dry; or to cleanse it, or prevent its subtil parts from being dissipated in grinding, or the like.

HUMECTATION is also used for the application of moistening remedies.

In this sense we say, embrocations, emplasters, unctions, humectations, fomentations, &c.

HUMERUS, or *Os HUMERI*, in anatomy, the uppermost bone of the arm, popularly called the *shoulder-bone*; extending from the scapula, or shoulder-blade, to the upper end of the cubitus, or elbow. See **ANATOMY**, p. 167.

HUMIDITY, that quality in bodies whereby they are capable of wetting other bodies. This differs very much from fluidity; and seems to be merely a relative thing, depending on the congruity of the component particles of the liquor to the pores of such particular bodies as it is capable of adhering to, penetrating a little into, or wetting. Thus, for instance, quicksilver is not a moist thing with regard to our hands or clothes; but may be called so in reference to gold, tin, or lead, to whose surfaces it will perfectly adhere, and render them soft and moist.

HUMILIATI, a congregation of religious in the church of Rome, established by some Milanese gentlemen on their release from prison, where they had been confined under the emperor Conrad, or, as others say, under Frederick I. in the year 1162. This order, which acquired great wealth, and had no less than 90 monasteries, was abolished by pope Pius V. in 1570, and their houses given to the Dominicans and Cordeliers for their luxury and cruelty.

HUMILIATION, the act of humbling, i. e. of abating a person's pride, and bringing him lower in his own opinion.

In this sense, humiliation stands distinguished from mortification: humiliation brings down the mind; mortification subdues the flesh.

HUMILITY, in ethics, is a virtue consisting in the moderate value which a person puts upon himself, and every thing relating to him. Or, more particularly, it consists in not attribut-

ing to ourselves any excellence or good which we have not; in not over-rating any thing which we have or do; in not taking an immoderate delight in one's self; in not assuming more of the praise of a quality or action than belongs to us; and in a lowly sense and acknowledgement of our imperfections, errors, and sins. This virtue expresses itself in the modesty of our appearance, of our pursuits, and of our behaviour towards other men. It is distinguished from affectation, bashfulness, and meanness.

HUMMING-BIRD. See TROCHILUS.

HUMMOCH, an island of Asia, in the Eastern Ocean, about six miles long. Here is a rajah, supported in his authority by the Dutch E. India Company. The natives have a great deal of the Malay, both in appearance and disposition, and speak the same language as at Mindanao. This island is exceedingly fertile, and produces most of the tropical fruits. But their principal articles of trade with the Dutch are bees-wax and honey. They lie five leagues S. of Mindanao. E. lon. 125. 12. N. lat. 5. 27.

HUMOUR, from the Latin, *humor*, in its original signification, stands for moisture in general; from whence it has been restrained to signify the moisture of animal bodies, or those fluids which circulate through them. It is distinguished from moisture in general, in this, that humours properly express the fluids of the body; when, in a vitiated state, it would not be improper to say, that the fluids of such a person's body were full of humours. The only fluids of the body, which, in their natural and healthful state, are called *humours*, are those in the eye: we talk of the aqueous humour, the crystalline humour, without meaning any thing that is morbid or diseased; yet, when we say in general, that such a person has got a humour in his eye, we understand it in the usual sense of a vitiated fluid.

As the temper of the mind is supposed to depend upon the state of the fluids in the body, *humour* has come to be synonymous with temper and disposition. A person's humour, however, is different from his *disposition*, in this, that humour seems to be the disease of a disposition: it would be proper to say that persons of a serious temper or disposition of mind, were subject to melancholy humours; that those of a delicate and tender disposition, were subject to peevish humours. Humour may be agreeable or disagreeable: but it is still humour; something that is whimsical, capricious, and not to be depended upon. An ill-natured man may have fits of good-humour, which seem to come upon him accidentally, without any regard to the common moral causes of happiness or misery. A fit of cheerfulness constitutes the whole of good-humour; and a man who has many such fits, is a good-humoured man: yet he may not be good-natured; which is a character that supposes something more constant, equable, and uniform, than what was requisite to constitute good-humour.

HUMOUR is often made use of to express the quality of the imagination, which bears a considerable resemblance to wit. Wit expresses something that is more designed, concerted, regular, and artificial; humour, something that is more wild, loose, extravagant, and fantastical; something which comes upon a man by fits, which he can neither command nor restrain, and which is not perfectly consistent with true politeness. Humour, it has been said, is often more diverting than wit; yet a man of wit is as much above a man of humour, as a gentleman is above a buffoon; a buffoon, however, will often divert more than a gentleman. The duke of Buckingham, however, makes humour to be all in all: wit, according to him, should never be used, but to add an agreeableness to some proper and just sentiment, which, without some such turn, might pass without its effect. See WIT.

HUMPHREY (Dr. LAWRENCE), a very learned English

divine in the 16th century, who, during the persecution under queen Mary, retired with other Protestant refugees to Zurich. He returned on the accession of queen Elizabeth; and was made president of Magdalen college, Oxford, dean of Gloucester, and then dean of Winchester. He was a great and general scholar, an able linguist, and a deep divine; and published, 1. *De religionis conservatione et reformatione, deque primatu regum.* 2. *De ratione interpretandi anachores.* 3. *Optimates; sive de nobilitate, ejusque origine.* 4. Sermons, and other works. He died in 1590.

HUMULUS, the hop; a genus of the pentandria order, belonging to the dicecia class of plants; and in the natural method ranking under the 53d order, *Scabridæ*. The male calyx is pentaphyllous; there is no corolla: the female calyx is monophyllous, patent obliquely, and entire; there is no corolla, but two styles; and one seed within the calyx, the latter consisting of one large leaf. There is only one species, viz the lupulus, which is sometimes found wild in hedges near houses and gardens, but probably is not indigenous. The stalk is weak and climbing; it creeps up the support in a spiral, ascending always from the right hand to the left. The stalk and the leaves are rough to the touch; the upper leaves are heart-shaped, the lower ones divided into three lobes serrated on the edges, and grow in pairs on long footstalks. The male flowers grow on a distinct plant on branched peduncles; the females on peduncles in pairs of the form of a *strobilus* or cone, composed of large imbricated calyces containing each one or two seeds. For the culture and uses of hops, see the articles HOP and HUSBANDRY.

HUNDRED, HUNDREDUM, or *Centuria*, a part or division of a county; which was anciently so called from its containing an hundred families, or from its furnishing an hundred able men for the king's wars. After king Alfred's dividing this kingdom into counties, and giving the government of each county to a sheriff, these counties were divided into hundreds, of which the constable was the chief officer. The grants of hundreds were at first made by the king to particular persons: but they are not now held by grant or prescription, their jurisdiction being devolved to the county-court; a few of them only excepted, that have been by privilege annexed to the crown, or granted to some great subjects, and still remain in the nature of a franchise.

HUNDRED Court. This is only a larger COURT-BARON, being held for all the inhabitants of a particular hundred instead of a manor. The free suitors are here also the judges, and the steward the register, as in the case of a court-baron. It is likewise no court of record; resembling the former in all points, except that in point of territory it is of a greater jurisdiction. This is said by Sir Edward Coke to have been derived out of the county-court for the ease of the people, that they might have justice done them at their own doors, without any charge or loss of time: but its institution was probably co-eval with that of hundreds themselves, which were formerly observed to have been introduced though not invented by ALFRED, being derived from the policy of the ancient Germans. The *centeni*, we may remember, were the principal inhabitants of a district composed of different villages, originally in number an hundred, but afterwards only called by that name; and who probably gave the same denomination to the district out of which they were chosen. Cæsar speaks positively of the judicial power exercised in their hundred-courts and courts-baron. "*Principes regionum atque pagorum*" (which we may fairly construe, the lords of hundreds and manors) "*inter suos jus dicunt, controversasque minuunt.*" And Tacitus, who had examined their constitution still more attentively, informs us not only of the authority of the lords, but that of the *centeni*, the hundredors, or jury; who were taken out of the common freeholders, and had themselves a share in the determination. "*Etigantur in*

conciliis et principibus, qui jura per pagos vicofque reddunt: centum in fingulis, ex obbe comites, confilium fimul et auctoritas, adfunt." This hundred court was denominated *horeda* in the Gothic conftitution. But this court, as caufes are equally liable to removal from hence as from the common court baron, and by the fame writs, and may alfo be reviewed by writ of falfe judgment, is therefore fallen into equal difufe with regard to the trial of actions.

HUNGARY, a kingdom of Europe, the greateft part of which was anciently called *Pannonia*. It had the name of *Hungary* from the Huns, a Scythian or Tartar nation, who fubdued it in the ninth century. It lies between the 18th and 22d degrees of eaft long. and betwixt the 45th and 49th degrees of north lat. being bounded to the north by the Carpathian mountains, which feperate it from Poland; to the fouth, by Servia, and the river Drave, which feperates it from Slavonia; to the weft, by Moravia, Austria, and Stiria; and to the eaft, by Wallachia and Tranfylvania. It is about 240 miles in length, and 235 in breadth; and is divided into the Upper and Lower Hungary, the former being that part which lies towards the eaft, and the latter that which lies towards the weft.

The northern parts of the kingdom are mountainous and barren, but healthy; the fouthern, on the contrary, are level, and exceeding fruitful, but not very healthy. The country along the Danube, from Prefburg to Belgrade, for upwards of 200 miles, is one continued plain, and no foil can be more fertile: but the air, by reafon of the many fwamps and moraffes, is not fo wholfome as on the higher and drier grounds. Here are mines of gold, filver, copper, iron, lead, quick-filver, cinnabar, antimony, yellow orpiment, fulphur, vitriol, marcafite, falt native and factitious, faltpetre, magnets, afbestos or ftone-flax, marble of feveral colours, alabafter, with diamonds, and all forts of precious ftones. Corn is in fuch plenty that it is fold for one fixth of its price in England. Their grapes are large and luscious; and their wines preferred to any in Europe. They have vaft numbers of cattle and horfes, the latter moffly moufe-coloured, with buffaloes, deer, wild fowl, game, and fifh, and many fpecies of wild beafts, particularly chamois, goats, bears and lynxes. Of vegetables, befides vines, and the common forts, here are tobacco, fadron, buck wheat, millet, melons, and chelnuts. Here alfo are excellent warm baths, and fprings of various kinds and qualities. The chief mountains of Hungary are the Crapack or Carpathian, which is the general name for all thofe that feperate this kingdom from Poland, Moravia, Silefia, and fome part of Austria. The fides of moft of them are covered with wood, and their tops with fnow. The chief rivers are the Danube, the Drave, the Save, the Wag or Waag, the Gran, the Temes, the Raab, and Theifs, all well ftocked with fifh. There are feveral lakes among the Carpathian mountains, and fome alfo in the lowlands.

The inhabitants are a mixture of the defcendants of the ancient Huns, Selavonians, Camani, Germans, Wallachians, Greeks, Jews, Turks, and a wandering people called *Zigduns*, faid to be of uncertain origin, but probably the fame as thofe we called *giffies*. The Hungarians are faid to be of a fanguine choleric temper, and fomewhat fierce, cruel, proud, and revengeful. They have been always reputed good foldiers, being much more inclined to arms, martial exercifes, and hunting, than to arts, learning, trade, or agriculture. The nobility affect great pomp and magnificence, and are much addicted to feafting and caroufing. The men in general are ftrong and well proportioned. They fhave their beards, but leave whifkers on the upper lip; wearing fur caps on their heads, a clofe-bodied coat girt with a fafh, with a fhort cloak or mantle over all, fo contrived as to be buckled under the arm, and leave the right hand at liberty. Their horfe are called *buffars*, and

their foot *heydukes*. The former wear a broad-fword, or feimitar, and carry a hatchet or battle-axe. Their horfes are fleet, but not near fo large as the German horfes, and therefore they ftand up on their fhort ftirrups when they ftrike. The heydukes ufually wear feathers in their caps, according to the number of the enemies they pretend to have killed. Both horfe and foot are an excellent militia, very good at a purfuit, or ravaging and plundering a country, but not equal to regular troops in a pitched battle. The women, when they go abroad, wear fhort cloaks and a veil.

There are five languages fpoken in this country, viz. the Hungarian, which, like the people, is of Scythian origin, and has little or no affinity with any European tongue; the German, Selavonian, Wallachian, and Latin. The laft is fpoken, not only by the better fort, but alfo by the common people, though very corruptly. The people called *Zigduns* have alfo a particular jargon.—Christianity was planted in Hungary in the ninth and tenth centuries. In the fixteenth the reformation made a great progrefs in it; but at prefent, though the Roman catholics hardly make a fourth part of the inhabitants, their religion is predominant, the Proteftants enjoying only a bare toleration. Befides feveral fefts of Proteftants, here are alfo great numbers of the Greek church and Jews; the laft pay double taxes of all kinds. Befides Jefuits colleges and other convents, there are feveral univerfities for the Roman catholics. The Lutherans alfo and Calvinifts have their gymnafiums and fchools, but under divers reftrictions.

As to the traffic of this country, it is almoft wholly in the hands of the Greeks and Jews. The exports confift chiefly of wine, horfes, cattle, metals, minerals, faffron, wool, and leather. Hungary, in particular, furnifhes Auftria, and other countries weft of it, with vaft droves of cattle, as well as variety of excellent wines, of which thofe of Tockay are reckoned the beft. The principal manufactures are thofe of copper, brafs, iron, and other hard wares. Great quantities of brafs and iron are exported, wrought and unwrought.

Hungary at firft, like moft other countries, was divided into many little principalities and ftates, which at length were united under one head, who had the title of *duke*. The laft of thefe dukes was Geysa: who, becoming a profelyte to Chriftianity, was baptized; after which he refigned the government to his fon Stephen, who took the title of *king*, anno 1000. But as the throne was filled by election, though generally cut of the fame family, the difpofal of the crown was difputed between the Turkish and German emperors for near 200 years: but after the year 1527, when Ferdinand archduke of Auftria was advanced to the throne, the Auftrians found means to influence the elections in fuch a manner as to keep the crown in their family till 1687, when it was fettled hereditarily on their heirs-male; and now, in confequence of an act made by the diet at Prefburg in 1723, in cafe of the failure of heirs-male, it is to defcend to females. The ftates of the kingdom confift of the prelates, the barons, the gentry, and the royal towns. To the fift clafs belong two archbifhops, about a dozen bifhops, near as many abbots and provofts, with the Pauline and Præmonftratenfian Jefuits. To the fecond, the ftadtholder or palatine, who represents the king; the court-judge; the ban or viceroy of Dalmatia, Croatia, and Selavonia; the ftadtholder of Tranfylvania; the great treafurer, the great cup-bearer, the fteward of the houfhould, the mafter of the horfe, the lord chamberlain, the captain of the yeomen of the guards, and the grand-marfhal of the courts who are ftyled the great barons, together with the inferior bans or counts and barons. To the third clafs belong the gentry, fome of whom have noble manors, and others only the privileges of nobles. To the fourth clafs belong the royal free cities, which are not fubject to the counts, but hold immediately of the king. The gentry alfo,

who hold of the archbishops and bishops, have the same privileges as the Hungarian nobility. The common people are vassals to the lords on whose lands they live, whether these lands belong to the crown, the clergy, nobility, or gentry.

The ordinary revenue of this kingdom is said to exceed a million sterling, arising from the mines, duties on cattle, royal demesnes, salt-works, contributions, customs, &c. The fortifications and garrisons constantly maintained on the frontiers against the Turks, are a great expence to the government. Hungary can easily bring into the field 100,000 men, regulars and militia; for there are 50,000 in actual pay, and the provinces furnish the other 50,000 when they are wanted.

HUNGARY Water, a distilled water prepared from the tops or flowers of rosemary; so denominated from a queen of Hungary, for whose use it was first made.

HUNGER, an uneasy sensation occasioned by long abstinence from food when the body is in a healthy state. See **ABSTINENCE**; **FASTING**; and **ANATOMY**, p. 189. The following useful observations upon hunger or famine are extracted from a paper by Dr. Percival in the second volume of the *Manchester Transactions*.

In famine, life may be protracted (the Doctor observes) with less pain and misery, by a moderate allowance of water: for the acrimony and putrefaction of the humours are obviated by such dilution, the small vessels are kept permeable, and the lungs are furnished with that moisture which is essential to the performance of their functions. Fontanus, a writer of respectable authority in the estimation of Morgagni, relates the history of a woman who obstinately refused to take any sustenance, except twice, during the space of 50 days, at the end of which period she died. But he adds, that she used water by way of drink, though in small quantity. Redi, who made many experiments (cruel and unjustifiable in my opinion) to ascertain the effects of fasting on fowls, observed, that none were able to support life beyond the ninth day to whom drink was denied; whereas one indulged with water lived more than 20 days.

Hippocrates has observed, that children are more affected by abstinence than young persons; these, more than the middle-aged; and the middle aged, more than old men. The power to endure famine, however, must depend no less upon the state of health and strength than on the age of the sufferer. There are also particular constitutions which do not suffer much pain from the calls of hunger. Dr. Percival was informed by a young physician from Geneva, that when he was a student at Montpellier, he fasted three nights and four days, with no other refreshment than a pint of water daily. His hunger was keen, but never painful, during the first and second days of his abstinence; and the two following days, he perceived only a faintness when he attempted either bodily or mental exertion: a sense of coldness was diffused over his whole frame, but more particularly affected the extremities. His mind was in a very unusual state of pusillanimity; and he experienced a great tendency to tears whenever he recollected the circumstance which had been the occasion of his fasting. During the whole period, the alvine excretions were suppressed, but not those by the kidneys: and at the close of it, his skin became tinged with a shade of yellow. The first food he took was veal broth; which had something of an intoxicating effect, producing a glow of warmth, and raising his spirits, so as to render him ashamed of his despondency. Perhaps in the case of Sextius Baculus, as recorded in the *Commentaries of Cæsar*, (lib. 6.) the extraordinary courage and prowess which he suddenly exerted, might be aided by the exhilarating effect of sustenance, which, under such circumstances, it is probable he would no longer decline. The fact, however, evinces, that neither his sickness nor the sensations of hunger had been so violent as much to impair his strength of body or vigour of mind.

Atticus, the celebrated friend of Cicero, who put a voluntary end to his life in the 77th year of his age by refusing all food, appears to have experienced ease from his disorder, rather than any acute sufferings by famine. "Sic cum biduo cibo se abstinuisset, subito febris decessit, leviorque morbus esse cepit: tamen propositum nihilo fecius peregit. Itaque die quinto, postquam id consilium inierat, decessit." *Corn. Nepos in Vit. Pomp. Attic.* From the former circumstance it has been conjectured, that he did not wholly deny himself the use of water, or of some other diluent. But though a few examples of this kind may be adduced, we have the evidence of numerous melancholy facts to show, that the pressure of want is agonizing to the human frame. "I have talked (says Dr. Goldsmith) with the captain of a ship, who was one of six that endured it in its extremity, and who was the only person that had not lost his senses when they received accidental relief. He assured me his pains at first were so great that he was often tempted to eat a part of one of the men who died, and which the rest of his crew actually for some time lived upon: He said, that during the continuance of this paroxysm he found his pains insupportable, and was desirous at one time of anticipating that death which he thought inevitable: But his pains, he said, gradually decreased after the sixth day (for they had water in the ship, which kept them alive so long), and then he was in a state rather of languor than desire; nor did he much wish for food, except when he saw others eating; and that for a while revived his appetite, though with diminished importunity. The latter part of the time, when his health was almost destroyed, a thousand strange images rose upon his mind; and every one of his senses began to bring him wrong information. The most fragrant perfumes appeared to him to have a fetid smell; and every thing he looked at took a greenish hue, and sometimes a yellow. When he was presented with food by the ship's company that took him and his men up, four of whom died shortly after, he could not help looking upon it with loathing instead of desire; and it was not till after four days that his stomach was brought to its natural tone; when the violence of his appetite returned with a sort of canine eagerness."

To those who by their occupations are exposed to such dreadful calamities, it is of serious importance to be instructed in the means of alleviating them. The American Indians are said to use a composition of the juice of tobacco, and the shells of snails, cockles, and oysters calcined, whenever they undertake a long journey, and are likely to be destitute of provisions. It is probable the shells are not burnt into quicklime, but only so as to destroy their tenacity, and to render them fit for levigation. The mafs is dried, and formed into pills, of a proper size to be held between the gum and lip, which, being gradually dissolved and swallowed, obtund the sensations both of hunger and of thirst. Tobacco, by its narcotic quality, seems well adapted to counteract the uneasy impressions which the gastric juice makes on the nerves of the stomach when it is empty; and the combination of testaceous powders with it may tend to correct the secretion that is supposed to be the chief agent in digestion, and which, if not acid, is always united with acidity. Certain at least it is, that their operation is both grateful and salutary; for we find the luxurious inhabitants of the East Indies mix them with the betel nut, to the chewing of which they are universally and immoderately addicted. Perhaps such absorbents may be usefully applied, both to divide the doses and to moderate the virulence of the tobacco. For, in the internal exhibition of this plant, much caution is required, as it produces sickness, vertigo, cold clammy sweats, and a train of other formidable symptoms, when taken in too large a quantity. During the time of war, the impressed sailors frequently bring on these maladies, that they may be admitted into the hospitals, and released from servitude. It would be an easy and safe experiment

to ascertain the efficacy, and to adjust the ingredients, of the Indian composition mentioned. And there is reason to believe, that the trial would be in some degree successful; for it is known that smoking tobacco gives relief in those habitual pains of the stomach which appear to arise from the irritation of the gastric secretions. The like effect is sometimes produced by increasing the flow of saliva, and swallowing what is thus discharged. And Dr. Percival has related the case of a gentleman, who used to masticate, many hours daily, a piece of lead; which being neither hard, friable, nor offensive to the palate, suited his purpose, as he thought, better than any other substance. He continued the custom many years, deriving great ease from it, and suffering no sensible injury from the poisonous quality of the metal. On mentioning this fact to a navy surgeon, the Doctor was told, that the sailors, when in hot climates, are wont to mitigate thirst by rolling a bullet in their mouths. A more innocent mean, the Doctor observes, might be devised; but the efficacy of this evinces, that the salivary glands are for a while capable of furnishing a substitute for drink. When a scarcity of water occurs at sea, Dr. Franklin has advised that the mariners should bathe themselves in tubs of salt-water: for, in pursuing the amusement of swimming, he observed that, however thirsty he was before immersion, he never continued so afterwards; and that, though he soaked himself several hours in the day, and several days successively in salt-water, he perceived not, in consequence of it, the least taste of saltiness in his mouth. He also further suggests, that the same good effect might perhaps be derived from dipping the sailors' apparel in the sea; and expresses a confidence that no danger of catching cold would ensue.

To prevent the calamity of famine at sea, it has been proposed by Dr. Lind, that the powder of salep should constitute part of the provisions of every ship's company. This powder and portable soup, dissolved in boiling water, form a rich thick jelly; and an ounce of each of these articles furnishes one day's subsistence to a healthy full-grown man. Indeed, from Dr. Percival's experiments it appears, that salep contains more nutritious matter, in proportion to its bulk, than any other vegetable production now used as food. It has the property also of concealing the nauseous taste of salt-water; and consequently may be of great advantage at sea, when the stock of fresh water is so far consumed that the mariners are put upon short allowance. By the same mucilaginous quality, it covers the offensiveness, and even in some measure corrects the acrimony of salted and putrescent meats. But, as a preservative against hunger, salep would be most efficacious combined with an equal weight of beef suet. By swallowing little balls of this lubricating compound at proper intervals, the coats of the stomach would be defended from irritation: and as oils and mucilages are highly nutritive, of slow digestion, and indisposed to pass off by perspiration, they are peculiarly well adapted to support life in small quantities. This composition is superior in simplicity, and perhaps equal in efficacy, to the following one, so much extolled by Avicenna the celebrated Arabian physician; to whom we are indebted for the introduction of rhubarb, calia, tamarinds, and fenna, into the materia medica. "Take sweet almonds and beef suet, of each one pound; of the oil of violets two ounces; and of the roots of marsh mallows one ounce: bray these ingredients together in a mortar, and form the mass into boluses, about the size of a common nut." Animal fat is singularly powerful in alluaging the most acute sensations of thirst, as appears from the narrative of the sufferings experienced by those who were confined in the black hole at Calcutta. A hundred and forty-six persons, exhausted by fatigue and military duty, were there thrust together into a chamber of 18 cubic feet, having only two windows, strongly barred with iron, from which, in a close sultry night, and in such a climate as that of

Bengal, little or no circulation of fresh air could be enjoyed. In a few minutes, these unhappy wretches fell into so profuse a perspiration, that an idea can hardly be formed of it; and this was succeeded by a raging thirst, which increased in proportion as the body was drained of its moisture. Water! Water! became the universal cry; and an old soldier on the outside, through pity, furnished them with a few skinfuls of it. But these scanty supplies, like sprinklings on the fire, served only to feed and increase the flame. From this experience of its effects, Mr. Holwell, their chief, determined to drink no more; and kept his mouth moist by sucking the perspiration out of his shirt sleeves, and catching the drops as they fell from his head and face. "You cannot imagine (says he) how unhappy I was if any of them escaped me." He came into the prison without his coat, the season being too hot to bear it: and one of his miserable companions, observing the expedient he had hit upon of allaying his thirst, robbed him from time to time of a considerable part of his store. This plunderer, whom he found to be a young gentleman in the service of the East India Company, afterwards acknowledged, that he owed his life to the many comfortable draughts which he derived from him. Before Mr. Holwell adopted this mode of relief, he had attempted, in an ungovernable fit of thirst, to drink his own urine: but it was so intensely bitter, that a second taste could not be endured; whereas, he assures us, no Bristol water could be more soft and pleasant than his perspiration. And this, we may presume, consisted chiefly of animal fat, melted by excessive heat, and exuding from the cellular membrane through the pores of the skin.

Persons who have been accustomed to animal food, are soon reduced when supplied only with the farinacea. Several years ago, to determine the comparative nutritive powers of different substances, an ingenious young physician, as Dr. Percival informs us, made a variety of experiments on himself, to which he unfortunately fell a sacrifice. He lived a month upon bread and water; and under this regimen of diet he every day diminished much in his weight. But, in 1784, a student of physic at Edinburgh confined himself for a longer space of time to a pint of milk and half a pound of white bread daily: And he assured our author, that he passed through the usual labours of study and exercise without feeling any decay of health or strength, and without any sensible loss of bulk. The cutaneous, urinary, and alvine excretions, were very scanty during the whole period; and the discharge of *scæces* occurred only once in a week. In this case the oily and coagulable parts of the milk probably furnished a larger proportion of aliment, and at the same time contributed to check the waste by perspiration and other discharges; for oleaginous substances are retained long in the body by their viscosity. Dr. Russel, in his Natural History of Aleppo, relates, that in those seasons when oil abounds, the inhabitants, by indulgence in it, are disposed to fever, and affected with infarctions of the lungs; maladies which indicate both retention and obstruction. Milk has been suspected by some of producing similar effects, though in a slighter degree; and the free use of it has been on this account forbidden to asthmatics.

Gum arabic might be a good substitute for salep in the composition already recommended; and as it will give such firmness to the mass as to require mastication, the saliva, by this means separated and carried into the stomach, would further contribute to alluage the sensations both of hunger and of thirst. See *GUM ARABIC*. This gum, combined with sugar and the whites of eggs, has been lately extolled in France, under the name of *patigumo*, as a remedy for catarrhal defluxions. Dr. Percival has seen cakes made of these ingredients, and thinks they might very well be applied to the purpose of obviating hunger. They are not perishable in the hottest climates, may be carried about the person with convenience, and, though very

tough, are pleasant to the taste. In the formula by which they are made, the proportion of sugar is too large, and that of gum arabic too small, if the mass be intended to alluige the cravings of appetite. According to our author's information, the receipt is as follows: "Take of fine sugar four ounces, and of gum arabic one ounce: levigate them well together; and add half an ounce of rose water, and of the white of eggs a sufficient quantity."

In our attempts to recover those who have suffered under the calamities of famine, great circumspection is required. Warmth, cordials, and food, are the means to be employed; and it is evident that these may prove too powerful in their operation, if not administered with caution and judgment. For the body, by long fasting, is reduced to a state of more than infantile debility; the minuter vessels of the brain, and of the other organs, collapse for want of fluids to distend them; the stomach and intestines shrink in their capacity; and the heart languidly vibrates, having scarcely sufficient energy to propel the scanty current of blood. Under such circumstances, a proper application of heat seems an essential measure, and may be effected by placing on each side a healthy man in contact with the patient. Pediluvia or fomentations may also be used with advantage. The temperature of these should be lower than that of the human body, and gradually increased according to the effects of their stimulus. New milk, weak broth, or water gruel, ought to be employed both for the one and the other; as nutriment may be conveyed into the system this way, by passages probably the most pervious in a state of fasting, if not too long protracted. "A lad at New-market, a few years ago, having been almost starved in order that he might be reduced to a proper weight for riding a match, was weighed at nine o'clock in the morning, and again at ten; and he was found to have gained near thirty ounces in weight in the course of an hour, though he had only drank half a glass of wine in the interval. The wine probably stimulated the action of the nervous system, and incited nature, exhausted by abstinence, to open the absorbent pores of the whole body, in order to suck in some nourishment from the air." But no such absorption as this can be expected in a state of extreme weakness and emaciation gradually induced; because the lymphatics must partake of the general want of tone and energy. And notwithstanding the salutary effects of wine in the case of the jockey, who, it is likely, had been reduced by sweating as well as by abstinence, such a stimulant might prove dangerous, and even fatal, in other cases. It appears safer therefore to advise the exhibition of cordials in very small doses, and at first considerably diluted. Slender wine-hey will perhaps best answer this purpose; and afford, at the same time, an easy and pleasant nourishment. When the stomach has been a little strengthened, an egg may be mixed with the whey, or administered under some other agreeable form. The yolk of one was, to Cornaro, sufficient for a meal; and the narrative of this noble Venetian, in whom a fever was excited by the addition of only two ounces of food to his daily allowance, shows, that the return to a full diet should be conducted with great caution, and by very slow gradations.

HUNGERFORD, a town of Berkshire in England, seated on the river Kennet, in a low and watery soil. It is a great thoroughfare in the Bath and Bristol road, 65 miles from London; and was formerly called *Inglford Charnamstreet*. The constable of this town, who is chosen annually, is lord of the manor, which he holds immediately of the crown. They have a horn here which holds about a quart, and appears by an inscription on it to have been given by John of Gaunt, together with a grant of the royal fishery in a part of the river which abounds with good trouts and cray-fish. Here is a market on Wednesdays, and a fair in August.

HUNNINGUEN, a town of France, in the department of

the Upper Rhine and late province of Alsace. It was fortified by Vauban, and is seated on the Rhine, five miles N. of Basle. E. lon. 11. 40. N. lat. 47. 40.

HUNNS, a fierce and savage nation, who formerly inhabited that part of Sarmatia bordering on the Palus Mæotis and the Tanais, the ancient boundary between Europe and Asia. Their country, as described by Procopius, lay north of mount Caucasus, which, extending from the Euxine to the Caspian Seas, parts Asiatic Sarmatia from Colchis, Iberia, and Albania; lying on the isthmus between the two seas above mentioned. Here they resided, unknown to other nations, and themselves ignorant of other countries, till the year 376. At this time, an hind pursued by the hunters, or, according to some authors, an ox stung by a gad fly, having passed the marsh, was followed by some Hunns to the other side, where they discovered a country much more agreeable than their own. On their return, having acquainted their countrymen with what they had seen, the whole nation passed the marsh, and, falling upon the Alans, who dwelt on the banks of the Tanais, almost exterminated them. They next fell upon the Ostrogoths, whom they drove out of their country, and forced to retire to the plains between the Borysthenes and the Tanais, now known by the name of *Podolia*. Then attacking the Visigoths, they obliged them to shelter themselves in the most mountainous parts of their country; till at last the Gothic nations, finding it impossible to withstand such an inundation of barbarians, obtained leave from the emperor Valens to settle in Thrace.

The Hunns thus became masters of all the country between the Tanais and Danube in 376, where they continued quietly till the year 388, when great numbers of them were taken into the pay of Theodosius I.; but, in the mean time, a party of them, called the *Nephtalite* or *White Hunns*, who had continued in Asia, over-ran all Mesopotamia, and even laid siege to Edessa, where they were repulsed with great slaughter by the Romans. The European Hunns frequently passed the Danube, committing the greatest ravages in the western empire; sometimes they fell upon the eastern provinces, where they put all to fire and sword. They were often defeated and repulsed by the Romans, but the empire was now too weak to subdue or confine them from making excursions; so that they continued to make daily encroachments, and became every day more formidable than before. In 441, the Hunns, under Attila, threatened the western empire with total destruction. This monarch, having made himself master of all the northern countries from the confines of Persia to the banks of the Rhine, invaded Mæsia, Thrace, and Illyricum; where he made such progress, that the emperor, not thinking himself safe in Constantinople, withdrew into Asia. Attila then broke into Gaul; where he took and destroyed several cities, massacring the inhabitants with the greatest cruelty. At last he was driven out with great slaughter by Aetius the Roman general and Theodoric king of the Goths, and could never afterwards make any great progress. About the year 452 or 453 Attila died, and his kingdom was immediately split into a number of small ones by his numerous children, who waged perpetual war with each other. The Hunns then ceased to be formidable, and became daily less able to cope with the other barbarous nations whom Attila had kept in subjection. Still, however, their dominion was considerable; and in the time of Charles the Great they were masters of Transylvania, Wallachia, Servia, Carniola, Carinthia, and the greater part of Austria, together with Bosnia, Slavonia, and that part of Hungary which lies beyond the Danube. In the year 776, while Charles was in Saxony, two princes of the Hunns, Caganus and Jugunus, sent ambassadors to him, desiring his friendship and alliance. Charles received them with extraordinary marks of friendship, and readily complied with their request. However, they entered, not long after, into an

alliance with Tassila duke of Bavaria, who had revolted from Charles, and raised great disturbances in Germany. Charles dissembled his resentment till he had entirely reduced Bavaria, when he resolved to revenge himself on the Hunns for those succours they had underhand given to his enemy. Accordingly, he ordered levies to be made throughout his dominions; and having by that means assembled a very numerous army, he divided it into two bodies, one of which he commanded himself, and the other he committed to the care of his generals. The two armies entered the country of the Hunns at different places, ravaged it far and near, burnt their villages, and took all their strong holds. This he continued for eight years, till the people were almost totally extirpated; nor did the Hunns ever afterwards recover themselves, or appear as a distinct nation.

There were two different nations that went by the name of *Hunns*; the Nephthalite or White Hunns, and the Sarmatian or Scythian Hunns. The former inhabited a rich country, bordering to the north on Persia, and at a great distance from the Sarmatian or Scythian Hunns, with whom they had no intercourse, nor the least resemblance either in their persons or manners. They were a powerful nation, and often served against the Romans in the Persian armies; but in the reign of the emperor Zeno, being provoked by Perozes king of Persia laying claim to part of their country, they defeated the Persians in two pitched battles, slew their king, over-ran all Persia, and held it in subjection for the space of two years, obliging Cahades, the son and successor of Perozes, to pay them a yearly tribute. These Hunns, called by the writers of those times the *White Hunns*, did not wander, like the others, from place to place; but, contented with their own country, which supplied them with all necessaries, they lived under a regular government, subject to one prince, and seldom made inroads, unless provoked, either into the Persian or Roman territories. They lived according to their own laws, and dealt uprightly with one another, as well as with the neighbouring people. Each of their great men used to choose 20 or more companions to enjoy with him his wealth, and partake of all his diversions; but, upon his decease, they were all buried with him in the same grave. This custom favours of barbarity; but in every other respect, the Nephthalite were a far more civilized nation than the Scythian Hunns, who, breaking into the empire, filled most of the provinces of Europe with blood and slaughter.

The latter were, according to Ammianus Marcellinus, a savage people, exceeding in cruelty the most barbarous nations. They begin to practise their cruelty, says Jornandes, upon their own children the very first day they come into the world, cutting and mangling the cheeks of their males, to prevent the growth of hair, which they must have looked upon, contrary to the sentiments of other nations, as unbecoming and unmanly. They had, perhaps, in this practice another view, which Jornandes seems to insinuate elsewhere, *viz.* to strike terror into the enemy with their countenances thus deformed and covered with scars. They had no other food but roots and raw meat, being quite unacquainted with the use of fire; and no houses at all, not even huts, but lived constantly exposed to the air, in the woods, and on the mountains, where, from their infancy, they were inured to hunger, thirst, and all manner of hardships: nay, they had such an aversion to houses, which they called the *sepulchres of the living*, that, when they went into other countries, they could hardly be prevailed upon to come within the walls of any house, not thinking themselves safe when shut up and covered. They used even to eat and sleep on horseback, scarce ever dismounting; which, in all likelihood, induced Zosimus to write, that the Hunns could not walk. They covered their nakedness with goat skins, or the skins of a sort of mice sewed together. Day and night were indifferent to them, as to buy-

ing, selling, eating, and drinking. They had no law, nor any kind of religion; but complied with their inclinations, whatever these prompted them to, without the least restraint, or distinction between good and evil. In war, they began the battle with great fury, and an hideous noise: but if they met with a vigorous opposition, their fury began to abate after the first onset, and when once put into disorder, they never rallied, but fled in the utmost confusion. They were quite unacquainted with the art of besieging towns; and authors observe, that they never attacked the enemy's camp. They were a faithless nation, and thought themselves no longer bound by the most solemn treaties, than they found their advantage in observing them. Hence we often find them, upon the least prospect of obtaining more advantageous conditions, breaking into the Roman empire, in defiance of the most solemn oaths and engagements. Several corps of Hunns, after their coming into Europe, served in the Roman armies against the Goths and other barbarous nations; nay, they were ready, for hire, to fight against each other, being blind to every other regard and consideration.

HUNTER, a name given to a horse qualified to carry a person in the chace. The shape of the horse designed for this service, should be strong and well knit together, as the jockeys express it. Irregular or unequal shapes in these creatures are always a token of weakness. The inequalities in shape which show a horse improper for the chace, are the having a large head and a small neck, a large leg and a small foot, and the like. The head of the hunter should indeed always be large, but the neck should also be thick and strong to support it. The head should be lean, the nostrils wide, and the windpipe straight.

The hunter, in order to his behaving well in the field, ought to have great care and indulgence in the stable: he ought to have as much rest and quiet as may be, to be kept well supplied with good meat, clean litter, and fresh water by him; he should be often dressed, and suffered to sleep as much as he pleases. He should be so fed, that his dung may be rather soft than hard, and it must be of a bright and clean colour. All this may be easily managed by the continual observance and change of his food, as occasion requires. After his usual scourings he should have exercises and mashes of sweet malt, or bread and beans; or wheat and beans mixed together, may be his best food, and beans and oats his worst.

Some very great sportsmen are for keeping their horses out at grass all the buck hunting season, never taking them up into the stable at all, but allowing them in the field as many oats with their grass as they will eat. The horse may be thus rid three days in the week for the whole season, and never damaged by it, nor ever showing any marks of harm afterwards.

The whole shape of a horse intended for a hunter, should be this: The ears should be small, open, and pricked; or though they be somewhat long, yet if they stand up erect and bold like those of a fox, it is a sign of toughness or hardness. The forehead should be long and broad; not flat, or, as it is usually termed, *mare-faced*, but rising in the middle like that of a hare; the feather should be placed above the eye, the contrary being thought by some to threaten blindness. The eyes should be full, large, and bright; the nostrils not only large, but looking red and fresh within; for an open and fresh nostril is always esteemed a sign of a good wind. The mouth should be large, deep in the wicks, and hairy. The wind-pipe should be large, and appear straight when he bridles his head; for if, on the contrary, it bends like a bow on his bridling, it is not formed for a free passage of the breath. This defect in a horse is expressed among the dealers by the phrase *cock throppled*. The head should be so set on to the neck, that a space may be felt between the neck and the chine; when there is no such space, the horse is said to be bull-necked; and this is not only a blemish in the beauty of the horse, but it also occasions his wind

not to be so good. The crest should be strong, firm, and well raised; the neck should be straight and firm, not loose and pliant; the breast should be strong and broad, the ribs round like a barrel, the fillets large, the buttocks rather oval than broad, the legs clean, flat, and straight; and, finally, the mane and tail ought to be long and thin, not short and bushy, the last being counted a mark of dulness. When a hunter is thus chosen, and has been taught such obedience that he will readily answer to the rider's signals both of the bridle and hand, the voice, the calf of the leg, and the spurs; that he knows how to make his way forward, and has gained a true temper of mouth, and a right placing of his head, and has learned to stop and to turn readily, if his age be sufficiently advanced, he is ready for the field. It is a rule with all staunch sportsmen, that no horse should be used in hunting till he is full five years old; some will hunt them at four, but the horse at this time is not come up to his true strength and courage, and will not only fail at every tough trial, but will be subject to strains and accidents of that kind, much more than if he were to be kept another year first, when his strength would be more confirmed.

When the hunter is five years old, he may be put to grass from the middle of May till Bartholomew-tide; for the weather between these is so hot, that it will be very proper to spare him from work. At Bartholomew-tide, the strength of the grass beginning to be nipped by frosts and cold dews, so that it is apt to engender crudities in the horse, he should be taken up, while his coat is yet smooth and sleek, and put into the stable. When he is first brought home, he should be put in some secure and spacious place, where he may evacuate his body by degrees, and be brought not all at once to the warm keeping; the next night he may be stabled up. It is a general rule with many not to clothe and stable up their horses till two or three days after they are taken from grass, and others who put them in the stable after the first night, yet will not dress and clothe them till three or four days afterward; but all this, except the keeping the horse one day in a large and cool place, is needless caution.

There is a general practice among the grooms, in many places, of giving their hunters wheat-straw as soon as they take them up from grass. They say they do this to take up their bellies; but there seems much reason to disapprove of this. The change is very violent, and the nature of the straw so heating and drying, that there seems great reason to fear that the astringent nature of it would be prejudicial, more than is at first perceived. It is always found that the dung is hard after this food, and is voided with pain and difficulty, which is in general very wrong for this sort of horse. It is better therefore to avoid this straw-feeding, and to depend upon moderate airing, warm clothing, and good old hay and old corn, than to have recourse to any thing of this kind.

When the horse has evacuated all his grass, and has been properly shod, and the shoes have had time to settle to his feet, he may be ridden abroad, and treated in this manner: The groom ought to visit him early in the morning, at five o'clock in the long days, and at six in the short ones; he must then clean out the stable, and feel the horse's neck, flank, and belly, to find the state of his health. If the flank feels soft and flabby, there is a necessity of good diet to harden it, otherwise any great exercise will occasion swellings and puffiness in the heels. After this examination, a handful or two of good old oats, well sifted, should be given him; this will make him have more inclination to water, and will also make the water sit better on his stomach, than if he drank fasting. After this he is to be tied up and dressed. If in the doing of this he opens his mouth, as if he would bite, or attempts to kick at the person, it is a proof that the teeth of the curry-comb are too sharp, and must be filed blunter. If after this he continues the same tricks,

it is through wantonness, and he should be corrected for it with the whip. The intent of currying being only to raise the dust, this is to be brushed off afterwards with a horse-tail nailed to a handle, or any other light brush. Then he is to be rubbed down with the brush, and dusted a second time; he should then be rubbed over with a wet hand, and all the loose hairs, and what-ever foulness there is, should be picked off. When this is done, and he is wiped dry as at first, a large saddle-cloth is to be put on, reaching down to the spurring place; then the saddle is to be put on, and a cloth thrown over it, that he may not take cold: then rub down his legs, and pick his feet with an iron picker, and let the mane and tail be combed with a wet mane-comb. Lastly, it is a custom to spurt some beer in his mouth just before the leading him out of the stable. He should then be mounted, and walked a mile at least to some running water, and there watered; but he must only be suffered to take about half his water at one drinking.

It is the custom of many to gallop the horse at a violent rate as soon as he comes out of the water; but this is extremely wrong, for many reasons. It endangers the breaking a horse's wind more than any other practice, and often has been the occasion of destroying very good horses. It uses them also to the disagreeable trick we find in many horses, of running away as soon as ever they come out of the water: and with some it makes them averse to drinking, so that they will rather endure thirst, and hurt themselves greatly by it, than bring on the violent exercise which they remember always follows it. The better way is to walk him a little after he is out of the water, then put him to a gentle gallop for a little while, and after this to bring him to the water again. This should be done three or four times, till he will not drink any more. If there is a hilly place near the watering place, it is always well to ride up to it; if otherwise, any place is to be chosen where there is free air and sun. That the creature may enjoy the benefit of this, he is not to be galloped, but walked about in this place an hour, and then taken home to the stable. The pleasure the horse himself takes in these airings when well managed is very evident; for he will gape, yawn, and shrug up his body: and in these, whenever he would stand still to stale, dung, or listen to any noise, he is not to be hindered from it, but encouraged in every thing of this kind.

The advantages of these airings are very evident; they purify the blood, teach the creature how to make his breathing agree with the rest of the motions of his body, and give him an appetite to his food, which hunters and racers that are kept stalled up are otherwise very apt to lose. On returning from airing, the litter of the stable should be fresh, and by stirring this and whistling, he will be brought to stale. Then he is to be led to his stall, and tied up, and again carefully rubbed down; then he should be covered with a linen cloth next his body, and a canvas one over that, made to fit him, and reaching down to his legs. This, as the duke of Newcastle observes, is a custom which we learned of the Turks, who are of all people the most nice and careful of their horses. Over this covering there should be put a body-cloth of six or eight straps; this keeps his belly in shape, and does not hurt him. This clothing will be sufficient while the weather is not very sharp; but in severe seasons, when the hair begins to rise and start in the uncovered parts, a woollen cloth is to be added, and this will always prove fully sufficient.

Different horses, and different seasons, make variety of the degree of clothing necessary; but there always is an obvious rule to point out the necessary changes, the roughness of the coat being a mark of the want of clothing, and the smoothness of it a proof that the clothing is sufficient. Therefore if at any time the hair is found to start, it is a notice that some farther clothing is to be added.

If the horse sweat much in the night, it is a sign that he is over-fed, and wants exercise; this therefore is easily remedied. An hour or more after the horse is come in from his airing, the groom should give him a wisp of clean hay, making him eat it out of his hand; after this let the manger be well cleaned out, and a quartern of oats clean sifted be given him. If he eats up this with an appetite, he should have more given him; but if he is slow and indifferent about it, he must have no more. The business is to give him enough, but not to cloy him with food.

If the horse gets flesh too fast on this home feeding, he is not to be stinted to prevent it, but only his exercise increased; this will take down his flesh, and at the same time give him strength and wind. After the feeding in the morning is over, the stable is to be shut up, only leaving him a little hay on his litter. He need be no more looked at till one o'clock, and then only rubbed down, and left again to the time of his evening watering, which is four o'clock in the summer, and three in the winter. When he has been watered, he must be kept out an hour or two, or more if necessary, and then taken home and rubbed as after the morning watering. Then he is to have a feed of corn at six o'clock, and another at nine at night; and being then cleaned, and his litter put in order, and hay enough left for the night, he is to be left till morning. This is the direction for one day, and in this manner he is to be treated every day for a fortnight; at the end of which time, his flesh will be so hardened, his wind so improved, his mouth so quickened, and his gallop brought to so good a stroke, that he will be fit to put to moderate hunting. During the time that he is used to hunting, he must be ordered on his days of rest exactly as he is directed for the fortnight when he is in preparation; but as his exercise is now greatly increased, he must be allowed a more strengthening food, mixing some old split beans at every feeding with his oats. And if this is not found to be sufficient, the following bread must be given: Let two pecks of old beans and one peck of wheat be ground together, and made into an indifferently fine meal; then knead it into dough with some warm water and a good quantity of yeast; let it lie a time that it may rise and swell, which will make the bread the lighter; then make it into loaves of a peck each, and let it be baked in a slow oven, that it may be thoroughly done without being burnt; when it is taken out of the oven, it must be set bottom upwards to cool; when it is one day old, the crust is to be chipped off, and the crumb given him for food. When this is ready, he should have some of it at least once in the day: but it is not to be made the only food, but some feeds are to be of oats alone, some of oats and this bread, and some of oats and beans mixed together; the making a variety in this manner being the best of all methods of keeping up the appetite, which is often apt to fail.

The day before the horse is to hunt, he must have no beans, because they are hard of digestion, but only some oats with this bread; or if he will be brought to eat the bread alone, that will be best of all. His evening feed should on this day be somewhat earlier than usual; and after this he is only to have a wisp of hay out of the groom's hand till he return from hunting.

HUNTER (Dr. William), a celebrated anatomist and physician, was born on the 23d of May 1718, at Kilbride in the county of Lanerk in Scotland. He was the seventh of ten children of John and Agnes Hunter, who resided on a small estate in that parish called *Long Calderwood*, which had been long in the possession of his family. His great grandfather by his father's side, was a younger son of Hunter of Hunterston, chief of the family of that name. At the age of fourteen his father sent him to the college of Glasgow. In this seminary he passed five years; and by his prudent behaviour and diligence acquired the esteem of the professors, and the reputation of being

a good scholar. His father had designed him for the church; but the idea of subscribing to articles of faith was so repugnant to the liberal mode of thinking he had already adopted, that he felt an insuperable aversion to his theological pursuits. In this state of mind he happened to become acquainted with Dr. Cullen, the late celebrated professor at Edinburgh, who was then just established in practice at Hamilton under the patronage of the duke of Hamilton. Dr. Cullen's conversation soon determined him to lay aside all thoughts of the church, and to devote himself to the profession of physic. His father's consent having been previously obtained, Mr. Hunter, in 1737, went to reside with Dr. Cullen. In the family of this excellent friend and preceptor he passed nearly three years; and these, as he has been often heard to acknowledge, were the happiest years of his life. It was then agreed, that he should go and prosecute his medical studies at Edinburgh and London, and afterwards return to settle at Hamilton in partnership with Dr. Cullen. He accordingly set out for Edinburgh in November 1740; and continued there till the following spring, attending the lectures of the medical professors, and amongst others those of the late Dr. Alexander Monro, who many years afterwards, in allusion to this circumstance, styled himself his *old master*.

Mr. Hunter arrived in London in the summer of 1741, and took up his residence at Mr. afterwards Dr. Smellie's, who was at that time an apothecary in Pall Mall. He brought with him a letter of recommendation to his countryman Dr. James Douglas, from Mr. Foulis printer at Glasgow, who had been useful to the Doctor in collecting for him different editions of Horace. Dr. Douglas was then intent on a great anatomical work on the bones, which he did not live to complete, and was looking out for a young man of abilities and industry whom he might employ as a dissector. This induced him to pay particular attention to Mr. Hunter; and finding him acute and sensible, he desired him to make him another visit. A second conversation confirmed the Doctor in the good opinion he had formed of Mr. Hunter; and without any farther hesitation he invited him into his family, to assist in his dissections, and to superintend the education of his son. Mr. Hunter having accepted Dr. Douglas's invitation, was by his friendly assistance enabled to enter himself as a surgeon's pupil at St. George's Hospital under Mr. James Wilkie, and as a dissecting pupil under Dr. Frank Nichols, who at that time taught anatomy with considerable reputation. He likewise attended a course of lectures on experimental philosophy by Dr. Defaguliers. Of these means of improvement he did not fail to make a proper use. He soon became expert in dissection, and Dr. Douglas was at the expense of having several of his preparations engraved. But before many months had elapsed, he had the misfortune to lose this excellent friend. The death of Dr. Douglas, however, made no change in the situation of our author. He continued to reside with the Doctor's family, and to pursue his studies with the same diligence as before.

In 1743 he communicated to the Royal Society an essay on the Structure and Diseases of articulating Cartilages. This ingenious paper, on a subject which till then had not been sufficiently investigated, affords a striking testimony of the rapid progress he had made in his anatomical inquiries. As he had it in contemplation to teach anatomy, his attention was directed principally to this object; and it deserves to be mentioned as an additional mark of his prudence, that he did not precipitately engage in this attempt, but passed several years in acquiring such a degree of knowledge, and such a collection of preparations, as might insure him success. Dr. Nichols, to whom he communicated his scheme, and who declined giving lectures about that time in favour of the late Dr. Lawrence, did not give him much encouragement to prosecute it. But at

length an opportunity presented itself for the display of his abilities as a teacher. A society of navy surgeons had an apartment in Covent Garden, where they engaged the late Mr. Samuel Sharpe to deliver a course of lectures on the operations of surgery. Mr. Sharpe continued to repeat this course, till finding that it interfered too much with his other engagements, he declined the task in favour of Mr. Hunter; who gave the society so much satisfaction, that they requested him to extend his plan to anatomy, and at first he had the use of their room for his lectures. This happened in the winter of 1746. He is said to have experienced much solicitude when he began to speak in public: but the applause he met with soon inspired him with courage; and by degrees he became so fond of teaching, that for many years before his death he was never happier than when employed in delivering a lecture. The profits of his two first courses were considerable; but by contributing to the wants of different friends, he found himself at the return of the next season obliged to defer his lectures for a fortnight, merely because he had not money enough to defray the necessary expence of advertisements.

In 1747 he was admitted a member of the corporation of surgeons; and in the spring of the following year, soon after the close of his lectures, he set out in company with his pupil, Mr. James Douglas, on a tour through Holland to Paris. His lectures suffered no interruption by this journey, as he returned to England soon enough to prepare for his winter-course, which began about the usual time.

At first he practised both surgery and midwifery; but to the former of these he had always an aversion. His patron, Dr. James Douglas, had acquired considerable reputation in midwifery; and this probably induced Mr. Hunter to direct his views chiefly to the same line of practice. His being elected one of the surgeon men-midwives, first to the Middlesex, and soon afterwards to the British Lying-in-Hospital, assisted in bringing him forward in this branch of his profession, in which he was recommended by several of the most eminent surgeons of that time, who respected his anatomical talents and wished to encourage him. But these were not the only circumstances that contributed to his success. He owed much to his abilities, and much to his person and manner, which eminently qualified him for the practice of midwifery.

In 1750 he seems to have entirely relinquished his views in surgery; as in that year he obtained the degree of Doctor of Physic from the University of Glasgow, and began to practise as a physician. About this time he quitted the family of Mrs. Douglas, and went to reside in Jermyn-street. In the summer of 1751 he revisited his native country, for which he always retained a cordial affection. His mother was still living at Long Calderwood, which was now become his property by the death of his brother James. Dr. Cullen, for whom he always entertained a sincere regard, was then established at Glasgow, and had acquired considerable reputation both as a practitioner and teacher of physic; so that the two friends had the pleasure of being able to congratulate each other on their mutual prosperity. During this visit he showed his attachment to his little paternal inheritance, by giving many instructions for repairing and improving it, and for purchasing any adjoining lands that might be offered for sale. After this journey to Scotland, to which he devoted only a few weeks, he was never absent from London, unless his professional engagements, as sometimes happened, required his attendance at a distance from the capital.

In 1755, on the resignation of Dr. Layard, one of the physicians of the British Lying-in-hospital, we find the governors of that institution voting their "thanks to Dr. Hunter for the services he had done the hospital, and for his continuing in it as one of the physicians:" so that he seems to have been established

in this office without the usual form of an election. The year following he was admitted a licentiate of the Royal College of Physicians. Soon afterwards he was elected a member of the Medical Society; and to the *Observations and Inquiries* published by that society, he at different periods contributed several valuable papers.

In 1762 we find him warmly engaged in controversy, supporting his claim to different anatomical discoveries, in a work intitled *Medical Commentaries*, the style of which is correct and spirited. As an excuse for the tardiness with which he brought forth this work, he observes in his introduction, that it required a good deal of time, and he had little to spare; that the subject was unpleasant, and therefore he was very seldom in the humour to take it up. In this publication he confined himself chiefly to a dispute with the present learned professor of anatomy at Edinburgh, concerning injections of the testicle, the ducts of the lachrymal gland, the origin and use of the lymphatic vessels, and absorption by veins. He likewise defended himself against a reproach thrown upon him by professor Monro senior, by giving a concise account of a controversy he was involved in with Mr. Pott concerning the discovery of the *Hernia Congenita*. It was not long before Mr. Pott took occasion to give the public his account of the dispute; and, in reply, Dr. Hunter added a supplement to his commentaries. No man was ever more tenacious than Dr. Hunter of what he conceived to be his anatomical rights. This was particularly evinced in the year 1780, when his brother communicated to the Royal Society a discovery he had made 25 years before, relative to the structure of the placenta, the communication between it and the uterus, and the vascularity of the spongy chorion. At the next meeting of the society, a letter was read, in which Dr. Hunter put in his claim to the discovery in question. This letter was, followed by a reply from Mr. John Hunter, and here the dispute ended.

In 1762, when the queen became pregnant, Dr. Hunter was consulted: and two years afterwards he had the honour to be appointed physician extraordinary to her majesty. About this time his avocations were so numerous, that he became desirous of lessening his fatigue; and having noticed the ingenuity and assiduous application of the late Mr. William Hewson, F. R. S. who was then one of his pupils, he engaged him first as an assistant, and afterwards as a partner, in his lectures. This connexion continued till the year 1770; when some disputes happened, which terminated in a separation. Mr. Hewson was succeeded in the partnership by Mr. Cruikshank, whose anatomical abilities are deservedly respected.

In 1767 Dr. Hunter was elected a fellow of the Royal Society: and in the year following communicated to that learned body observations on the bones, commonly supposed to be elephants' bones, which have been found near the river Ohio in America. This was not the only subject of natural history on which our author employed his pen; for, in a subsequent volume of the *Philosophical Transactions*, we find him offering his remarks on some bones found in the rock of Gibraltar, and which he proves to have belonged to some quadruped. In the same work, likewise, he published an account of the *nyl-ghau*, an Indian animal not described before. In 1768 Dr. Hunter became a fellow of the Society of Antiquaries; and the same year, at the institution of a Royal Academy of Arts, he was appointed by his majesty to the office of professor of anatomy. This appointment opened a new field for his abilities; and he engaged in it, as he did in every other pursuit of his life, with unabating zeal. He now adapted his anatomical knowledge to the objects of painting and sculpture, and the novelty and justness of his observations proved at once the readiness and extent of his genius. In January 1781 he was unanimously elected to succeed the late Dr. John Fothergill as president of the Me-

dical Society. As his name and talents were known and respected in every part of Europe, so the honours conferred on him were not limited to his own country. In 1780 the Royal Medical Society at Paris elected him one of their foreign associates; and in 1782 he received a similar mark of distinction from the Royal Academy of Sciences in that city.

The most splendid of Dr. Hunter's medical publications was the *Anatomy of the Human Gravid Uterus*. The appearance of this work, which had been begun so early as the year 1751 (at which time 10 of the 34 plates it contains were completed), was retarded till the year 1775, only by the author's desire of sending it into the world with fewer imperfections. This great work is dedicated to the king. In his preface to it, we find the author very candidly acknowledging, that in most of the dissections he had been assisted by his brother Mr. John Hunter, "whose accuracy (he adds) in anatomical researches is so well known, that, to omit this opportunity of thanking him for that assistance, would be in some measure to disregard the future reputation of the work itself." He likewise confesses his obligations to the ingenious artists who made the drawings and engravings; "but particularly to Mr. Strange, not only for having by his hand secured a sort of immortality to two of the plates, but for having given his advice and assistance in every part with a steady and disinterested friendship. An anatomical description of the gravid uterus was a work which Dr. Hunter had in contemplation to give the public. He had likewise long been employed in collecting and arranging materials for a history of the various concretions that are formed in the human body. Amongst Dr. Hunter's papers were found two excellent introductory lectures on anatomy, which have been published by his nephew Dr. Matthew Baillie. Besides these manuscripts, he has also left behind him a considerable number of cases of dissection; mostly relating to pregnant women.

The same year in which the *Tables of the Gravid Uterus* made their appearance, Dr. Hunter communicated to the Royal Society an *Essay on the Origin of the Venereal Disease*. In this paper he attempted to prove, that this dreadful malady was not brought from America to Europe by the crew of Columbus, as had been commonly supposed, although it made its first appearance about that period. After this paper had been read to the Royal Society, Dr. Hunter, in a conversation with the late Dr. Musgrave, was convinced that the testimony on which he placed his chief dependence was of less weight than he had at first imagined, as many of Martyr's letters afford the most convincing proofs of their having been written a considerable time after the period of their dates. He therefore very properly laid aside his intention of giving his essay to the public. In the year 1777 Dr. Hunter joined with Mr. Watson in presenting to the Royal Society a short account of the late Dr. Maty's illness, and of the appearances on dissection; and the year following he published his *Reflections on the Section of the Symphysis Pubis*.

We must now go back a little into the order of time to describe the origin and progress of Dr. Hunter's museum, without some account of which the history of his life would be very incomplete. When he began to practise midwifery, he was desirous of acquiring a fortune sufficient to place him in easy and independent circumstances. Before many years had elapsed, he found himself in possession of a sum adequate to his wishes in this respect; and this he set apart as a resource of which he might avail himself whenever age or infirmities should oblige him to retire from business. After he had obtained this competency, as his wealth continued to accumulate, he formed a laudable design of engaging in some scheme of public utility, and at first had it in contemplation to found an anatomical school in this metropolis. For this purpose, about the year 1765, during the administration of Mr. Grenville, he presented a me-

memorial to that minister, in which he requested the grant of a piece of ground in the Mews, for the site of an anatomical theatre. Dr. Hunter undertook to expend 7000*l.* on the building, and to endow a professorship of anatomy in perpetuity. This scheme did not meet with the reception it deserved. In a conversation on this subject soon afterwards with the earl of Shelburne, his lordship expressed a wish that the plan might be carried into execution by subscription, and very generously requested to have his name set down for a thousand guineas. Dr. Hunter's delicacy would not allow him to adopt this proposal. He chose rather to execute it at his own expence; and accordingly purchased a spot of ground in Great Windmill-street, where he erected a spacious house, to which he removed from Jermyn-street in 1770. In this building, besides a handsome amphitheatre and other convenient apartments for his lectures and dissections, there was one magnificent room, fitted up with great elegance and propriety as a museum. Of the magnitude and value of his anatomical collection some idea may be formed, when we consider the great length of years he employed in the making of anatomical preparations and in the dissection of morbid bodies, added to the eagerness with which he procured additions from the collections of Sandys, Hewson, Falconer, Blackall, and others, that were at different times offered for sale in this metropolis. His specimens of rare diseases were likewise frequently increased by presents from his medical friends and pupils; who, when any thing of this sort occurred to them, very justly thought they could not dispose of it more properly than by placing it in Dr. Hunter's museum. Speaking of an acquisition in this way in one of his publications, he says, "I look upon every thing of this kind which is given to me, as a present to the public; and consider myself as thereby called upon to serve the public with more diligence."

Before his removal to Windmill-street, he had confined his collection chiefly to specimens of human and comparative anatomy and of diseases; but now he extended his views to fossils, and likewise to the promotion of polite literature and erudition. In a short space of time he became possessed of "the most magnificent treasure of Greek and Latin books that has been accumulated by any person now living since the days of Mead." A cabinet of ancient medals contributed likewise much to the richness of his museum. A description of part of the coins in this collection, struck by the Greek free cities, has lately been published by the Doctor's learned friend Mr. Combe. In a classical dedication of this elegant volume to the queen, Dr. Hunter acknowledges his obligations to her majesty. In the preface some account is given of the progress of the collection, which has been brought together since the year 1770 with singular taste, and at the expence of upwards of 20,000*l.* In 1781 the museum received a valuable addition of shells, corals, and other curious subjects of natural history, which had been collected by the late worthy Dr. Fothergill, who gave directions by his will, that his collection should be appraised at 500*l.* under the valuation. This was accordingly done, and Dr. Hunter purchased it for the sum of 1200*l.* The fame of this museum spread throughout Europe. Few foreigners distinguished for their rank or learning visited this metropolis without requesting to see it. Men of science of our own country always had easy access to it. Considered in a collective point of view, it is perhaps without a rival.

Dr. Hunter, at the head of his profession, honoured with the esteem of his sovereign, and in possession of every thing that reputation and wealth could confer, seemed now to have attained the summit of his wishes. But these sources of gratification were embittered by a disposition to the gout, which harassed him frequently during the latter part of his life, notwithstanding his very abstemious manner of living. On Saturday the

15th of March 1783, after having for several days experienced a return of a wandering gout, he complained of great head-ach and nausea. In this state he went to bed, and for several days felt more pain than usual both in his stomach and limbs. On the Thursday following he found himself so much recovered, that he determined to give the introductory lecture to the operations of surgery. It was to no purpose that his friends urged to him the impropriety of such an attempt. He was determined to make the experiment, and accordingly delivered the lecture; but towards the conclusion his strength was so exhausted that he fainted away, and was obliged to be carried to bed by two servants. The following night and day his symptoms were such as indicated danger; and on Saturday morning Mr. Combe, who made him an early visit, was alarmed on being told by Dr. Hunter himself that during the night he had certainly had a paralytic stroke. As neither his speech nor his pulse were affected, and he was able to raise himself in bed, Mr. Combe encouraged him to hope that he was mistaken. But the event proved the Doctor's idea of his complaint to be but too well founded; for from that time till his death, which happened on Sunday the 30th of March, he voided no urine without the assistance of the catheter, which was occasionally introduced by his brother; and purgative medicines were administered repeatedly without procuring a passage by stool. These circumstances, and the absence of pain, seemed to show, that the intestines and urinary bladder had lost their sensibility and power of contraction; and it was reasonable to presume that a partial palsy had affected the nerves distributed to those parts.

By his will, the use of his museum, under the direction of trustees, devolved to his nephew Matthew Baillie, and in case of his death to Mr. Cruikshank for the term of thirty years, at the end of which period the whole collection is bequeathed to the university of Glasgow. He left the sum of 8000*l.* as a fund for the support and augmentation of the collection.

Dr. Hunter was regularly shaped, but of a slender make, and rather below a middle stature. His manner of living was extremely simple and frugal, and the quantity of his food was small as well as plain. He was an early riser; and when business was over, was constantly engaged in his anatomical pursuits, or in his museum. There was something very engaging in his manner and address; and he had such an appearance of attention to his patients, when he was making his inquiries, as could hardly fail to conciliate their confidence and esteem. In consultation with his medical brethren, he delivered his opinions with diffidence and candour. In familiar conversation he was cheerful and unassuming. As a teacher of anatomy he became most deservedly celebrated. He was a good orator; and having a clear and accurate conception of what he taught, he knew how to place in distinct and intelligible points of view the most abstruse subjects of anatomy and physiology. Among other methods of explaining and illustrating his doctrines, he used frequently to introduce some apposite story or case that had occurred to him in his practice; and few men had acquired a more interesting fund of anecdotes of this kind, or related them in a more agreeable manner.

HUNTING, the exercise or diversion of pursuing four-footed beasts of game. See the article GAME. Four-footed beasts are hunted in the fields, woods, and thickets, and that both with guns and grey-hounds. Birds, on the contrary, are either shot in the air, or taken with nets and other devices, which exercise is called *fowling*; or they are pursued and taken by birds of prey, which is called *hawking*. See the articles FOWLING, HAWKING, FALCONRY, SHOOTING, BIRD-Catching, and DECOY, &c.

F de Launay, professor of the French laws, has an express treatise of hunting. From those words of God to Adam, Gen. i. 26 and 28. and to Noah, Gen. ix. 2, 3. hunting was confi-

dered as a right devolved or made over to man; and the following ages appear to have been of the same sentiment. Accordingly we find, that among the more civilized nations it made one of their diversions; and as to the wilder and more barbarous, it served them with food and necessaries. The Roman jurisprudence, which was formed on the manners of the first ages, made a law of it, and established it as a maxim, that as the natural right of things which have no master belongs to the first possessor, wild beasts, birds, and fishes, are the property of whoever can take them first.

But the northern nations of barbarians who over-ran the Roman empire, bringing with them a stronger taste for the diversion, and the people being now possessed of other and more easy means of subsistence from the lands and possessions of those they had vanquished, their chiefs and leaders began to appropriate the right of hunting, and, instead of a natural right, to make it a royal one. Thus it continues to this day; the right of hunting, among us, belonging only to the king, and those who derive it from him.

The hunting used by the ancients was much like that now practised for the rein-deer; which is seldom hunted at force, or with hounds; but only drawn with a blood-hound, and forestalled with nets and engines. Thus did they with all beasts; whence a dog is never commended by them for opening before he has discovered where the beast lies. Hence, they were not in any manner curious as to the music of their hounds, or the composition of their kennel or pack, either for deepness, loudness, or sweetness of cry, which is a principal point in the hunting of our days. Their huntsmen, indeed, were accustomed to shout and make a great noise, as Virgil observes in the third of his Georgics: *Ingentem clamore preme ad retia cer-vum*. But that confusion was only to bring the deer to the nets laid for him.

The Sicilian way of hunting had something in it very extraordinary. The nobles or gentry being informed which way a herd of deer passed, gave notice to one another, and appointed a meeting; every one bringing with him a cross bow or long-bow, and a bundle of staves shod with iron, the heads bored, with a cord passing through them all: thus provided, they came to the herd, and, casting themselves about in a large ring, surrounded the deer. Then, each taking his stand, unbound his faggot, set up his stake, and tied the end of the cord to that of his next neighbour, at the distance of ten feet from one another. Then taking feathers, dyed in crimson, and fastened on a thread, they tied them to the cord; so that with the least breath of wind they would whirl round. Which done, the persons who kept the stands withdrew, and hid themselves in the next covert. Then the chief ranger entering within the line with hounds to draw after the herd, roused the game with their cry; which flying towards the line, were turned off, and, still gazing on the shaking and shining feathers, wandered about as if kept in with a real wall or pale. The ranger still pursued, and calling every person by name as he passed by their stand, commanded him to shoot the first, third, or sixth, as he pleased: and if any of them missed, or singled out another than that assigned him, it was accounted a grievous disgrace. By such means, as they passed by the several stations, the whole herd was killed by the several hands. *Pier. Hieroglyphic. lib. vii. cap. 6.*

Hunting formed the greatest part of the employment of the ancient Germans, and probably of the Britons also, when they were not engaged in war. We are informed by some ancient historians, that this was the case even as late as the third century with the unconquered Britons who lived beyond Adrian's wall; nay, that they subsisted chiefly by the prey they took in this way. The great attachment shown by all the Celtic nations to hunting, however, proceeded most probably from its being a kind of apprenticeship to war. Thus their youth ac-

quired that courage, strength, swiftness, and dexterity in handling their arms, which made them so formidable in time of war to their enemies. Thus also they freed the country from many mischievous animals which abounded in the forests, furnishing themselves also with materials for those feasts which seem to have constituted their greatest pleasure. The young chieftains had thus likewise an opportunity of paying court to their mistresses, by displaying their bravery and agility, and making them presents of their game; nay, so strong and universal was the passion for hunting among the ancient Britons, that young ladies of the highest quality and greatest beauty spent much of their time in the chase. They employed much the same weapons in hunting that they did in war, viz. long spears, javelins, and bows and arrows; having also great numbers of dogs to assist them in finding and pursuing their game. These dogs, we are also told, were much admired among other nations, on account of their swiftness, strength, fierceness, and exquisite sense of smelling. They were of several different kinds, called by different names, and formed a considerable article of commerce. They were highly valued by all the Celtic nations, insomuch that some very comical penalties were inflicted upon those who were convicted of stealing them. From the poems of Ossian also it appears, that the Britons were not unacquainted with the art of catching birds with hawks trained for that purpose; but they seem to have been absolutely ignorant of the method of catching fish; for there is not a single allusion to this art in all the works of that venerable bard. Their ignorance of this art is both confirmed and accounted for by Dio Niceus, who assures us, that the ancient Britons never tasted fish, though they had innumerable multitudes in their seas, rivers, and lakes. "By the by (says Dr. Henry), we may observe that this agreement between the poems of Ossian and the Greek historian, in a circumstance so singular, is at once a proof of the genuine antiquity of these poems, and that the Greek and Roman writers were not so ill informed about the affairs and manners of the ancient Britons as some have imagined."

The Mexicans, whatever imbecility may be imputed to them in other respects, were very dexterous in hunting. They used bows and arrows, darts, nets, snares, and a kind of tubes named *carbottane*, through which they shot by blowing out little balls at birds. Those which the kings and great men made use of were curiously carved and painted, and likewise adorned with gold and silver. Besides the exercise of the chase which private individuals took either for amusement or to provide food for themselves, there were general hunting-matches, sometimes appointed by the king; at others, undertaken with a view to provide plenty of victims for sacrifices. A large wood, generally that of Zacatapec, not far distant from the capital, was pitched upon as the scene of these grand hunting-matches. Here they chose the place best adapted for setting a great number of snares and nets. The wood was inclosed by some thousands of hunters, forming a circle of six, seven, or eight miles, according to the number of animals they intended to take. Fire was then set to the grass in a great number of places, and a terrible noise made with drums, horns, shouting, and whistling. The hunters gradually contracted their circle, continuing the noise till the game were inclosed in a very small space. They were then killed or taken in snares, or with the hands of the hunters. The number of animals taken or destroyed on these occasions was so great, that the first Spanish viceroy of Mexico would not believe it without making the experiment himself. The place chosen for his hunting-match was a great plain in the country of the Otomies, lying between the villages of Xilotepec and S. Giovanni del Rio; the Indians being ordered to proceed according to their usual customs in the times of their paganism. The viceroy, attended by a vast retinue of

Spaniards, repaired to the place appointed, where accommodations were prepared for them in houses of wood erected for the purpose. A circle of more than 15 miles was formed by 11,000 Otomies, who started such a quantity of game on the plain, that the viceroy was quite astonished, and commanded the greater part of them to be set at liberty; which was accordingly done. The number retained, however, was still incredibly great, were it not attested by a witness of the highest credit. On this occasion they kept 600 deer and wild goats, 100 cajotes, with a surprising number of hares, rabbits, and other smaller animals. The plain still retains the Spanish name *Cazadero*, which signifies the "place of the chase."

The Mexicans, besides the usual methods of the chase, had particular contrivances for catching certain animals. Thus, to catch young asses, they made a small fire in the woods, putting among the burning coals a particular kind of stone named *cacalottl*, "raven or black stone," which bursts with a loud noise when heated. The fire was covered with earth, and a little maize laid around it. The asses quickly assembled with their young, in order to feed upon the maize; but while they were thus employed the stone burst, and scared away the old ones by the explosion, while the young ones, unable to fly, were carried off by the hunters. Serpents were taken even by the hands, seizing them intrepidly by the neck with one hand, and sewing up their mouths with the other. This method is still practised. They showed the greatest dexterity in tracing the steps of wild beasts, even when an European could not have discerned the smallest print of their feet. The Indian method, however, was by observing sometimes the herbs or leaves broken down by their feet; sometimes the drops of blood which fell from them when wounded. It is said that some of the American Indians show still greater dexterity in discovering the tracks of their enemies, which to an European would be altogether imperceptible.

Hunting was a favourite diversion of the great and bloody conqueror Jenghiz Khan, if indeed we can apply the word *diversion* to a monster whose mind was set upon the destruction of his own species, and who only endeavoured to make the murder of brutes subservient to that of men, by keeping his soldiers in a kind of warfare with the beasts when they had no human enemies to contend with. His expeditions were conducted on a plan similar to that of the Mexicans already mentioned; and were no doubt attended with still greater success, as his numerous army could inclose a much greater space than all the Indians whom the Spanish viceroy could muster. The East Indian princes still show the same inclination to the chase; and Mr. Blane, who attended the hunting excursions of Asoph Ul Dowlah, vizir of the Mogul empire and nabob of Oude in 1785 and 1786, gives the following account of the method practised on this occasion:

"The time chosen for the hunting party is about the beginning of December; and the diversion is continued till the heats, which commence about the beginning of March, oblige them to stop. During this time a circuit of between 400 and 600 miles is generally made; the hunters bending their course towards the skirts of the northern mountains, where the country is wild and uncultivated. The vizir takes along with him not only his court and seraglio, but a great part of the inhabitants of his capital. His immediate attendants may amount to about 2000; but besides these he is also followed by 500 or 600 horse, and several battalions of regular sepoy with their field pieces. Four or five hundred elephants are also carried along with him; of which some are used for riding, others for fighting, and some for clearing the jungles and forests of the game. About as many sumpter horses of the beautiful Persian and Arabian breeds are carried along with him. A great many wheel carriages drawn by bullocks likewise attend, which are

used chiefly for the convenience of the women; sometimes also he has an English chaise or two, and sometimes a chariot; but all these as well as the horses are merely for show, the visir himself never using any other conveyance than an elephant, or sometimes when fatigued or indisposed a palanquin. The animals used in the sport are principally gre-hounds, of which there may be about 300; he has also about 200 hawks, and a few trained leopards for hunting deer. There are a great number of marksmen, whose profession it is to shoot deer; with many fowlers, who provide game; as none of the natives of India know how to shoot game with small shot, or to hunt with slow hounds. A vast number of matchlocks are carried along with the company, with many English pieces of various kinds, 40 or 50 pairs of pistols, bows and arrows, besides swords, daggers, and sabres without number. There are also nets of various kinds, some for quail, and others very large for fishing, which are carried along with him upon elephants, attended by fishermen, so as always to be ready for throwing into any river or lake that may be met with. Every article that can contribute to luxury or pleasure is likewise carried along with the army. A great many carts are loaded with the Ganges water, and even ice is transported for cooling the drink. The fruits of the season and fresh vegetables are daily sent to him from his gardens by bearers stationed at the distance of every ten miles; by which means each article is conveyed day or night at the rate of four miles an hour. Besides the animals already mentioned, there are also fighting antelopes, buffaloes, and rams in great numbers; also several hundred pigeons, some fighting cocks, with a vast variety of parrots, nightingales, &c.

“To complete the magnificence or extravagance of this expedition, there is always a large bazar, or moving town, which attends the camp; consisting of shop-keepers and artificers of all kinds, money-changers, dancing-women; so that, on the most moderate calculation, the whole number of people in his camp cannot be computed at fewer than 20,000. The nabob himself, and all the gentlemen of his camp, are provided with double sets of tents and equipage, which are always sent on the day before to the place to which he intends to go; and this is generally eight or ten miles in whatever direction most game is expected; so that by the time he has finished his sport in the morning, he finds his whole camp ready pitched for his reception.

“The nabob and the attending gentlemen proceed in a regular moving court or durbar, and thus they keep conversing together and looking out for game. A great many foxes, hares, jackals, and sometimes deer, are picked up by the dogs as they pass along; the hawks are carried immediately before the elephants, and let fly at whatever game is sprung for them, which is generally partridges, bustards, quails, and different kinds of herons; these last affording excellent sport with the falcons or sharp-winged hawks. Wild boars are sometimes started, and either shot or run down by the dogs and horsemen. Hunting the tyger, however, is looked upon as the principal diversion, and the discovery of one of these animals is accounted a matter of great joy. The cover in which the tyger is found is commonly long grass, or reeds of such an height as frequently to reach above the elephants; and it is difficult to find him in such a place, as he commonly endeavours either to steal off, or lies so close to the ground that he cannot be roused till the elephants are almost upon him. He then roars and skulks away, but is shot at as soon as he can be seen; it being generally contrived that the nabob shall have the compliment of firing first. If he be not disabled, the tyger continues to skulk along, followed by the line of elephants; the nabob and others shooting at him as often as he can be seen till he falls. The elephants themselves are very much afraid of this terrible animal, and discover their apprehensions by shrieking and roaring as soon as

they begin to smell him or hear him growl; generally attempting to turn away from the place where he is. When the tyger can be traced to a particular spot, the elephants are disposed of in a circle round him; in which case he will at last make a desperate attack, springing upon the elephant that is nearest, and attempting to tear him with his teeth or claws. Some, but very few, of the elephants, can be brought to attack the tyger; and this they do by curling up their trunks under their mouths, and then attempting to toss, or otherwise destroy him with their tusks, or to crush him with their feet or knees. It is considered as good sport to kill one tyger in a day; though sometimes, when a female is met with her young ones, two or three will be killed.”

The other objects of pursuit in these excursions are wild elephants, buffaloes, and rhinoceroses. Our author was present at the hunting of a wild elephant of vast size and strength. “An attempt was first made to take him alive by surrounding him with tame elephants, while he was kept at bay by crackers and other fire-works; but he constantly eluded every effort of this kind. Sometimes the drivers of the tame elephants got so near him, that they threw strong ropes over his head, and endeavoured to detain him by fastening them around trees; but he constantly snapped the ropes like pack-threads, and pursued his way to the forest. Some of the strongest and most furious of the fighting elephants were then brought up to engage him: but he attacked them with such fury that they were all obliged to desist. In his struggle with one of them he broke one of his tusks; and the broken piece, which was upwards of two inches in diameter, of solid ivory, flew up into the air several yards above their heads. Orders were now given to kill him, as it appeared impossible to take him alive; but even this was not accomplished without the greatest difficulty. He twice turned and attacked the party who pursued him; and in one of these attacks struck the elephant obliquely on which the prince rode, threw him upon his side, but then passed on without offering farther injury. At last he fell dead, after having received as was supposed upwards of a thousand balls into his body.

Notwithstanding the general passion among most nations for hunting, however, it has by many been deemed an exercise inconsistent with the principles of humanity. The late king of Prussia expressed himself on this subject in the following manner: “The chase is one of the most sensual of pleasures, by which the powers of the body are strongly exerted, but those of the mind remain unemployed. It is an exercise which makes the limbs strong, active, and pliable; but leaves the head without improvement. It consists in a violent desire in the pursuit, and the indulgence of a cruel pleasure in the death, of the game. I am convinced, that man is more cruel and savage than any beast of prey: We exercise the dominion given us over these our fellow-creatures in the most tyrannical manner. If we pretend to any superiority over the beasts, it ought certainly to consist in reason; but we commonly find that the most passionate lovers of the chase renounce this privilege, and converse only with their dogs, horses, and other irrational animals. This renders them wild and unfeeling; and it is probable that they cannot be very merciful to the human species. For a man who can in cold blood torture a poor innocent animal, cannot feel much compassion for the distresses of his own species. And, besides, can the chase be a proper employment for a thinking mind?”

The arguments used by this monarch against hunting seem indeed to be much confirmed by considering the various nations who have most addicted themselves to it. These, as must be seen from what has already been said, were all barbarous; and it is remarkable, that Nimrod, the first great hunter of whom we have any account, was likewise the first who oppressed and enslaved his own species. As nations advanced in civilization,

it always became necessary to restrain by law the inclination of the people for hunting. This was done by the wise legislator Solon, lest the Athenians should neglect the mechanic arts on its account. The Lacedemonians, on the contrary, indulged themselves in this diversion without controul; but they were barbarians, and most cruelly oppressed those whom they had in their power, as is evident from their treatment of the Helots. The like may be said of the Egyptians, Persians, and Scythians; all of whom delighted in war, and oppressed their own species. The Romans, on the other hand, who were somewhat more civilized, were less addicted to hunting. Even they, however, were exceedingly barbarous, and found it necessary to make death and slaughter familiar to their citizens from their infancy. Hence their diversions of the amphitheatre and circus, where the hunting of wild beasts was shown in the most magnificent and cruel manner; not to mention their still more cruel sports of gladiators, &c.

In two cases only does it seem possible to reconcile the practice of hunting with humanity; viz. either when an uncultivated country is over-run with noxious animals; or when it is necessary to kill wild animals for food. In the former case, the noxious animals are killed because they themselves would kill if they were allowed to live; but if we kill even a lion or a tyger merely for the pleasure of killing him, we are undoubtedly chargeable with cruelty. In like manner, our modern fox-hunters expressly kill foxes, not in order to destroy the breed of these noxious animals, but for the pleasure of seeing them exert all their power and cunning to save their lives, and then beholding them torn in pieces after being half dead with fatigue.

As sportsmen have invented a set of terms which may not improperly be called the *bunting-language*, our readers would not deem this article complete were we to omit mentioning them.

1. Speaking of beasts as they are in company. They say, a *berd* of harts, and all manner of deer. A *hey* of roes. A *sounder* of swine. A *rouf* of wolves. A *richefs* of martens. A *brace* or *leash* of bucks, foxes, or hares. A *couple* of rabbits or coney.

2. For their lodging. A hart is said to *barbour*. A buck *lodges*. A roe *beds*. A hare *seats* or *forms*. A coney *sits*. A fox *kennels*. A marten *trees*. An otter *watches*. A badger *earths*. A boar *couches*. Hence, to express their dislodging, they say, *Unbarbour* the hart. *Rouse* the buck. *Start* the hare. *Bolt* the coney. *Unkennel* the fox. *Untree* the marten. *Vent* the otter. *Dig* the badger. *Rear* the boar.

3. For their noise at rutting time. A hart *belleib*. A buck *growns* or *troats*. A roe *bellows*. A hare *beats* or *taps*. An otter *wbines*. A boar *freams*. A fox *barks*. A badger *sbrieks*. A wolf *bowls*. A goat *rattles*.

4. For their copulation. A hart or buck goes to *rut*. A roe goes to *tourn*. A boar goes to *brim*. A hare or coney goes to *buck*. A fox goes to *clickitting*. A wolf goes to *match* or *make*. An otter *buntetb* for his kind.

5. For the footing and treading. Of a hart, we say the *slot*. Of a buck, and all fallow-deer, the *view*. Of all deer, if on the grass and scarce visible, the *foiling*. Of a fox, the *print*; and of other the like vermin, the *footing*. Of an otter, the *marks*. Of a boar, the *track*. The hare, when in open field, is said to *fore*; when she winds about to deceive the hounds, she *d ubles*; when she beats on the hard highway, and her footing comes to be perceived, she *pricketb*: in snow, it is called the *trace* of the hare.

6. The tail of a hart, buck, or other deer, is called the *single*. That of a boar, the *wreatb*. Of a fox, the *brush* or *drag*; and the tip at the end, the *chape*. Of a wolf, the *stern*. Of a hare and coney, the *scut*.

7. The ordure or excrement of a hart and all deer is called

fumets or *fumishing*. Of a hare, *crotils* or *crotifing*. Of a boar, *lesses*. Of a fox, the *billing*; and of other the like vermin, the *fuants*. Of an otter, the *spraints*.

8. As to the attire of deer, or parts thereof, those of a stag, if perfect, are the *bur*, the *pearls*, the little *knobs* on it, the *beam*, the *gutters*, the *antler*, the *fur-antler*, *royal*, *fur-royal*, and all at top the *croches*. Of the buck, the *bur-beam*, *brow-antler*, *black-antler*, *advancer*, *palm*, and *spellers*. If the croches grow in the form of a man's hand, it is called a *palmed head*. Heads bearing not above three or four, and the croches placed aloft, all of one height, are called *crowned beads*. Heads having double croches, are called *forked beads*, because the croches are planted on the top of the beam like forks.

9. They say, a *litter* of cubs, a *nest* of rabbits, a squirrel's *dray*.

10. The terms used in respect of the dogs, &c. are as follow: Of gre-hounds, two make a *brace*; of hounds, a *couple*. Of gre-hounds, three make a *leash*; of hounds, a *couple* and *half*. They say, *let slip* a gre-hound; and, *cast off* a hound. The string wherein a gre-hound is led, is called a *leash*; and that of a hound, a *lyome*. The gre-hound has his *collar*, and the hound his *couples*. We say a *kennel* of hounds, and a *pack* of beagles.

Hunting, as practised among us, is chiefly performed with dogs; of which we have various kinds, accommodated to the various kinds of game, as *bounds*, *gre-bounds*, *blood bounds*, *terriers*, &c. See those articles. In the kennels or packs they generally rank them under the heads of *enterers*, *drivers*, *flyers*, *tyers*, &c. On some occasions, nets, spears, and instruments for digging the ground, are also required: nor is the hunting-horn to be omitted.

The usual chases among us are, the *hart*, *buck*, *roe*, *bare*, *fox*, *badger*, and *otter*. We shall here give something of what relates to each of these, first premising an explanation of some general terms and phrases, more immediately used in the progress of the sport itself; what belongs to the several sorts of game in particular being reserved for the respective articles.

When the hounds, then, being cast off, and finding the scent of some game, begin to open and cry; they are said to *challenge*. When they are too busy ere the scent be good, they are said to *babble*. When too busy where the scent is good, to *barwl*. When they run it endwise orderly, holding in together merrily, and making it good, they are said to be in *full cry*. When they run along without opening at all, it is called *running mute*.

When spaniels open in the string, or a gre-hound in the course, they are said to *lapse*. When beagles bark and cry at their prey, they are said to *yearn*. When the dogs hit the scent the contrary way, they are said to *draw amifs*. When they take fresh scent, and quit the former chase for a new one, it is called *bunting change*. When they *hunt* the game by the heel or track, they are said to *bunt count.r*. When the chase goes off, and returns again, traversing the same ground, it is called *bunting the foil*. When the dogs run at a whole herd of deer, instead of a single one, it is called *running riot*.

Dogs set in readiness where the game is expected to come by, and cast off after the other hounds are passed, are called a *relay*. If they be cast off ere the other dogs be come up, it is called *vauntlay*. When, finding where the chase has been, they make a proffer to enter, but return, it is called a *Ulemish*. A lesson on the horn to encourage the hounds, is named a *call*, or a *rebeat*. That blown at the death of a deer, is called the *mort*. The part belonging to the dogs of any chase they have killed, is the *reward*. They say, *take off* a deer's skin; *strip* or *case* a hare, fox, and all sorts of vermin; which is done by beginning at the snout, and turning the skin over the ears down to the tail.

Hunting is practised in a different manner, and with different

apparatus, according to the nature of the beasts which are hunted, a description of whom may be found under their respective articles, *infra*. With regard to the seasons, that for hart and buck-hunting begins a fortnight after midsummer, and lasts till Holy-rood day; that for the hind and doe, begins on Holy-rood day, and lasts till Candlemas; that for fox-hunting begins at Christmas, and holds till Lady-day; that for roe-hunting begins at Michaelmas, and ends at Christmas; hare-hunting commences at Michaelmas, and lasts till the end of February; and where the wolf and boar are hunted, the season for each begins at Christmas, the first ending at Lady-day, and the latter at the Purification.

When the sportsmen have provided themselves with nets, spears, and a hunting-horn to call the dogs together, and likewise with instruments for digging the ground, the following directions will be of use to them in the pursuit of each sort of game.

Badger-HUNTING. In doing this, you must seek the earths and burrows where he lies, and in a clear moonshine night go and stop all the burrows, except one or two, and therein place some sacks, fastened with drawing strings, which may shut him in as soon as he straineth the bag. Some use no more than to set a hoop in the mouth of the sack, and so put it into the hole; and as soon as the badger is in the sack and straineth it, the sack slippeth off the hoop and follows him to the earth, so he lies tumbling therein till he is taken. These sacks or bags being thus set, cast off the hounds, beating about all the woods, coppices, hedges, and tufts, round about, for the compass of a mile or two; and what badgers are abroad, being alarmed by the hounds, will soon betake themselves to their burrows: and observe, that he who is placed to watch the sacks, must stand close and upon a clear wind; otherwise the badger will discover him, and will immediately fly some other way into his burrow. But if the hounds can encounter him before he can take his sanctuary, he will then stand at bay like a boar, and make good sport, grievously biting and clawing the dogs; for the manner of their fighting is lying on their backs, using both teeth and nails; and blowing up their skins, defend themselves against all bites of the dogs, and blows of the men upon their noses. And for the better preservation of your dogs, it is good to put broad collars about their necks made of dried skins.

When the badger perceives the terriers to begin to yearn him in his burrow, he will stop the hole betwixt him and the terriers; and if they still continue baying, he will remove his couch into another chamber or part of the burrow, and so from one to another, barricading the way before them, as they retreat, until they can go no farther. If you intend to dig the badger out of his burrow, you must be provided with the same tools as for digging out a fox; and besides, you should have a pail of water to refresh the terriers, when they come out of the earth to take breath and cool themselves. It will also be necessary to put collars of bells about the necks of your terriers, which making a noise may cause the badger to bolt out. The tools used for digging out of the badger, being troublesome to be carried on men's backs, may be brought in a cart. In digging, you must consider the situation of the ground, by which you may judge where the chief angles are; for else, instead of advancing the work, you will hinder it. In this order you may besiege them in their holds, or castles; and may break their platforms, parapets, casemates, and work to them with mines and countermines until you have overcome them.

Boar-HUNTING. When a boar is roused out of the thicket, he always goes from it, if possible, the same way by which he came to it; and when he is once up, he will never stop till he comes to some place of more security. If it happens that a sinder of them are found together, when any one breaks away, the rest all follow the same way. When the boar is hunted in the

wood where he was bred, he will scarce ever be brought to quit it; he will sometimes make towards the sides to listen to the noise of the dogs, but retires into the middle again, and usually dies or escapes there. When it happens that a boar runs a-head, he will not be stopped or put out of his way, by man or beast, so long as he has any strength left. He makes no doubles nor crossings when chased; and when killed makes no noise, if an old boar; the fows and pigs will squeak when wounded.

The season for hunting the wild boar begins in September, and ends in December, when they go to rut. If it be a large boar, and one that has lain long at rest, he must be hunted with a great number of dogs, and those such as will keep close to him; and the huntsman, with his spear, should always be riding in among them, and charging the boar as often as he can, to discourage him: such a boar as this, with five or six couple of dogs, will run to the first convenient place of shelter, and there stand at bay and make at them as they attempt to come up with him. There ought always to be relays also set of the best and staunchest hounds in the kennel; for if they are of young eager dogs, they will be apt to seize him, and be killed or spoiled before the rest come up. The putting collars with bells about the dogs' necks is a great security for them; for the boar will not so soon strike at them when they have these, but will rather run before them. The huntsmen generally kill the boar with their swords or spears: but great caution is necessary in making the blows; for he is very apt to catch them upon his snout or tusks; and if wounded and not killed, he will attack the huntsman in the most furious manner. The place to give the wound with the spear is either between the eyes in the middle of the forehead, or in the shoulder; both these places make the wound mortal.

When this creature makes at the hunter, there is nothing for it but courage and address: if he flies for it, he is surely overtaken and killed. If the boar comes straight up, he is to be received at the point of the spear: but if he makes doubles and windings, he is to be watched very cautiously, for he will attempt getting hold of the spear in his mouth; and if he does so, nothing can save the huntsman but another person attacking him behind: he will on this attack the second person, and the first must then attack him again: two people will thus have enough to do with him; and were it not for the forks of the boar-spears that make it impossible to press forward upon them, the huntsman who gives the creature his death's wound would seldom escape falling a sacrifice to his revenge for it. The modern way of boar-hunting is generally to dispatch the creature by all the huntsmen striking him at once: but the ancient Roman way was, for a person on foot, armed with a spear, to keep the creature at bay; and in this case the boar would run of himself upon the spear to come at the huntsman, and push forward till the spear pierced him through.

Buck-HUNTING. Here the same hounds and methods are used as in running the stag; and, indeed, he that can hunt a hart or stag well, will not hunt a buck ill. In order to facilitate the chace, the game-keeper commonly selects a fat buck out of the herd, which he shoots in order to maim him, and then he is run down by the hounds.

As to the method of hunting the buck. The company generally go out very early for the benefit of the morning. Sometimes they have a deer ready lodged; if not, the coverts are drawn till one is roused: or sometimes in a park a deer is pitched upon, and forced from the herd, then more hounds are laid on to run the chace. If you come to be at a fault, the old staunch hounds are only to be relied upon till you recover him again: if he be sunk, and the hounds thrust him up, it is called an *imprime*, and the company all sound a reheat: when he is run down, every one strives to get in to prevent his

being torn by the hounds, fallow deer seldom or never standing at bay.

He that first gets in cries *boo up!* to give notice that he is down, and blows a death. When the company are all come in, they paunch him, and reward the hounds; and generally the chief person of quality amongst them *takes say*, that is, cuts his belly open, to see how fat he is. When this is done, every one has a chop at his neck; and the head being cut off, is shewed to the hounds, to encourage them to run only at male deer, which they see by the horns, and to teach them to bite only at the head: then the company all standing in a ring, one blows a single death; which being done, all blow a double recheat, and so conclude the chace with a general halloo of hoo-up, and depart the field to their several homes, or to the place of meeting; and the huntsman, or some other, hath the deer cast across the buttocks of his horse, and so carries him home.

FOX-HUNTING, a very favourite exercise among our country gentlemen, is of two descriptions, viz. either above or below ground.

I. *Above ground.* To hunt a fox with hounds, you must draw about groves, thickets, and bushes near villages. When you find one, it will be necessary to stop up his earth the night before you design to hunt, and that about midnight; at which time he is gone out to prey: this may be done by laying two white sticks across in his way, which he will imagine to be some gin or trap laid for him; or else they may be stopp'd up with black thorns and earth mixed together.

Mr. Beckford is of opinion that for fox-hunting the pack should consist of 25 couple. The hour most favourable for the diversion is an early one; and he thinks that the hounds should be at the cover at sun-rising. The huntsman should then throw in his hounds as quietly as he can; and let the two whippers-in keep wide of him on either hand; so that a single hound may not escape them: let them be attentive to his halloo, and let the sportsmen be ready to encourage or rate as that directs. The fox ought on no account to be halloed too soon, as in that case he would most certainly turn back again, and spoil all the sport. Two things our author particularly recommends, viz. the making all the hounds steady, and making them all draw. "Many huntmen (says he) are fond of having them at their horse's heels; but they never can get so well or so soon together as when they spread the cover: besides, I have often known, when there have been only a few finders, that they have found their fox gone down the wind, and been heard of no more that day. Much depends upon the first finding of your fox; for I look upon a fox well found to be half killed. I think people are generally in too great a hurry on this occasion. There are but few instances where sportsmen are not too noisy, and too fond of encouraging their hounds, which seldom do their business so well as when little is said to them. The huntsman ought certainly to begin with his foremost hounds; and I should wish him to keep as close to them as he conveniently can; nor can any harm arise from it, unless he should not have common sense. No hounds can then slip down the wind and get out of his hearing; he will also see how far they carry the scent, a necessary requisite; for without it he never can make a cast with any certainty. You will find it not less necessary for your huntsman to be active in pressing his hounds forward when the scent is good, than to be prudent in not hurrying them beyond it when it is bad. It is his business to be ready at all times to lend them that assistance which they so frequently need, and which when they are first at a fault is then most critical. A fox-hound at that time will exert himself most; he afterwards cools, and becomes more indifferent about his game. Those huntmen who do not get forward enough to take advantage of this eagerness and impetuosity, and direct it properly, seldom

know enough of hunting to be of much use to them afterwards. Though a huntsman cannot be too fond of hunting, a whipper-in easily may. His business will seldom allow him to be forward enough with the hounds to see much of the sport. His only thought therefore should be to keep the hounds together, and to contribute as much as he can to the killing of the fox: keeping the hounds together is the surest means to make them steady. When left to themselves they seldom refuse any blood they can get; they become conceited; learn to tie upon the scent; and besides this they frequently get a trick of hunting by themselves, and are seldom good for much afterwards.

"Every country is soon known; and nine foxes out of ten, with the wind in the same quarter, will follow the same track. It is easy therefore for the whipper-in to cut short, and catch the hounds again. With a high scent you cannot push on hounds too much. Screams keep the fox forward, at the same time that they keep the hounds together, or let in the tail-hounds: they also enliven the sport; and, if discreetly used, are always of service; but in cover they should be given with the greatest caution. Halloos seldom do any hurt when you are running up the wind, for then none but the tail-hounds can hear you: when you are running down the wind, you should halloo no more than may be necessary to bring the tail-hounds forward; for a hound that knows his business seldom wants encouragement when he is upon a scent. Most fox-hunters wish to see their hounds run in a *good style*. I confess I myself am one of those; I hate to see a string of them; nor can I bear to see them creep where they can leap. A pack of harriers, if they have time, may kill a fox: but I defy them to kill him in the style in which he ought to be killed; they must hunt him down. If you intend to tire him out, you must expect to be tired also yourself; I never wish a chace to be less than one hour, or to exceed two: it is sufficiently long if properly followed: it will seldom be longer unless there be a fault somewhere; either in the day, the huntsman, or the hounds.

"Changing from the hunted fox to a fresh one is as bad an accident as can happen to a pack of fox-hounds, and requires all the ingenuity and observation that man is capable of to guard against it. Could a fox-hound distinguish a hunted fox as the deer hound does the deer that is blown, fox-hunting would then be perfect. A huntsman should always listen to his hounds while they are running in cover; he should be particularly attentive to the headmost hounds, and he should be constantly on his guard against a skirter; for, if there be two scents, he must be wrong. Generally speaking, the best scent is least likely to be that of the hunted fox: and as a fox seldom suffers hounds to run up to him as long as he is able to prevent it; so, nine times out of ten, when foxes are halloed early in the day, they are all fresh foxes. The hounds most likely to be right are the hard running line-hunting ones; or such as the huntsman knows had the lead before there arose any doubt of changing. With regard to the fox, if he break over an open country, it is no sign that he is hard run; for they seldom at any time will do that unless they are a great way before the hounds. Also if he run up the wind; they seldom or never do that when they have been long hunted and grow weak; and when they run their soil, that also may direct him. All this requires a good ear and nice observation; and indeed in that consists the chief excellence of a huntsman.

"When the hounds divide and are in two parts, the whipper-in, in stopping, must attend to the huntsman and wait for his halloo, before he attempts to stop either: for want of proper management in this respect I have known the hounds stopped at both places, and both foxes lost. If they have many scents, and it is quite uncertain which is the hunted fox, let him stop those that are farthest down the wind; as they can

hear the others, and will reach them soonest: in such a case there will be little use in stopping those that are up the wind. When hounds are at a check, let every one be silent and stand still. Whippers-in are frequently at this time coming on with the tail hounds. They should never halloo to them when the hounds are at fault; the least thing does them harm at such a time, but a halloo more than any other. The huntsman, at a check, had better let his hounds alone; or content himself with holding them forward, without taking them off their noses.—Should they be at a fault, after having made their own cast (which the huntsman should always first encourage them to do), it is then his business to assist them further; but except in some particular instances, I never approve of their being cast as long as they are inclined to hunt. The first cast I bid my huntsman make is generally a regular one, not choosing to rely entirely on his judgment: if that should not succeed, he is then at liberty to follow his own opinion, and proceed as observation or genius may direct. When such a cast is made, I like to see some mark of good sense and meaning in it; whether down the wind, or towards some likely cover or strong earth. However, as it is at best uncertain, I always wish to see a regular cast before I see a knowing one; which, as a last resource, should not be called forth till it be wanted. The letting hounds alone is but a negative goodness in a huntsman; whereas it is true this last shows real genius; and to be perfect, it must be born with him. There is a fault, however, which a knowing huntsman is too apt to commit: he will find a fresh fox, and then claim the merit of having recovered the hunted one. It is always dangerous to throw hounds into a cover to retrieve a lost scent; and, unless they hit him in, is not to be depended on.

“Gentlemen, when hounds are at fault, are too apt themselves to prolong it. They should always stop their horses some distance behind the hounds; and if it be possible to remain silent, this is the time to be so. They should be careful not to ride before the hounds or over the scent; nor should they ever meet a hound in the face unless with a design to stop him. Should you at any time be before the hounds, turn your horse's head the way they are going, get out of their track, and let them pass by you. In dry weather, and particularly in heathy countries, foxes will run the roads. If gentlemen at such times will ride close upon the hounds, they may drive them miles without any scent.—High-mettled fox hounds are seldom inclined to stop whilst horses are close at their heels. No one should ever ride in a direction which if persisted in would carry him amongst the hounds, unless he be at a great distance behind them.

“The first moment that hounds are at fault is a critical one for the sport-people, who should then be very attentive. Those who look forward may perhaps see the fox; or the running of sheep, or the pursuit of crows, may give them some tidings of him. Those who listen may sometimes take a hint which way he is gone from the chattering of a magpie; or perhaps be at a certainty from a distant halloo: nothing that can give any intelligence at such a time ought to be neglected. Gentlemen are too apt to ride all together: were they to spread more, they might sometimes be of service; particularly those who, from a knowledge of the sport, keep down the wind: it would then be difficult for either hounds or fox to escape their observation.—You should, however, be cautious how you go to a halloo. The halloo itself must in a great measure direct you; and though it afford no certain rule, yet you may frequently guess whether it can be depended upon or not. At the sowing-time, when boys are keeping off the birds, you will sometimes be deceived by their halloo; so that it is best, when you are in doubt, to send a whipper-in to know the certainty of the matter.”

Hounds ought not to be cast as long as they are able to hunt. It is a common, though not a very just idea, that a hunted fox never stops; but our author informs us that he has known them

stop even in wheel-ruts in the middle of a down, and get up in the middle of the bounds. The greatest danger of losing a fox is at the first finding him, and when he is sinking; at both which times he frequently will run short, and the eagerness of the hounds will frequently carry them beyond the scent. When a fox is first found, every one ought to keep behind the hounds till they are well settled to the scent; and when the hounds are catching him, our author wishes them to be as silent as possible; and likewise to eat him eagerly after he is caught. In some places they have a method of *trecing* him; that is, throwing him across the branch of a tree, and suffering the hounds to bay at him for some minutes before he is thrown among them; the intention of which is to make them more eager, and to let in the tail-hounds; during this interval also they recover their wind, and are apt to eat him more readily. Our author, however, advises not to keep him too long, as he supposes that the hounds have not any appetite to eat him longer than while they are angry with him.

2. *Under ground.* In case a fox does so far escape as to earth, countrymen must be got together with shovels, spades, mattocks, pickaxes, &c. to dig him out, if they think the earth not too great. They make their earths as near as they can in ground that is hard to dig, as in clay, stony ground, or amongst the roots of trees; and their earths have commonly but one hole, and that is straight a long way in before you come at their couch. Sometimes craftily they take possession of a badger's old burrow, which hath a variety of chambers, holes, and angles.

Now to facilitate this way of hunting the fox, the huntsman must be provided with one or two terriers to put into the earth after him, that is, to fix him into an angle; for the earth often consists of many angles: the use of the terrier is to know where he lies; for as soon as he finds him, he continues baying or barking, so that which way the noise is heard that way dig to him. Your terriers must be garnished with bells hung in collars, to make the fox bolt the sooner; besides, the collars will be some small defence to the terriers.

The instruments to dig withal are these: a sharp-pointed spade, which serves to begin the trench where the ground is hardest and broader tools will not so well enter; the round hollowed spade, which is useful to dig among roots, having very sharp edges; the broad flat spade to dig likewise, when the trench has been pretty well opened, and the ground softer; mattocks and pickaxes to dig in hard ground, where a spade will do but little service; the coal-rake to cleanse the hole, and to keep it from stopping up; clamps, wherewith you may take either fox or badger out alive to make sport with afterwards. And it would be very convenient to have a pail of water to refresh your terriers with, after they are come out of the earth to take breath.

Hare-HUNTING. As, of all chaces, the hare makes the greatest pastime, so it gives no little pleasure to see the craft of this small animal for her self-preservation. If it be rainy, the hare usually takes to the high-ways; and if she come to the side of a young grove, or spring, she seldom enters, but squats down till the hounds have over-shot her; and then she will return the very way she came, for fear of the wet and dew that hangs on the boughs. In this case, the huntsman ought to stay an hundred paces before he comes to the wood-side, by which means he will perceive whether she return as aforesaid; which if she do, he must halloo in his hounds, and call them back; and that presently, that the hounds may not think it the counter she came first.

The next thing that is to be observed, is the place where the hare sits, and upon what wind she makes her form, either upon the north or south wind: she will not willingly run into the wind, but run upon a side, or down the wind; but if she form in the water, it is a sign she is sick and mealed: if you hunt

such a one, have a special regard all the day to the brook-fides; for there, and near plashes, she will make all her crossings, doublings, &c.

Some hares have been so crafty, that as soon as they have heard the sound of a horn, they would instantly start out of their form, though it was at the distance of a quarter of a mile, and go and swim in some pool, and rest upon some rush-bed in the midst of it, and would not stir from thence till they have heard the sound of the horn again, and then have started out again, swimming to land, and have stood up before the hounds four hours before they could kill them, swimming and using all subtleties and crossings in the water. Nay, such is the natural craft and subtlety of a hare, that sometimes after she has been hunted three hours, she will start a fresh hare, and squat in the same form. Others having been hunted a considerable time, will creep under the door of a sheep-cot, and hide themselves among the sheep; or, when they have been hard hunted, will run in among a flock of sheep, and will by no means be gotten out from among them till the hounds are coupled up, and the sheep driven into their pens. Some of them (and that seems somewhat strange) will take the ground like a coney, and that is called *going to the vault*. Some hares will go up one side of the hedge and come down the other, the thickness of the hedge being the only distance between the courses. A hare that has been hard hunted, has got upon a quickset hedge, and run a good way upon the top thereof, and then leapt off upon the ground. And they will frequently betake themselves to furze bushes, and will leap from one to the other, whereby the hounds are frequently at fault.

Having found where a hare hath relieved in some pasture or corn-field, you must then consider the season of the year, and what weather it is: for if it be in the spring-time or summer, a hare will not then sit in bushes, because they are frequently infested with pismires, snakes, and adders; but will sit in corn-fields, and open places. In the winter-time, they sit near towns and villages, in tufts of thorns and brambles, especially when the wind is northerly or southerly. According to the season and nature of the place where the hare is accustomed to sit, there beat with your hounds, and start her; which is much better sport than trailing of her from her relief to her form.

After the hare has been started and is on foot, then step in where you saw her pass, and halloo in your hounds, until they have all undertaken it and go on with it in full cry: then retreat to them with your horn, following fair and softly at first, making not too much noise either with horn or voice; for at the first, hounds are apt to overshoot the chace through too much heat. But when they have run the space of an hour, and you see the hounds are well in with it, and stick well upon it, then you may come in nearer with the hounds, because by that time their heat will be cooled, and they will hunt more soberly. But above all things, mark the first doubling, which must be your direction for the whole day; for all the doublings that she shall make afterwards will be like the former; and according to the policies that you shall see her use, and the place where you hunt, you must make your compasses great or little, long or short, to help the defaults, always seeking the moistest and most commodious places for the hounds to scent in.

Lastly: Those who delight in hunting the hare must rise early, lest they be deprived of the scent of her foot-steps.

Stag HUNTING. Gesner, speaking of stag-hunting, observes, that this wild, deceitful, and subtle beast frequently deceives its hunter by windings and turnings. Wherefore the prudent hunter must train his dogs with words of art, that he may be able to set them on and take them off again at pleasure.

First of all, he should encompass the beast in her own layer, and so unharbour her in the view of the dogs, that so they may never lose her slot or footing. Neither must he set upon every

one, either of the herd or those that wander solitary alone, or a little one; but partly by sight, and partly by their footing and fumets, make a judgment of the game, and also observe the largeness of his layer.

The huntsman, having made these discoveries in order to the chace, takes off the couplings of the dogs; and some on horse-back, others on foot, follow the cry, with the greatest art, observation, and speed; remembering and intercepting him in his subtle turnings and headings; with all agility leaping hedges, gates, pales, ditches; neither fearing thorns, down hills, nor woods, but mounting a fresh horse if the first tire. Follow the largest head of the whole herd, which must be singled out of the chace; which the dogs perceiving, must follow; not following any other. The dogs are animated to the sport by the winding of horns, and the voices of the huntsmen. But sometimes the crafty beast sends forth his little squire to be sacrificed to the dogs and hunters, instead of himself, lying close the mean time. In this case, the huntsman must sound a retreat, break off the dogs, and take them in, that is, leam them again, until they be brought to the fairer game; which riseth with fear, yet still striveth by flight, until he be wearied and breathless. The nobles call the beast *a wise hart*, who, to avoid all his enemies, runneth into the greatest herds, and so brings a cloud of error on the dogs, to obstruct their farther pursuit; sometimes also bearing some of the herd into his footings, that so he may the more easily escape by amusing the dogs. Afterwards he betakes himself to his heels again, still running with the wind, not only for the sake of refreshment, but also because by that means he can the more easily hear the voice of his pursuers whether they be far from him or near to him. But at last being again discovered by the hunters and sagacious scent of the dogs, he flies into the herds of cattle, as cows, sheep, &c. leaping on a cow or ox, laying the fore-parts of his body thereon, that so touching the earth only with his hinder feet, he may leave a very small or no scent at all behind for the hounds to discern. But their usual manner is, when they see themselves hard beset and every way intercepted, to make force at their enemy with their horns, who first comes upon him, unless they be prevented by spear or sword. When the beast is slain, the huntsman with his horn windeth the fall of the beast; and then the whole company comes up, blowing their horns in triumph for such a conquest; among whom, the skilfullest opens the beast, and rewards the hounds with what properly belongs to them, for their future encouragement; for which purpose the huntsmen dip bread in the streaming blood of the beast to give to the hounds.

It is very dangerous to go in to a hart at bay; of which there are two sorts, one on land and the other in water. Now, if the hart be in a deep water, where you cannot well come at him, then couple up your dogs: for should they continue long in the water, it would endanger their furbating or foundering. In this case, get a boat, and swim to him, with dagger drawn, or else with a rope that has a noose, and throw it over his horns: for if the water be so deep that the hart swims, there is no danger in approaching him; otherwise you must be very cautious.

As to the land bay, if a hart be burnished, then you must consider the place; for if it be in a plain and open place, where there is no wood nor covert, it is dangerous and difficult to come in to him; but if he be on a hedge-side, or in a thicket, then, while the hart is staring on the hounds, you may come softly and covertly behind him, and cut his throat. If you miss your aim, and the hart turn head upon you, then take refuge at some tree; and when the hart is at bay, couple up your hounds; and when you see the hart turn head to fly, gallop in roundly to him, and kill him with your sword.

The first ceremony, when the huntsman comes in to the death of a deer, is to cry "*ware haunch!*" that the hounds may

not break in to the deer; which being done, the next is the cutting his throat, and there blooding the youngest hounds, that they may the better love a deer, and learn to leap at his throat: then the most having been blown, and all the company come in, the best person who hath not taken say before, is to take up the knife that the keeper or huntsman is to lay across the belly of the deer, some holding by the fore-legs, and the keeper or huntsman drawing down the pizzle, the person who takes say, is to draw the edge of the knife leisurely along the middle of the belly, beginning near the brisket, and drawing a little upon it, enough in the length and depth to discover how fat the deer is; then he that is to break up the deer, first slits the skin from the cutting of the throat downwards, making the arber, that so the ordure may not break forth, and then he paunches him, rewarding the hounds with it.

In the next place, he is to present the same person who took say, with a drawn hanger, to cut off the head of the deer. Which being done, and the hounds rewarded, the concluding ceremony is, if it be a stag, to blow a triple mort; and if a buck, a double one; and then all who have horns, blow a recheat in concert, and immediately a general whoop, whoop.

Otter-HUNTING is performed with dogs, and also with a sort of instruments called *otter-spears*; with which when they find themselves wounded, they make to land, and fight with the dogs, and that most furiously. There is indeed much craft to be used in hunting them; but they may be caught in snares under water, and by river-sides: but great care must be taken, for they bite sorely and venomously; and if they happen to remain long in the snare, they will not fail to get themselves free by their teeth.

In hunting them, one man must be on one side of the river, and another on the other, both beating the banks with dogs; and the beast not being able to endure the water long, you will soon discover if there be an otter or not in that quarter; for he must come out to make his spraints, and in the night sometimes to feed on grass and herbs.

If any of the hounds find out an otter, then view the soft grounds and moist places, to find out which way he bent his head: if you cannot discover this by the marks, you may partly perceive it by the spraints; and then follow the hounds, and lodge him as a hart or deer. But if you do not find him quickly, you may imagine he is gone to couch somewhere farther off from the river; for sometimes they will go to feed a considerable way from the place of their rest, choosing rather to go up the river than down it. The persons that go a-hunting otters, must carry their spears, to watch his vents, that being the chief advantage; and if they perceive him swimming under water, they must endeavour to strike him with their spears, and if they miss, must pursue him with the hounds; which, if they be good and perfectly entered, will go chanting and trailing along by the river-side, and will beat every root of a tree, and cover-bed, and tuft of bulrushes; nay, they will sometimes take water, and bait the beast, like a spaniel, by which means he will hardly escape.

Roe-buck HUNTING is performed in various ways, but most easily in the woods. When these animals are chased, they usually run against the wind, because the coolness of the air refreshes them in their course; therefore the huntsmen place their dogs with the wind: they usually, when hunted, first take a large ring, and afterwards hunt the hounds. They are also often taken by counterfeiting their voice, which a skilful huntsman knows how to do by means of a leaf in his mouth. When they are hunted, they turn much and often, and come back upon the dogs directly; and when they can no longer endure, they take foil, as the hart does, and will hang by a bough in such a manner, that nothing of them shall appear above the water but

their snout, and they will suffer the dogs to come just upon them before they will stir.

The venison of a roe-buck is never out of season, being never fat, and therefore they are hunted at any time; only that some favour ought to be shown the doe while she is big with fawn, and afterwards till her fawn is able to shift for himself; but some roe does have been killed with five fawns in their bellies.

He is not called, by skilful hunters, a *great roe-buck*, but a *fair roe-buck*; the herd of them is called a *bevy*: and if he hath not bevy-grease upon his tail, when he is broken up, he is more fit to be dog's meat than man's meat. The hounds must be rewarded with the bowels, the blood, and feet slit asunder, and boiled all together; this is more properly called a *dose* than a *reward*.

HUNTINGDON, the county town of Huntingdonshire, with a market on Saturday. It is seated on a rising ascent, on the river Ouse, over which is a handsome stone bridge, which leads to Godmanchester. It was once a large place, having no less than fifteen churches, which are now reduced to two; and sends two members to parliament. Huntingdon was the birth-place of Oliver Cromwell. It is 16 miles W. by N. of Cambridge, and 65 N. by W. of London. W. lon. 0. 25. N. lat. 52. 17.

HUNTINGDONSHIRE, a county of England, bounded on the W. and N. W. by Northamptonshire, on the N. E. the E. and S. E. by Cambridgeshire, and on the S. W. by Bedfordshire. It extends 25 miles from N. to S. and about 20 from E. to W. in its broadest part. The principal rivers are the Ouse and Nen. The borders of the Ouse, which flows across the S. E. part, consist of fertile and beautiful meadows. The middle and western parts are finely varied in their surface, fertile in corn, and sprinkled with woods. The whole upland part was, in ancient times, a forest, peculiarly adapted for hunting, whence the name of the county took its rise. The N. E. part consists of fens, which join those of Ely. They are drained, so as to afford rich pasturage for cattle, and even large crops of corn. In the midst of them are some shallow pools, abounding with fish. The largest of these is a lake of considerable size, called Whittlesea Mere. The air is good, except in the fenny parts, which are agueish. Its chief commodities are corn, malt, and cheese; and they fatten abundance of cattle. It sends four members to parliament; and the high sheriff, who is chosen alternately from Cambridgeshire and Huntingdonshire, is sheriff of both counties at the same time.

HUNTSPIL, a small town in Somersetshire, seated at the mouth of the river Parret, five miles N. of Bridgewater, and 143 W. by S. of London. W. lon. 3. 12. N. lat. 51. 11.

HU-QUANG, a province of the kingdom of China, in Asia, which has a great river called *Yang*, and *Tsechiang*, which runs across it from east to west. It is divided into the north and south parts, the former of which contains eight cities of the first rank, and sixty of the second and third; and the latter, seven of the first rank, and five of the second and third. It is a flat, open country, watered every-where with brooks, lakes, and rivers, in which there are great numbers of fish. Here is plenty of wild-fowls; the fields nourish cattle without number, and the soil produces corn, and various kinds of fruits. There is gold found in the sands of the rivers; and in the mines they have iron, tin, &c. In short, there is such a variety of all sorts of commodities, that it is called *the magazine of the empire*.

HURA, in botany; a genus of the monadelphia order, belonging to the monœcia class of plants; and in the natural method ranking under the 38th order, *Tricocœæ*. The amentum of the male is imbricated, the perianthium truncated: there is no corolla; the filaments are cylindrical, peltated on top, and surrounded with numerous or double antheræ. The female has

neither calyx nor corolla; the style is funnel-shaped; the stigma cleft in twelve parts; the capsule is twelve-celled, with a single seed in each cell. There is but one species, *viz.* the crepitans, a native of the West Indies. It rises with a soft ligneous stem to the height of 24 feet, dividing into many branches, which abound with a milky juice, and have scars on their bark where the leaves have fallen off. The male flowers come out from between the leaves upon foot-stalks three inches long; and are formed into a close spike or column, lying over each other like the scales of fish. The female flowers are situated at a distance from them; and have a long funnel-shaped tube spreading at the top, where it is cut into 12 reflected parts. After the flower, the germen swells, and becomes a round compressed ligneous capsule, having 12 deep furrows, each being a distinct cell, containing one large round compressed seed. When the pods are ripe, they burst with violence, and throw out their seeds to a considerable distance. It is propagated by seeds raised on a hot-bed; and the plants must be constantly kept in a stove. The kernels are said to be purgative, and sometimes emetic.

HURDLE, is the name of a kind of sledge used to draw traitors to the place of execution.

HURDLES, in fortification, are made of twigs of willows or osiers interwoven close together, sustained by long stakes. They are made in the figure of a long square, the length being five or six feet, and the breadth three and an half. The closer they are wattled together, the better. They serve to render the batteries firm, or to consolidate the passage over muddy ditches; or to cover traverses and lodgments for the defence of the workmen against fire-works or stones thrown against them.

The Romans had a kind of military execution for mutineers, called *putting to death under the hurdle*. The manner of it was this: The criminal was laid at his length in a shallow water, under an hurdle, upon which stones were heaped, and so pressed down till he was drowned.

HURDLES, in husbandry, certain frames made either of split timber, or of hazle-rods wattled together, to serve for gates in inclosures, or to make sheep-folds, &c.

HURDS, or **HORDS**, of flax or hemp; the coarser parts separated in the dressings from the tear, or fine stuff. See **FLAX**.

HURDWAR, a town of the province of Delhi, where the Ganges first enters the plains of Hindoostan. It is 117 miles N. by E. of the city of Delhi. E. lon. 78. 15. N. lat. 29. 35.

HURL-BONE, in a horse, a bone near the middle of the buttock, falsely supposed to go out of its sockets with a hurt or strain.

HURLERS, a number of large stones, set in a kind of square figure, near St. Clare in Cornwall, so called from an odd opinion held by the common people, that they are so many men petrified, or changed into stones, for profaning the sabbath-day by hurling the ball, an exercise for which the people of that country have been always famous. The hurlers are oblong, rude, and unhewed. Many authors suppose them to have been trophies erected in memory of some battle; others take them for boundaries to distinguish lands. Lastly, others, with more probability, hold them to have been sepulchral monuments.

HURLY-BURLY, in vulgar language, denotes confusion or tumult, and is said to owe its origin to two neighbouring families, Hurleigh and Burleigh, which filled their part of the kingdom with contest and violence.

HURON, a lake of N. America, which lies between 80° and 85° W. lon. and 42° and 46° N. lat. With lake Michigan, which lies to the W. it has a communication by the straits of Michillimackinac; with the lake Superior to the N. E. by

the straits of St. Mary; and with lake Erie to the S. by the straits of Detroit. Its shape is nearly triangular, and its circumference about 1000 miles. The Chipeway Indians live scattered around this lake; and on its banks are found amazing quantities of sand cherries. See **MANATAULIN** and **THUNDER BAY**.

HURRICANE, a general name for any violent storm of wind; but which is commonly applied to those storms which happen in the warmer climates, and which greatly exceed the most violent storms known in this country. Dr. Mosely; in his Treatise on Tropical Diseases, observes, that the ruin and desolation accompanying a hurricane can scarcely be described. Like fire, its resistless force consumes every thing in its track, in the most terrible and rapid manner. It is generally preceded by an awful stillness of the elements, and a closeness and mistiness in the atmosphere, which makes the sun appear red, and the stars larger. But a dreadful reverse succeeding, the sky is suddenly overcast and wild; the sea rises at once from a profound calm into mountains; the wind rages and roars like the noise of cannon; the rain descends in a deluge; a dismal obscurity envelops the earth with darkness; and the superior regions appear rent with lightning and thunder. The earth on these occasions often does and always seems to tremble, whilst terror and consternation distract all nature: birds are carried from the woods into the ocean; and those whose element is the sea, seek for refuge on land; the frightened animals in the field assemble together, and are almost suffocated by the impetuosity of the wind in searching for shelter; which, when found, serves them only for destruction. The roofs of houses are carried to vast distances from their walls, which are beat to the ground, burying their inhabitants under them. Large trees are torn up by the roots, and huge branches shivered off, and driven through the air in every direction, with immense velocity. Every tree and shrub that withstands the shock, is stripped of its boughs and foliage. Plants and grass are laid flat on the earth. Luxuriant spring is changed in a moment to dreary winter. This direful tragedy ended, when it happens in a town, the devastation is surveyed with accumulated horror: the harbour is covered with wrecks of boats and vessels; and the shore has not a vestige of its former state remaining. Mounds of rubbish and rafters in one place, heaps of earth and trunks of trees in another, deep gullies from torrents of water, and the dead and dying bodies of men, women, and children, half buried, and scattered about, where streets but a few hours before were, present the miserable survivors with a shocking conclusion of a spectacle to be followed by famine, and, when accompanied by an earthquake, by mortal diseases.

Philosophers are now inclined to attribute these terrible phenomena to electricity, though the manner in which it acts in this case is by no means known. It seems probable, indeed, that not only hurricanes, but even the most gentle gales of wind, are produced by the action of the electric fluid. See the articles **ELECTRICITY**, **WIND**, **WHIRLWIND**, &c.

HURST, **HYRST**, or **HERST**, are derived from the Saxon *hyrst*, i. e. a wood, or grove of trees. There are many places in Kent, Suffex, and Hampshire, which begin and end with this syllable; and the reason may be, because the great wood called *Andreswald* extended through those countries.

HURST-CASTLE, a castle in Hampshire, not far from Lymington. It is seated on the extreme point of a neck of land, which shoots into the sea toward the Isle of Wight, from which it is distant two miles. In this castle Charles I. was confined previously to his being brought to trial.

H U S B A N D R Y,

IN the extensive signification of the word, implies the art of preparing, cultivating and improving the ground by manures or other means, so as to render it the most fruitful and productive in the easiest manner and at the least expence: but in the more common acceptation of the term, it signifies the business or employment of the farmer; consequently, comprehends the various processes and operations which are necessary in the management of the different articles and products of the farm.

Under this head we shall therefore consider whatever relates to agriculture or the modes of improving the earth, and also the management of the several articles which are produced by it, and which are objects of the attention of the farmer.

I N T R O D U C T I O N.

HUSBANDRY may, with the greatest propriety, be placed at the head of human arts, having a great advantage over all others both in regard to its antiquity and usefulness. It would not, however, be of much utility to trace its origin in the very early ages, or to mark its progressive steps in those which immediately succeeded them. It is here sufficient to observe that it was cultivated with great assiduity by the Chaldeans, the Egyptians, the Phenicians and the Athenians.

We also find that among the ancient Romans husbandry was considered so very honourable an employment, that, in the earliest periods of the republic, the highest praise that could be conferred upon a person was to say of him, that he had well cultivated his spot of ground.

Indeed the most illustrious senators of the empire, in the intervals of public business, applied themselves to the cultivation of this highly useful art.

It also received considerable improvements from their writings. Cato the Censor, Varro, Virgil, Columella and Palladius composed useful works on this important science. But from this period to that of the reign of Constantine Paganatus, husbandry continued in a declining state: that wise emperor, however, caused a large collection of the most useful precepts relating to the art to be extracted from the best writers, and published them under the title of Geoponics. It has even been asserted, that he made this collection with his own hand; which seems not improbable, as it is well known, that after he had conquered the Saracens and the Arabians, he not only practised and encouraged, but studied the arts of peace, fixing his principal attention on this science, as their surest basis. However, after the decease of Constantine, the increasing attention of the people to commerce, and the ignorance and gross superstition of the ages which succeeded, rendered agriculture an almost neglected science. We find no vestiges of any thing tolerably written on this department of knowledge. No new attempts were made to revive or improve it until the year 1478, when the excellent performance of Crescenzo a Florentine roused the slumbering attention of his countrymen, several of whom soon followed his example.

In respect to the state and progress of husbandry in our own country previous to the fourteenth century, we are very imperfectly informed. That it was pretty generally practised, particularly in the eastern, midland, and southern parts of the kingdom, is certain; but of the mode, and the success, we are left almost wholly ignorant. About the close of the fifteenth century, however, it seems to have been cultivated as a science, and received very considerable additions. For at this period

Fitzherbert, Judge of the Common-Pleas, distinguished himself in the practical parts of the art. He appears to have been the first of our countrymen who studied the nature of soils, and the laws of vegetation, with philosophical attention. He published two works on the subject; the first, entitled "*The Book of Husbandry*," in 1534; the second, called "*The Book of Surveying and Improvements*," in 1539. These treatises, being composed at a period when philosophy and science were but just emerging from that gloom in which they had long been involved, were doubtless in many respects erroneous; but they contained the principles of true knowledge, and revived the study and love of an art, the advantages of which were so very obvious. They therefore soon raised a spirit of emulation in the nation, and many works of the same kind successively appeared.

In France, about the year 1600, considerable efforts were made to revive the arts of husbandry, as appears from several important works, such as *Les Moyens de devenir Riche*; and the *Cosmopolite*, by Bernard de Piliilly, an indigent porter.

About the same period, also, the practice of husbandry became more prevalent among this people and the Flemings than that of publishing their improvements on the subject. Their intention evidently was to carry on a private lucrative employment, without instructing their neighbours. Whoever therefore was desirous of knowing their mode of husbandry was under the necessity of visiting that country, in order to make his remarks on their practice. Their principal attention seems to have been directed to keeping the lands clean and in fine tilth. This judicious principle at first led them to undertake the culture of only little farms, which they kept free from weeds, continually turning the ground, and manuring it properly. The soil by this means being brought to a proper degree of cleanliness, health, and richness, the more delicate grasses were attentively cultivated as the safest way of obtaining a certain profit upon a small estate, without the expence of keeping many horses and servants. The advantages of this plan were quickly perceived, and as quickly led to other improvements. The importance of the secret of this husbandry, however, consisted in letting farms on improvement. Of the discoveries of these people concerning the nature of manures, we are not well informed. It is certain, however, that they were the first among modern farmers who ploughed in green crops for the sake of fertilizing the soil; and who confined their sheep at night in large sheds, the floors of which were covered with sand or virgin earth, in order that it might be converted into good manure by the evacuations of these animals.

In England, the progress of improvement in husbandry was considerably retarded at this period by the civil wars. There were, however, several works produced, which tended to revive a taste for the neglected art of agriculture, and it is probable that even Cromwell himself gave encouragement to it.

Sir Hugh Platt, by his application to husbandry, and cultivating the acquaintance and correspondence of the lovers and patrons of agriculture and gardening, promoted in a considerable degree the improvement of the art. Perhaps no man brought so many new kinds of manure into use. This is evident from his account of compost and covered dung-hills, and his useful observations on the fertilizing qualities of salt, street-dirt, and the *fullage* of streets, clay, fuller's-earth, moorish earths, dung-hills made in layers, fern, hair, calcination of all vegetables, malt-dust, willow-tree earth, soaper's ashes, urine, marle, &c.

The excellent observations and ingenious writings of the unfortunate Plattes, as well as those of Hartlib, contributed greatly to the improvement of agricultural knowledge. Indeed the period in which the latter flourished seems to have been an æra when husbandry in this country rose to great perfection, compared with that of former periods. This attention to improve the land was not however of long duration; for we find soon after this, that the improvement of husbandry depended almost solely on the common or unenlightened cultivator of the earth.

About this time Evelyn however inspired his countrymen with the desire of promoting the study of agriculture; and was supported by the valuable labours of the celebrated Jethro Tull. The former, by his excellent Treatises on earth and on planting, and the latter by shewing the superior advantages of the new or drill husbandry, did much to augment and advance the profession; and their united executions opened a new and extensive field of practical enquiry. Other valuable improvements have also been made since that period in English husbandry. Ireland, too, about the middle of the last century, began to extend and improve the art of husbandry. The valuable labours of Blythe seem to have awakened the attention of the people, and stimulated them to the cultivation of agriculture upon better and more rational principles. And the establishment of a society in Dublin, for the purpose of encouraging husbandry, sufficiently shews that considerable attention is now paid to the improvement of this useful art. Lately, indeed, the rapidity of its advancement in that kingdom would seem to have been nearly equal to that which it has made in this country.

Not only France, but many other nations, when peace had been restored by the treaty of Aix-la-Chapelle, turned their attention to the study of agriculture. It was even encouraged publicly by the King of France, and many of the great and rich inhabitants of that country laudably followed his example.

But the distress of that nation, in the war that succeeded, rendered the necessity of promoting this peaceful art still more evident. Different societies and academies were consequently established in different parts of the kingdom, and prize questions proposed, in order to extend and improve the knowledge of husbandry. And the practical observations contained in the writings of the Marquis de Tourbilly tended probably still more to forward the design.

In Switzerland too the same methods were pursued, in order to advance the knowledge of agriculture.

Considerable exertions were also made, about this period, to introduce approved systems of European husbandry into Russia. And for a considerable length of time agriculture has constituted a part of academical education in Sweden, Denmark and Germany; and the different States of Italy, though extremely enfeebled by luxury, have not been wholly inattentive to the art. Their progress has not, however, been rapid, or their improvements numerous.

The new husbandry has also, on several occasions, been applied to the fertile lands of Poland with great advantage by M. de Bieluski. Therefore Holland, probably alone, has exhibited an example of the neglect of husbandry; and now even there the utility of this art begins to be understood.

The fact is, however, that in our own country husbandry has received the greatest improvement. The practical exertions

of many of those who are engaged in this healthy employment have very considerably promoted the advancement of the art, by separating the useful from the visionary. The dissemination of the periodical labours of different provincial societies, which have within these few years been established in the kingdom, have also contributed largely to the same purpose. And the excellent writings of Young, Marshall, Kent, Mills, and a great many others equally valuable, have now created in the mind of the farmer an anxiety for improvement, and taught him the most convenient and economical means of applying new modes of cultivation to different branches of his art.

The utility and influence of so excellent an institution as that of the BOARD OF AGRICULTURE, must also be considerable in rendering improvements in husbandry more numerous, extensive, and important.

But, notwithstanding these different sources from which agriculture has been promoted, the art is still far from having attained that degree of perfection which might have been expected from the great length of time that it has been cultivated; the reason of which would seem to be, that it has been practised without much regard to scientific principles, consequently has derived few advantages from modern improvements in natural philosophy or chemistry. Vague and fortuitous experience has indeed contributed more to the present flourishing state of the art than any general principles deduced from the knowledge which we have lately acquired, either of the process of vegetation, or of the nature of soils. The skill thus fortuitously acquired must however necessarily be partial, and mostly local; even the very terms employed by those who most eminently possess it, are generally of a vague and uncertain signification. Thus, clay is frequently mistaken for marle, marle for chalk, and the first again for loam. The philosophical enquiries which have been made on this important subject have therefore not yet been sufficiently attended to by the practical farmer. Much useful information may however be derived from the researches of Monsieur Du Hamel, and still more from the well-directed experiments of Mr. Tillet. The labours of the illustrious Bergman also deserve considerable attention. Dr. Priestley by his ingenious experiments has likewise thrown new light on many parts of this subject. And the important Chemical Theory of Mr. Lavoisier has led to the explanation of many circumstances which before seemed inexplicable. Valuable discoveries have also been made by Mr. Senebier and Dr. Ingenhoufz; but the fullest information on the subject would seem to be conveyed by the late enquiries of Mr. Hassenfraz.

It is evident, however, from the nature of the subject, that no solid progress can be made in the important art of husbandry, without an attentive application of the principles of chemistry. "Every farmer, says an excellent writer (the Earl of Dundonald), to a certain extent should be a chemist, so that he may be enabled to understand the nature and properties of the several substances in the management of which he is daily engaged; and that, in all his attempts to improve the soil, the success of his operations may no longer depend on guess-work, or on chance, but be regulated by a proper knowledge of the materials he may have to work with, how each may best be applied or acted upon, and what effects will ensue from their different combinations."

P A R T I.

THEORY OF HUSBANDRY.

IT may naturally be supposed, from the very remote period at which this art began to be exercised and attended to, that its theory should approach to a considerable state of perfection.

Such, however, has been the vague manner in which it has been cultivated, such the number and variety of facts which it embraces, and so difficult and tedious the experiments by which

they are to be ascertained, that the science is yet by no means capable of receiving a final arrangement.

It is indeed probably to the peculiar difficulties of the investigation, that the intimate connection of effects with their causes has not been so fully or so extensively traced in this as in some other subjects. In several other sciences, exposed to the united operations of many causes, the effects of each, singly and exclusively taken, may be particularly examined: the experimenter may work with the object constantly in his view; but the mysterious processes of vegetation take place in the dark, exposed to the various and indeterminable influences of the atmosphere, and require a considerable length of time for their completion. Hence the extreme difficulty of determining on what particular circumstance success or failure depends: the diversified experience of a great number of years can only afford rational foundation for a few conclusions. Therefore the industry and attentive experience of many ages must yet be required, in order to form any thing like a perfect theory of this extensively useful science.

SECT. I. *Of the constituent Principles of Soils.*

As a knowledge of the nature of the principles of soils is of the greatest importance to the farmer, and indeed forms the basis of agriculture, it will be necessary to begin by enquiring into their respective properties.

Land, when considered as the basis of different vegetable products, is commonly termed *soil*.

Soils are formed by different combinations of two or more of the primitive earths, viz. the *argillaceous*, the *calcareous*, the *siliceous*, and *magnesian*. Iron also, when it exists in the state of an oxyd calx or earth, frequently enters into the composition of soils.

Argillaceous matter. This forms a large portion of the surface soil of most countries, and is also found in the mineral strata to a very great depth. It is no where found pure, but always more or less mixed with the different earths, and with other materials, such as mineral, vegetable, and animal matters. This earth is the most retentive of moisture of any, by which means it becomes ductile and tenacious; but loses these properties by the action of fire, and is converted into brick.

Calcareous matter. This substance constitutes in many countries not merely the surface or soil, but also the under stratum to a considerable depth. Under this general title may be included chalk, marble, limestone, coral, shells, &c. The three first are frequently mixed with iron, and with different proportions of the simple earths; but are considered as calcareous when the proportion of that earth predominates. This matter is capable of absorbing and retaining moisture, though in considerably less degree than clay. When sufficiently acted upon by fire it becomes lime, and returns again to the state of chalk or calcareous matter on being exposed for some time to the atmosphere.

Siliceous matter. Extensive tracts of the surface of the earth in different countries are of this kind; and large masses of the under stratum also consist of the same substance: the former in the state of loose sand, and the latter in an indurated or solid state, denominated sand-stone or free-stone. It is the least retentive of moisture of all the different earths.

Magnesian earth. This earth is no where found in such quantities as to form a soil of itself; but it is contained in various proportions in different soils, and forms a component part of steatites or soap rock. It is to a certain degree retentive of moisture.

It may here be necessary to attend more fully to these substances, as constituting the different soils, which for our purpose may be considered as the following, viz. *clay, chalk, sand,*

gravel, loam, clayey loam, chalky loam, sandy loam, gravelly loam, ferruginous loam, boggy soil, and brathy soil.

Clay. This is of various colours, as white, grey, brownish-red, brownish black, yellow, and blue; it feels smooth and somewhat unctuous; if moist it adheres to the fingers, and when sufficiently so, becomes tough and ductile, as has been already observed. In its dry state it adheres more or less to the tongue; when thrown into water it gradually diffuses itself through it, and separates slowly from it. With acids it does not usually effervesce, unless a strong heat be applied, or it should contain some calcareous particles, or magnesia.

The blue, the red, and the white clays, if strong, are said to be unfavourable to vegetation; but the stony and looser sorts much less so. However, none of them are valuable until their texture be loosened by a mixture of other substances, by which means other agents in vegetation are admitted to operate upon them. The proportions of argill or *pure clay*, sand, and ferruginous matter, which are commonly contained in this substance, are extremely various. The first is, however, generally in a very large proportion to the other two. Soils of this kind must therefore obviously be retentive of humidity, in proportion to the quantity of the argillaceous or principal ingredient.

Chalk, when not very impure, is of a white colour, moderate hardness, and dusty surface, soils the fingers, adheres slightly to the tongue, does not harden on heating, but in a strong fire burns to lime, and loses very considerably of its weight. It effervesces, and almost entirely dissolves in acids; but the solution is not disturbed by ammoniac or caustic volatile alkali. It promotes putrefaction in substances to which it is applied.

A soil of this kind, when little mixed with other substances, is always unproductive. It therefore requires a due admixture of other earths, and a proper quantity of vegetable and animal matters, in order to render it fertile and productive.

Sand. This substance is generally met with in small loose particles or grains, of considerable hardness, which do not cohere with water or become soft by it. It is most commonly of the siliceous kind, and consequently insoluble in acids.

Gravel. The principal variation of this from the above substance is in the magnitude of the particles. Stones which are of a calcareous quality, when small and rounded in shape, are frequently comprehended under this appellation.

Soils which are principally constituted of these two substances are barren, and consequently require considerable labour and expence to improve or render them capable of producing good crops.

Loam. By this term is understood any soil which has a moderate degree of cohesion; that is, one which has less than clay and more than loose chalk. Some writers, however, give a different definition of it. The intelligent author of the *Body of Agriculture* calls it a clay mixed with sand; and by Doctor Hill it is said to be an earth composed of dissimilar particles, hard, stiff, dense, harsh, and rough to the touch, not easily ductile while moist, readily dissoluble in water, and composed of sand with a tough viscid clay.

Clayey loam is that kind of compound soil in which, besides being moderately cohesive, the argillaceous ingredient predominates. Its coherence is consequently greater than that of any other loam, but still less than that of pure clay. The other substance of which it is composed is a *coarse* sand, with or without a slight mixture of calcareous matter. By those who are engaged in cultivating the ground, this is commonly denominated *strong, stiff, cold, or heavy* loam, in proportion to the quantity of clay which it contains.

Chalky loam is a term which denotes a compound soil that is composed of clay, coarse sand, and chalk; but in which the

calcareous or chalky part considerably predominates. It is found to be less cohesive than clayey loams.

Sandy loam furnishes us with an example of that sort of loam or soil in which the sandy part is most abundant. It has less coherence than either of those which have been just mentioned. Sand partly coarse and partly fine constitutes from eighty to ninety parts out of each hundred of this kind of soil.

Gravelly loam varies from the above only in this, that it contains a larger proportion of the coarse sand, or pebbles. This, and the two which have been just described, are generally termed, by those employed in farming, *light* or *hungry* soils, especially when their depth is not considerable.

Ferruginous loam. This denotes a soil which is generally of a dark brown, or reddish colour, and is much harder than any of those which have been described above. It is formed of clay and the oxyds or calces of iron more or less intimately blended together. It is capable of being distinguished not only by its colour, but also by its superior weight. It is sometimes found to effervesce with acids, at other times not; but when it does, a considerable portion of the iron part may be separated by proper chemical processes.

Some, which have been called *vitriolic soils* have a near relation to this. These are generally of a blue colour, but when heated become of a red cast.

Boggy soil. This is a soil which is chiefly composed of the ligneous roots of decayed vegetables, mixed with earth generally of the argillaceous kind, with sand, and a coaly substance produced from decayed vegetable matter. There are two kinds of bogs, viz. the *black*, which contains a large proportion of clay and of roots more perfectly rotten and destroyed, with a mineral oil; and the *red*, in which the roots of the vegetables appear less perfectly decayed, but to constitute the principal part of the soil.

Heathy soil. This is that kind of soil in which there is a natural tendency to the production of heath.

Having thus briefly explained the nature of the constituent principles of various kinds of soil, we shall proceed to the consideration of the nature of the different substances which may be employed as manures.

SECT. II. *Of the Substances and Operations employed for improving Soils.*

By the term manure is understood any substance by means of which a soil is improved; and the improving a soil signifies the rendering it capable of producing corn, legumens, the most useful grasses, &c. Some operations in farming have also a similar tendency.

Those substances which have principally been employed as manures, are chalk, lime, clay, sand, marle, gypsum, ashes, stable-dung, mucks, farm-yard dung, pounded bones, sea-weeds, sweepings of ditches, old ditches, and such-like materials. The other kinds of manures or top-dressings, as they are used chiefly to promote the growth of vegetables, and not merely with a view to improve the soil, must be considered in a subsequent part of the Treatise.

With respect to the operations which have been made use of to improve soils, they may be reduced to the following, viz. fallowing, draining, paring and burning.

Clays. These substances have yet been but little employed for the purposes of improving the ground. It is however known, that a proper mixture of clay with other substances contributes to some important purposes: it keeps in the soils to which it is applied, the attenuated particles of animal, vegetable, and oily matters. The general qualities of these substances have been shewn above.

Chalk. We have already described the general properties of this substance. It is found to be a pretty durable manure when

applied to those soils with which it agrees; but has perhaps been used with too little discrimination by the practical farmer. Of the different kinds of chalk, that which is hard, dry, and firm is much the properest for burning into lime; but that which is fat and unctuous is more proper to be used in the crude state as a manure. Chalk, as being saturated with carbonic acid gas, or fixed air, is not by any means so powerful as lime in promoting the destruction of the texture of organic bodies; it has however a considerable action on such substances.

Sand. This substance may be usefully employed in the improvement of soils. It has been chiefly used for the purpose of loosening and rendering less compact such soils as were too firm and coherent. By this means lands have frequently been rendered fertile, and capable of producing good vegetables. The properties of sand have been considered in the preceding section.

Lime. This is a substance whose external characters and mode of production are very generally known. It differs from chalk and powdered limestone chiefly by the absence of carbonic acid gas or fixed air, which is expelled from these during their calcination. It eagerly re-absorbs this air from the atmosphere, and all other bodies with which it comes in contact, and which can furnish it; but it cannot unite with the air, unless it is previously moistened. One hundred parts of quick-lime absorb about twenty-eight of water. It is soluble in about seven hundred parts of this fluid. To regain its full portion of air from the atmosphere, it requires a considerable length of time, even a year or more, if not purposely spread out. When in a dry state it resists putrefaction; but with the assistance of moisture it resolves organic substances into a mucus very speedily. All lime is good as a manure, but that which is made from stone is said to be better than that from chalk.

Marle. Of this substance there are three sorts; *calcareous*, *argillaceous*, and *siliceous* or *sandy*. All these are mixtures of mild calx or chalk with clay, in such a manner as to fall to pieces, on being exposed to the atmosphere, more or less readily.

Calcareous marle. This is that kind which is most commonly understood by the term *marle* without addition. It is generally of a yellowish-white, or yellowish-grey colour; but rarely brown or lead-coloured. It is seldom found on the surface of land, but commonly a few feet under it, and on the sides of hills, or rivers that flow through calcareous countries, or under turf in bogs. It is frequently of a loose texture, sometimes moderately coherent; rarely of a stony hardness, but when in this state is called *stone-marle*. Sometimes of a compact, sometimes of a lamellar texture; often so thin as to be called *paper-marle*. It often abounds with shells, and then is called *shell-marle*; which is looked upon as the best sort. When in powder, it feels dry between the fingers; put in water, it quickly falls to pieces or powder, and does not form a viscid mass. It chips and moulders by exposure to the air and moisture, sooner or later, according to its hardness and the proportion of its ingredients: if heated, it does not form a brick, but lime. It effervesces with all acids. It consists of from thirty-three to eighty parts of mild calx, and from sixty-six to twenty of clay, in the hundred.

In order to find its composition, Mr. Kirwan gives the following directions: Pour a few ounces of weak but pure spirit of nitre or common salt into a Florence flask; place them in a scale, and let them be balanced; then reduce a few ounces of dry marle into powder, and let this powder be carefully and gradually thrown into the flask, until after repeated agitation no effervescence is any longer perceived: let the remainder of the powdered marle be then weighed, by which the quantity projected will be known: let the balance be then restored: the difference of weight between the quantity projected and that requisite to restore the balance will discover the weight of air lost during effervescence: if the loss amounts to thirteen in the hundred of

the quantity of marle projected, or from thirteen to thirty-two, the marle essayed is calcareous marle. This experiment is decisive, when we are assured by the external characters above mentioned, that the substance employed is marle of any kind; otherwise some sorts of the sparry iron-ore may be mistaken for marle.

Argillaceous marle. This kind of marle contains from sixty-eight to eighty parts in the hundred of clay, and consequently from thirty-two to twenty of aerated calx. Its colour is grey or brown, or reddish-brown, or yellowish, or blueish-grey. It feels more unctuous than the former, and adheres to the tongue: its hardness is generally much greater. In water it falls to pieces more slowly, and often into square pieces: it also moulders more slowly by exposure to the air and moisture, if of a loose consistence: it hardens when heated, and forms an imperfect brick. It effervesces with spirit of nitre or common salt, but frequently refuses to do so with vinegar. When dried and projected into spirit of nitre in a Florence flask, with the attentions above mentioned, it is found to lose from eight to ten parts in the hundred of its weight. The undissolved part, well washed, will, when properly heated, harden into a kind of brick.

Siliceous, or sandy marles. These are marles the clayey part of which contains an excess of sand: for, if treated with acids in the manner above mentioned, the residuum or clayey part will be found to contain above seventy-five parts in the hundred of sand; consequently chalk and sand are the predominant ingredients in them.

With regard to the colour of this marle, it is brownish-grey, or lead-coloured; generally friable and flakey, but sometimes forms very hard lumps. It does not readily fall to pieces in water. It chips and moulders by exposure to the air and moisture, but slowly. It effervesces with acids; but the residuum after solution will not form a brick, as in the above kind.

Limestone-gravel. This is found to be a marle mixed with large lumps of limestone. The marle may be either calcareous or argillaceous; but it is most commonly of the former kind; and the sandy part is also generally calcareous.

Gypsum. This substance is a compound of calcareous earth and vitriolic acid, and forms a distinct species of the calcareous genus of fossils; of which species there are many different families. The general characters of this species are the following: It is soluble in about five hundred times its weight of water, in the temperature of sixty degrees; and is precipitated therefrom by all mild alkalis, and also by caustic fixed, but not by ammoniac or caustic volatile, alkali; does not effervesce with acids, if the gypsum be pure; but some families of this species, being contaminated with mild calx, slightly effervesce; is insoluble, or nearly so, in the nitrous acid, in the usual temperature of the atmosphere, having a *specific gravity* reaching from 216 to 231; and a degree of *hardness* such as to admit being scraped by the nail. When heated nearly to redness, it calcines; and if then it be slightly sprinkled with water, it again concretes and hardens. It promotes putrefaction in a very high degree.

It will here only be necessary to describe one of the families of this species; namely, that which has been most advantageously employed as a manure. It is called *fibrous gypsum*; and its colours are grey, yellowish or reddish, or silvery white, or light red, or brownish-yellow, or striped with one or more of these dark colours. It is composed of fibres or stræ either straight or curved, parallel or converging to a common centre, sometimes thick, sometimes fine and subtil, adhering to each other, and very brittle: its hardness such as to admit being scraped with the nail: commonly semitransparent; in some, often in a very considerable degree.

Asbes. Substances of this kind have frequently been employed as manures. Sifted coal-ashes, those of peat and white turf-ashes, have been found the most useful; red turf-ashes have appeared to be not only useless, but generally hurtful. Wood-ashes

have however been employed advantageously in many cases: they contain, as Mr. Bergman asserts, the four primitive earths, but according to Achard, chiefly calcareous earths; and according to D'Arcet, calcareous and magnesian earth. They also contain some proportion of phosphorated selenite, or calcareous earth united to the phosphoric acid; and almost all of them contain also a small and variable proportion of common salt, Glauber's salt, and terrene salts, which, when in a small quantity, all accelerate putrefaction; also small bits of charcoal are to be met with among them.

Charcoal. This is a substance very well known; and which has frequently and successfully been used as a manure. The most convenient mode of applying it seems to be in the form of dust.

Soap-boiler's waste. This has been found to form an excellent manure for some soils: it contains, as appears from the excellent analysis of Mr. Ruckert, fifty-seven parts in the hundred of mild calx, eleven of magnesia, six of argill, and twenty-one of silex.

Stable-dung. Manure of this kind is used either fresh or putrefied; the first is called *long*, the other *short dung*; it abounds in animal matter, easily runs into putrefaction, and when putrefied serves as a leaven to hasten the decay of other dead vegetable substances: its fermentation is promoted by frequent agitation and exposure to the air: it should however be covered, to prevent water from carrying off most of its important ingredients; or at least the water that imbibes them should not be permitted to be dissipated.

Farm-yard dung. This manure consists of various vegetables, such as straw, weeds, leaves, fern, &c. impregnated with animal matter; it ferments more slowly than the former; should be piled in heaps, and stirred from time to time. Fern putrefies very slowly. The water that issues from it should be preserved with great care.

On the subject of stable and farmyard dung the Earl of Donald has many judicious observations. When animal dung and vegetable are mixed together, such as horse-dung, urine, straw and hay, a degree of heat is generated and disengaged by the absorption of oxygen or vital air, and water is decomposed. As the process of putrefaction proceeds, ammoniac or volatile alkali is formed; and, in its tendency to escape from the heap, combines with such parts of the vegetables and matters of the dung as had advanced to the oxygenated state; forming therewith a saponaceous saline matter. The formation of this saponaceous matter in the greatest possible quantity will be promoted by mixing and covering the dung with a due proportion of earth. Hence the dung of hot-beds is the most completely rotted, and most assimilated to this saponaceous saline state, in which state it is more capable of promoting vegetation than dung that has not arrived to an equally advanced state of putrefaction.

This ingenious writer also suggests it as probable, that the particular advantages arising from the use of long dung or litter in some cases depend on the atmospheric air contained in the intervals of the soil made by the straw or litter suffering a degree of separation or decomposition in its imprisoned state, by which means the pure air or oxygen may combine with the straw and inflammable or vegetable matter in the soil; while the azote or phlogisticated air will contribute to the growth of the plants. This explanation of the beneficial effects arising to vegetation by a stagnated air, will also, he thinks, account for the benefit which plants of a certain construction of stem and leaf, and which very much overshadow and cover the ground, ultimately receive by preventing a free circulation of air.

In the application of long and short kinds of dung, preference should in general be given to such as has most completely undergone the putrefactive process. Dung and urine newly

voided are not in a putrescent state; they are only advancing towards putridity, or in a very small degree putrid. The further putrescency of these substances is promoted by a due degree of heat and moisture, particularly when aided by certain saline matters. The most powerful of these are the neutral salts, containing the sulphuric or vitriolic acid, such as vitriolated tar-

tar, Glauber's salt, Epsom salt, and gypsum. These neutral salts, on being mixed with putrescent substances, are changed into the state of hepar: hence the very offensive smell arising from dung and other matters containing such salts. The best means of forming dunghills &c. will be mentioned in the practical part of the Treatise.

Table of the Constituent Principles of Manures, as given by Mr. Kirwan.

105 lb.	Heavy Inflamm. Air. Cub. Inc.	Fixed Air. Cub. Inc.	Water. lb.	Coal. lb.	Calx and Magnesia. lb.	Argill. lb.	Silex. lb.	Vol. Alk. lb.	Fixed Salts. lb.
Fresh cow-dung -	—	—	—	3,75	1, 2	0,15	2, 4	—	0, 6
Fresh horse-dung -	—	—	88	10,2	1, 5	0,5	3	—	0,21
Sheeps dung -	—	—	—	25,0	9,28 Calx. 1, Magn.	3	29	—	0,72
Rotten cow-dung -	1360	120	81	10	3.	0,6	5	0.65	Gyps. 0,9
Earth resulting from rotten horse-dung -	1.64	1.	Water and oil 38,15	18,75	6, 2	1, 5	23,43		F. Salts, 0,24
Soapboilers waste -									

It is evident therefore that manures should not be applied indiscriminately, but according to circumstances, which will be shewn in its proper place.

Pounded bones. These also form a manure much used in the neighbourhood of great towns. They gradually deposit their oily part, which contains a large proportion of animal coal, which is extricated by putrefaction, and phosphorated calx. Hence bone-ash is also found to be serviceable.

Sea-weed. These weeds, particularly if mixed with earth, soon putrefy, and make manure of an excellent quality.

Sweepings of ditches. These abound with putrid matter from decayed vegetables, and consequently form a manure which is very useful.

Old ditches. These, from their exposing a large surface to vegetation, contain, when destroyed, a quantity of decayed vegetables, which putrefy and make a good manure; but both in this and the former case, it may be proper to distinguish of what soil they are composed, for reasons that will hereafter be mentioned.

Draining. This is an operation which is frequently essentially necessary, and which is well known to the practical farmer. It is an extensively useful process in moist and wet countries, and must generally be accomplished before the land can be cultivated or improved. See DRAINS.

Under-draining seems at present to be deservedly gaining the attention and becoming the practice of intelligent farmers. This is a method that unquestionably prevents the waste of much useful land, that more certainly and more completely fulfils the intention with which it is made, that is of much longer duration, and, what is still a greater recommendation, that is finally much less expensive. The ingenious author just quoted has remarked, that a method has lately been discovered and practised with success, by which, in many places, the upper stratum is drained by the assistance of the mineral strata which are beneath it, through which the water is made to drop, and thus taken from the surface. By these means, and by open drains, lands are principally to be rendered dry: there are, however, a few other methods of a different kind, but which must be inserted in another part of this Treatise.

Fallowing. This is one of the principal operations by which exhausted lands are restored to fertility; its use seems to Mr. Kirwan to consist in exposing the roots of vegetables to decay, whereby food for a fresh growth is prepared; the atmosphere also deposits fixed air and carbonaceous substance on earth which has been long exposed to its influence.

Paring and burning. By these means the roots of vegetables are reduced to coal and ashes; and thus are prepared both a stimulant and nutriment for plants. It is a comburatory dissipating process, by which nineteen parts out of twenty of the vegetable matter, the only substance the fire can act upon, is dissipated and carried off by the air. From this process having been injudiciously employed, and carried to such an excess, by the frequency of its repetition, as to destroy almost the whole of the vegetable matter contained in lands to which it has been applied, it is now become much less frequent in this country; and in Ireland it is said to be entirely prohibited. In a subsequent part of the work we shall speak of the manner in which it may be advantageously employed, and of the kinds of land in which it is most likely to be useful.

SECT. III. Of the Food of Plants.

In the two preceding sections we have considered the principles and the nature of the different soils known in agriculture, and described the different substances or manures, the general utility of which has been ascertained by long experience. We shall now therefore enquire which of these manures are most advantageously applicable to each of those particular soils, and what are the causes to which their beneficial effects in each particular instance are to be ascribed.

But in order to proceed with method in this enquiry, it must be observed, that the general effect expected from the application of manure is fertility; that is, the most copious production of corn, grasses, and other herbage; and that since fertility is itself the result of the due administration of the food of those vegetables, it must first be seen what that food is, and of what ingredients a soil ought to be composed, in order to contain or administer it; after which we shall endeavour to shew by what manures each particular sort of soil is brought into a fertile

state, which is the advantage to be expected from them, and how in each particular instance they contribute to the due administration of the vegetable food, which is the cause by which their beneficial effect is produced.

In order to discover the food of plants, especially of those which form the object of our present enquiry, it will be necessary to examine the nature and proportion of the substances in which they grow, and of those which they themselves contain: thus we shall be enabled to determine which of the latter are derived from the former, and to make other useful conclusions.

In the first place, all plants, excepting the subaqueous, grow in a mixed earth, moistened with rain and dew, and exposed to the atmosphere. Mr. Kirwan observes, that if this earth be chemically examined, it will be found to consist of siliceous, calcareous, and argillaceous particles, often also of magnesia, in various proportions, a very considerable quantity of water, and some fixed air. The most fertile, also, contain a small proportion of oil, roots of decayed vegetables, a coaly substance arising from putrefaction, some traces of marine acid, and gypsum. But if, on the other hand, vegetables be analysed, they will be found to contain a large proportion of water and charcoal; also fat and essential oils, resins, gums, and vegetable acids; all which are reducible to water, pure air, inflammable air, and charcoal: a small proportion of fixed alkali is also found, some neutral salts, most commonly gypsum, tartar vitriolate, common salt, and salt of sylvius. In corn, and particularly wheat, phosphorated selenite is also met with.

It is evident therefore that, on the last analysis, the only substances common to the growing vegetables and the soils in which they grow, are water, coal, different earths, and salts. These, then, are the true food of vegetables: to them we should however add fixed air, though, by reason of its decomposition, it may not be distinctly found in them, or at least not distinguishable from that newly formed during the decomposition of these substances.

According to the Earl of Dundonald, however, vegetables are nourished, supported, and formed by air, water, earth, heat, light, and certain saline substances; and in a particular manner by their own *exuviae* or remains, when reduced to a state fit to answer that purpose.

And the Rev. Doctor Gregory, in his useful work, the Economy of Nature, observes that the nourishment of vegetables may fairly be said to consist principally of water. He is, however, inclined to believe that calcareous earth, in small portions, may enter into the composition of at least many vegetables; since animals, which exist entirely on vegetable food, are found to have in their solid parts, the bones for instance, a portion of this substance, though he confesses that chemical analysis, as far as it has yet gone, does not warrant the supposition that calcareous earth is an essential constituent of all vegetable matter. On some occasions, he farther remarks, the addition of other matters; as of different kinds of manure, adds greatly to the growth of vegetables; but that in whatever degree a rich soil or dung may add to the luxuriance of growth, other facts seem to prove that it is not essential to vegetation. It is well known that many herbs flourish in pure water, and that pear, plum, and cherry trees, planted in pure moss, have arrived at such perfection as to produce good fruit.

We may now examine the separated functions of each of these ingredients or principles.

Of water. That the agency of water is necessary in the process of vegetation, has never been doubted, though the manner in which it contributes to it has not, until of late, been distinctly explained. Doctor Hales has shewn, that in the summer months a sun-flower, weighing three pounds avoird-

dupois, and regularly watered every day, passed through it, or perspired, twenty-two ounces each day; that is, nearly half its weight. He also found that a cabbage-plant, weighing one pound nine ounces, sometimes perspired one pound and three ounces; but at a medium about half its weight. Doctor Woodward found that a sprig of common spearmint, a plant that thrives best in moist soils, weighing only 2825 grains, passed through it three thousand and four grains in seventy-seven days, between July and October, that is somewhat more than its own weight each day. He did even more; for he also found that in that space of time the plant increased seventeen grains in weight, and yet had no other food but pure rain-water. He likewise found that it increased more in weight when it lived on spring-water, and still more when its food was Thames water. From whence it may be deduced that grasses and corn, during the time of their growth, absorb about one-half their weight of water each day if the weather be favourable for them. And secondly, that the water they thus pass nourishes them merely as water, without taking any foreign substance into the account; for three thousand grains of rain-water, in Doctor Woodward's experiment, afforded an increase of seventeen grains; whereas by Margraaf's experiments, five thousand seven hundred and sixty grains of that water contained only one-third of a grain of earth: and thirdly, that water contributes still more to their nourishment when it conveys to them earthy and saline particles, as is done by spring and Thames waters. The particular manner in which pure water contributes to the nourishment of plants, besides the service it renders them in distributing the nutritive parts throughout their whole structure, and forming itself a constituent part of all of them, may be readily understood from modern experiments. Doctor Ingenhousz and Mr. Senebier have shewn that the leaves of plants exposed to the sun produce pure air: now water has of late been proved to contain about eighty-seven parts in the hundred of pure air, the remainder being inflammable air. Water is then decomposed by the assistance of light within the vegetable; its inflammable part is employed in the formation of oils, resins, gums, &c.; its pure air is partly applied to the production of vegetable acids, and partly expelled as excrementitious and useless.

It has indeed been asserted by some, that water is the sole food of vegetables; and among the experiments adduced to prove the fact, that of Van Helmont, which has been quoted by the illustrious Mr. Boyle, is by far the most specious. He planted a trunk of willow, weighing five pounds, in an earthen vessel filled with earth dried in an oven, and then moistened with rain-water. This vessel was sunk in the earth, and watered partly with rain-water, and occasionally with distilled. After five years he found the tree to weigh one hundred and sixty-nine pounds; and the earth in which it was planted, being again dried, to have lost only two ounces of its former weight, though the tree had received an increase in weight which amounted to one hundred and sixty-four pounds.

In proceeding to the explication of this experiment, Mr. Kirwan says it must be remarked first, that the weight of the earth contained in the vessel at the commencement and at the end of five years, could not be exactly compared, because the same degrees of desiccation could not be exactly ascertained, and because many of the fibrillæ of the roots of the tree must have remained in the earth after the tree was taken out of the vessel, and these must have prevented the true loss of earth from being perceived. Secondly, that the earthen vessel must have frequently absorbed water impregnated with whatever substance it might contain, from the surrounding earth in which it was inserted; for unglazed earthen vessels easily transmit moisture, as has been shewn by Hales and Tillat. Thirdly, as it appears-

that the pot was sunk in the earth, and received rain-water, it is probable that distilled water was seldom employed in this trial.

From the consideration of these circumstances, it will easily appear that the rain-water, absorbed by the tree, contained as much earth as the tree can be supposed to contain. On this experiment Mr. Kirwan observes farther, that, first, the willow increased in weight one hundred and sixty-four pounds in five years; that is, at the rate of 2,7 pounds nearly per month; and it being an aquatic, it cannot be supposed to pass less than its own weight of water each day during the six vegetating months. In the first month, therefore, it absorbed and passed $5 \times 30 = 150$ pounds; and as each pound of rain-water contains $\frac{1}{4}$ grain of earth, fifty grains of earth must have been deposited in the plant; and allowing no more than fifty grains for the deposit of each of the six months, we shall have $50 \times 6 = 300$ for the deposit of the first year; but at the end of the first year the plant gains an accession of thirty-two pounds; therefore in each of the six summer months of the succeeding year, it passes $37 \times 30 = 1110$ pounds of water, and receives a deposit of three hundred and seventy grains; and at the end of the second year the deposit amounts to two thousand two hundred and twenty grains. At the commencement of the third year, the tree gaining a farther accession of 32 pounds must weigh 69 pounds, and pass in each of the summer months $69 \times 30 = 270$ pounds of water, and receive a deposit of 690 grains, which multiplied into 6 = 4140 grains. At the commencement of the fourth year, the tree still gaining 32 pounds must weigh 101 pounds; and if it passes 101×30 in each of the summer months, it must gain a deposit in each of 1010 grains of earth, and at the end of the year 6060. At the commencement of the fifth year it weighs 133 pounds, and gains at the end of the six months 23940 grains of earth. The quantities of earth deposited each year exceed 5 pounds avoirdupois, a quantity equal to that which 169 pounds of willow can be supposed to contain; for the commisioners employed to inspect the fabrication of saltpetre in France, having examined the quantities of ashes afforded by trees of various kinds, found that 1000 pounds of fallow, a tree much resembling the willow, afforded 28 pounds of ashes, and consequently 169 pounds should produce 4,7. Mr. Kirwan does not give this calculation, however, as rigorously exact. It is certain that if the deposit left at the end of every month were exactly taken, the total would exceed the quantity just mentioned; but that found even by this rude mode, sufficiently proves that water conveys a portion of earth into vegetables equal to any that the experiments hitherto made can prove to be present in them.

In respect to the coal, or carbonaceous principle, which this willow must also have contained, Mr. Kirwan observes, that it is probable that much of it existed in the earth in which the willow grew. Some is contained in all moulds or vegetable earth; and as we are not told what sort of earth Van Helmont used, we may well suppose it was good vegetable earth, its quantity amounting to 200 pounds. This principle may also have been contained in the water; for the purest rain-water contains some oleaginous particles, though in an exceeding small proportion, as Mr. Margraaf has observed; and all oil contains coal. Some also may have passed from the surrounding vegetable earth through the pores of the earthen vessel. All the other experiments, adduced to prove that water is the sole food of plants, may, he thinks, be explained in the same manner. Grains of wheat have been made to grow on cotton moistened with water; each produced an ear, but that ear contained but one grain. Here the carbonaceous substance was derived from the grain, and afterwards diffused and transported

through the whole plant by the water absorbed; for it must be observed that grain, like an egg, contains much of the nourishment of its future offspring. It is thus that tulips, hyacinths, and other plants, expand and grow in mere water, without any other substance being added.

It has been shewn by Margraaf, that the earth contained in rain-water is united partly with the nitrous and marine acids, but far the greater part only with fixed air; for the feeble traces of the two former acids could not hold in solution the 100 grains of earth which he found 300 pounds of rain-water contained.

It is therefore evident that by far the greatest proportion of vegetable substances consists of water. The trials of Mr. Young and Mr. Ruckert shew that grass loses about $\frac{2}{3}$ of its weight on being dried into hay. Dr. Hales found a sun-flower plant, which weighed forty-eight ounces, to lose thirty-six ounces by drying in the air during thirty days, and consequently to have lost 3-fourths of its weight. Even vegetables, to appearance thoroughly dry, contain from 3-fifths to 3-fourths of their weight of water. This water is not all in a liquid state, but, by the loss of much of its specific heat, in a great measure becomes in a solid state.

Of coal, or carbonaceous matter. It is to Mr. Hassenfraz that we are indebted for the discovery, that coal is an essential ingredient in the food of all vegetables. Although it has hitherto been but little attended to, it would appear to be one of the primæval principles, even as ancient as the present constitution of our globe: for it is found in fixed air, of which it constitutes above $\frac{1}{4}$ part; and fixed air exists in lime stones and other substances, which date from the very earliest periods.

This substance not only forms the residuum of all vegetable substances that have undergone a slow and smothered combustion, that is, to which the free access of air has been prevented, but also of all putrid vegetable and animal bodies. Hence it is found in vegetable and animal manures that have undergone putrefaction, and is the true basis of their ameliorating powers. If the water that passes through a putrefying dunghill be examined, it will be found of a brown colour; and if subjected to evaporation, the principal part of the residuum will be found to consist of coal. All soils steeped in water communicate the same colour to it in proportion to their fertility; and this water being evaporated, leaves also a coal, as has been attested by Mr. Hassenfraz and Fourcroy. They also observed, that shavings of wood being left in a moist place for nine or ten months, began to receive the fermentative motion, and, being then spread on land, putrefied after some time, and proved an excellent manure. Coal, however, cannot produce its beneficial effects but in as much as it is soluble in water. The means of rendering it soluble are not as yet well ascertained; nevertheless, it is even now used as a manure, and with good effect, as has been shewn by Mr. Young. In fact, the fertilizing powers of putrid animal and vegetable substances were fully known even in the remotest ages, but most speculatists have hitherto attributed them to the oleaginous, mucilaginous, or saline particles then developed, forgetting that land is fertilized by *paring and burning*, though the oleaginous and mucilaginous particles are thereby consumed or reduced to a coal, and that the quantity of mucilage oil or salt in fertile land is so small, that it could not contribute the 100th part of the weight of any vegetable; whereas coal is supplied not only by the land, but also by the fixed air combined with the earths, and also by that which is constantly set loose by various processes, and soon precipitates by the superiority of its specific gravity, and is then condensed in, or mechanically absorbed by soils, or contained in dew. Lands which contain iron in a semi calcined state are thereby enabled to decompose fixed air, the iron, by the help of

water, gradually attracting the pure air which enters into the composition of fixed air, as Mr. Gadolin has shewn: a discovery which appears to Mr. Kirwan the most important of any that has been made in these later times; but these calces of iron may again be restored to their former state by union with oleaginous substances, as Mr. Beaumé has noticed: and this is one of the benefits resulting from the application of dung before it has fully putrefied. Hence we may understand how soils become effete and exhausted, this effect arising in a great measure from the gradual loss of the carbonaceous principle deposited by vegetable and animal manures, and from their passing into the growing vegetables; and also from the loss of the fixed air contained in the argillaceous part of the soil, which is decomposed by vegetables; and from the calcination of the ferruginous particles contained in the soil. This epithet in a great measure is used because other causes contribute to the diminution of fertility; which shall presently be mentioned. Hence also it is evident why lands pastured remain longer fertile than those whose vegetable crop is carried off, as much of the carbonaceous principle is restored by the excrements of the pasturing animals: why some crops exhaust more than others; because corn, and particularly wheat, contains more of the carbonic principle than grasses, and very little of its *exuviz* is left behind: why fallows are of some use; as the putrefaction of the roots of weeds and the absorption of fixed air by clays, are thereby promoted: why vegetables thrive most in the vicinity of towns; because the carbonic principle is copiously dispersed by the smoke of the various combustibles consumed in inhabited places: why foot is so powerful a manure: why burning the clods of grassy land contributes so much to its fertility, and then only when the fire is smothered and coal produced; besides many other agricultural phenomena, which it would be too tedious to relate in this place: but it must not be omitted that the phosphoric acid is found in coal; which is a substance that enters into the composition of different vegetables.

It is evident that the quantity of coal or carbonaceous matter in vegetables must be various, according to their various species, age, and degrees of perfection: wood and corn contain most, grasses least. Wiegleb found dry beech wood to contain one-fifth of its weight of coal. Westrumb has discovered that *trifolium pratense*, a sort of clover, contains about one-seventh. From this it would appear, that, after water, it is the most abundant ingredient in vegetables.

Of earths. That which is next in importance as an ingredient for the nourishment of plants is earth; and of the different earths the calcareous seems the most necessary, as it is contained in rain-water; and, absolutely speaking, many plants may grow without imbibing any other. Mr. Tillet found corn would grow in pounded glass; Mr. Succow in pounded fluor spar, or ponderous spar, or gypsum; but Tillet owns it grew very ill; and Haslenfraz, who repeated this experiment, found it scarcely grow at all when the glass or sand was contained in pots that had no hole in the bottom, through which other nutritive matter might be conveyed. It is certain, at least from common experience, that neither grasses nor corn grow well either in mere clay, sand, or chalk; and that in vegetables that grow most vigorously, and in a proper soil, three or four of the simple earths are found. Mr. Berginon, on the other hand, assures us he extracted the four earths, the siliceous, argillaceous, calcareous, and muriatic, in different proportions from the different sorts of corn. Mr. Ruckert, who has analysed most species of corn and grasses, found also the four abovementioned earths in various proportions in every one of them. It may not be improper to introduce a specimen of his analysis, comprehending however the calcareous and muriatic in the same column, as this last hardly deserves to be noticed in a particular way.

One hundred parts of the lixiviated ashes of

Rye	- - 63	21	16
Potatoes	- - 4	66	30
Red clover	- - 37	33	30

Mr. Ruckert seems to have persuaded himself that earth and water, in proper proportions, are the two principles which form the sole nutriment of plants; but Mr. Giobert has clearly demonstrated the contrary; for, having mixed pure earth of alum, siliceous earth, and magnesia, in various proportions, and moistened them with water, he found that no grain would grow in them; but when they were moistened with water from a dunghill, corn grew in them luxuriantly. It is therefore evident that the carbonic principle is essentially necessary.

It is well known that the absolute quantity of earth in vegetables is very small. Dr. Watson informs us that 106 avoirdupois pounds = 1696 ozs. of oak, being carefully burned, left but 19 ozs. of ashes; and from these we must deduct 1,5 for salt, then the earthy part amounts only to 17,5; that is, little more than one part in the hundred. The commissioners appointed to inspect the saltpetre manufactory, found nearly the same result; namely, 1,2 in the hundred: in beech 0,453, and in fir only 0,003. Hence we need not wonder at trees growing among rocks where scarce any earth is to be seen; but in the stalks of Turkey-wheat, or maize, they found seven parts in the hundred of earth, in the sun-flower plant 3,7; so that, on the whole, weeds and culmiferous plants contain more earth than trees do. Mr. Westrumb found *trifolium pratense* to contain about 4,7 parts in the hundred of earth, of which 2 parts in the hundred were mild calx, nearly 2 more siliceous, 0,7 argill, together with phosphorated iron, calx of iron, and manganese in a small proportion.

As it is therefore evident that plants derive some proportion of earth from the soil on which they grow, it cannot be surprising that these soils should at length be exhausted by crops that are carried off; such as those of corn and hay, particularly the former: even lands pastured must at last be exhausted, as the excrements of animals do not restore the exact quantity that the animals have consumed; and hence the utility of mucks, as the restoration is performed by more animals than have been employed in the consumption. Hence also a succession of different crops injures land less than a succession of crops of the same kind, as different proportions of the different earths are taken up by the different vegetables. Finally, we may hence derive the utility of marling land, as the deficient earths are thereby replaced. This subject indeed admits of more precision than has been hitherto imagined, and may even be subjected to calculation. The absolute quantity and relative proportions of the various earths in an acre of land may be determined, so may that in the crops of different vegetables; and by comparing both, the time also may be found in which the land must be exhausted, unless renovated by various manures: thus the necessity of marling. We may also very nearly determine the kind of marle or other manures, and the quantity necessary to an acre of land.

It is very obvious that earths cannot enter into plants but in a state of solution, or at least only when suspended in water in a state of division as minute as if they had been really dissolved. That siliceous earth may be suspended in such a state of division appears from various experiments, particularly those of Mr. Bergman, who found it thus diffused in the purest waters of Upsal; and it is equally certain that it enters copiously into vege-

tables. His experiments, and more particularly those of Mr. Macie, establish this point beyond dispute. Argillaceous earth may also be so finely diffused as to pass through the best filters; it also may calc, as appears from the quantity Margraaf found in the purest rain-water. This earth is even soluble by means of an excess of fixed air in about 1500 times its weight of water. It may also be and most frequently is converted into gypsum by the vitriolic acid which is contained in most clays, as Mr. Morveau has shewn, and then it is capable of being dissolved in 500 times its weight of water, or thereabouts.

It must also be remembered that vegetables not only require food, but that this food be duly administered to them; a surfeit being as fatal to them as absolute privation. Doctor Hales observed that a young pear-tree, whose roots were set in water, absorbed a smaller quantity of it every day, the sap-vessels being saturated and clogged by it; and Mr. Miller found that too much water rotted the young fibres of the roots as fast as they pushed out. Saturated solutions of dung appeared to Mr. Du Hamel equally hurtful. Now the preservation and due administration of this liquid food are effected by due proportions of the simple earths and their loose or condensed state. Their situation in other respects being the same, those that abound in the argillaceous principle are the most retentive of water: those that abound in the coarse siliceous, least, the calcareous being intermediate between both; various species of vegetables requiring various quantities of water and other food: hence it is that every sort of soil bears vegetables peculiarly adapted to it, while others do not grow at all, or but ill in it. It is plain, from the experiments of M. Bergman, that argill takes up 2,5 times its weight of water when saturated so as to let none drop.

Magnesia	-	-	1,05
Chalk	-	-	0,5
Siliceous sand	-	-	0,25

Of carbonic acid gas or fixed air. This is an important agent in husbandry; though plants do not thrive, but most frequently perish, when surrounded by an atmosphere of it. This is a fact that has long been observed by that excellent enquirer into the most hidden processes of nature, Doctor Priestley. Fixed air, when imbibed by the roots, is however favourable to their growth, as is shewn by the experiments of Doctor Percival of Manchester, and fully confirmed by those of Mr. Ruckert. This last-mentioned philosopher planted two beans in pots of equal dimensions filled with garden-mould. The one was watered almost daily with distilled, the other with water impregnated with fixed air, in the proportion of half a cubic inch to an ounce of water: both were exposed to all the influences of the atmosphere, except rain. The bean treated with aerated water appeared over ground nine days sooner than that moistened with distilled water, and produced twenty-five beans; whereas the other pot produced only fifteen. The same experiment was made on stock-julyflowers and other plants with equal success. The manner in which fixed air acts in promoting vegetation, seems well explained by Mr. Senebier: he first discovered that fresh leaves exposed to the sun in spring-water, or water slightly impregnated with fixed air, always produce pure air as long as this impregnation lasts; but as soon as it is exhausted, or if the leaves be placed in water, out of which this air has been expelled by boiling, they no longer afford pure air: from whence he infers that fixed air is decomposed, its carbonic principle being retained by the plant, and its pure air expelled. Mr. Kirwan thinks also, that by acting as a stimulant, it may help the decomposition of water. Mr. Hatfenfraz, indeed, denies its decomposition; but his arguments do not appear to Mr. Kirwan to be conclusive. The vitriolic acid contained in various clays brought into multiplied contact with calcareous earth by the agitation of soils in agricultural opera-

tions, and the motion of the roots, gradually sets loose the fixed air contained in this last-mentioned earth; that portion also of this earth, which is by water introduced into the plant, is decomposed, and its air set loose by the vegetable acids which the plant contains within it.

Of saline substances. Substances of this kind, gypsum and phosphorated calx being excepted, seem to serve vegetables in the way they do animals, rather as a *condimentum*, or promoter of digestion, than as a *pabulum*. This idea is suggested by the smallness of their quantity, and the offices they are known to perform. Their quantity is always smaller than that of the earth; and this we have already seen to be exceeding small indeed when compared with the other parts.

Hence, one thousand pounds of	lb.
Oak give of saline matter only	1,5
Elm	3,9
Beech	1,27
Fir	0,45
Vine branches	5,5
Fern	4,25
Stalks of Turkey wheat	17,5
Wormwood	73,
Fumitory	79,
Trifolium pratense	0,78
Vetches	27,5
Beans with their stalks	20,

All the experiments that have hitherto been made, shew that the proportion of saline matter to the earthy is the smallest in woods; in other plants, generally as 1 to 1,3, 1,5, or 2: however, Mr. Ruckert has marked some exceptions, which may be mentioned as deserving of the attention of those engaged in the improvement of land. It is found that the proportion of saline substances to the earthy, is,

In Hemp	-	as	1	to	8.
Flax	-	-	1	to	1,7 nearly.
Parsnips	-	-	1,1	to	1.
Potatoes	-	-	1	to	1,3
Turnips	-	-	1	to	3,33
Wheat	-	-	1	to	3-
Rye	-	-	1	to	8.
Oats	-	-	1	to	8.

It might be shewn that these proportions have some analogy to the quantity and sort of manure proper to be employed in the cultivation of these plants and the succession of crops; but such an enquiry would be too extensive for the present purpose.

Those salts that are generally extracted from the ashes of vegetables, are vitriolated tartar, Glauber's salt, common salt, salt of Sylvius, gypsum, phosphorated calx, and fixed alkaline salts.

Alkalis. These salts seem to be the product of the vegetable process, for either none or scarce any are found in the soils, or in rain-water, while in the vegetable they are most probably neutralized, partly by vegetable acids which are decomposed in the process of combustion, and partly by the vitriolic and marine acids. Westrumb found vitriolated tartar and digestive salts in the juices of the trifolium.

Gypsum. It is probable that this substance exists in greater quantity in plants than it appears to amount to after combustion and lixiviation; much of it must be decomposed during the combustion, and still more during lixiviation, by the alkalis existing in the solution. Thus the apparent quantity of vitriolated tartar is increased.

Phosphorated calx. This substance is found in the greatest quantity in wheat, where it contributes to the formation of the animal gluten. Hence in rainy years the quantity of gluten in wheat has been observed to be smaller than in dry ones. Hence also the excellence of bone-ashes as a manure for wheat; and

hence wheat succeeds best after clover, if the clover be fed off, but not if it be mowed, as Mr. Young has observed, because much of the phosphoric acid is communicated by the dung of animals, which is scattered on the ground.

It would seem that the chief use of vitriolated tartar is its promoting the decomposition of water, a circumstance which Mr. Senebier has pointed out with great ingenuity.

SECT. IV. *Of the Constitution of Fertile Soils.*

FROM what has been already said, it will appear that the most fertile soil is that which contains the greatest quantity of the food of those vegetables that nourish men and useful animals, and which administers it to them in due proportions. Therefore the first essential requisite to a fruitful soil is, that it contain a sufficient quantity of the three or four simple earths which have been mentioned above, and of the soluble carbonaceous principle. The other requisites are, that the proportion of each, and general texture of the soil, be such as to enable it to admit and retain as much water as is necessary to vegetation, and not any superabundant quantity.

It must be pretty evident from what has been said above, that the retentive powers of moisture are very different in the simple earths: therefore the proportions in which the fertility of a soil requires them to be mixed, must be different in climates and countries that differ considerably in moisture; in the *drier*, they must be such as are most retentive; in the *moister*, such as suffer it to pass or evaporate in a more speedy and free manner. The same observation also extends to situation. Lands on a plain should be so constituted as to be less retentive of water than those situated on a declivity; this is extremely evident from the very nature of their different positions. So likewise lands that have a retentive or impermeable subsoil, should be differently constituted from those that have one less retentive or more permeable. The time of the year in which rain most abundantly falls is also deserving of particular attention. These different circumstances must undoubtedly modify the conclusions which are to be drawn from the following experiments, which have been made with a view to determine the principles of fruitful soils.

Analysis of a fertile soil in a climate extremely rainy. By an analysis of Mr. Giobert, which has been communicated to the public, of a fertile soil in the vicinity of Turin, where it rains yearly above 40 inches on the square foot; it was found that 1 pound of it contained from 20 to 30 grains of extractive matter which flamed and burned, and therefore was a coal soluble in water; 26 pounds of it contained 1808 grains of water. The simple earths were in the following proportion in the hundred weight:

Of Silex, from	-	77 to 79
Argill	-	9 - 14
Calx	-	5 - 12

From this the pound troy should contain

	grs.
Carbonic matter	- 25
Water	- 70
Silix, from	4362 to 4475
Argill	- 509 - 793
Calx	- 283 - 679

The above author also found that it contained a great deal of air, even as much as 19 grains, of which one-third was fixed, and the remainder heavy inflammable air; but not any ammoniac or volatile alkali. In this account both the weight of the cubic foot of this soil and its specific gravity are omitted; therefore neither its texture, nor the quantity of each ingredient, can be directly ascertained; but, from the necessity of its being in some degree open, and the weights of good soil as found by Mr. Fabroni, Mr. Kirwan is led to conclude that its

specific gravity could not exceed 1,58; consequently a cubic foot of it should weigh about 120 pounds troy, or 100 avoirdupois.

In other soils which were less fertile, Mr. Giobert has determined the proportions as follow:

Silix, from	48 to 80
Argill	- 7 - 22
Calx	- 6 - 11

It is therefore evident that the troy pound contained, of

Silix, from	2716 to 4528
Argill	- 396 - 1245
Calx	- 339 - 622

allowing 100 grains for moisture, as either the calx or argill exceeds the proportions in more fertile kinds of ground. There is an omission of the specific gravity of these soils in the experiments of Mr. Giobert; it is probably, however, not very different from that of the more fruitful soils, perhaps a little above or below them.

Inbarren soils, the proportions were found by the same author to be

Of Silex, from	42 to 88
Argill	- 20 - 30
Calx	- 4 - 20

Therefore the troy pound contained, allowing 120 grains for water,

Silix, from	2368 to 4963
Argill	- 1128 - 1622
Calx	- 225 - 620

Here also there is an omission of the specific gravity of the soils; but Mr. Kirwan supposes it to be either much above or much below that of the former, as they are either too close or too open. Mr. Fabroni found that of barren sandy land 2,21. It is also necessary to observe, that if the proportion of water be different from that here supposed, the contents of the troy pound will also be different; but this is a circumstance that may readily be adjusted.

Analysis of a fertile soil, on which the fall of rain was 24 inches. It was found by Mr. Bergman that a fertile soil, situated on a plain, where the yearly fall of rain amounted to 23,9 English inches, contained four parts clay, three of siliceous sand, two of calcareous earth, and one of magnesia. The composition of the clay he has not expressly mentioned, but it may be supposed that it was such as most frequently occurs, containing 66 parts in the hundred of fine siliceous sand; and 34 of mere argill; consequently 0,40 of it contained nearly 0,14 of mere argill, and 0,26 of fine siliceous sand. The siliceous sand, which he has mentioned, is what we call gravel, consisting of stone from the size of a pea, or less, to that of a nut. This amounts to 30 parts in the hundred. Therefore the proportions may be thus stated:

Coarse Silex	-	-	30
Finer	-	-	26
			56 parts
Argill	-	-	14
Calx	-	-	39
			100

It is obvious that the use of the gravel is to keep the soil open and loose: a circumstance absolutely necessary, and which has been already adverted to. The specific gravity is not stated, but Mr. Kirwan thinks that it should not much exceed 1,600. Muschenbroek found that of garden-mould 1,630. With the carbonic matter Mr. Bergman was unacquainted. On the whole the proportion in a troy pound, supposing the quantity of water and coal not to exceed 100 grains, will stand thus, fractions being omitted:

Gravel	-	-	1698
Fine fand	-	-	1471
			<hr/> 3169
Argill	-	-	792
Calx	-	-	1698

In this we see that the quantity of calx is much greater than in the soil of Turin, where the fall of rain is greater; for in the drier climates there is a necessity to retain the rain; and the argill, if increased, would retain it too long and too much, and, besides, enters very sparingly into the constitution of plants, as has been already shewn.

For the following experiments we are indebted to Mr. Tillet; they were made at Paris, where the fall of rain, on an average, amounts to 20 inches. This ingenious philosopher filled a number of pots twelve inches in diameter at the top, ten at bottom, and seven or eight deep, with mixtures of different earths. It seems also that they were porous enough to absorb moisture, and that they were perforated at the bottom. These he buried up to the surface in a garden, having previously sowed in each some grains of wheat, when they were left to themselves.

Fertile mixtures. The first mixture he found fertile consisted of three-eighths of the potters' clay of Gentilly = 0,375, three eighths of the parings of limestone, and two-eighths of river-fand = 0,25. In this the corn grew very well for three years; which was the length of time that the experiment continued. But as potters' clay is not pure argill, and as Mr. Tillet has not mentioned the proportion the mere argillaceous part bore to the siliceous, Mr. Kirwan has endeavoured to supply this deficiency, by supposing the clay to contain near one-half its weight of pure argill, it being clay of this sort that potters generally make use of: and that of Gentilly being esteemed one of the best. Both the clay and limestone, Mr. Tillet observes, were pulverized, that they might more exactly incorporate when mixed. In this case the centesimal proportions will stand in the following manner:

Coarse Silex	-	25
Finer	-	21
		<hr/> 46
Argill	-	16,5
Calx	-	37,5
		<hr/> 100

It is therefore plain that the quantities in the troy pound, supposing the water, &c. to amount to 100 grains, will be

Coarse fand	-	1415
Finer	-	1188
		<hr/> 2603
Argill	-	934
Calx	-	2122
		<hr/> 5659

The second mixture contained two-eighths of potters clay, three-eighths parings of limestone, and three-eighths coarse fand. The centesimal proportions are therefore,

Coarse fand	-	37,5
Finer	-	14
		<hr/> 51,5
Argill	-	11
Calx	-	37,5
		<hr/> 100

Hence in the troy pound, supposing the quantity of water to

amount to 100 grains, the quantities of the three earths will be as follows:

Coarse Silex	-	2122
Finer	-	792
		<hr/> 2914
Argill	-	622
Calx	-	2122
		<hr/> 5658

It is obvious therefore that in the drier countries, where the fall of rain is but 10 inches, the soil, to be fertile, must be closer, and the quantity of calcareous earth much increased, and that of the siliceous much diminished. Thus, in the climate of Turin, where the fall of rain exceeds 40 inches, the proportion of siliceous earth is from 77 to 80 in the hundred, and that of calcareous, from 9 to 14; in order to suffer this excess of rain more easily to evaporate. In the climate of Upsal, where the fall of rain is 24 inches, the proportion of siliceous earth is only 56 in the hundred, but that of calx is 30; and in the climate of Paris, which is still drier, the proportion of siliceous earth is only 46 to 51, and that of calx 37,5 in the hundred; and hence we may perceive the necessity of attending to the average quantity of rain to judge of the proper constitution of fertile lands on fixed principles.

The proportions vary considerably in the two last mixtures: The first may serve as a model for the heavier soils, and the second for the lighter. In these and the following experiments, the carbonic principle seems to have been extracted from the surrounding garden-mould with which the pots communicated, by means of their bottoms being perforated with holes.

Barren mixtures. 1. In his sixth and eighth experiments, Mr. Tillet mixed three-eighths of potters' clay with three-eighths of parings of limestone and two-eighths of fine fand: the only difference between this mixture and that of the first experiment was, that in the first experiment coarse fand was used, and in this fine, yet the former was fruitful in the highest degree; but in this the grain prospered indeed the first year, but sickened in the second, and failed in the third: the proportions have been already stated. In this case we have a clear proof of the necessity of an open texture in soils, without which the best proportions will not be successful.

2. In the thirteenth experiment a mixture of two-eighths potters' clay, four-eighths coarse fand, and two-eighths marle was employed. In this case the corn grew well the first year, poorly the second, and decayed the third. The composition of the marle is not mentioned; but supposing it to contain 70 in the hundred of calx, and 30 of clay, of which the one-half is argill, it would form one of the richest sorts of marles. The centesimal proportions of this mixture should be as follow:

Silex	-	50 + 14 = 64
Argill	-	11 + 8 = 19
Calx	-	17
		<hr/> 100

Also in the troy pound, supposing the water, &c. to amount to 100 grains, the quantities will be these:

Silex	-	3622
Argill	-	1075
Calx	-	962
		<hr/> 5659

It would seem that the sterility of this mixture proceeds from a defect of calcareous earth. If we suppose the marle poorer in that earth, the defect will be still greater. The retentive

powers of the different earths with respect to water, being expressed by the quantities which each can retain without suffering any to drop, as stated above, and the quantities retained by the mixed mass of these earths being proportional to the respective quantities of each, it should seem that in fertile soils, where the fall of rain is from 20 to 30 inches, this power should not exceed 70, nor fall short of 50 in the hundred. It would be of great consequence, Mr. Kirwan thinks, to settle this point with precision; but to do it would require more numerous experiments. In explanation of which one example may be given.

The retentive power of the fertile soils which have been mentioned by Bergman, will furnish us with an instance. A soil of this kind contains, as has been already shewn,

Of Silex	-	56
Argill	-	14
Calx	-	30
And the retentive power of 100 parts		
Silix	=	25
Argill	=	250
Calx	=	50
Therefore the retentive power of		
56 parts Silix	=	13
14 - Argill	=	35
30 - Calx	=	15

————— 63.

But before we leave the experiments of Mr. Tillet, it may be proper to mention a few others which have been made by the same author, but which seem to invalidate the necessity of the presence of the three simple earths in such soils as are fruitful.

1. It appears by his 26th experiment, that he only employed pure sand, such as is used for making glass; yet corn grew well in it the first year, indifferently the second, and nearly failed in the third. But Mr. Hassenfraz having repeated the experiment in pots unperforated, did not find it to succeed even the first year; therefore the success of Mr. Tillet was owing to the perforation at the bottom of his pot, through which water impregnated with the different earths, and coal must have passed. In fact, Mr. Tillet's conclusion is contradicted by the universal experience of those who have attended to this point.

2. We find by his 28th experiment, in which powdered limestone only was employed, that the corn sown prospered exceedingly during the three years. To the cause mentioned in treating of the 26th, Mr. Kirwan adds, that the limestone he used was that of St. Leu, which contains clay, and consequently siliceous and argill; and which is so porous as to admit from 3-19ths to 1-5th of its weight of water, as Mr. Brisson has shewn; it thus becomes easily decomposed. The coarse powder to which it was reduced answered the same purpose as coarse siliceous; and the finer might nourish the plants which were contained in it.

3. The 30th experiment is that in which he employed mere potters' clay; the grain grew tolerably well the first year, but perished the second; on the third it flourished most. It would be difficult to draw any specific conclusion from this experiment, for it is plain that if the texture were not much looser than that of clay, the corn could not grow at all, as was the case in his 6th and 8th experiments, already mentioned, and as Mr. Hassenfraz, who repeated this experiment, observed. Rain-water might however, as Mr. Kirwan supposes, supply a small quantity of calx sufficient for a small produce of corn in this instance.

Mr. Kirwan also thinks that soils on the declivity of hills, ought to be more retentive of water than those on plains.

SECT. V. *Of the most suitable Manures and Processes for different Soils.*

This is a subject of great difficulty, and which can only be satisfactorily explained from the general practice of the most

skilful farmers, corrected and improved by the more precise determinations and restrictions of theory. The causes of the beneficial effects of many different kinds of manure in various instances may however in some degree be ascertained by the theory which we have endeavoured to establish in the preceding sections. The whole would seem to rest on this simple proposition;—that *manures are applied to supply either the defective ingredients of a soil, improve its texture, or correct its vices.*

It will now be necessary to consider each soil in particular, as well as the manures which are most adapted to render them fertile.

Of clayey soils and their proper manures. Experience has shewn that the best manure for clayey soils is marle; and in this indeed all the books of agriculture are agreed; but of the different sorts of marle, that which is most calcareous is found to be the best; the siliceous next best; limestone-gravel best of all; and argillaceous marle least advantageous of any of them.

It is now pretty well known that clayey soils are defective both in constitution and in texture; they want the calcareous ingredient and coarse sand. Calcareous marle supplies the calcareous ingredient chiefly: limestone-gravel both. The other marles supply them in a lesser degree. If the clay be analysed, and its proportion of sand and argill known, the species of marle most advantageously applicable may be determined still more certainly. For instance, if the argill notably exceeds or even amounts to the proportion of 40 or 50 in the hundred weight, calcareous marle or limestone-gravel will be the best improving manure, as they contain most of the calcareous ingredient; but if the siliceous ingredient amounts to 75 or 80 in the hundred, as it sometimes does, argillaceous marle will be the most suitable, and afford the greatest improvement. But a mixture of marle and dung is still more advantageous, because the dung supplies the carbonaceous ingredient. But the marle must be used in the same quantity as if dung had not been applied, otherwise the operation must be more frequently repeated. How the quantity of marle or other manure can be estimated, will be shewn hereafter.

But in situations where marle cannot be had, a mixture of coarse sand and lime perfectly effete or extinguished, or even chalk, will answer the same purpose, as it will supply the defective ingredient, and open the texture of the clay; so also sand alone, or chalk, or powdered limestone, may answer, though less advantageously. Lime alone appears to Mr. Kirwan to be less proper, as it is apt to cake, and does not sufficiently open the soil. However, where these manures cannot be had, coal-ashes, chips of wood, burned clay, brick-dust, gravel, or even pebbles, are useful, as Mr. Young has shewn; for all these improve the texture, and the former also supply the carbonaceous ingredient. Here Mr. Kirwan lays down another general maxim; which is, That *dung is a proper ingredient in the appropriated manures of all sorts of soils*, as it supplies the carbonaceous principle to them.

Of clayey loam, and the manures proper for it. It appears that this soil is defective either in the calcareous ingredient, in the sandy, or in both: if in the first, the proper manure is chalk; if in the second, sand; if in both, siliceous marle or limestone-gravel, or effete lime and sand, are the most proper.

In respect to the quantity of chalk that should be employed, considered abstractedly, it should be directly proportional to the defect of the calcareous matter; but as such a quantity cannot be added without diminishing the proportion of one of the other ingredients, a much smaller quantity must be employed, or else a substance which may convey some proportion of the other ingredient. The same observation holds also with respect to sand. Thus we have seen, in the preceding section, a clayey loam, in which the sandy ingredient was defective, and the argillaceous superabundant, but the calcareous exact. The composition of it stood thus:

Of Sand and Gravel	-	47
— Argill	-	22
— Mild calx	-	31

In this soil the sandy part wants 10 in the hundred: the argill is superabundant; but we cannot increase the proportion of sand without diminishing that of calx. Hence we must either use a smaller proportion of the sandy ingredient than its defect requires, or apply a substance that would supply some proportion of the calcareous ingredient also: such are limestone-gravel, siliceous marle, effete lime, mixed with sand or pounded limestone. Suppose the proportion of the substance to be employed were six in the hundred; that is, six pounds for every hundred pounds of the soil, the quantity requisite for an acre would be about 208 cart-loads, reckoning the cart-load at 1,500 pounds.

The Earl of Dundonald says, that the process of paring and burning may be practised with advantage on some clayey soils, as the burnt clay will diminish the stiffness of them, and render them more porous to water.

Chalky soil, and the manures proper for it. It has been found that this soil wants both the argillaceous and the stony, sandy, or gravelly ingredients; therefore the best manure for it is clayey loam, or sandy loam; but when the chalk is so hard, as it frequently is in this country, and so difficultly reducible to impalpable powder as to keep of itself the soil sufficiently open, then clay is the best manure, as in such cases the coarse sand or gravelly ingredients of loams are of no use. Some think, it is true, that pebbles in a field serve to preserve or communicate heat. This use, however, is not yet ascertained with sufficient accuracy.

Chalky loam, and the proper manures for it. Experience has shewn that the best manure for this soil is clay, or argillaceous marle, if clay cannot be had; because this soil is defective principally in the argillaceous ingredient. In Ireland, chalky soils or loams seldom occur, but light limestone soils frequently, and these do not differ essentially from chalky loams poor in argill: clay, therefore, and often the soil of bogs, may serve as a manure for them. Soils of this kind are frequently fertile, and well adapted to the culture of wheat and beans.

Sandy soils, and their proper manures. Mr. Young asserts that the best manure for these is calcareous marle, which exactly corresponds with the theory which has been advanced above; for these soils want both the argillaceous and the calcareous ingredients; and this marle supplies both: the next best is argillaceous marle; and next to these, clay mixed with lime, or calcareous or clayey loams. In Norfolk, they seem to value clay more than marle, probably because their sandy soils already contain calcareous parts; possibly also they misname marle, calling mere chalk by that name. Lime or chalk are less proper, as they do not give sufficient coherence to the soil; however, when mixed with earth or dung, they answer well, because in that case they form a sort of marle or compound, comprehending the defective ingredients, or those which are wanted in order to render this soil fertile.

Sandy loams, and their proper manures. It seems that these soils are defective chiefly in the calcareous ingredient, and in some degree also in the argillaceous; their texture too is imperfect, as they abound both in fine and coarse sand; chalk or lime would supply the first defect, but would leave the texture unamended. Hence they are used when better manures cannot be had; yet calcareous or argillaceous marles are most proper. Clay, after land has been chalked, we are informed, answers remarkably well, because it remedies the texture very conveniently.

Gravelly loams, and their proper manures. It is certain that these soils are benefited by the application of marle, whether argillaceous or calcareous, for reasons which are now sufficiently apparent: if the gravel be calcareous, clay may be employed. A mixture of effete lime and clay should answer in all cases of this kind of soil.

Ferruginous or vitriolic soils, and their proper manures. Soils of this kind necessarily require the calcareous ingredient, in order to neutralize their peccant acid: hence chalk, limestone-gravel, lime and calcareous marle, are most advantageously applied to these sorts of land.

Boggy soils, and their proper manures. After these have been well dried by sufficient drains, the nature of their soil should be explored by analysis, and an appropriate manure applied. In general, they should first be burned, if capable of that operation; then gravelled. If their upper parts contain a sufficiency of the carbonaceous principle, as often happens, they need not be burned. Limestone-gravel will answer best, or lime mixed with coarse sand or gravel, because in general they are of a clayey nature; if more sandy, lime may answer well, or calcareous marle. The preference in these cases must be decided by the result of the analysis which has been made.

Heathy soils, and their proper manures. It is necessary, in the first place, that these should be burned in order to destroy the heath and increase the carbonaceous principle; they should then be analysed, and the defective principles supplied. Lime is said to destroy heath, and so does limestone-gravel: this is fittest when the soil is clayey; lime when it is gravelly. Gypsum also answers remarkably well in cases where the soils are dry and hard.

SECT. VI. Of Particular Manures and Processes.

IN the preceding part of the Treatise we have considered most of the known soils, and examined the manures which tend most to their improvement. But there are yet some other manures and processes employed by the practical farmer, the mode of action of which is by no means generally understood. It will therefore be proper to consider their nature more particularly, and explain their manner of operating more fully in this place.

Of the process of draining as a means of improving the soil. The general object or intention with which this process is employed, has been already described. We must therefore now give some account of the means by which the beneficial effects produced by its operation are accomplished. The observations of the Earl of Dundonald on this subject seem to deserve attention. He says that though water constitutes a principal part of the food of plants, it is obvious that certain degrees of cold must prevent its being absorbed by them. Therefore water, during the continuance of such degrees of cold, cannot be of any service; its presence at these times generally proving hurtful to the future growth of the vegetables. For this reason rain, during the cold winter months, is prejudicial, while the warm summer showers have an opposite effect. From which it is plain, he thinks, that, when vegetation is not advancing, or but tardily proceeding, the land should be preserved as dry as it is possible to keep it.

Though advantages may be yielded to certain soils at particular seasons, by artificial watering, he thinks that greater and more extensive benefits may be derived from a more complete and general drainage of the surface. The attention of the farmer should not therefore, in his opinion, be called away to other objects, such as the irrigation of meadows, &c. before he has relieved his grounds of their injurious surface water, as the full advantage cannot previously be obtained from such means.

Besides the method of perfect drains, lands may be made dry, he observes, by such a mechanical change in the component parts of the soil, as render it less retentive of moisture. In stiff lands this is to be effected by lime, chalk, marle, coal-ashes, brick-dust, or calcined clay, and by sand when applied in large proportions.

Fallowing. This is an important operation in the practice of farming, though the reason of its producing such beneficial effects is not yet generally known.

The Earl of Dundonald supposes, that as alkaline salts act more powerfully on some kinds of peat and inert vegetable matters than on others, especially on those which become oxygenated by exposure to the action of the air, the practice of fallowing ground containing much vegetable matter, by repeatedly exposing fresh surfaces to the operation of the air, may occasion the peat or vegetable matter to be more easily dissolved or acted upon by these salts; but that when no such application is made, the insolubility of the vegetable matter is increased by the process of fallowing, which to certain grounds may, he thinks, prove an injury, rather than a benefit. The solution or putrefaction of vegetable substances is, in his opinion, more speedily promoted by a close or stagnated state of the air, than by a constant supply and addition of oxygen or pure air, as happens to these substances when subjected to the process of fallowing.

He therefore contends that clover, sainfoin, cabbages, turnips, leguminous crops, hemp, and those plants which overshadow the ground, and cause a stagnation of air, thereby preventing the excessive exhalation of moisture, and promoting the putrefaction or decomposition of vegetable matters contained in the soil, will prove more economical and advantageous to subsequent crops than the present practice of fallowing. By this last process, says he, not only one year's rent and labour are lost, but the vegetable matter contained in the soil is thereby rendered less fit to promote the growth of subsequent crops. Consequently fallowing, he thinks, should be practised sparingly; its principal use consisting in altering the mechanical arrangement of the soil, either by pulverizing it, or making it more compact, both of which effects, according to circumstances, being thereby produced, and in destroying root, seed weeds, or insects. These objects being therefore obtained, recourse, in his opinion, should never be had to the same operation, unless it becomes necessary from the failure of crops, or other incidental causes, which, he says, are best provided against by substituting the culture of drill crops instead of a fallow.

The same author suggests it as probable, that soils which contain much inert vegetable matter, may derive advantages from umbrageous green crops without the process of fallowing, equal to those experienced when hemp is made to precede a crop of wheat; without which preparation this crop would not have been equal to the expectations of the farmer.

It is therefore, he thinks, sufficiently evident, that if ground receive benefit by being overshadowed, the same ground, by a directly opposite method of treatment, must be injured.

The Rev. Doctor Gregory, in a very judicious work intitled "The Economy of Nature," observes, that the custom of letting lands lie fallow has not yet been satisfactorily explained; something may no doubt be attributed to the destruction of weeds, but more probably to some change produced in the soil, by its being exposed to the action of the sun and air. The management of nitre-beds may, he thinks, tend to throw some light on this subject. These are composed of calcareous earth and dung cemented together. After being exposed for some months to the air, they are found to contain a quantity of nitrous acid, which, uniting to the calcareous earth, forms a kind of salt, which is extracted by lixiviation. Now calcareous earth and dung are two of the most powerful kinds of manure, and it does not seem improbable that their fertilizing powers may be in some manner connected with their property of affording nitrous acid.

Of paring and burning. It has been found that this mode of improvement is not particular to any species of soil, though poor soils, that have few vegetables growing in them, will certainly profit by it in the least degree.

Its particular advantages are, first, that it converts vegetables and their roots into coal. Hence it is that agricultural

writers tell us, though without knowing the reason, that all violence of fire is to be avoided, and that a slow smothering fire is the most proper for this purpose. Secondly, that it destroys the old sickly roots, and thus leaves room for others younger and more vigorous. Many have imagined that it diminishes and consumes the soil; but repeated experience has shewn the contrary. It is well known that clays and loams are rather hardened than consumed by heat. However, unless fresh seeds be committed to the earth, the soil will be unproductive for a number of years; the coaly principle may also be exhausted by too much cropping.

We are told by an ingenious writer, whom we have frequently quoted, the Earl of Dundonald, that moors overgrown with ling or heath, peaty soils, or such as are covered with a sward of coarse unprofitable herbage, and contain a superabundance of vegetable matter, may, with due precaution, be subjected to this process with very beneficial effects. It may also, he supposes, be attended with advantage to strong clayey soils, from the effect that burned or half-burned clay has in rendering such soils more open and less tenacious. In which case the benefit arising from the mechanical arrangement of the soil will probably more than compensate for the dissipation of the vegetable matter of the sward. It is however suggested, that it would be more economical, when the soil is thus intended to be made more open, to calcine the clay in clamps or kilns, and afterwards spread it on the ground, either in its simple state or mixed with lime. Paring and burning are the processes which, in the cultivation of peat mosses and fens, are made to succeed the operation of draining. In this case, care, the author observes, should be taken to burn only as much of the peat as will yield the proportion of ashes necessary to alter the arrangement of the parts of the soil: an effect, he thinks, which with still more advantageous consequences may be attained by lime, limestone-gravel, or even by common mould.

The ashes of fresh or growing vegetables alone produce saline substances or alkaline salts; none can be procured from peat or decayed vegetable matter. The proportion of alkaline or other salts produced by paring and burning is so very small, that if the benefits immediately arising from these processes were to be ascribed solely to them, it might, he says, perhaps be more economical to purchase them at the market price.

The saline matter produced in these processes generally consists of vitriolated tartar, the alkali of the burnt vegetable combining with the sulphuric or vitriolic acid, which, in different states of combination, is contained in most soils. Vitriolated tartar has very powerful effects in promoting vegetation; but as it is not to be procured in sufficient quantity for the purposes of agriculture, the deficiency may be supplied by Epsom and Glauber salts, the effects of which he asserts to be equally beneficial when applied to the ground.

But although these processes of paring and burning have been much recommended, our author thinks that they require great limitation and restriction, and considerable judgment to direct them properly.

If it should be found hereafter that the same advantages can be derived from the application of lime, alkaline, neutral and other salts, without the disadvantages, a decided preference will be due to these methods.

Of gypsum. This is a manure which was first discovered by Mr. Mayer, a German clergyman, in the year 1768: it has since been applied with signal success in Germany, Switzerland, France, and America. If, in our own country, it has not been so much approved of, it is probably because the calcareous principle prevails almost universally. It is clayey lands that are most improved by this manure. The time for spreading this substance is February, March, or even later in the spring, when it is to be thinly sowed on the land at the rate of about

eight bushels to the acre: more would be hurtful. The *rationality* of its effects may be deduced from its extraordinary septic power, for it is found to accelerate putrefaction in a higher degree than any other substance; and for this reason it is not ploughed-in like other manures, but barely strewed on the surface of the land: and this is done in the month of February, or later, in order to convert the old grass quickly into coal, to nourish the young growth.

Mr. Kirwan thinks that it may also be useful, from its being itself no inconsiderable part of the food of many plants, particularly of clover, pulse, and corn; but the land on which it is strewed should be dry, such as would naturally suit clover, &c. otherwise it would be useless to make such a trial.

In America this manure has been sown on sand, loam, and clay-land, without there being much difference in the beneficial effects which it produced. Its effects were however soonest evident on the sandy soils.

The duration of this manure seems to be from seven to twelve years; but, like other manures, its continuance very much depends on the nature of the soil to which it is applied.

A piece of grass land in a worn-out field being covered upwards of two inches thick with barn manure, and another piece in the same field being sown with gypsum for the purpose of contrasting it with that which was dunged; of three crops, that piece of ground to which the gypsum was applied, in every one, produced the greatest quantity.

P A R T II.

OF THE PRACTICE OF HUSBANDRY.

AFTER this view of the principles and theory of the Science of Husbandry, we may proceed to the consideration of the practical part, or the particular management which is necessary in order to render the ground the most highly productive and advantageous.

SECT. I. *Of the different Kinds of Husbandry.*

IN the practice of this useful art two different methods have chiefly been followed; which has occasioned its division into two distinct kinds, to which the titles of *Old* and *New* Husbandry have been applied. The former is that which has been practised in all countries from the most early periods; and the latter that introduced by the ingenious Mr. Tull, and which is also frequently called the *horse-hoeing husbandry*. In the first method of proceeding the farmer evidently attended too little to the advantages of properly breaking, crumbling, and pulverizing the soil; these operations being performed in a very inadequate and imperfect manner.

It has since, however, been found by experience, that the more perfectly these processes are performed, and the cleaner from weeds the soil is kept, the larger, the clearer, and more valuable is the produce. At the same time, however, attention must be paid to the nature of the soil and climate: a thin light soil, from its weakness, must be less disturbed than land that is strong and heavy, and it will be necessary in the former to have the intervals larger than in the latter. It is clear, however, that land, though ever so well tilled in the autumn, when wheat for instance is sown, hardens and soddens in the winter; its particles, beaten down by heavy rains, and sunk by their own weight, approach each other daily more and more: the roots of the plants cultivated have consequently less and less room to extend themselves in quest of their necessary food; and their interstices in the earth become of course so few and close, that they are not able to pierce through them, while weeds spring up, and rob them of their nourishment. By this means the earth, reduced to nearly the same condition as if it had not been ploughed at all, is unable to assist the plants sown in it, in the spring, when they ought to shoot with the greatest vigour. They consequently then stand most in need of the plough to destroy the weeds, to lay fresh earth to their roots in the room of that earth which they have exhausted, to break the particles of the ground anew, so as to enable their roots to spread, in order to their gathering an ample provision of food, which at that time is of the greatest service in promoting their growth.

It is obvious that, in the old or common husbandry, the whole attention is to provide a great store of nourishment for the grain, at a time when it scarcely consumes any, as it then

produces only a few blades, after which it is left to itself, at a season when it might and should be most assisted by proper culture; a management which seems to be extremely preposterous and inconsistent.

That there is a very great advantage in having land in a fine state of cultivation or tillage before it is sown, is universally acknowledged; but the farmer should not stop at those first preparations. Plants require a continuation of culture while they grow, and therefore should not be forsaken until they have attained a state of maturity, and are perfectly formed.

Those who object to the frequent ploughings used in the *New* Husbandry, are afraid of drying the earth too much; because they suppose the moisture escapes more easily from a soil which is well loosened, than from a hard and compact earth. But on the contrary, it is evident from many experiments, that, even in the driest weather, land cultivated according to the new method, continues constantly moister than that which is managed in the old way. Instead of a stagnant wet, more hurtful, probably, than beneficial, to vegetation; earth, when made fine to a considerable depth, is better prepared to absorb and retain the dew, which, when it falls upon the land that is untilled, or but poorly tilled, does not sink far, but is quickly carried off by the heat of the sun. That dew is a great fertilizer of the earth, has been repeatedly proved; and that it will penetrate so deep in a fine loose soil, as to keep that moist, while the ground badly tilled is parched up, seems evident from many experiments.

But further and perhaps stronger proof of the benefits which arise from stirring the ground well and often between plants while they are growing, may be deduced from the common method of raising Indian corn; for in this case there is a constant repetition of ploughing and hoeing between the rows of the grain.

Experience also shews, that if several rows of wheat be sown in a poor but well-ploughed land, the blades of the corn will turn yellow in the spring, especially in dry weather. But that if the earth bordering upon these rows be ploughed deep, in some places near, and in others farther from the rows, the plants will resume their proper colour; first in the places nearest to the new ploughed ground, and afterwards gradually in the others, according to their distance; which proves that they recover their verdure, in proportion as their roots reach the loose mould. This holds equally true in all plants; for Mr. Tull declares, that he does not remember ever to have seen a poor one contiguous to a well-hoed interval, unless overpowered by a too great multitude of other plants—an exception which must be equally made if it were a plant that required more or less heat or

moisture than the soil or climate afforded; and that, on the contrary, he has seen plants grow to an amazing size, when the earth around them has been frequently tilled. He mentions several instances in which the plants acquired an uncommon size from the frequency of hoeing. In short, the stirring of the earth about the plants whilst they grow, is productive of such excellent effects, that, in some parts of this country, and in many places in France, they hand-hoe their corn, particularly wheat, and find that the crops amply repay all the charge and trouble of this expensive operation: which, however, cannot be performed but in well-peopled countries. Every husbandman will immediately see how much a hoe-plough is preferable for this work, and that, to use it rightly, the corn must necessarily be planted in regular rows, as it is in the New Method of Husbandry.

It is obvious, however, that the longest-lived plants stand most in need of this culture. Perennial plants require it more than annual ones; and wheat which is sown in autumn, and does not ripen till nine months after, wants it more than spring-corn, which occupies the ground only for a few months. The former has to conquer a soil rendered hard during the course of the winter: but the other has not that difficulty to surmount; though both of them, and indeed all sorts of plants, are greatly invigorated by the repeated laying of fine fresh earth to their roots. Every farmer knows the vast efficacy of wood-land, before its native strength and vigour are exhausted; and such, in some degree, is that which this mode of cultivation furnishes; besides being constantly attended with the advantage of destroying weeds.

But these are not the only immediate benefits accruing from a due state of tillage; grubs, beetles, worms, and maggots of many different kinds, which abound in many fields, may be greatly diminished, if not entirely extirpated and destroyed, by the well-timed use of the plough, and its auxiliary instruments necessary to the reduction and due pulverization of the soil. Nothing so effectually prevents the ravages of the several tribes of subterraneous insects, as the frequent stirring and crumbling the ground.

It is also observed by an excellent farmer (Mr. Wimpey), that the saving of seed in the modern practice is very great. It is very certain, says he, from experiments most satisfactorily authenticated, that about one-third of the seed which was formerly used, and indeed is still in most places, is fully sufficient. In general it produces a better crop than the whole quantity. In the old husbandry or broad-cast method of sowing, it is usual to allow from two to three bushels of seed-wheat, as the season happens, to a statute acre; but in drilling or setting, as practised in the eastern counties, it is found that from three to five pecks is quite sufficient; so that the difference between the two modes of planting amounts at least to a saving of one bushel and a half per acre. If then these new modes of planting all sorts of grain were equally adopted, the saving, he conceives, would be an addition to the year's produce, of a tenth or twelfth of its whole amount. The farmer, therefore, who in any one year might plant one hundred acres of wheat in the new method, would save at least one hundred and fifty bushels of seed. If the savings of seed then on one hundred acres would be one hundred and fifty bushels, how amazing would be the amount of the quantity saved on all the tillage lands of Great Britain!

Mr. Duhamel observes in his Elements of Agriculture, that it is frequently more advantageous to increase the fertility of land by ploughing than by the use of dung. The benefit derived from the latter he considers as limited, while scarcely any bounds can be set to the utility of the former.

It is for this reason, says he, that land intended for wheat is ploughed three or four times before the grain is sowed. Some farmers, who could not dung all their lands, ploughed part of them double the usual number of times, and reaped greater crops

from these, than from those which were dunged. The expence of the ploughings extraordinary will be much less than the price of the dung necessary for the land, if the farmer is obliged to purchase it. The farmer must not however think of practising the New Husbandry in land which cannot be brought to a fine tilth: for as no remedies are proper for all diseases, so no one culture can suit every kind of soil. In order, says the same author, to answer the ends of this husbandry, the seeds must be distributed so sparingly, that each plant may have room to extend its roots in such manner, that they may be able to collect an abundant quantity of food; each plant must be enabled to tiller greatly, so as to produce a considerable number of stalks; and each stalk must be enabled to bear a fine long ear, well filled with grains to its very point. And to effect the first of these qualities, the field, after being thoroughly ploughed and well harrowed, must be divided by furrows, the spaces between which may be of such breadth as shall be judged most proper. In the middle of these spaces, which will be distinguished by the name of beds, the wheat, or other grain, is to be sown in one, two, or more rows. An inch will be sufficient for the distance between the grains lengthwise of the row; though that may be somewhat less, if the ground be not very good for wheat; or, on the contrary, somewhat more, if it be excellent for that grain. By this distribution, each plant will find, in the intermediate spaces between the beds, and in the beds themselves, a sufficient extent of earth wherein to collect its necessary food; for those intermediate spaces, which I shall call alleys, must be wide enough to admit of stirring the ground in them while the plants grow: but to answer the second and third intentions, it is of consequence that these stirrings be performed at proper seasons, because each of them is to produce its particular effect.

It is likewise essentially necessary that the rows of corn be sown very straight; a circumstance which, though it be attended with some trouble, ought not to discourage the husbandman, because the great difficulty will be only the first time. After the ground has been once rightly sown, it will be easy to continue in the same regular track every following year. The only precaution necessary is, that the furrows be made as straight as possible, and that care be taken to leave a proper interval between one furrow and another, if three rows are to be sown. It will be right, when convenient, also to suit the direction of the furrows to the declivity of the land, that the water may drain down to the lowest part of the field, where a ditch should be dug to carry it off: and it will also be necessary to make them lengthwise of the field, if possible, that the less ground may be lost by the space which must be left for the plough to turn in.

After the seed is put into the hoppers of the drill, the horse which draws this instrument must be made to walk slowly in the furrow first made by way of guide: and in order to drop as nearly as possible the intended quantity of seed, the outlet of the hopper must be proportioned to the size of the grain.

The distance which Mr. Tull found to produce the greatest crops was two rows upon a ridge of four feet eight inches, with ten-inch partitions.

Hoeing. This sort of tillage is performed in various ways, and by means of different instruments, which will be described.

Land which retains water should be ploughed once about October, when the weather is fine. In doing this, a furrow should be first cut in the middle of the alleys, and then it should be filled with the earth on each side, even so far as to arch it up, and leave only a small furrow on either side, close to the beds, to drain off the wet, which would prove very prejudicial to the plants if it were to remain long near their roots. This loosening of the earth will also fit it for being mellowed by the winter's frosts; to which, however, care must be taken not to expose the roots of the corn, by leaving them too bare of mould.

The most proper time for this stirring of the ground is when the plants have shot out some blades.

The second horse-hoeing, which should be given as soon as the hard frosts are past, that is to say, by the end of March, is intended to make the plants tiller; and will have this effect, if, after the earth near the rows has been stirred a little, that which was before laid up in the middle of the alleys be returned back to the furrows at their sides. This earth, having been mellowed during the winter, will afford excellent nourishment to the plants now beginning to vegetate apace, and they will soon put forth their multiplied stalks.

The third hoeing, which is the second after winter, and is intended to strengthen the stalks, should be performed when the ears of the corn begin to appear. This culture, which is looked upon as the least important of all, and is sometimes even omitted without any great inconvenience, need not be any thing more than a slight stirring of the earth, in which it will however be right to begin to hollow the alleys.

The last stirring of the earth between the rows of corn is one of the most important, being that which makes the grains swell and grow full bodied to the very point of the ear. The most proper time for this is when the ears begin to bloom: but as the corn is then high, only one furrow can be cut in the middle of the alleys, the earth of which should be laid up to the stem of the plants on each side. The plough will hardly be able to pass more than twice in this furrow, which should, however, be made as deep as possible, in order to bank up the greater quantity of earth. By this operation, the now fallow alleys are prepared for the next sowing; for it is in the middle of them that the corn is to be planted the following year; and the now eared wheat is earthed up, to prevent its being lodged; though in general corn thus cultivated is less apt to be beaten down than that which is raised in the common way, because the straw of this, being more exposed to the air, becomes harder and acquires a firmer texture, especially toward its bottom. It is for this reason that a tuft of corn, which stands quite single, is scarcely ever beaten down by the weather.

When the corn is reaped, all possible care should be taken not to trample upon the adjoining ploughed ground.

It is well known, that vigorous plants do not ripen their seeds so soon as those which have been stunted in their growth: for this reason, the corn cultivated according to the principles of the New Husbandry ripens later than in the common way, and should therefore be sown somewhat earlier. We will now suppose that the crop is reaped, and that the same field is to be sown again with wheat the next year, and every year after, as it may be, because the rows of corn are placed each time in the middle of the former alleys, which have been ploughed during the whole year, without producing any thing. Thus, the only difference between this New method and the Old Husbandry, is, that instead of resting, or fallowing, a whole field, whilst another whole field is under corn, and each of them separate from the other, the fallow here is in the same field as the corn, being interposed by means of alleys, which is the part rested between the beds, and is the part cultivated: but there is this great advantage here, that the stirring of the earth in the alleys which are not planted, not only prepares the soil admirably for being sown the next year, but invigorates the plants actually growing in the beds.

If it be thought proper to dung the alleys in order to prepare them for the reception of the seed, the dung, which should be thoroughly rotten, must be laid in the bottom of the deep furrow before made in the middle of them, and there covered with the earth which was thrown up towards the rows of wheat. If the land does not want dunging, this deep furrow is filled up without it; and this should be done immediately after harvest: that there may be time to give the ground another stirring,

which need only be a slight one, before the sowing of the rows, which are now to be in the middle of the former alleys; and the alleys of this year will be in the place of the last year's stubble.

Though land, cultivated according to the principles of the New Husbandry, does not require so much dunging as that which is managed in the old way, yet this manure will always help to enrich the soil, especially if it be used in the manner here directed. By being thoroughly rotten when it is laid in the furrow, and there covered over immediately after harvest, it will have time to mellow and diffuse its influence, and not be apt afterwards to choke up the shares of the drill.

It is obvious, says Mr. Winpey, that the improvement the soil acquires by means of frequent and well-timed tillage, must be gradual and progressive, and that the longer it is kept in tillage, if duly performed, the more fertile it becomes. He adds, that one ploughing in the beginning of winter, and a second in the winter, or early in the spring, will be more effectual in pulverizing and fertilizing the soil than half a dozen at any other time of the year.

This improvement in tillage, says he, is so very clear and certain, that it surprises one much that it is not universally practised. He therefore concludes, that these improvements in tillage may be considered of the greatest importance, as forming the basis or foundation on which the successful introduction of the several new articles of field culture depend.

SECT. II. *Of the Instruments of Husbandry.*

FROM what has been observed in the preceding section, it will be evident that all kinds of lands are not capable of receiving the New Husbandry; consequently, in the description of implements, it will be necessary to give an account of those which are most advantageously useful both in the old and new method of cultivating the ground.

Various instruments are employed in these different kinds of husbandry, such as ploughs, harrows, rollers, horse and hand hoes, drill machines, &c. which are still more diversified by various modifications and constructions, in order to adapt them to particular purposes. Ploughs are probably not yet arrived at that degree of perfection of which they are capable; they have however lately been very much improved. Formerly, Mr. Winpey justly observes, some of them little more than scratched the ground; others were made so heavy and clumsy as to require great strength to work them; but that at present there are several in use which perform much better. Of the last description are the *Rotherham*, the *One-wheeled*, the *Norfolk*, and the *Double* ploughs. And of those which have been contrived for particular uses, that with two mould boards is highly useful. With this plough the open furrows for potatoes may be conveniently made, and the sets be afterwards completely covered by splitting the ridges. And when they have been horse-hoed, it again splits the ridges in the intervals, and earths up the plants. It effectually answers the same purpose in all broad drilled crops where the horse-hoe is used, and with half the labour performs the same work as could be done with the common plough, and in half the time which that instrument requires.

The *Miner* is a kind of plough which has lately been much employed in the cultivation of arable land in Lancashire, and is highly useful in opening the soil to such depths as may be thought necessary. It is made very strong, with a share only without any mould board, for the purpose of raising the earth; it therefore loosens without turning up the soil, an operation which is performed still more effectually if two shares or coulter be added. In practice, it is made to follow the common plough in the same furrow, so as to penetrate to a considerable depth below the bottom of it. Doctor Anderson considers it as an extremely useful implement in lands that are capable of admitting it to work, and which no farmer should be without.

Common Plough. This is a plough which is much in use in the North of England and in Scotland, and which answers all common purposes tolerably well, especially the breaking up of stiff and rough land, where stones abound and hard strong clayey soils. It is represented at Pl. 13, fig. 1. The great length of its head gives it a pretty firm hold of the ground, while its weight prevents it from being thrown out by any obstructing substance; the length of the handles also gives the ploughman great command over it, and by the length of its mould-board it lays the furrow-slice well over.

The *Chain Plough*, Pl. 13, fig. 2. is likewise much in use in the Northern parts of the kingdom. From the shortness of its head and mould-board, friction is considerably lessened, being only thirty inches from the point of the sock to the hind part of the head, and about eight feet from the point of the beam to the end of the handles. The sock and mould-board form a gently curving line, which prevents the gathering of earth. It is calculated so as to make a wide furrow without leaving any part unfurrowed. It is termed the Chain Plough, from its being drawn by an iron chain fixed to the back part of the beam just before the coulter. This produces two advantages; which are, that by means of a muzzle it makes the plough go deeper or shallower, and causes less fires on the beam than if it were fixed at the end. This plough is proper for loams, coarse clays, and those tender soils which are free from stones. It may also be employed for opening up pasture grounds, which have formerly been well cultivated.

Another chain-plough of smaller dimensions than common, and which is drawn by one horse, may be employed very advantageously for horse-hoeing where the land is mellow, which it ought always to be for this process. It is sufficient for making furrows to receive the dung, for ploughing the drills after dunging, and for hoeing the crop. A still smaller plough of the same kind may be recommended also for a kitchen-garden. It can be reduced to the smallest size, by being made of iron; and where the land is properly dressed for a kitchen-garden, an iron plough of the smallest size drawn by a horse will save much spade-work. Nor is this the only case where a single-horse plough may be profitably employed. It is sufficient for seed-furrowing barley, where the land is light and well-dressed; and it may be used in the second or third ploughing of fallow, to encourage annual weeds, which are destroyed in subsequent ploughings.

The *Rotherham Plough*, Pl. 13, fig. 3. is a machine of very simple construction, and easily worked. AB is the beam, CD the sheath, EBD the main handle, FR the smaller handle, GH the coulter, KI the sock or share, NP the bridle, S the sly-band, and ML a piece of wood in place of a head. The difference between this and the common plough seems to consist in the bridle at the end of the beam, by which the ploughman can give the plough more or less land by notches at N, or make it cut deeper or shallower by the holes at P; in the coulter or share, which is so made and set as to cut off the new furrow without tearing; and in the mould-board, which is so shaped as first to raise a little, and then gradually turn over the new cut furrow with very little resistance. But the greatest advantage attending it, is its being so easy of draught, that it will do double the work of any common plough. An improved plough of this kind has lately been invented by Mr. Cook.

The *Paring Plough*, Pl. 13, fig. 4. is an instrument used in several parts of this country for paring off the surface of the ground, in order to its being burned, &c. From A to A is the plough-beam, about 7 feet long, mortised and pinioned into the block B. CC are the sheaths or standards, made flat on the inside, to close equally with the paring plate, and fastened to it with a bolt and key on each side, as at D. E is the paring plate of iron laid with steel, about four inches wide, and from

12 to 18 inches long. FF are two iron braces to keep the standards from giving way. GG are the plough handles, which must be fixed slope-ways between the beam and the standards. The use of the pin-holes in the beam, is to make this plough cut more or less deep, by fixing the wheels nearer to or farther from the paring plate.

The *Four-coultered Plough* is represented at Pl. 14, fig. 13. Its beam is ten feet four inches long, whereas that of the common plough is but eight. The beam is straight in some common ploughs, but in this it is first straight, and then arched. It is thus contrived to avoid the too great length of the three foremost coulters, which, if the beam were straight all the way, would bend and be displaced, unless they were very heavy and clumsy. The sheath in this plough should be seven inches broad. The fixing of the share in this, as well as in the common plough, is the nicest part, and requires the utmost art of the maker; for the well-going of the plough wholly depends upon it. Another matter of importance is the placing the four coulters; which must be so set, that their four edges, as the plough moves forward, may be all parallel to each other, or very nearly so; for if any one of them should much incline to, or recede from, either of the other, then they would not enter the ground together. The coulter is two feet eight inches long before it is worn; the handle takes up sixteen inches of this length, which is allowed in order that the coulter may be driven down as the point wears away. As to the wheels, the left-hand wheel is 20 inches diameter, and that on the right 2 feet 3 inches; and the distance at which they are set from each other, is 2 feet 5½ inches.

The *Patent Sward-cutter*. The different parts of this machine are represented by N^o 1. 2. 3. of Pl. 13, fig. 5. AA, &c. is a square frame 3 feet 4 inches from the fore to the hind part, by 4 feet 3 inches, the breadth of the machine within side; the timber (when of fir) 4 inches square, placed on two wheels BB, 3 feet diameter. CC, &c. are six strong pieces of wood, called *bulls*, 3 feet long, 5 inches and a half broad, the thickness 6 inches at E, and tapering to 3 inches at F. Into these are fixed the cutting wheels, which are iron, 13 inches diameter, ¾ths of an inch thick at the centre, about an inch diameter for piercing holes to fix the iron axles in; from that they are to be of such thickness as will allow the edges to be well steered. The wheels are fixed by two bolts going through the bulls. GG, &c. are hollow pieces of wood, called *bolts*, each 3½ inches long, which inclose the bolt M. M. and keep the bulls CC, &c. at their proper distances, but may be made longer or shorter at pleasure, according as the sward requires to be cut in larger or smaller pieces. The iron bolt MM goes through two pieces of wood or iron, PP, 7 inches long, clear of the wood, supported by iron stays fixed to the frame, and through all the bulls. HH, N^o 2. and 3. a cylinder or segment of wood, 7 inches diameter, called a *rocking tree*, which goes across the frame, and moves on the pivots fixed into it, one at each end, supported by an iron bolt or piece of wood mortised into the frame, 8 inches high, as appears in N^o 2. and 3. to which 6 chains or ropes are fixed by hooks, at different distances, as you want your cuts, 9, 8, 7, or 6 inches from one another, and are joined to the end of each bull in which the cutting wheels run; so that when the rocking tree is turned about by the lever I, fixed in the middle of it, all the bulls, with their cutting wheels, are raised out of the ground at once, as in N^o 3. by which means the machine may be turned without any danger of straining the wheels. LLL, &c. N^o 1. 2. 3. are weights of freestone, 26 inches long and 6 inches broad; the under one 4 inches thick, the upper one 3 inches thick; weighing about 64lb. the under, and 48 the upper; each of them having two holes, through which iron spikes, firmly fixed in the bulls, pass, in order to keep them steady. When the ground is easily cut, the under stone may answer; when more difficult, the other stone may be added; so that every

wheel may have 7 stone weight upon it, which has been found sufficient for the stiffest land and toughest sward the machine has ever been tried on. Weights will answer fully better, but are more expensive. The lever I, N^o 2. 3. which ought to be 5 feet long, must have a sliding rope on it, fixed to the back part of the frame; so that when the cutting wheels are all taken out of the ground three or four inches, by the rocking tree's being turned partly round by the lever, the rope may be fixed to it by a loop over the pin R, N^o 3. Thus all the cutting wheels are kept out of the ground till the machine is turned; and then by moving the loop off the pin, it slips back towards the frame, and the lever is gently let back to its place, as in N^o 2. by which the cutting wheels are put into their former posture, by the weights fixed on the bulls in which they run. PP, N^o 1. a small bolt of iron, with a hook on one end of it, to strengthen the bolt MM, to be hooked on the centre of it, and joined to the frame by a nut and screw. For a single-horse sward-cutter (which has only four cutting wheels), a pair of shafts are used, and may make the two sides of the frame without any joinings. The width of the frame, in proportion to the double-horse sward-cutter, is as four to six.

The original intention of this machine was to prepare old grass-ground for the plough, by cutting it across the ridges, in the beginning of or during winter, when the ground is soft, in order to answer all the purposes designed by the four-coultered plough, so strongly recommended for bringing into tilth grass ground that has been long rested. This the sward-cutter has been found to do much more effectually and expeditiously: for the machine just mentioned cuts the sward in the same direction with the plough; and is liable, from every obstruction the coulter meet with, to be broken or thrown out of its work altogether; to which the sward-cutter consisting of four, six, or more cutting wheels is never liable, from these being entirely independent of one another, cutting the ground across the ridges before ploughing, and rendering that operation easier to two horses than it would otherwise be to three. The furrow being cut across, falls finely from the plough in squares of any size, not under six inches, in place of long slips of tough sward seldom and imperfectly broken by the four-coultered plough.

This instrument is very fit for preparing ground for burn-beating, as it will save much hand-labour. It may also be properly used in cross-cutting clover of one or two years standing, to prepare the ground for wheat, if the land is stiff and moist enough. It may be applied to cutting and cross cutting pasture ground, intended to have manure of any kind put upon it to meliorate the grass: and in this it will far exceed the scarificator mentioned in one of Mr. Young's tours. In preparing for barley, it excels a roller of any kind in reducing the large hard clods in clay land, occasioned by a sudden drought, after its being ploughed too wet; and it is likewise very proper for reducing such clay land when under a summer-fallow. In this operation, the sward-cutter is greatly preferable to the cutting roller, likewise mentioned by Mr. Young; for the wheels of the latter being all dependent one on another, when one is thrown out by a stone, three or four must share the same fate. Besides, the cutting roller has but seven wheels in six feet; whereas the sward cutter has six in four feet three inches, at nine inches distance; and, if necessary, may have them so near as six inches.

Two horses are sufficient for the draught of a double-horse sward-cutter, and one horse for a single-horse one. One man manages the machine and drives the horses. He begins his operation by first measuring off 20 or 30 paces from the machine, and there fixing a pole. He then cuts the field across, as near at right angles with the ridges as he can. When the cutting wheels are past the last furrow about a yard or so, and the machine is upon the outmost ridge of the field on which it

must turn, he must stop the horses; then take hold of the lever I, N^o 2. and by pulling it to him he raises the cutting-wheels out of the ground, which are kept so by the loop of the rope being put over the pin R, in the lever I, N^o 3. till the machine is turned and brought to its proper place, which is done by measuring off the same distance formerly done on the opposite side of the field. When the cutting-wheels are exactly over the outmost furrow, then, on the horses being stopped, the rope is slipped off the pin R, and the lever returned to its former place, as represented N^o 2. which allows the weights LL, &c. to force the cutting wheels into the ground again. He then goes on till the interval betwixt the first and second stroke of the machine is all cut, and in this manner the field is to be finished.

One sward-cutter will cut as much in one day as six ploughs can plough. The land may lie several months in winter after being sward-cut, when there is no vegetation to make the cuts grow together again before it is ploughed; but the sooner it is ploughed after cutting the better, that it may have the benefit of all the winter's frost, which makes it harrow better at seed-time.

Any common wright and smith may make this machine. It is very strong, and simple, easily managed and moved from place to place; and costs only about 5l. or 6l.

Harrow. These instruments are commonly considered as of no use but to cover the seed; but they have another use scarcely less essential, which is to prepare land for the seed. This is a circumstance of importance for producing a good crop; but the imperfect way in which these purposes are answered by the common harrow, render it a matter of importance to enquire into the merits of other inventions of the same sort.

Brake-Harrow. This is a large and weighty harrow, the purpose of which is to reduce a stubborn soil, where an ordinary harrow makes little impression. It consists of four square bulls, each side five inches, and six feet and a half in length. The teeth are 17 inches long, bending forward like a coulter. Four of them are inserted into each bull, fixed above with a screw-nut, having 12 inches free below, with a heel close to the under part of the bull, to prevent them from being pushed back by stones.

This instrument may be of advantage in the following strong clay that requires frequent ploughings. A brakeing between every ploughing will pulverize the soil, and render the subsequent ploughings more easy. In the month of March or April, when strong ground is ploughed for barley, especially if bound with couch-grass, a cross-brakeing is preferable to a cross-ploughing, and is done at half the expence. When ground is ploughed from the state of nature, and after a competent time is cross-ploughed, the brake is applied with great success, immediately after the cross ploughing, to reduce the whole to proper tilth.

A little reflection, however, even without experience, will make it evident, that the same harrows, whatever be their form, can never answer all the different purposes of harrowing, nor can operate equally in all soils. The following, therefore, of three different forms are adapted for different purposes, but equal perhaps to all that is designed from the use of such an implement. They are all of the same weight, drawn each by two horses. Birch is the best wood for them, because it is cheap, and not apt to split.

First Harrow, Pl. 13. fig. 6. is composed of four bulls, each four feet ten inches long, three and a quarter inches broad, and three and a half deep; the interval between the bulls 11 and three-fourths inches; so that the breadth of the whole harrow is four feet. The bulls are connected by four sheaths, which go through each bull, and are fixed by timber nails driven through both. In each bull five teeth are inserted, ten inches free under the bull, and ten inches asunder. They are of the same form with those of the brake, and inserted into the wood in the same man-

ner. Each of these teeth is three pounds weight; and where the harrow is made of birch, the weight of the whole is 6 stone 14 pounds Dutch.

The *Second Harrow*, Pl. 13. fig. 7. consists of two parts, connected together by a crank or hinge in the middle, and two chains of equal length, one at each end, which keep the two parts always parallel, and at the same distance from each other. The crank is so contrived, as to allow the two parts to ply to the ground like two unconnected harrows; but neither of them to rise above the other, more than if they were a single harrow without a joint. In a word, they may form an angle downward, but not upward. Thus they have the effect of two harrows in curved ground, and of one weighty harrow in a plain.

The *Third Harrow*, Pl. 13. fig. 8. consists also of two parts, connected together like that last mentioned. It has eight bulls, each four feet long, two and a half inches broad, and three deep. The interval between the bulls is eight inches; and the breadth of the whole harrow, including the length of the crank, is six feet four inches. In each bull are inserted five teeth, seven inches free under the wood, and ten and a half inches asunder, each tooth weighing one pound. The rest as in the foregoing harrows.

These harrows are a considerable improvement. They ply to curved ground like two unconnected harrows; and when drawn in one plain, they are in effect one harrow of double weight, which makes the teeth pierce deep into the ground. The imperfection of common harrows, known to almost every farmer, will suggest the advantages of this set of harrows. The first is proper for land that has long lain after ploughing, as where oats are sown on a winter furrow, and in general for harrowing stiff land: it pierces deep into the soil by its long teeth, and divides it minutely. The second is intended for covering the seed: its long teeth lay the seed deeper than the common harrow can do; which is no slight advantage. Seed slightly covered by the common harrows wants moisture, and is burnt up by the sun; beside, that a proportion of it is left upon the surface uncovered. The third harrow supplies what may be deficient in the second, by smoothing the surface, and covering the seed more accurately. The three harrows make the ground finer and finer, as heckles do lint; or, to use a different comparison, the first harrow makes the bed, the second lays the feed in it, the third smooths the clothes. They are contrived in fact to answer an established principle in agriculture, That fertility depends greatly on pulverizing the soil, and on an intimate mixture of manure with it, whether dung, lime, marle, or any other.

Chain and Screw Harrow. But in addition to these, in Pl. 13. fig. 9. is a harrow, to which this name is given. Its properties are, that if your ridges be high, and you wish to harrow them from one end to the other; by lengthening the chain (which the screw commands), the harrow, when drawn along, forms an angle downwards, and misses none of the curve of the ridge, so far as it extends (which may be nine feet, the distance from A to B. The extent, in the contrary direction, is five feet six inches). When the crowns of the ridges have got what is thought sufficient harrowing lengthwise, you shorten the chain by the screw, which forms an angle upwards: the harrow is then drawn by the horses, one on each side of the furrow; which completely harrows it, and the sides of the ridge, if 18 feet broad. When you want to harrow even ground or high ridges across with the screw, you can bring the harrow to be horizontal, so as to work as a solid harrow without a joint.

The teeth are formed and fixed in the common manner, square, not in the fashion of counters; and are nine or ten inches below the wood, and of such strength as is required. The figures 1, 2, &c. point out where the 12 teeth on each side of the harrow are placed. Where a strong-brake harrow is not necessary, by making the teeth shorter and lighter, you

may have 48 teeth, which will tear the ground at every two inches, cover the seed well, and make a fine mould. It is recommended, that harrows for every purpose, and of any size, be made on the above principle; by which no tooth can ever follow the track of another, and all of them will be kept constantly acting.

Many inconveniences have however been found to attend the use of harrows, even when constructed on these improved plans; therefore Mr. Knight has been induced to form one upon a very different principle. It is made with wheels and an axle tree, by which means it performs its work with much greater ease to the horses, and the too great stress on its fore-part as well as its liability to be choked up is prevented.

Knight's Harrow. This harrow is constructed with two joints AA in the axle-tree, Pl. 16. fig. 3. one of which is covered, as when the harrows are at work, the other uncovered, to shew the construction of the joint; and two joints, aa, in the front of the bar; by means of which the pliability of the tree, and that of the bar, humours the wheels, and keeps them in their proper directions in the furrow; and, requiring very little scope of ground, the turnings are rendered very convenient and easy.

If, in the course of working the land, a farmer varies in the breadth of his furrows, it is contrived, in order to make the harrow narrower, that part of the bar B, which is fastened by two pins bb, may be taken off when requisite; part of the axle-tree, and part of the hind-bar C, both which are fastened by the iron bolt D, are also to be removed; and the remaining outward parts to be joined and fastened by one of the two pins in the bar, and by a shorter bolt d, shewn separate, and intended for the axle-tree and hind-bar.

If the farmer should work two horses which are unequal in height, the horizontal direction, or evenness of the joints, may be destroyed in some degree: to remedy and supply this deficiency in the horses, the whipple-tree E, is made to be heightened or lowered by means of notches e, shewn separate, to which it is connected by a ring. In light barley-lands, when you accommodate your harrow for one horse, by narrowing it as before directed, there are two frings conveyed by two rings from the axle-tree, through two loops ff, under the front bar. The wheel F, under the hind-bar, which is shewn enlarged and separate in the plate, will support the bar; and, by this assistance, the harrow is conveyed to the field on the axle-tree bar, as a substitute for a sledge: there are also two wooden pegs gg, by which the harrows, when turned upon the carriage, are secured.

Should it be objected, that the harrow will prove expensive on account of the iron, an axle-tree and joints may be readily constructed in wood, upon the same principles as shewn in the plate separate at G; though preference should be given to iron. If the wheel under the hind-bars should not be adopted, there is a slider H, shewn separate, which works with a pin, and, when not wanted, is turned and fastened under the axle-tree.

As it is found by experience to be very useful to heighten or lower the harrows occasionally, particularly on broad lands rising in the middle; where of course the middle harrow takes most hold, and generally requires the least; this may be easily effected, by fixing irons, with notches, like those on the fore-bar, by which the whipple-trees are supported, on the hind-bar, instead of the hooks, and putting the hooks on those irons.

The *Fallow-cleansing Machine* is intended for cleansing fallows from weeds, &c. AA, Pl. 13. fig. 10. is the frame; B the first, C the second roller; in which last are two cranks to move the arms DD, which work the rake up the directors fixed on the plank E. The under side of the lower ends or shares of these directors are sharp, to cut the clods and let them come on the upper side. Each alternate heel of the share is longer than

the intermediate one, that they may not have more than one-half to cut at once. At the back of the plank E are two screws to let it loose, that the directors may be set higher or lower. The shares are to penetrate the ground two or three inches, to raise the quicks till the rake II fetches them into the cart H, where a man must be ready with a muck-hook to clear them backward when gathered. In the rake I are two teeth for every space of the directors, that stones, &c. may be gathered without damage. At KK are two staples, by which the machine is drawn: under them at *b* are two hooks, placed low to raise the machine in turning, by the help of the traces; and the axle-tree of the cart should be fixed upon a pin, that it may turn like a waggon. FF are the triggers to throw the rake behind the roots. The long teeth at GG are to cleanse the roller C. II is the rake which gathers up the weeds into the cart H, and is drawn above the trigger F by the working of the arms D, expressed by the dotted lines at *dd, iii*. The triggers F, of which there is one on each side, move on the pivots *a*; so that when the points *b* of the rake I have been drawn up by the directors E to the part marked *c*, the trigger, giving way, permits the rake to pass; but immediately falling, the rake returns along the upper surface of the trigger marked *cc*, and of course falls on the weeds when it comes to the end, a little beyond the pivot *a*. The reader will observe, that the boarding is taken away on one side, in the Plate, in order to give a more perfect view of the inner parts of the machine.

Universal Sowing Machine. This, whether worked by hand, drawn by a horse, or fixed to a plough, and used with it, is extremely simple in the construction. It will sow wheat, barley, oats, rye, clover, cole-feed, hemp, flax, canary, rape, turnip, besides a great variety of other kinds of grain and seeds, broadcast, with great accuracy. It is equally useful in the new husbandry, particularly when fixed to a plough; it will then drill a more extensive variety of grain, pulse, and seed, through every gradation, with regard to quantity, and deliver each kind with greater regularity than any drill plough whatever. When used in this manner, it will likewise suit farmers who are partial to the old husbandry, as it will not only sow in the broadcast way with the most singular exactness, but save the expence of a seedsmen; the seed being sown either over or under furrow at pleasure, and the land ploughed by the same operation.

Perhaps a fair and decisive experiment for ascertaining the comparative merits of broadcast or drilling any particular crop, was never before rendered so practicable as by this machine; since the seed may now be put in with the utmost degree of regularity, in both methods of culture, by the same movement; and without this it is perhaps impossible to make a just decision.

The advantages of this machine consist in its spreading any given quantity of seed over any given number of acres with a mathematical exactness, which cannot be done by hand; and by which great saving may be made in seeding the ground, as well as benefiting the expected crop. It will likewise broadcast beans, pease, and tares, or drill them with the greatest exactness, particularly when constructed to be used with a plough. And these advantages are accompanied with another, viz. that the wind can have no effect on the falling of the seed.

Of the Machine when used without a plough, and drawn by a horse. It may in this case be made of different lengths, at the desire of the purchaser. The upper part AAAA, Pl. 14. fig. 2. contains the hoppers from which the grain or seed descends into the spouts. The several spouts all rest upon a bar, which hangs and plays freely by two diagonal supporters BB; a trigger fixed to this bar bears a catch wheel: this being fixed on the axle, occasions a regular and continual motion, or jogging of the spouts, quicker or slower in proportion to the pace the person

sowing with it drives; and of course, if he quickens his pace, the bar will receive a greater number of strokes from the catch-wheel, and the grain or seed will feed the faster. At the bottom of the machine is placed an apron or shelf in a sloping position, and the seed, by falling thereon from the spouts above, is scattered about in every direction under the machine, and covers the ground in a most regular and uniform manner. To sow the corn or seed in drills, there are moveable spouts (see fig. 3.), which are fixed on or taken off at pleasure, to direct the seed from the upper spout to the bottom of the furrow.

The machine is regulated for sowing any particular quantity of seed on an acre by a brass slider, A, fig. 4. fixed by screws against a brass bridge on each of the spouts. The machine is prevented from seeding while turning at the ends, by only removing the lever E, fig. 5. out of the channel G, to another at H, on the right hand of it, which carries back the bar from the catch wheel, and occasions the motion of the spouts to cease, and at the same time brings them upon a level by the action of the diagonal supporters; so that no corn or seed can fall from them. The machine in this form is particularly useful for broadcast sowing clover upon barley or wheat; or for sowing any other kind of seed, where it is necessary that the land should first be harrowed exceedingly fine and even.

This machine, when used, must be placed about two feet from the ends of the furrows where you intend it shall begin to sow. Fill the hoppers with seed, and drive it forwards with the outside wheel in the first furrow. When you are at the end of the length, at the opposite side of the field, lift the lever E, fig. 2. into the channel H, and the machine will instantly stop sowing. Drive it on about two feet, and then turn. Fill the hoppers again if necessary; then remove the lever back again into the channel G, and in returning, let the outside wheel of the machine go one furrow within the track which was made by it, in passing from the opposite end.

Method of regulating the Machine. There is fixed in each spout a bridge (see fig. 4.), with an aperture B, for the grain or seed to pass through. This aperture is enlarged or contracted by a slider A, which passes over it; and when properly fixed for the quantity of seed designed to be sown on an acre, is fastened by means of two strong screws firmly against the bridge. This is made use of in sowing all kinds of seed, where it is required to sow from one bushel upwards on an acre. To sow one, two, three gallons, or any of the intermediate quantities, as of clover, cole-feed, &c. the brass plate, fig. 5. is placed between the bridge and the slider, with the largest aperture B downwards, which aperture is enlarged or contracted by the slider as before. To sow turnips, the same plate is placed between the bridge and the slider, with its smallest aperture A downwards, and the hollow part about the same aperture inwards.

A view of the regulator is had at fig. 6. by which the apertures in the several spouts are all set exactly alike, with the utmost ease, to make them feed equally. The extreme height of the largest aperture is equal to the breadth AB, and the breadth at C is equal to the height of the smallest aperture used, viz. that for turnips. The side AC is divided into 60 equal parts, and on it moves the slider or horse D; which being placed at any particular degree, according to the quantity of seed required to be sown on an acre, is fixed upon it, by a screw on the side of the slider or horse. When this is done, the end of the regulator is put through the aperture in the bridge or plate (whichever is intended to be used), and the slider against the bridge in the spout, raised by it, till it stops against the horse on the regulator; then the slider is fastened against the bridge firmly by the two screws, care being taken at the same time that it stands nearly square. Thus the spouts, being all fixed in the same manner, will feed equally.

It is easy to conceive that the size of the apertures, and con-

frequently the quantity of seed to be sown on an acre, may be regulated with a far greater accuracy than is required in common practice.

The spouts may be regulated with the utmost nicety, in five minutes, to sow each particular seed for the whole season. But a little practice will enable any person, who possesses but a very moderate capacity, to make the spouts feed equally, even without using the regulator.

Of the Machine, when made to be used by hand. The chief difference in this case is, that it is made lighter, with but three spouts, without shafts, and is driven forwards by the handles. It has also a bolt in front, which being pushed in by the thumb, releases the machine; so that it can then easily be placed in a perpendicular position. This alteration is necessary to keep the handles of a convenient height, in sowing up and down a hill, where the slope is considerable; and is done while the machine is turning at the end of the length. The method of regulating and using it is the same as when made to be drawn by a horse.

Of the Machine, when formed so as to be used with a plough. This is seen at fig. 1. pl. 14. and is, without doubt, the most useful application of the machine; it can be fixed without difficulty to any kind of plough, in the same manner as here represented. The advantages arising from its use are considerable; for, besides the increase in the crop, which will be insured by the seeds being broad-cast with a mathematical nicety, a large proportion of seed (the value of which alone, in a few months, will amount to more than the price of the machine) and the seedman's labour will be saved. The seed may likewise be sown either under or over furrow; or one cast each way, as is practised by some farmers. The seed also, being cast by the machine upon the fresh ploughed land, may be immediately harrowed in, before the mould has lost any part of its moisture; which in a dry season will greatly promote the crop. In drilling any kind of grain, pulse, or seed, it possesses every property that can be wished for in the best drill-plough, nor will it (as most of them do) bruise the seed, or feed irregularly. The construction of the machine is nearly the same as the large ones.

To prepare it for drilling, instead of the apron, place the long spout, fig. 3. upon the brackets, on the front of the machine, by the ears AA, to receive the seed from the upper spout, and fasten the lower end of it, by a small cord, to that hook upon which the apron is hung for broad-casting, which is next the plough (see fig. 7.); the seed will then be directed by the long spout, to the centre of the furrow, near the heel of the plough. The spring for correcting the strength of the stroke, is necessary only when they are required to go along the side of a considerable declivity. The machine, when fixed to a plough, does not require the smallest degree of skill in using, as nothing is necessary but to keep the hopper filled, which will contain a sufficient quantity of seed to go upwards of 140 rods before it will want re-filling, when three bushels and a half are sown on an acre. The accuracy with which it will broad-cast, may in some measure be conceived, by considering that the seed regularly descends upon the apron or shelf, and is from thence scattered upon the ground, in quantity exactly proportioned to the speed of the plough: also that each cast spreads to the third furrow; and by this means shuts upon the last. In this manner it is continually filling up till the whole field is completely covered; so that it is impossible to leave the smallest space without its proper quantity of seed. When the plough is wanted for any other purpose, the machine, with the wheel at the heel of the plough for giving it motion, can be removed or replaced at any time in a few minutes.

At fig. 11. pl. 14. the machine is represented fixed to a double furrow creasing plough, as prepared for drilling. When thus connected, it is made with two upper and two long spouts for drill-

ling, two aprons for broad-casting, and with a double hopper; but in other respects the same as when intended for a single furrow plough: it is used in all cases with the greatest ease imaginable. The interval between the points of the two shares of a creasing plough is usually ten inches; the beam about nine feet long; and the whole made of a light construction.

A full explanation of all the figures. In Pl. 14. fig. 1. the machine is fixed to a Kentish turn wrest plough. A the machine. B the apron upon which the seed falls and rebounds upon the land, in broad-casting. C lid to cover the hopper. D wheel at the heel of the plough. E strap. FF hooks upon which the apron turns by a pivot on each side. G stay to keep the machine steady. H lever to prevent it from sowing.

Fig. 2. The machine constructed to be drawn by a horse. AAAA the hoppers. BB the diagonal supporters. CCCC the upper spouts. D the apron or shelf upon which the seed falls from the upper spouts. E the lever, which carries back the bar, and prevents the machine from sowing. FF staples upon the handles, through which the reins pass, for the man who conducts the machine to direct the horse by. I, screw, to fix the machine occasionally. N. R. The knobs (by turning which each particular spout may be taken from off the bar, and thereby prevented from feeding) are over each upper spout; but, to prevent confusion, are not lettered in the Plate.

Fig. 3. The long spout. AA the ears by which it hangs.

Fig. 4. The bridge, fixed in the upper spouts. A the slider, which contracts or enlarges the different apertures. B the aperture in the bridge, through which the seed passes, when sowing any quantity from one bushel upwards on an acre.

Fig. 5. The plate which is placed between the bridge and the slider, for sowing small seeds: the aperture A being downwards for sowing turnips; the larger one B downwards for sowing clover, &c.

Fig. 6. The regulator, made of brass. D the slider or horse which moves upon it, and is fixed at any particular degree by a screw in its side.

Fig. 7. Is the same machine with that in fig. 1. The dotted lines, expressing the situation of the long spout, when the apron is removed, and the machine adapted for drilling.

Fig. 8. Also the same machine, with the front laid open to show the inside. A the catch-wheel fixed upon the axle. BB the axle upon which the machine hangs between the handles of the plough. C the pulley, by which the strap from the wheel at the heel of the plough turns the catch-wheel. D the bar upon which the upper spout rests, suspended by the diagonal supporters EE, bearing against the catch-wheel by the trigger F, and thereby kept in motion while the plough is going. G the apron in a sloping position, upon which the corn or seed falls from the upper spout, and is scattered by rebounding upon the land. It turns upon pivots, and by this means throws the seed either towards the right hand or left at pleasure.

Fig. 9. The upper spout.

Fig. 10. represents the movement in the machine fig. 2. AAAA cleets between which the upper spouts rest. BB the diagonal supporters, by which the bar with the upper spouts hang. C the catch-wheel. DD the axle. E the trigger upon the bar which bears against the catch-wheel. FF stays from the back of the machine by which the bar plays.

The Roller. This implement is of great use in husbandry, though scarcely known in ordinary practice; or, where introduced, it is commonly so slight as to prove very insufficient. Rollers are made of stone, cast iron, or wood, and each has its advantages; but that of wood should be constructed in the following manner. From the body of a tree, six feet ten inches long, make a cylinder. Surround this with three rows of filices, one in the middle, and one at each end. Line these filices with planks of wood equally long with the roller, and so narrow

as to ply into a circle. Bind them fast together with iron rings. The roller, thus mounted, ought to have a diameter of three feet ten inches. It has a double pair of shafts for two horses abreast, and those are sufficient in level ground; though four may be necessary. The roller without the shafts ought to weigh 200 stone Dutch; and its large diameter makes it by no means difficult in the draught.

The Spike Roller is a very useful instrument for many purposes in husbandry. It is constructed nearly in the manner of the common roller, except its having the addition of a great number of spikes. It is represented in Pl. 14. fig. 12.

Rolling wheat in the month of April is very important in a loose soil; as the winter rains leave many roots exposed to the air. Barley ought to be rolled immediately, especially where grass-seeds are sown with it. In a gravelly soil, the mould should be so dry as to bear the roller without clinging to it. A clay soil ought neither to be tilled, harrowed, nor rolled, till the field be perfectly dry. There is the greater reason for this precaution, because much rain immediately after rolling is apt to cake the surface when drought follows. Oats in a light soil may be rolled immediately after the seed is sown, unless the ground be too wet. In a clay soil, delay rolling till the grain be above ground. The proper time for sowing grass-seeds in an oat-field, is when the grain is three inches high; and rolling should immediately succeed, whatever the soil be. Flax ought invariably to be rolled immediately after sowing. The first year's crop of sown grasses ought to be rolled as early the next spring as the ground will bear the horses. It fixes all the roots precisely as in the case of wheat. Rolling the second and third crops in a loose soil is useful; though not so essential as rolling the first crop.

Rolling encourages the growth of plants, by bringing the earth close to their roots. It also keeps in the moisture, which is sometimes of great moment. And lastly, besides the foregoing advantages, it facilitates the mowing for hay; and it is to be hoped, the advantage of this practice will induce farmers to mow their corn also, which will increase the quantity of straw both for food and for the dunghill.

There is a small roller for breaking clods in land intended for barley. The common way is, to break clods with a mull; which requires many hands. This the roller does more effectually, and at much less expence. Let a harrowing first break the clods a little; and after lying a day to dry, this roller will reduce them to powder. This however does not supersede the use of the great roller, to make the soil compact, and keep out the summer-drought. A stone-roller four feet long and fifteen inches diameter, drawn by one horse, as a preparation for barley, is gaining ground daily; but in a clay soil, the clods are sometimes too firm, or too tough, for so light a machine. In that case, a roller of the same size, but of a different construction, is necessary. It ought to be surrounded with circles of iron, six inches asunder, and seven inches deep; which will cut even the most stubborn clods, and reduce them to powder.

Explanation of the instruments commonly employed in the new husbandry. In Pl. 15. fig. 1. is represented a *marking-plough*. The chief use of this plough is to straighten and regulate the ridges. The first line is traced by the eye, by means of three poles placed in a straight line. The plough draws the first furrow in the direction of this line; and, at the same time, with the tooth A, fixed in the block of wood near the end of the cross-pole or slider BB, marks the breadth of the ridge at the distance intended. The ploughman then traces the second line or ruit made by the tooth, and draws a small furrow along it; and continues in this manner till the whole field is laid out in straight and equidistant ridges.

A *plough* for the purpose of breaking up ley, or turning up the bottom of land when greatly exhausted, is seen at Pl. 15.

fig. 2. By the particular construction of this instrument, the width and depth of the furrows can be regulated to a greater certainty than by any other hitherto discovered. It appears heavy, but two horses are sufficient to plough with it in ordinary free land; and four are only necessary in the stiffest clay-soils. It is likewise easily held and tempered. A is the sword fixed in the fizers B, which runs through a mortise E, at the end of the beam C, and regulates the depth of the furrow by raising or depressing the beam; it is fixed by putting the pin D through the beam and sword, and is moveable at E.

A *jointed Brake-harrow*, with 24 teeth, shaped like coulter, and standing at about an angle of 80 degrees, is represented at Fig. 3. pl. 15. By this instrument the land is finely pulverized, and prepared for receiving the seed from the drill. It requires four horses in stiff, and two in open, land. This harrow is likewise used for levelling the ridges; which is done by pressing it down by the handles where the ridge is high, and raising it up when low.

Fig. 4. pl. 15. is an *angular Weeding-harrow*, which may follow the brake when necessary. The seven hindmost teeth should stand at a more acute angle than the rest, in order to collect the weeds, which the holder can drop at pleasure, by raising the hinder part, which is fixed to the body of the harrow by two joints.

Fig. 5. pl. 15. exhibits a *pair of barrows with shafts*. This harrow is used for covering the seed in the drills, the horse going in the furrow.

At Fig. 6. pl. 15. is seen a *Drill-plough*, constructed in such a manner as to sow at once two rows of beans, pease, or wheat. This machine is easily wrought by two horses. A is the hopper for containing the seed; B, circular boxes for receiving the seed from the hopper; CC two square boxes which receive the seed from small holes in the circular boxes as they turn round; and last of all, the seed is dropped into the drills through holes in the square boxes behind the coulter D. The cylinder E follows, which, together with the wheel F, regulates the depth of the coulter, and covers the seed; the harrow G comes behind all, and covers the seed more completely. HH, two sliders, which, when drawn out, prevent the seed from falling into the boxes; and, I, is a ketch which holds the rungs, and prevents the boxes from turning, and losing seed at the ends of the ridges.

Pl. 15. fig. 7. represents a *single Hoe-plough* of a very simple construction, by which the earth in the intervals is stirred and laid up on both sides to the roots of the plants, and at the same time the weeds are destroyed. AA the mould-boards, which may be raised or depressed at pleasure, according as the farmer wants to throw the earth higher or lower upon the roots of the plants.

A *Drill-Rake* for pease is given at Pl. 15. fig. 8. This instrument, which is chiefly calculated for small inclosures of light grounds, is a sort of strong plough rake, with four large teeth at *a, a, b, b*, a little incurvated. The distance from *a* to *a*, and from *b* to *b*, is nine inches. The interval between the two inner teeth, *a* and *b*, is three feet six inches, which allows sufficient room for the hole-plough to move in. To the piece of timber *cc*, forming the head of the rake, are fixed the handles *d*, and the beam *e* to which the horse is fastened. When this instrument is drawn over a piece of land made perfectly fine, and the man who holds it bears upon the handles, four furrows, *f, g, b, i*, will be formed at the distances determined by the construction of the instrument. These distances may be accurately preserved, provided that the teeth *a a* return when the ploughman comes back, after having ploughed one turn, in two of the channels formed before, marked *b b*: thus all the furrows in the field will be traced with the same regularity. When the ground is thus formed into drills, the pease may be

scattered by a single motion of the hand at a certain distance from one another into the channels, and then covered with the flat part of a hand-rake, and pressed down gently. This is an extremely simple instrument, and may be made or repaired by any workman.

At Fig. 9. pl. 15 is represented *Cook's Drill Machine*. A, the upper part of the seed-box, B, the lower part of the same box. C, a moveable partition, with a lever, by which the grain or seed is let fall at pleasure from the upper to the lower part of the seed-box, from whence it is taken up by cups or ladles applied to the cylinder D, and dropped into the funnel E, and conveyed thereby into the furrow or drill made in the land by the coulter F, and covered by the rake or harrow G. H, a lever, by which the wheel I is lifted out of gear with the wheel K, to prevent the grain or seed being scattered upon the ground, while the machine is turning round at the end of the land, by which the harrow G is also lifted from the ground at the same time, and by the same motion, by means of the crank, and the horizontal lever *b b*. L, a sliding lever, with a weight upon it, by means of which, the depth of the furrows or drills, and consequently the depth that the grain or seed will be deposited in the land, may be readily ascertained. M, a screw in the coulter beam, by turning of which, the seed-box B is elevated or depressed, in order to prevent the grain or seed being crushed or bruised by the revolution of the cups or ladles. Fig. 11. a rake with iron teeth, to be applied to the under side of the rails of the machine, with staples and screw nuts at *nn*, by which many useful purposes are answered, viz. in accumulating cutch or hay into rows, and as a scarificator for young crops of wheat in the spring, or to be used upon a fallow; in which case, the seed-box, the ladle cylinder, the coulters, the funnels, and harrows, are all removed.

In this side view the machine is delineated, for the sake of perspicuity, only with one seed-box, one coulter, one funnel, one harrow, &c. but the complete machine is furnished with five coulters, five harrows, seven funnels, a seed-box in eight partitions, &c. with ladles of different sizes, for different sorts of grain, seeds, &c.

These machines equally excel in setting or planting all sorts of grain and seeds, even carrot seed, to exactness, after the rate of from eight to ten chain acres per day, with one man, a boy, and two horses. They deposit the grain or seed without grinding or bruising it in any quantity, from one peck to three bushels per acre, regularly and uniformly, and at any given depth, from half an inch to half a dozen inches, in rows at the distance of twelve, sixteen, and twenty-four inches, or any other at pleasure. They are equally useful on all lands, durable, and easy to manage.

The ladle cylinder D is furnished with cups or ladles of four different sizes for different sorts of grain or seeds, which may be distinguished by the numbers 1, 2, 3, 4. N^o 1. (the smallest size) is calculated for turnip-seed, clover-seed, cole-seed, rape, &c. and will sow something more than one pound per statute acre. N^o 2. for wheat, rye, hemp, flax, &c. and will sow something more than one bushel per acre. N^o 3. for barley; and will sow one bushel and a half per acre. N^o 4. for beans, oats, pease, vetches, &c. and will sow two bushels per acre. But notwithstanding the above specified quantities of grain or seeds, a greater or less quantity of each may be sown at pleasure, by stopping up with a little clay, or by adding a few ladles to each respective box. The grain or seeds intended to be sown, must be put in those boxes, to which the cups or ladles as above described respectively belong, an equal quantity into each box, and all the other boxes empty. The ladle cylinder may be reversed, or turned end for end at pleasure, for different sorts of grain, as occasion may require. And for sowing beans, oats, pease, &c. with a five-coulter machine, four large ladles must occasionally be applied at equal distances round those

parts of the cylinder which sustain the two end boxes. For sowing barley, eight large ones must be applied as above; or four ladles, N^o 2. to each of the wheat boxes. These additional ladles are fixed on the cylinder with nails, or taken off in a few minutes; but for sowing with a four coulter machine, these alterations are unnecessary. The funnels are applied to their respective places by corresponding numbers. Care should be taken, that the points of the funnel stand directly behind the backs of the coulters, which is done by wedges being applied to one side or other of the coulters, at the time they are fixed in their respective positions.

The machine being properly prepared, the seed put in, and the land reduced to a proper state by plowing, harrowing, and rolling, the driver should walk down the furrow or edge of the land, and having hold of the last horse's head with his hand, keep him in such a direction as will bring the outside coulter of the machine within three or four inches of the edges of the land or ridge, at which uniform extent his arm must be kept till he comes to the end of the land; where having turned round, he must come to the other side of his horses, and walk upon the last outside drill, having hold of the horse's head with his hand as before, keep the machine in such a direction as will strike the succeeding drill at such a distance from the last outside one, or that he walks upon, as the coulters are distant from each other.

The person attending the machine should put down the lever H soon enough at the end of the land, that the cups or ladles may have time to fill before he begins to sow; and at the end of the land, he must apply his right hand to the middle of the rail between the handles, by which he will keep the coulters in the ground, while he is lifting up the lever H with his left hand, to prevent the grain being scattered on the headland while the machine is turning round; this he will do with great ease, by continuing his right hand upon the rail between the handles, and applying his left arm under the left handle, in order to lift the coulters out of the ground while the machine is turning round.

The chief difficulty in using the machine consists in driving it straight. When seed is wanting in the lower boxes B, they must be supplied from the upper boxes A, by applying the hand, as the machine goes along, to the lever C. The lower boxes B should not be suffered to become empty before they are supplied with seed, but should be kept nearly full, or within an inch or so of the edge of the box. If chalk lines are made across the backs of the coulters, at such a distance from the ends as the seed should be deposited in the ground (viz. about two inches for wheat, and from two to three for spring corn), the person that attends the machine will be better able to ascertain the depth the seed should be deposited in the drills, by observing, as the machine goes along, whether the chalk lines are above or below the surface of the land; if above, a proper weight must be applied to the lever L, which will force the coulters into the ground; if below, the lever L, and weight must be reversed, which will prevent their sinking too much.

As the lands or ridges are of different sizes, in different parts of the country, where the machine is too wide for the land, one or more funnels may occasionally be stopped with a little loose paper, and the seed received into such funnel returned at the end of the land, or sooner if required, into the upper seed-box. But for regularity and expedition, lands consisting of so many feet wide from outside to outside, as the machine contains coulters, when fixed at twelve inches distance, or twice or three times the number, &c. are best calculated for the machine. In wet soils or strong clays, lands or ridges of the width of the machine, and in dry soils, of twice the width, are recommended. For sowing of narrow high ridged lands, the outside coulters should be let down, and the middle ones raised, so that the

points of the coulters may form the same curve that the land or ridge forms. And the loose soil harrowed down into the furrows should be returned to the edges of the lands or ridges from whence it came, by a double mould-board or other plough, whether the land be in a wet or in a dry state. Clover and other lays, intended to be sown by the machine, should be ploughed a deep strong furrow and well harrowed, in order to level the surface, and to get as much loose soil as possible for the coulters to work in; and when sown, if any of the seed appears in the drills uncovered by reason of the stiff texture of the soil, or toughness of the roots, a light harrow may be taken over the land, once in a place, which will effectually cover the seed, without displacing it at all in the drills. For sowing lays, a considerable weight must be applied to the lever L, to force the coulters into the ground; and a set of wrought-iron coulters, well-steelled, and made sharp at the front edge and bottom, are recommended; they will pervade the soil more readily, consequently require less draught, and expedite business.

When carrots are to be sown, one bushel of saw-dust is to be added to each pound of carrot seed, which is sufficient for half an acre. The saw-dust should be made dry, and sifted to take out all the lumps and chips, and divided into eight equal parts or heaps; the carrot-feed should likewise be dried, and well rubbed between the hands, to take off the beards, so that it will separate readily, and being divided into eight equal parts or heaps, one part of the carrot-feed must be well mixed with one part of the saw-dust, and so on, till all the parts of carrot-feed and saw dust are mixed and incorporated together; in which state it may be sown very regularly in drills at twelve inches distance, by the cups or ladles N^o 2. A ladle full of this dust will, upon an average, contain three or four carrot seeds, by which means the carrot-feed cannot be otherwise than regular in the drills. In attempting to deposit small seeds near the surface, it may sometimes happen that some of the seeds will not be covered with soil; in this case, a light roller may be drawn over the land after the seed is sown, which, besides covering the seeds, will level the surface, and prepare the land for an earlier hoeing. With this machine the lightest kinds of grain or seed may be sown, even in the highest winds, by only using the precaution of placing a screen of any kind of cloth, or a sack, supported by two uprights nailed to their sides behind the funnels, which will prevent the grain or seed being blown out of its direction in falling from the ladles into the funnels. The same may be accomplished by small pipes of tin fitted on to the ends of the funnels, to convey the grain or seed near the surface of the land.

Pl. 15. fig. 10. exhibits a *Hand Hoe*, of a simple construction, by which one man will effectually hoe two chain acres per day, earthing up the soil at the same time to the rows of corn or pulse. This hoe is worked much in the same manner as a common Dutch hoe, or scuffle, is worked in gardens. The handle is elevated or depressed, to suit the size of the person who works it, by an iron wedge applied to the upper or under side of the handle inserted into the socket of the hoe. The wings or moulding plates of the hoe, which are intended to earth up the soil to the rows of corn, should never be used for the first hoeing, but always for the last.

Cooke's improved Drill Machine and Horse-Hoe. The advantages of this improved drill over the former chiefly consist, 1st, In the wheels BB, Pl. 16. fig. 5. being so large that the machine can travel on any road without trouble or danger of breaking; also from the farm to the field, &c. without taking to pieces; requiring only half the draught which the old machine requires. 2d, In the coulters CC, with all the coulters, moving with great ease, on the principle of the pentagraph, to the right or left, so as to counteract the irregularity of the horse's draught, by which means the drills may be made

straight: and where lands or ridges are made $4\frac{1}{2}$ or $9\frac{1}{2}$ feet wide, the horse may always go in the furrow, without setting a foot on the land, either in drilling or horse-hoeing. 3d, In the feed supplying itself regularly, without any attention, from the upper to the lower boxes as it is distributed. 4th, In lifting the pin M on the coulters-beam to a hook L on the axis of the wheels; by which means the coulters are kept out of the ground at the end of the land, without the least labour or fatigue to the person who attends the machine. 5th, In going up or down steep hills, the seed-box is elevated or depressed accordingly, so as to render the distribution of the seed regular; and the seed, being covered by a lid, is screened from wind or rain.

These are the principal advantages appertaining to this machine, which, though considerable in the process of drilling, are as nothing compared with those which arise from the use of the horse-hoe, by which from eight to ten acres of land can be hoed in one day, with one man, a boy, and one horse, at the trifling expence of 6d. or 8d. per acre, in a style far superior to, and more effectual than any hand hoeing whatever, and also at seasons when it is impossible for the hand-hoe to be used at all.

At AA, Pl. 16. fig. 5. are seen the shafts of the machine, applied to the axis of the wheels, so that the horse may go on the land, or in the furrow without setting a foot upon the land, either for the purpose of drilling or horse-hoeing.

BB, the wheels.

CC, coulters-beam, with holes or mortises for the coulters at different distances.

DD, handles of the machine, applied to the coulters-beam, also to the axis of the wheels, by hooks and eyes, or staples.

EE, upper seed-box in partitions, covered by a lid, to protect the grain or seed from wind or rain.

FF, lower seed-box in partitions.

GG, slides between the upper and lower seed-boxes, for regulating the quantity of seed sown.

HH, cylinder with cups or ladles of different sizes, for different sorts of grain or seeds; by which the grain or seeds are taken up, and dropped into the funnels II, and conducted thereby into incisions or drills made in the land by the coulters KK.

L, a hook applied to the axis of the wheels.

I, a chain applied to the coulters-beam, the last link of which, being put upon the lowest hook, will prevent the tubes of the funnels from being displaced, when the machine is crossing deep furrows or gutters.

M, a pin of iron projecting from the coulters-beam, which being lifted on the hook L, at the end of the land, will bear the coulters out of the ground, while the machine is turning round, or on any other occasion, without any labour to the person who attends the machine, in supporting them.

N, a cog-wheel.

O, a cog-wheel, turned by the wheel N.

P, a lever and string, passing over a pulley to the axis of the cylinder H, by moving the lever P to the notch in the staple Q, the wheel O will be lifted out of generation with the wheel N, by which means the distribution of grain or seed may be stopped at pleasure, in an instant, at the end of the land, or on any other occasion.

R, an iron bar with holes in it, by means of which, and a pin going through the holes, the seed-box may be elevated or depressed, so as to keep the lid of the box horizontally level, whether going up or down steep hills, or on level ground.

SS, two staples in the ends of the seed-box, for the reception of two slips of wood, with canvas to prevent the wind from interrupting the grain or seed; also to prevent dirt or soil falling from the wheels into the funnels II.

Horse Hoe. Pl. 16. fig. 6. represents the shafts, the axis

and wheels, the couler-beam, with handles, &c. as in fig. 5. being part of the said machine, and is convertible into a horse-hoe with six shares, by taking away the seed-box EE, the cylinder HH, the funnels II, and the coulters KK, as in fig. 5. and introducing the hoes AAAAAA, fig. 6. in the places of the coulters.

B, a guide projecting from the hoe-beam, which is useful in influencing the direction of the hoes, so as to avoid cutting up the rows of corn.

Manner of using the machine. The process of drilling should never be attempted but when the soil is tolerably dry, and when it has undergone proper ploughing, harrowing, &c. The method of using this machine is in many respects the same as that which has been mentioned above.

Pl. 16. fig. 5. represents a back view of the machine, when put together for working. When the horse is put in the shafts, care should be taken that the chains or tugs by which he draws are of equal lengths; otherwise the machine will have a constant tendency to deviate from the horse's line of traction. But when the horse goes in the furrow, the near side may be somewhat shorter; and a chain may be extended from the end of the cross-bar to a part of the shaft near the horse's shoulder.

In going from the farm to the field, or returning from the field to the farm, the pin or guide M must be lifted on to the hook L, which will bear the coulters off the ground. And when going on rough roads, if the couler-beam CC and the axis of the wheels are lashed together by a rope or chain, it will prevent the coulters receiving any injury by coming suddenly to the ground.

The grain or seed must be put in the upper boxes EE, an equal quantity in each box.

The cups or ladles upon the cylinders are of four different sizes, and are distinguished by the numbers 1. 2. 3. 4.

No. 1. the smallest size, is painted white for lucerne, clover, cole, rape, &c. and will sow two pounds per acre. Also for turnip, and will sow one pound per acre; every other cup being stopped up with a little soft clay.

No. 2. is painted red for wheat.

No. 3. is painted green for barley.

No. 4. is painted yellow for beans, oats, pease, tares, &c.

By raising or lowering the slides GG, fig. 5. a greater or less quantity of grain or seed may be sown at pleasure.

When the slides GG are as low as they can be, the wheat cups painted red, will sow something more than three pecks of wheat per acre; and more in proportion the higher they are raised, not exceeding one bushel and a half, when raised as high as they can be, in rows at nine inches apart.

The cups painted green, when the slides are as low as they can be, will sow one bushel of barley per acre; and more in proportion as the slides are raised, not exceeding two bushels, in rows at nine inches apart.

The cups painted yellow, when the slides are as low as they can be, will sow almost two bushels of beans, oats, pease, &c. per acre; and more in proportion as they are raised.

The funnels II, fig. 5. are all numbered 1. 2. 3. 4. 5. 6. and for drilling at nine inches, must be applied to their respective places, so as to correspond with the number 1. 2. 3. 4. 5. 6. of the seed box; six coulters being fixed in the couler-beam, at the distance of nine inches from each other.

For drilling at twelve inches apart, five coulters must be fixed in the beam, at eleven inches and a quarter from each other, when the order of the funnels will stand 1. 4. 5. 2. 3. 6. and no seed put in the box opposite the funnel N^o 5. when placed as above; the waste funnel may be stopped with paper to receive any seed that may accidentally fall therein.

For drilling at eighteen inches apart, three coulters must be fixed in the left end of the beam at eighteen inches from each

other, when the order of the funnels will stand 1. 2. 3. 4. 5. 6. and seed put in the boxes opposite the funnels 1. 3. 5. only, the other boxes being empty.

For drilling at twenty-two inches, three coulters must be fixed in the beam, one at each end, and one in the middle, when the order of the funnels will stand 1. 4. 5. 2. 3. 6. Seed being put in the boxes, opposite the funnels 1. 5. 6. only, the other boxes being empty. Two rows of pease at nine or twelve inches apart, and a space of twenty-two inches alternately, has been tried and approved. In level lands, without ridge and furrow, if the attendant on the machine cannot find a straight side to begin at, he should mark out with sticks or bushes a straight line, along one side of the field, for his direction; and when drilling at nine inches, in order to make the space between the two adjoining rills, as he returns, equal to the rest, the wheel of the machine must be brought very near the last impression of the couler, and three inches more distant from the last impression of the couler when drilling at twelve inches. And of other distances accordingly.

As the machine approaches the land intended to be drilled, the lever P, fig. 5. should be lifted from the notch in the staple Q, when the coulters are two feet on this side the exact place where seed should be deposited; and the pin M removed from the hook L, by lifting up the handles DD.

When the machine arrives at the end of the land, the lever P must be moved to the notch Q, which will stop in an instant the distribution of the feed, and the pin M lifted on the hook L, which will support the coulters out of the ground while the machine is turning round.

If the couler should not make the incisions or drills something more than two inches deep in light sands or loams, and one and a half in strong clays or wet soils, they may be forced into the ground by the hand; or by weights, or a beam of wood four feet long and three or four inches thick, being suspended by chains or cords at the hooks TT in the handles of the machine for that purpose. If, in attempting to make the drills straight, the horse should deviate from his proper direction, the couler-beam with all the coulters will be readily moved, this way or that way at pleasure, so as to make the drills straight by counteracting the irregularity of the horse's line of traction. If the machine should happen to be too wide for any given ridge, one or more funnels may be stopped with a little loose paper, and the seed received into such funnel returned into the upper seed-box. In drilling narrow high-ridged lands, the outside coulters may be lowered, and the middle ones raised, so that the points of the coulters may form the same curve which the ridge forms. The top of the feed-box when shut, should be kept horizontally level, whether going up or down steep hills or on level ground. This will make the distribution of the seed uniformly the same. The higher the front edge of the box is raised upon the bar R, the seed will descend more copiously into the lower boxes, consequently a greater quantity will be distributed.

The lower funnels placed behind the coulters should be lashed fast to the coulters with leathern thongs, or cords: and if in lifting up the couler-beam at the ends of lands, the upper funnels should, by chance, be displaced, a small nail may be driven into the edge of the feed-box, close above the edge of each funnel, which will prevent the funnels being displaced.

Method of using the Horse-hoe. For horse-hoeing a crop of any kind of corn, drilled at nine inches apart, the horse must be conducted along the third row or drill, beginning to number the rows from the left-hand side of the six rows drilled at one operation of the machine. And the person who attends the hoes must keep the pin B, fig. 6. directly over the third row of corn; and so long as he does this, it will be impossible for him to injure it in the least. But for horse-hoeing corn at twelve inches apart, the horse must be conducted along the second space, between the rows or drills, beginning to number the

spaces from the left-hand side of the five rows drilled at one operation of the machine.—And the person who attends the hoes must keep the pin B, fig. 6. directly over the middle of the second space, described as above: the same rule will hold good for hoeing at different distances. Where the space between the two adjoining outside drills shall happen to be irregular (i. e.) too narrow at some places for the hoe to pass, it may be advisable to take out the share, which would otherwise hoe that space, and leave it to be hoed by hand.

Soils of different textures will require to be hoed with shares of different sizes; nothing but experience can point out the size which is best adapted to any particular soil. In all light sandy soils or loams, or any other soils sufficiently pulverized, shares from five to six inches broad, for nine-inch drills, and eight inches broad for twelve-inch drills, will work safely and effectually. In strong clays intermixed with pebbles, the hoe-shares must not be so broad; and it may not be impossible to find some such soils as will bid defiance to all flat hoeing whatever. If, nevertheless, the texture of the soil in the spaces of the rows of corn is torn to pieces by long narrow plates of iron, resembling points or chisels, being introduced in the hoe-share shanks, A A A A A, fig. 6. instead of the hoe plates, the advantages resulting from such a process will be very considerable.

The hoe plates or shares may be set to enter the soil deeper or shallower, by lowering or raising the shanks A A A A A, in the respective mortises in the beam, or by lowering or raising the hooks applied to the shank C C, on the axis of the wheels, by which the hoes are drawn.

Lands cannot be too level on the surface, for practical, effectual, and expeditious horse-hoeing. But where lands, or ridges, are formed so round, that all the hoe-plates cannot be brought to work at equal depths in the soil at the same time, so many as cannot be brought into use may be laid aside.

This horse-hoe may be applied to many useful purposes, besides hoeing crops of drilled corn, particularly for cutting up the rows of stubble as soon as the crop is carried, with such weeds as might escape the hoe; and for stirring of fallows, &c. &c. after the rate of ten acres a day, with one man, a boy, and two horses, particularly in the busy time of harvest, when it would be impossible to spare so many men and horses as would be required to stir the land with common ploughs, so as to answer the intended purpose. And by means of the same expeditious method of cutting up stubbles, immediately after the crop is carried, or rather before it is carried, as soon as it is cut and set up, in order to gain time for the sowing of grass seeds a second time, where they may have missed, or cole, or rape, or turnip, for food of sheep or cattle, in winter or spring, extraordinary advantages may be derived.

M'Dougal's improved Hoe. This hoe, as seen in plate 16. fig. 4. is extremely simple in its construction, and answers all the purposes of a hand-hoe in a very superior manner, particularly the clearing from weeds and loosening the soil in the intermediate spaces of pulse or grain which has been sown in equidistant rows, and at the same time for earthing up the plants. It consists of two principal parts; the first a beam of wood, having at its fore end a semicircle forming two handles, between which one man walks, and draws the instrument forwards: this beam at the other end is divided, and moves on two small gudgeons, by which it is accommodated to the height of the hands of the person drawing, and room allowed for a wheel to move in.

The other beam is held at its further end by another man, who guides the instrument and regulates its depth in the ground, at the same time that he assists its action by thrusting it forwards. This beam is also divided at its fore end, so as to admit a wheel to run between the sides, which wheel serves to adjust the depth and ease the draught in working. The hoes are made of cast iron, and fixed in a mortise, in the hinder beam, by a

proper wedge, and may be made of different forms or dimensions, as the work to be performed may require.

Middleton's Hay-collecting machine. This machine, which is seen in Pl. 16. fig. 1. is invented for the purpose of preventing the labour of dragging hay together by hand. It is drawn by four horses, in pairs, with a boy to manage and drive each pair.

But it will first be necessary that the hay should be put into rows, as is universally done before the loading of carts, waggons, or sledges; then, in order to sweep the hay together with greater facility, a man with a fork must go and turn the end of a row up, two or three yards, so as to form a sort of heap, and then walk on ten, twenty, or forty paces, and break the row, by turning the hay forward into another similar heap; and let him go on and repeat this operation to the end of the row, which he should do as fast as he can walk; then the boy who has the management of that pair of horses, to whom the empty machine is attached, must draw it across the end of the row; and, the moment the centre of the machine is at the middle of the row, let him turn his horses short round, to within a yard or two of the hay, so as to be in a proper position to set off: the other boy must instantly place his horses on the opposite side of the row, and hook the chain of his splinter-bar to the machine, pulling the gate or side of the machine round, so as it were to clasp the hay as at *a* fig. 1. The boys being mounted, and all now ready to start, let them draw slowly on for the first twenty or forty yards; they may then, if the business requires dispatch, increase their pace, urging the horses into their fastest walk, and from that into a slow trot, until as much hay is collected as the horses can draw: then, unhooking one end, let the horses at the other turn from the hay, and draw out the machine from behind it: then trot away to the end of the next row, and repeat the process, taking care to keep the horses on each side of the hay at equal distances from the row, and opposite to each other. When the machine is loaded, and the intention is to draw the load to a distant place, the four horses cannot be kept too neat together.

The elevation of the machine, as it appears when drawn by one end, and empty, is shewn separate in the plate, where the scantlings of the several parts of the machine are marked.

The plan of the machine, when in the action of drawing the hay, is shewn in the plate at fig. 2, and lettered as follows: *a. a. a. a.* The places occupied by the horses, when drawing (though in many cases one horse on each side would be sufficient). *b.* The back, or principal part of the machine. *c. c.* The sides, or gates of the machine, which swing on the iron rods fixed in the back at *d. d.* *e.* The row of hay.

SECT. III. Of Ridges.

THE forming of land into ridges is advantageous in many respects. It is useful for removing wetness. Every furrow becomes a kind of drain: the rain that falls upon the ridge makes its way to the furrows, and by means of them is conveyed away from the field. It is also proper for enlarging the surface, as thereby not only a greater quantity of soil is exposed to the influence of the air, but also a great quantity of it actually employed in vegetation. There is no more soil indeed added to the field by enlarging the surface; but some of the soil that lies buried, while a field is in its natural state, is exposed to the air and brought within reach of the roots of plants, when it is laid up in ridges. Some of the plants which we cultivate in our fields, have what are called horizontal roots, that is, roots that creep along the surface, and go down but a short way. Now, it is obviously an advantage to these plants, to have a quantity of the soil below, to which their roots cannot extend, brought within their reach, which is done by enlarging the surface.

Fig. 11.

Even the tap-rooted plants, that is, such as push one principal root perpendicularly downwards, have horizontal roots, by which they are nourished; it must therefore be an advantage to them to have the surface extended. Having thus shown, that ridges are advantageous, as they remove wetness, and enlarge the surface, it is necessary now to consider what kind of ridges are most proper for answering the different ends. For removing wetness, the ridges ought to be narrow; as, the greater the number of ridges, the greater are the number of drains. When the soil is wet, the ridges ought also to be steep. For the steeper the ridges are, the water more easily finds its way to the furrows or hollows. And when the soil is very dry, it is submitted, if narrow ridges are not proper likewise. For by altering the ridges, and turning the furrows into the crowns, and the crowns into the furrows, a quantity of fresh soil is always employed in vegetation. When the crown of a ridge is turned into a furrow, it is obvious that some fresh soil must be turned up, which was not employed in vegetation in its former situation; and consequently the greater number there are of ridges, the greater the quantity of fresh soil employed. In cases in which the soil is just so wet as to occasion loss in the furrows, then the ridges should be somewhat broader. For, in such cases, the fewer the furrows are, the less is the loss.

It must also be observed, that a difference should be made betwixt the situation of land in the winter, and its situation in the summer. It may be convenient sometimes, when winter grain is to be sown, or when the land is to get winter fallowing, to make the ridges very narrow; and when summer grain is to be sown, to make them broader. And as it is an advantage to have the surface enlarged, the ridges ought to be made high in the middle or crown; for the higher that the ridge is made, the more is the surface enlarged and increased. But where the soil is shallow, the ridges, if broad, cannot be raised without depriving the furrows of soil: and therefore, to enlarge the surface on such land, the ridges must be made narrow; for this both enlarges the surface, and prevents the furrows from going below the soil. Where the soil is deep, the ridges may be made broader: for though they be raised in the crown, still there will be soil left in the furrows. The ridges must not however be made too broad: for it is evident that narrow ridges give more surface than broad ridges of the same degree of steepness, and do not cover the lower parts of the ridges so much from the influence of the sun and winds. But though, in general, it be recommended to raise the ridges in the crown, to enlarge the surface, and to allow the water more easily to find its way to the furrows; yet, in some low flat-lying land, it is proper to make the ridges as flat as possible, in order to raise the furrows. For the higher that the furrows are raised, there is, in some cases, the greater command of the water, and it is the more easy to find a fall for conveying it from the land. And flat ridges have this advantage over steep ridges; they can be sown, especially in the broad-cast method, with greater exactness. It is obvious from the method of sowing, that, in sowing steep ridges, it is not possible to prevent a great proportion of the seed from falling into the furrows. This proportion is also greatly increased by harrowing. Whereas, in sowing flat ridges, the seed is equally scattered, and the harrows do not remove it from its situation. It is therefore evident from these observations, that soils in different situations require to be laid out in different kinds of ridges. It is absurd to assert, that, in every case, one kind of ridges is preferable to another; that narrow ridges are better than broad ridges, and flat ridges better than steep ridges. In some situations, one kind of ridges is most proper; and, in other situations, another kind is most proper. Every farmer ought, therefore, to consider the nature of the soil he has to deal with, the advantages and disadvantages of each kind of ridges, and then determine which are most proper to be adopted.

If there be nothing in the nature of the soil to determine what kind of ridges are most proper, then narrow ridges are to be preferred; for this reason, that a quantity of land in narrow ridges is sooner ploughed than when in broad. It is obvious, that the two first furrows which the plough takes off from the ridge, are wider than any taken off afterwards, especially if the plough begins in the furrow, as is frequently the case; so that the greater number there are of ridges, the field is the sooner ploughed. Besides, when ridges are broad, it is obvious that the plough has more work, and must take longer time in turning, than when they are narrow. But then it is supposed that the ridges are straight and equal. If they are not, the greater number there are of them, the greater is the trouble, and the more time is spent in ploughing. This, however, is of no very great importance, since it seldom happens that the kind of soil does not determine the kind of ridges to be made.

In the making of ridges some other particulars must be attended to. All ridges ought to be made straight, crooked ridges being attended with several inconveniences. In ploughing them, the cattle are not always going exactly in the same direction with the plough; short turnings are often necessary, as fields are generally bounded by straight lines, or lines not crooked in the same manner with the ridges; and when there is a small descent, the water in the furrows does not so easily run off. There are also many other inconveniences attending crooked ridges, both in ploughing and other operations. But straight ridges not only remove the inconveniences with which crooked ridges are attended, but are attended with no inconveniences themselves: they require indeed a little attention in the ploughman, which is itself an advantage; and therefore upon all occasions are to be preferred. In all kinds of soil, ridges ought not only to be straight, but likewise equal to one another, and the same in all parts. Unequal ridges are attended with inconveniences, as well as crooked ridges. It is difficult to sow them with exactness; it is difficult to alter them when necessary; and the plough must often turn in the middle of the ridge, which does great harm, or be driven to the end without being of any use.

In different parts of this country the ridges are still crooked and unequal; and, in many places, they are much broader, and much higher raised in the crown, than the nature of the soil allows. Were the ridges altered, and the fields laid down in a proper manner, as the soil requires, it would be highly useful. At the same time, it must be observed, that much harm is done, by proceeding in this matter with too much precipitation. If the soil be very dry, ridges may however be altered without great danger, though high; and they may be made straight without being levelled. For, though the old furrows are still lower than the rest of the field, yet this is attended with no bad consequences in dry land; and by degrees, they are filled up in ploughing. But if the soil be wet, the ridges cannot be made straight till the ground is level, without great danger. For the water will lodge in the hollows of the old furrows, whence it will not be possible to force it. Some farmers indeed make their ridges straight before they are sufficiently levelled, draw water-furrows along the hollows of the old furrows, to carry off the water that is apt to lodge there. This is of some use, but does not fully answer the purpose. A quantity of loose earth, in ploughing, is thrown into the old furrows. The water, as it falls, penetrates this loose earth, and is retained by it, notwithstanding the water-furrows. Besides, these water-furrows must be neatly cleaned out with a spade, and made deeper in the places where they are intercepted by the crowns of the new ridges, otherwise they are of very little utility. Before ridges can be properly made straight, it is necessary therefore that the land be made level; but it is as dangerous to level ridges rashly, as to alter them before they are levelled: for if ridges are levelled too fast, and thereby a great depth of loose earth

thrown suddenly into the furrows, it will not be possible to convey away the water that falls upon them. The farmer should therefore consider the nature of the soil he has to deal with, before he proceeds to the altering old ridges; and if it be wet, to level the ridges very gradually.

In levelling ridges a great hollow is made in the crowns. This is occasioned by frequent successive cleavings, which is the method commonly used. It is obvious, that, by the first cleaving, a hollow is made in the crown of the ridge equal to the depth and breadth of the furrow which the plough makes; whereas the parts on each side of the ridge are but little levelled, and at each successive cleaving this hollow is made greater. Such a quantity of new earth immediately turned up, is not fit for vegetation. Besides, this hollow becomes so great, and the parts of the ridges on each side of it so steep, that it is impossible to plough them in a proper manner. In cases of this kind, when levelling is still thought proper, some furrows from each side must be thrown back by the plough into this hollow, by which a new small ridge is formed upon the crown of the old one, and then the remaining parts of the ridge may be levelled as before. Some persons, instead of this, plough across the ridges. This method serves the same purposes; it both throws some earth into the hollows, and levels the ridges; for the plough in going carries off some earth from every height, and leaves some in every hollow. But then land must not be left in this situation during the wet season, unless the water-furrows are drawn along the furrows, and also in some cases along the crowns; for unless this is done, the water that falls upon the field cannot be conveyed away. At the next ploughing, the whole old ridges may be levelled in the same manner as at the first ploughing; or, if thought more proper, may be divided into two equal ridges, ploughed in such a manner that the furrows betwixt them may be exactly in the crown of the old ridge, and the other furrows exactly in the furrows of the old ridge. By this means the old ridge is raised from the furrows, and levelled from the crown. This method of dividing the ridges into two, will be found very proper, either when winter-grain is to be sown, or when the barley-land has a winter-ploughing.

With regard to the placing of ridges when the land is wet, they ought to be with a view to the conveying away the water: but when dry, they should be placed with a view to the retaining the water. The common way of placing ridges where there is a slope, is along the declivity in a straight line from the top to the bottom; and land is commonly laid out with a view to this. Where the declivity is gentle, this is, no doubt, a very proper way of placing the ridges; but if the declivity be great, this way of placing the ridges allows the soil to be washed away by the rain. Therefore, in this case, placing ridges across the declivity is the most proper way; for when ridges are placed across, the water meets with many interruptions in its course, and does not run off with such violence as when placed along from top to bottom. But instead of this some farmers make the ridges very narrow. This serves the same purpose; for in proportion to the number of furrows, there is the less water in each furrow, and consequently it runs with less violence. But, placing the ridges in this manner is not so proper for this purpose as placing them across the declivity, nor so proper for retaining the water in a dry season.

If land be very dry, and in no danger of being damaged by the stagnation of water, the ridges ought to be placed across the declivity, as near the level as possible; for this retains both the water and the soil. It is obvious, that when ridges are placed in this manner, the water cannot get off by running along the surface, by which the soil is in great danger of being carried away. And when land is dry at the head of the ridges, and wet at the foot, and no proper fall for carrying off the water, as is frequently the case, the ridges should be placed in the same manner. For, in this case, every furrow in some mea-

sure retains the water that falls upon the ridge above, and thereby prevents it from sinking towards the bottom of the field, and lodging there.

This is likewise a very proper way of placing the ridges, even when the declivity is but small, if the land is in the situation mentioned, dry at the head, and wet at the foot. It must be owned, however, that this will not entirely answer the end proposed: for the water will penetrate the soil, and, when it is resisted by till or clay, will find its way along these to the bottom of the field. But this will not be so sudden as in the other way of placing the ridges: and the soil at the head, which is naturally dry, will receive more benefit from the rain as it falls.

In cases where land is wet, and the water can be conveyed away from the bottom of the field, the ridges should be placed across likewise; not directly, but with a small slope to a drain or furrow on the side of the field from top to bottom, by which the whole water is conveyed away. And where land is wet from the breaking out of small springs, this way of placing the ridges is also very proper; the furrows conveying away the water as it rises. Ridges placed in this manner for these purposes should not be altered.

However, where proper attention is first paid to the different means of draining, &c. many of the above directions will be unnecessary.

Different opinions have been maintained by farmers in respect to the direction, or way of placing ridges, in order to expose the land best to the influence of the sun and air: but this matter being not yet well determined, it is needless to pay any attention to the point; for where the placing of ridges makes no difference as to the wetness of land, we are chiefly to have in view the conveniency of ploughing and laying out the land in proper divisions.

There are three different methods of forming ridges by the plough: viz. gathering, casting, and cleaving. The 1st keeps the crown and furrows of the ridge in the same place in which they were before. The plough begins in the crown, and ploughs out the ridge, turning the earth towards the crown, where it entered. Every ridge is ploughed by itself; or, instead of this, the halves of two contiguous ridges may be ploughed together. By this method the ridge is higher raised than before. The 2d method keeps the crowns and furrows also in the same place in which they were before. The ridges are ploughed in pairs. The plough may enter in the furrow betwixt the ridges, and plough out the ridges, turning the earth towards the furrow, where it entered. Or, it may enter in the furrow on the right side of the two ridges, then turn to the one on the left, and plough out the ridges, turning the earth to these furrows, and from the furrow that is betwixt them. By this method the ridges are kept of the same height in the crown, and one of the furrows made a little higher, and the other a little lower than before. The 3d is the reverse of gathering. The plough enters in the furrow on the right side of the ridge, turns to the furrow on the left side, and ploughs out the ridge, turning the earth from the crown towards the furrows. Every ridge is ploughed by itself; or, instead of this, the halves of two contiguous ridges may be ploughed together. If the ridge has been raised in the crown, by this method it is made flatter.

A field being laid out in the manner judged most proper, in respect to the breadth and height of the ridges, should be ploughed in one or other of these ways, according to its situation. If the ridges are broad and high, casting will be found to be the most proper method; for this is the only way by which they can be ploughed, and kept in the same situation: cleaving will make them flatter; and gathering will raise them higher. If they are flat and narrow, cleaving will be found to be the best method. Cleaving flat ridges, and thereby turning the crowns into furrows, and the furrows into crowns, has these peculiar advantages: a field is much sooner ploughed in this way, than

in any other; and a quantity of fresh earth, at every ploughing, is exposed to the air, and employed in vegetation; and the ridges being kept level, are sown with exactness. Gathering is only proper when the situation of the ridge renders it too wet for winter grain.

SECT. IV. *Of the Methods of destroying Weeds.*

It is evident from the following circumstances, that weeds rob the plants we desire to cultivate, of their food; prevent them from branching out from the root, and lessen the vegetable pasture in the land where they are suffered to grow. They are nourished by the same food that would nourish useful plants; and therefore, when allowed to grow along with them, must rob them of part of their food. Although it be allowed that the food of all plants is not exactly of the same kind; yet, as plants draw their food from what touches their roots, it may be justly concluded that all kinds deprive the earth of that vegetable food which would nourish others. And experience convinces the farmer of the truth of this: for he finds, that his crop is bad in proportion to the quantity and kinds of weeds with which his land is infested. They also cover the surface of the land on which they grow; thereby confining the plants which are to be cultivated.

By some farmers it has, however, been attempted to be shown, that corn never wants room to grow; and that it is the want of food alone which makes some plants decay, when they are set too thick. If this be true, weeds can do no harm to plants, by covering the surface, and confining them while they grow. But let a person cast his eyes upon a plantation of any kind, and he will immediately observe, that where the plants are placed very near to each other, they stretch out chiefly to the length; and where they are placed at a greater distance, they grow not so much to the length, but more to the thickness, and branch out on all sides. So that the proportion of nourishment which the plants receive, makes them grow either to the length principally, or to the thickness, and branch out, according as they are placed near, or at a distance from each other. The same thing happens when there are many weeds growing amongst corn. Some fields are so much infested with weeds, that, though no grain is sown, the weeds come up very thick. This obliges the farmer to give plenty of seed: in consequence of which the surface is quite covered; and the plants of corn being confined by the weeds, instead of branching out from the root, and producing two or more stalks, as they are naturally disposed to do, push up one stalk only, that they may the more easily get above their rivals. The proportion of nourishment which they receive, makes them grow to the length, instead of branching out from the roots, and forces them to produce one stalk and ear only, instead of many. Experience confirms the truth of this; for when land is rich, and at the same time much infested with weeds, the plants of corn grow tall enough; but seldom have more stalks than one. There are some kinds of weeds which have great numbers of small roots, which they extend to a great distance. These roots bind the soil in such a manner, as to lessen the vegetable pasture; or rather make it difficult to enlarge it by tillage. When a field is much infested with quickening grass, the soil is so firmly bound together by the roots, that it is not possible to pulverize it. In ploughing, the earth of the furrow is turned over whole, and scarcely any impression is made on it by the harrow. Therefore it is of great importance to know how to destroy these useless and noxious weeds, that all the vegetable food in the soil may be applied to the nourishment of the useful plants which are to be cultivated, that these useful plants may have room to extend themselves, and branch from the root on all sides; and that the vegetable pasture, which is always lessening, may be enlarged more readily.

Weeds, like plants, may be properly divided into *annuals* and *perennials*. But, in considering the methods of destroying them, they may be distinguished into such as are propagated by the seed, and such as are propagated by the root.

Of destroying weeds that are propagated by seed. The destruction of weeds is certainly one of the most important parts of husbandry; but it is a task of extreme difficulty, as they differ very much in their natures. The seeds of some of them will putrefy in a few years, if they lie moist in the earth, and are prevented from vegetating. But the seeds of others will lie many years in this situation, without having their vegetative power destroyed. This is obvious from experience. Land infested with different kinds of weeds, has been thrown out into grass, and allowed to lie only a few years; and some of the weeds have been found to be destroyed, when the land was broken up again; but though it lie twenty years, some other kinds are found, in as great plenty as ever. The first sort may be destroyed by turning the land infested with them, from tillage into grass, and allowing it to remain in that situation for a few years; and both sorts may be destroyed by bringing the seeds to vegetate, and then tearing up the young plants. By frequently stirring and turning over the land, both these points will be accomplished. For every time the land is stirred and turned over, some seeds, that before lay deep, are brought near the surface; the earth about them is rendered free and open; and the air, which is necessary to vegetation, freely admitted: besides, the plants that have appeared are thereby torn up and destroyed. Of the truth of this, every farmer that practises summer-fallowing is now fully convinced. For he observes, when the season is favourable, and his fallow is well and frequently ploughed and harrowed, and time allowed betwixt every ploughing and harrowing for the weeds to vegetate, that his land, for several years, is not so much infested with weeds as it used to be. But in the performance of the operations by which the land is stirred and turned over, to promote the vegetation of the small seeds, great care should be taken to preserve the sap or moisture as much as possible. This will be done, if, in stirring the land, the surface is made smooth and plain: for when the surface is rough and uneven, the drought has easy access; but, when it is smooth and plain, the winds have less influence, and the sap is better preserved.

The vegetation of seeds in land is also promoted by the application of dung and some other manures. If therefore dung be laid upon land infested with weeds, and the land carefully stirred and turned over several times, all the seeds in it, by degrees, will be brought to vegetate; and thus the weeds may be destroyed. But this practice, though proper for destroying weeds, may, in some cases, destroy some of the virtues of the dung, before it is applied to promote the vegetation of the useful plants which are to be cultivated. Therefore, though it may be improper to follow this method when seed cannot be sown for a considerable time after the dung is laid on, as is the case sometimes when summer barley is sown on fallow, yet it may answer very well when seed is to be sown soon after, as is the case when wheat is sown.

Manures can however only be employed as destroyers of weeds, in so far as they tend to promote the vegetation of the seeds.

It is necessary to observe here, that the seeds of some weeds, particularly the different species of thistle, are carried to a considerable distance by the wind; and where any earth is thrown up in such a manner as to entangle them, as at the root of a hedge, or side of a ditch, there they appear in great plenty. Many farmers allow them to grow there undisturbed; the consequence of which is; that their seeds are carried into the adjacent fields, and thereby great damage is done, which might have been prevented by cutting them down before their seeds were ripened. This is a circumstance which ought to be more attended to. The best and most certain method of destroying

thistles on grass lands, Mr Boys says, is to let them alone till they are in full bloom, and then to mow them with a scythe; for, if they are cut while young, they produce fresh shoots from the sides of each plant.

Of destroying weeds that are propagated by the root. Weeds of different kinds and natures are propagated by the root. Some of them infest the land that is in tillage, and others the land that is in grass. The first sort have such a tender blade, and such tender roots, that they cannot pierce earth that is hard; but are of a kind that increase very fast, when the soil is free and open; while the second sort have the blade and roots so strong, that there is scarcely any soil that, of itself, will become so hard and stiff as to prevent them from making their way through it; but are of such a nature as to be easily torn up when the land is free and open, and do not easily strike root again when thus eradicated.

With respect to the first sort, as they chiefly infest land in tillage, they may be destroyed by turning the land from tillage into grass, and allowing it to remain for some years in that situation. This is confirmed by experience. Land over-run with quickening grass, and other root-weeds of the same kind, is frequently laid down in grass, and allowed to continue for some years without being ploughed. This land, when broke up again, if allowed to lie in grass for some years, is found to be clean, and the roots of the weeds destroyed. The number of years necessary for destroying the roots, depends upon the nature of the soil. If the soil be naturally hard and stiff, it is the sooner brought to such a situation as to prevent the roots and blades of the weeds from piercing it. But, if it is naturally soft and spongy, it takes a longer time before it is brought to that situation. For while the blade or roots of the weed can pierce the soil, their vegetation is not prevented. In some soils it is six or seven years before the roots of the quickening grass are destroyed. The number of years that are found requisite for destroying these root-weeds, has, no doubt, been partly the cause of establishing the practice commonly followed. Three crops of corn are taken, and then the land is allowed to lie six years in grass, or lea. At the end of these, the farmer supposes that the lea is come to maturity, and fit again for being ploughed. When it is only two or three years old, it is called, in some parts of the country, *calf-lea*; and, if ploughed at that age, the roots are commonly very abundant.

But the sowing land with grass-seeds, instead of turning it out into lea, destroys the roots of these weeds some years sooner. For thereby a sward being brought immediately upon the surface, the land becomes firm, the blades of the weeds are unable to pierce it, and the roots are deprived of air. Ryegrass seed, or the common hay seed, is the most proper for this purpose. For the plants arising from these soon cover the surface, and, by the number and smallness of their roots, bind the soil. Clover, particularly the broad clover, is improper; for the roots of it being large, they open the soil in growing and extending themselves, and thereby prevent it from arriving at that degree of firmness necessary for destroying the weeds so soon as if no grass seeds had been sown.

In regard to the second sort, they may be destroyed by turning the land infested with them from grass into tillage; and it is not necessary to continue it long in this situation, for the weeds commonly disappear after the first ploughing. But as it may be inconvenient to turn a field infested with weeds from grass into tillage, or from tillage into grass; it is necessary to consider the methods of destroying these weeds, without altering the situation of the land. When land in tillage is infested with weeds, they may be destroyed by frequently stirring and turning it over in dry weather. For, the weeds being removed out of their places, the drought prevents them from striking root again. The stirring the land in wet weather is rather hurtful

than beneficial: for though the roots of the weeds are removed from their places, yet the weeds themselves are only transplanted. If the land be wet, they soon strike root again; and the quickening-grass in particular, having its pasture enlarged, makes quicker progress than ever. But, if the land be dry, the weeds do not so easily strike root again: or, if some of them should strike root, they continue for some time in a languishing condition, and, if removed out of their places while in that condition, are easily destroyed by the drought. If land then be frequently stirred and turned over, by degrees all the weeds may be destroyed: for, by every stirring or ploughing, such of them as are in a languishing condition are destroyed, and those that are strong and vigorous are enfeebled.

If land is to be freed from seed-weeds, it cannot be made too fine, nor the surface too smooth; for the more perfectly this is done, the greater number of seeds are brought to vegetate. But, when land is to be freed from root-weeds, it cannot be turned up in too large pieces, nor the surface left too rough: for the larger the pieces, and the rougher the surface, the drought has the easier access, and the roots are the more effectually destroyed and removed.

If land in grass be infested with weeds, and it be inconvenient to turn it into tillage, the weeds themselves must be pulled up by the roots, or frequently cut.

It has been suggested that the *yellow rag-weed* may be destroyed by pasturing the light lands on which it appears with sheep.

Some land, after being a few years in grass, is liable to be over-run with *fog*. This, it is supposed, is owing to the soil becoming soft and spongy near the surface. If this be the case, rolling, which makes the surface firm, may be of some use in destroying this pernicious weed.

A third sort of weed is found to infest both the land that is in tillage, and the land that is in grass. These have not only the blade and roots very strong, so as to be able to pierce the soil, though hard, but also of such a nature as makes it difficult to tear them up; or have their roots of such a kind, that they may be divided into a great number of plants. These weeds cannot be destroyed, either by turning the land infested with them from tillage into grass, or from grass into tillage: but they may be destroyed by the methods mentioned, where the situation of the land is not changed. If the land is in grass, they may be destroyed by digging them out, or by frequently cutting them: and if the land is in tillage, they may be destroyed by frequently stirring and turning it over in dry weather. But this work must be performed with ploughs properly made for cutting their roots.

There is a fourth kind of weeds that chiefly infests land that is wet. Frequent cutting, and even digging out by the root, have been tried to destroy them, but to no purpose. They are not to be seen on dry land, and, when on land only inclining to be wet, appear very weak. Therefore draining seems to be the proper method of destroying them.

In concluding this article, it must be observed, that all kinds of root-weeds, and many kinds of the seeds of weeds, may probably be destroyed by depriving them of air, as it would seem necessary not only to the vegetation, but also to the life of plants. And when land is in tillage, the weeds may be deprived of air, either by burying them deep in the earth, or covering the surface. Trenching accomplishes the one, and a good crop of peas, potatoes, or any other plants that lie thick on the surface, effects the other.

SECT. V. *Of the Uses of Manures, and the Means of preparing and collecting them.*

As the manuring of land is in all places a necessary part of husbandry; rich-land not yielding a long succession of crops without help, and poor land requiring it in the very outset of

its culture; it must be obvious that the easier this article can be obtained, the greater will be the advantages which a country receives from it.

In farming it should therefore always be a primary object to procure the greatest possible quantity of manure in the highest state of preparation, as the quantity of dung produced annually on a farm, from the consumption of hay, straw, and grain, by cattle or other ways, is frequently very insufficient for the insuring of full crops. This is a point which, however, has been too much neglected by those engaged in husbandry. Indeed no very advantageous methods of increasing the produce of this useful article have yet been proposed. The reservoir described by Mr. Pew in the Transactions of the Bath Society, seems however to be useful, where the situation will admit of its being made, for the purpose of collecting the liquors which flow from the houses of different animals. The cow-stalls, says the author, stand nearly on the top, but a little on one side of a nap, or hill; and by means of gutters behind, the liquor is carried into a sink which runs under the stable, where it meets, by the help of another sink, with the stable liquor; and these, together with the liquor of the pig-sties, run through an under-ground drain into the reservoir, into which Mr. Powell, the inventor of the contrivance, throws all kinds of weeds or other refuse vegetable or animal matters, where it of course rots. If the weather prove wet, he stirs it well by means of poles, then draws up the hatch, and by means of the trenches it is conducted to all or any part of the mead below, which mead is rendered almost incredibly productive by it.

It would probably be of more advantage to the farmer, to allow these liquors to be mixed with rich mould or other substances of the same kind, and thereby form a good manure.

It is a judicious practice to keep farm-yards, and places in the vicinity of them, well littered with haum, or inferior kinds of straw, which, by being trodden, and from receiving the urine of the passing cattle, soon become putrid, and form a good manure. The most desirable situations for this practice are those which are most completely overshadowed by trees or other means.

Different modes are employed in the feeding and management of horses and cattle with a view to the production of manure: some supply them with hay, and use all the straw for litter; while others consume all their hay and straw in feeding the cattle. By the latter mode the greatest quantity of manure will be produced.

The able author of a Treatise on the connection of agriculture with chemistry, observes, that food in its passage through the bodies of animals becomes mixed with animalized matter, and consequently more rich and valuable weight for weight, as a manure, than dung produced by the littering cattle; although these must necessarily be much less in bulk and quantity, from the large proportion of the food of animals which goes off by breathing and insensible perspiration: besides which, without the utmost care, it is extremely difficult to prevent the valuable juices of the dung from sinking through the floors of the cow-houses and stables, or the soils of farm-yards. Could these inconveniences be effectually provided against, says he, by a proper flooring of clay or chalk, a preference appears due to the consumption of the whole of the produce by cattle, provided that attention be paid to the mixing daily a sufficient quantity of peat or mould with the dung and urine, so as completely to absorb and take up whatever may remain of these matters in a fluid state. By this process, there can be no doubt that a greater quantity, and a still more valuable dung may be obtained, than by the other practice of a less number of cattle, and littering them with straw.

Stable-dung should only be kept a certain length of time: for,

when kept some years, it has been found inodorous and insoluble; consequently useless as a manure.

There is a difference of opinion among farmers respecting the propriety and advantages attending the use of long or fresh dung, or dung which is completely rotted. The above author supposes, that where the views of the farmer are to promote only the next immediate crop of grass or grain, the dung when applied should be fully and completely rotted; but that if his views extend to subsequent crops, or the soil be of a nature to receive benefit by the fermentation and heat produced by the application of fresh dung, preference should undoubtedly be given to dung in a long state, provided it be immediately ploughed in and totally covered, which is not easily accomplished with dung of this description. Long dung is however always to be preferred in the culture of potatoes; for dung completely rotted frequently causes this crop to be watery and warm-eaten.

It is observed by Doctor Anderson, that wherever the dung of sheep can be properly collected, as by folding, and judiciously applied along with lime, aided by a skilful culture and good management, it will furnish the means of gradually meliorating the soil, and rendering it productive of grass as well as corn in a much greater degree than has been generally supposed.

Lime. This and other calcareous matters the same author considers as the best kinds of manure that can be obtained for improving waste lands. Where this manure can be obtained in large quantity and at a cheap rate, there are very few soils so barren as, under a proper management, may not by degrees be very much meliorated.

But lime, on *poor* soils, continues he, is a trifling and inefficacious manure; unless where it is applied in *very considerable quantities at once*. A chaldron or half a chaldron *per acre*, says he, I should consider as nearly as efficacious in this case as sprinkling a pinch of snuff. Six hundred bushels of slaked lime *per acre* he considers as not an over dose; and less than three hundred he accounts too little in almost any case.

But to this, for a dressing for poor ground newly broken up from waste fields, in order to bring it into proper heart, he thinks fifty or sixty cart loads of yard dung, as much as two horses can properly draw upon ploughed land, should be added *per acre*.

When lime and dung are thus applied in the same season, they produce more powerful aggregate effects than if either had been singly applied; much benefit therefore results from this practice. Lime he thinks acts both as an alterative and a fertilizer. In its alterative capacity, it not only enables the soil to produce crops it never otherwise could have yielded; but it also enables dung to operate upon the soil in a manner it never otherwise would have done. Of the two, lime alone is better than dung alone, on unproductive soils.

The practice of applying these manures in *great quantities together*, is still more beneficial, where care is taken not to exhaust the soil after it has been thus enriched, before it is laid down into grass. This the Doctor considers as a fundamental maxim in farming.

In every case, the sooner the lime is laid upon the soil after it has been prepared, and the more quickly and intimately it can be blended with the mould, the better it will be on every account. For as the lime never acts till it becomes blended with the soil, and acts the more powerfully in proportion as this mixing is the more complete, it should be applied as early as possible, that it may have the full benefit of the subsequent ploughings for blending it thoroughly. For the same reasons, the lime should always be spread while it is yet in its dry and powdery state, and should be ploughed or harrowed in as soon as possible after it is spread, to prevent its running into clots by moisture, as these become afterwards stony masses that never can be properly divided. This circumstance is particularly mentioned,

because in this state it will not produce the same effect upon the soil, that half the quantity of lime judiciously applied would have done.

Marle. This is also both a very good manure, and one of the most lasting. The Norfolk marle is probably the best in quality, and the most easily obtained. It is of different kinds. Mr. Kent, in his Survey of that county, observes that twelve cart-loads to an acre, of the white, or rather yellow marle, will, the second year after it is laid on, change the nature of land; most of the exhausting weeds which impoverish the soil, and choke the corn in its infancy, being effectually destroyed; as it has a great tendency to keep land clean, and increases its fertility to a surprising degree: its benefit, though not to the effect it produces at first, is felt for thirty years, when a second marling, of about half the original quantity, may with propriety be used; but it has been found by experience, that it does best the second time compounded with muck or maiden earth. As it is of a ponderous nature, he thinks it suits best when spread on ley land, by which means it mixes sooner and better with the native soil. The other species of marle, or, more properly speaking, clay impregnated with marley particles, though good in quality, is certainly much inferior to the above, as it requires more than double the quantity to carry the same improvement. But he is inclined to think that this last is more durable than the former; not, however, from its quality, but from its mixing better with the earth, and not escaping downwards so soon as it does.

According to the Survey of Mr. Holt, marle is the great article of fertilization, and the foundation of the improvements in agriculture in Lancashire; and this earth, or fossil, is fortunately wanting but in few places in that county. There are several kinds of this article, valuable in proportion to the intrinsic quality of each, or the calcareous matter which it contains, or the nature of soil to which it is applied. To the stiff clay lands, the blue or reddish slate marle, full of calcareous earth, is more beneficial: but to the light sand lands, the strong clay marle is more genial. Thus not only a calcareous stimulus is given, but additional matter is afforded, to correct the nature of the soils, by loosening the texture of the one, or giving adherence to the particles of the other, by the opposite qualities of the different marles applied. Barren sand lands, and poor heaths, in the south of that county, have been, under the effects of marle, rendered productive; but this has been done at very considerable expence. Marle has also been tried as a manure after being burned, which may be in a kiln after the manner of lime, or laid over a gutter, under which faggots, &c. for fuel, have been previously laid. The best season is the summer for laying it upon the land, sometimes immediately after a crop of hay has been taken. Its effects upon the grass are soon visible, from the rich verdure it produces. Long experience has sufficiently proved the propriety of the general practice of the county; which is, to lay the marle upon grass lands—the older the better; the sward and grass united cause a fermentation and putrefaction, which seem necessary to produce a proper effect. In regard to the quantity laid on in this county, it is from two to three, or three and a half cubic roods, of 66 yards to every statute acre. It is however reckoned a better practice to have the marlings repeated with a gentle covering, than to use thick coats of marle in order to last a long time. It must also be observed, that the marle should partake both of one summer's sun, and one winter's frost, at least. After being exposed to the effects of the weather, in large lumps, it begins to fall, or melt; the particles appear unctuous and soapy, and the quality of the substance seems quite changed from its original state. Then, in the ensuing spring, it should be divided (the parts now separate with ease), and equally distributed upon every part of the surface. This is with facility effected by har-

rows, &c. after which it is usually ploughed under; but, if permitted to remain a year or two longer, the lands would be more improved in the issue, by the length of time given previous to the marle being ploughed in. But the marle does not produce its full effects upon the soil, till intermixed and incorporated by a repetition of ploughings and an intermixture of dung or other manures. Marle, Mr. Pitt also remarks, is much used in Staffordshire and in large quantity. But the improvement by marle there is believed to be much more adapted for tillage than pasture, and its good effects on corn-lands are long visible; and in the case of the thin light unimproved lands the benefit of marling he thinks must endure for ever, as it not only consolidates the soil, but gives it thickness and staple.

In Norfolk, Mr. Kent remarks that those farmers who live near the sea, have lately begun to make use of the small sand from the beach, which they lay in the bottom of their yards; and when their muck, which is laid upon it, is sufficiently rotten, turn up the whole and mix it together; but the more general practice is, to lay it a foot deep in the stables, during the summer, and to feed their horses with green vetches, in the stables; the dung of which being afterwards mixed up with the sand, makes a most excellent manure, as well for grass as arable land. In many parts of the kingdom great advantage may, he thinks, be obtained, by turning up the borders of corn-fields, and the banks of maiden earth in the roads, and mixing them with the common yard muck, which would multiply the quantity of manure in a very great degree without doing any injury.

The judicious writer just quoted, also suggests another means of increasing the quantity of manure, particularly to gentlemen who are in possession of parks, plantations, and lands in hand; which is, to cause a permanent fold, during the winter months, to be pitched, in some sheltered spot, near their woods, and to pen their store flock in it, giving the sheep the quantity of hay they are accustomed to have, in racks, in the fold, and littering it every night with fresh leaves of trees, with rushes, moss, or any other similar rubbish that can be collected. This turned up together in the month of April, and mixed with about one-sixth part of lime, rubble from old walls, or any sort of ashes, will make as good a sort of manure as can be laid on turnips—and the quantity will be very considerable. In one winter he has obtained in this way six hundred cart-loads from six hundred sheep.

A mixture of peat and lime, which has been suggested by Dr. Hinton, Mr. Kent considers as a manure very useful on clover when laid on early in the spring, which, in general, not only adds greatly to the crop of hay when mowed, but insures a good crop of wheat in succession: it is likewise peculiarly good upon sainfoin, and, he apprehends, well adapted for turnips: as to lime, his opinion is, that it is always best to compound it with some other substance, and with maiden earth in preference to any other substance.

Mr. Pitt, in his Survey of Staffordshire, observes that the muck and farm-yard manure in that county is generally laid on wheat fallows, or on land in preparation for turnips, but sometimes on young clover, pasture and meadow land; and that town manure is used with equal advantage either in tillage land, or upon turf. Lime is also much employed there, generally on tillage land, either for barley, turnips or wheat, and is said to be most advantageous when laid on in a quick state, soon after slaking, and to harrow it in when the land is dry. It is sometimes laid on turf land, and it is said with good effect.

Mr. Boys, in his View of the Agriculture of Kent, says, that in that county the dung of horses, cattle, and hogs, is mixed together in large heaps, and laid in the fields intended to be manured, usually on a layer of fresh earth, a foot or two in depth, dug out of hedge-rows, waste banks, or useless spots of

land. When the heap of dung is made up, some persons give it a covering of mould; and it is an excellent practice to keep it moist, and prevent evaporation. After it has lain a month or two to ferment, it is trenched over; and then, after lying a few weeks longer, it is fit for use. This manure is laid on the land at the rate of from forty to sixty cart-loads of twenty bushels each per acre. The principal part of this sort of manure is carried out for wheat or beans; but some farmers dung for barley, and others for turnips. Manuring with the sheep-fold dung is practised on fallow lands in the spring months, after barley sowing, for turnips; then on fallows or clover lays, for wheat; and when that season is over, the fold is removed to either wheat stubbles or turnips, in order to fold the land for the succeeding crop of barley or oats. Two hundred sheep will fold about an acre in a week; the value of which is from 20s. to 30s. in proportion to the time of the year; the last folding in the autumn, next to the ploughing for wheat, being the most valuable and important.

He also remarks, that chalk is used to great advantage as a manure on some wet stiff soils, having no calcareous earth; in quantity from fifty to eighty cart-loads per acre. Its beneficial effects are said to last twenty years; but there are many soils (indeed throughout the greatest part of this county, where chalk is in plenty) which derive no benefit from it. The best method of using it, is to spread it early in the autumn, in order that it may be thoroughly drenched with rain, and that the frost may have its full operation upon it; by which means it is well pulverized when the thaw comes on, and will mix the more readily with the soil, or earth.

He also says, that old grass-lands or wet sandy or clay soils, over-run with furze or rushes, are greatly improved by the application of this substance; and turf-ashes, if spread on poor chalky thin lands for turnips, at the rate of about twenty cart-loads of thirty bushels each per acre, will seldom fail to produce a good crop. Turf-ashes are also often used for wheat, and sometimes for other crops; but there is no application of them equally advantageous with that of using them for turnips.

Sea-weed is a most excellent manure, being a mass of vegetable matter strongly impregnated with salt. Immense quantities are sometimes thrown by the winds and tides on the different shores, whence it is carted to the land on which it is to be placed. In Kent, the principal method of using it is by mixing it in layers among the farm-yard dung in the mix-hills. It is of great use in helping to rot the dry part of dung carried out of the farm-yard in the summer season.

Another manure employed in Kent for hops is woollen rags. They are laid round the hills of hops, &c. The method is to open the hill, and place the rags, ready cut into small pieces, two or three inches square, close round the roots, a little below the surface of the land, and immediately cover them up with mould. A ton of rags per acre is the usual quantity, which is about two pounds and a quarter to every hill of hops: they cost from 4l. to 6l. per ton. For dry gravelly soils, this is a good manure, as the rags operate in the nature of a sponge, to retain the moisture in a dry season, and thereby support vegetation; but, on the contrary, in a rainy summer it is supposed they do great injury, by their retentive quality on the mould, which is highly destructive.

Mr. Pitt says, that bone-filings or shavings, from the Birmingham manufactories, are esteemed valuable manures for light tillage land in Staffordshire. And Mr. Holt informs us that bone-dust, or bones ground in a mill, have been used with success by William Mayor of Ashworth-Hall near Rochdale. He has two fluted iron rollers placed at the end of a corn-mill shaft, which grinds them expeditiously. It seems that he not only

applies them to his own grounds, but also disposes of them to different purchasers who wish to employ them.

The same writer also suggests, that near the sea good composts may be sometimes made of sand, lime, earth, dung, and sea-weeds, with a species of shell-fish growing upon the rocks. This is found to be an excellent manure for barley in some parts of Lancashire.

We shall now introduce the experiments of Mr. Henry Harper on manures, as detailed by himself in Mr. Holt's Survey of Lancashire.

"The following experiments, says he, of different kinds of manure will shew the difference of both the quantity and the quality of produce on the different kinds of land on my farm, on which I manured half an acre of eight yards to the rod with every kind of the following manures; and when made into hay, as nearly all alike as possible, I weighed one average square rod from every lot.

Lot the 1st. Horse, cow, and butchers dung, all mixed together, of each about an equal quantity, which lay in that state about two months, and then turned it over, and let it lie eight or ten days, and then put it on the land before it had done fermenting, and spread it immediately. This was set on in September 1793. The produce 3 stone 15 pounds per rod, at 20 pounds to the stone.

Lot the 2d. Horse and cow dung, mixed and turned over the same as Lot the 1st, and set and spread on the land at the same time. Produce 3 stone 14 pounds per rod.

Lot the 3d. Horse dung, turned over and set on the land the same as Lot the 1st. Produce 3 stone 13 pounds 8 ounces per rod.

Lot the 4th. Cow dung, turned over and set on the land the same as Lot the 1st. Produce 3 stone 13 pounds 8 ounces per rod.

Lot the 5th. Night-soil, coal-ashes, and cleanings of the streets, and about 40 measures of lime to every ton weight, and turned over while the lime was in its floury state, and not suffered to run to mortar, for then it is of little benefit; one part of this was set on in September 1793, the other part the middle of March 1794, but no difference in the crop to be perceived. Produce 3 stone 13 pounds per rod.

Lot the 6th. Night-soil, coal-ashes, and cleanings of streets, set on the land in the same manner and times as Lot the 5th, and no difference in the cropping part. Produce 3 stone 2 pounds 8 ounces per rod.

Lot the 7th. Marle fresh got, and mixed with an equal quantity of horse and cow dung, and lay about three months and then turned over, and lay a month and then turned over again, and put on the land in six or eight days, and at the same different times as the two last lots, but no difference in the cropping. Produce 3 stone 8 pounds 12 ounces per rod.

Lot the 8th. Water from a reservoir that all the urine from the stables, cow-houses, and all drainings from the dung-hills, farm-yard, hog-styes, and all the waste water from the house runs into, and is carried on the land in a watering-cart made on purpose that holds four hundred gallons; and the water was put on the land in April, about 12,000 gallons to the acre of 8 yards to the rod; and again in May 12,000 more. Produce 3 stone 5 pounds per rod.

Lot the 9th. Blubber, the offal of whale-oil, mixed with soil, and set on the land the 1st of April 1794. Produce 3 stone 2 pounds 8 ounces per rod.

Lot the 10th. Soot, sowed on the land the middle of April 1794. Produce 3 stone 1 pound per rod.

Lot the 11th. Plaster of Paris (gypsum) sowed on the land in April, the weather then showery and favourable for it. Produce 2 stone 2 pounds per rod.

Lot the 12th. No manure at all. Produce 2 stone 2 pounds per rod: so much for gypsum, that has been made such account of.

Lot the 13th. Soap-ashes or muck, set on in March 1794. Produce 2 stone 10 pounds per rod.

Lot the 14th. Lime, set on in March, clean by itself. Produce 2 stone 8 pounds per rod.

An improvement by way of experiment upon Lots the 1st, 2d, 3d, 4th, and 5th, water from the reservoir put on these lots the beginning of May 1794, at the rate of 12,000 gallons per acre. Produce 4 stone 8 pounds per rod.

"Now, says he, these lots are all in one field, which is old meadow land all of one quality, the soil 11 inches deep, and a strong loam betwixt sand and clay with a reddish cast, and is what I call fox-land; and under the soil is a black loam sand six inches deep, and then marle of four yards deep, and bottoms on a red sand. I approve most of the manure the five first lots were manured with, although it comes higher; they require the least labour, which mostly pays the best in the end, although it appears that some of the other lots afford more clear profit; but the most profit comes from that manure that continues its strength the longest in the land.

"The most clear profit I experience is from Lot the 8th, water from the reservoir, which is no cost, but labour, and that not so much as any other kind of manure; but it will not answer put on in hot dry weather (for it burns up all before it), except it was to be kept constantly wet, of which the supply is mostly scarce at that time.

"Lots the 9th and 10th. Blubber and foot I would not put on land for meadowing upon any condition, for the hay is bad; and, by a constant use of them, they exhaust the land, so that it will not produce any thing at all; and they are only manures for just the crop, with little or no after-grass.

"Soot is good for wheat, and other spring corn, if it is sown in showery weather.

"Lot the 11th. Gypsum is of no use on my farm, neither for corn nor grass.

"Lots the 13th and 14th. Soap-ashes and lime: they do not answer on my farm; they keep me too long out of the profit. What they might do in time, I have not experienced; but I always think the quickest return pays the best, so that the manure is not exhausting to the land.

"The water from the reservoir paid not amiss, which was set on the five first lots, which was an equal improvement of 2l. 10s. 8d. per acre; and if the extra labour was to be charged, it would be a discount of fifteen shillings, which would reduce it to 1l. 15s. 8d. clear profit per acre."

For the calculations of the different profits arising from the use of these different manures, we must refer the reader to the Survey itself, being too extensive to be introduced here.

The following observations on the proper season for laying dung on lands are given in the Survey of Lancashire, on the authority of the same experienced farmer: "If cow-dung, the fresher the better, provided it be the proper season for putting it upon the land; which is, if meadow, from the time of getting the hay off the land, till the middle of October. For, if the grass has done springing, the dung lies exposed all the winter to rain, snow, frosts, and the vicissitudes of seasons, which exhaust the strength, so as to destroy much of its good qualities: if it cannot be accomplished in autumn, then the ensuing spring; and if the season should not suit, the strength of the manure will be reaped the ensuing crop. He recommends turning over the dung previous to its being put upon the land, and to lie till it begins to ferment; then to carry it upon the land, and even spread it before the heat be gone off, by which the dung takes to the land the better. He prefers mixing cow-dung, horse-

dung, butchers-dung, and night-soil, together, in preference to each separate; and this mixture is in its best state from six to eight months old."

There are many other substances which may be employed in order to bring land into cultivation, as top-dressings. The principal of these, and which are most generally in use, are lime mixed with rich black mould, lime mixed with peat, peat-ashes, coal-ashes, and foot. The refuse or waste articles in different kinds of manufactures may also be applied in this way with advantage, when they can be procured in sufficient quantity. On this point the Earl of Dundonald remarks, that such adventitious aids or helps to a farm are of a nature that answers a much better purpose as top-dressings to grass lands, than for lands which are constantly kept under the plough. The application of top-dressings has, he says, been too little attended to, in consequence of farmers being unacquainted with the resulting advantages to ground, when converted from pasture to arable, by previously promoting the most luxuriant growth of perennial grasses. By assisting the vegetation, and increasing the vigour of perennial plants, their roots are made to strike deeper down and improve the staple of the soil: with annual plants the same benefit is not to be expected, as their growth and decay are limited to one season. Were manures exclusively applied under a system of convertible husbandry to grass grounds, the lands would regularly be broken up, in due rotation of cropping; and there can be no doubt but that a greater quantity of corn and herbage would annually be produced: and it is very probable, he thinks, that wheat and other grain would be less liable than at present to diseases, many of which, there is reason to believe, are occasioned by the immediate application of dung previous to sowing the ground. He considers top-dressings, especially to meadows and pasture ground, as the best mode of applying manure. This practice seems to be well understood in this country; but it cannot become general, unless the lands of farms be kept under a regular course of tillage and pasture.

Mr. Pitt, in his View of the Agriculture of Staffordshire, observes, that composts, consisting of shovellings of soils, scrapings of roads, scourings of ditches, mud from pits and ponds, used alone, or mixed with lime or dung, are generally used for a top-dressing, for meadow and pasture land; the ashes of the culinary fires are used in the same way; coarse pastures are improved by being mixed with night soil; foot is used as a top-dressing on wheat and other crops. In Kent, Mr. Boys says, this last article is employed in this way for sainfoin, clover, lucern, and meadows. It is sown on the land at the rate of forty or fifty bushels an acre, early in the spring. Coal-ashes are also used in the same manner in this county, at the rate of four or five chaldrons an acre, for the purpose of improving cold wet clay meadows.

In Lancashire, Mr. Holt says, marle has been burned in a common oven, and been found to answer as a top-dressing at about ten bushels per statute acre, after being bruised into a kind of powder, and sown with the hand. With respect to the application of lime alone to the surface of the soil, Doctor Anderson observes, that although, when laid on in *very large quantities*, it may have a sensible effect in sweetening the pile, and augmenting the quantity of produce also; he knows that the effect of it will be so much greater when mixed with the soil, that it is only in very particular situations that it can ever be an economical practice to apply it to the surface only; and never, he apprehends, where the soil is of a retentive nature. In this last kind of soil, he advises digging the ground and mixing the lime with the mould.

But where the soil is not retentive, and stones are abundant, there is not a necessity for digging it up: under these circum-

stances lime may be sometimes applied on grafs with profit; but in this cafe it will always be advisable, firft, to mix the lime with fome good mould, if it can be got, in the proportions of nearly two parts of earth for one of lime, and incorporate them well together by frequent turnings during the course of feveral months: for in this way it is found that lime, applied on the fward, operates much more powerfully than it ever does when fo applied by itfelf.

SECT. VI. *Of the Preparation of Land for Cropping.*

As ploughing is one of the principal means of accomplifhing this purpofe, it is neceffary that the ftones and fuch other obftuctions as may be liable to retard the progrefs of this operation fhould be firft cleared away. This may be performed in various ways, as by digging, blowing with gunpowder, &c.

Another circumftance which impedes the preparation of the ground for cropping, is the wetnefs of the land: this inconvenience is to be remedied by draining, the means of doing which we have already noticed. This difficulty may however in many instances be removed, without having recourfe to the more expenfive proceffes of draining, by means of the plough, and a proper construction of the ridges, as has been already fhewn.

There are various other means of preparing the ground for crops, which muft be confidered in this part of the work.

The procefs of *Fallowing*, when judiciously managed, may in fome instances be employed as a means of improving and rendering land proper for the reception of crops. This practice is however by no means fo frequent as formerly. Mr. Kent, in his account of Norfolk husbandry, feems to think the idea of leaving land to reft, is ridiculous: Keep it clean, fays he, and intermix the crops fown upon it judiciously, fo that one may fertilize as much as another exhausts; and it may be fown, as a garden is planted, from one generation to another.

But Mr. Boys, in his View of the Agriculture of Kent, feems of a different opinion. In Eaft Kent, he informs us that fallows are made on poor lands, more or lefs, as occafion requires; in fome cafes, to get the land clean from weeds; and in others, where weeds do not abound, to make a good tilth for a crop of wheat, if a ftiff, and barley, if a light foil. On the very worft foils, where wheat is never fown, fallows are frequently made for oats or barley, and for getting land into fine tilth for rye-grafs, or other feeds. When any kind of foil has borne three or four crops of corn in fucceffion, and is become full of weeds, a well-made fummer-fallow he thinks requifite, not only to deftroy the weeds, but likewise to meliorate and invigorate the foil: It is, fays he, the moft certain cure, the fpeedieft, and, in the end, the cheapeft.

The foils which moft require fallowing are the ftiff and wet, which will not admit the operation of the ploughs and harrows but at certain intervals, when the land is between wet and dry. Opportunities of working fuch foils are frequently loft by bad feafons; in which cafe, weeds will undoubtedly increafe, and it is then impoffible to eradicate them but by making a good fummer-fallow, or what is by fome called a fallow-crop, viz. cabbages, or winter-tares; neither of which will perhaps turn to fo good an account in the end as a complete fummer-fallow. The cold wet clays of this county, fays he, even if they are tolerably clear from weeds, are fubject, after two or three crops, to run together; and they then become fo exceedingly ftiff and cold, that, without the intervention of a fummer-fallow to meliorate the foil, very poor crops only are to be expected; whereas, when a good fallow is made, an abundant crop of wheat, and two or three good crops of fpring corn, are frequently produced.

It is further obferved, that a good fummer fallow is the beft preparation for a crop of clover; and that a clover-lay, of all the tilths known, is the beft for every other crop. But to fow clover on moft

foils, without a previous fallow, is a certain method of running the fand to couch-grafs. In order to make a good fallow, he fays that all kinds of foils fhould be ploughed about five inches deep before Chriftmas; and as foon as the land is tolerably dry in March, it fhould be crofs-ploughed about fix inches deep. Stiff foils muft be left rough until meliorated by rain, and then worked fine when between wet and dry; and all light foils immediately harrowed clofe after the plough, in order to promote the vegetation of feedling weeds, that they may be deftroyed by fubfequent ploughings, which muft be repeated two or three times more, at intervals, as opportunities occur, during the months of May, June, and July; every time reducing the land fine immediately after each ploughing, while the land is moift, for the purpofe before mentioned, of promoting the vegetation of weeds. Particular care fhould be taken not to touch the land, either with the plough or harrows, when it is the leaft wet, as that only kneads it together, and creates more work to reduce it; befides locking up many of the feeds of weeds within the hard clods, and thereby preventing vegetation; by which fuch feeds are referved for mifchievous effects in the fubfequent crops of grain.

In preparing wafte lands in this way, Doctor Anderfon thinks that it ought to be an invariable rule to make the *fecond* ploughing as deep as the nature of the foil and other circumftances will admit. If the fub-foil be retentive, and the ftratum below of a good quality, efpecially if it be better than that which lies on the furface, it ought on this occafion to be opened up to the depth of twelve inches at leaft; and if it be to fourteen or fixteen inches, the foil being ftill good, fo much the better. On ordinary occafions, however, a moderate depth of ploughing is generally fufficient.

There are other means, fuch as *Paring and Burning*, which when praftifed with caution, may be employed in order to bring land into a ftate fit for the reception of crops.

Of all the improvements in the cultivation of land that have been hitherto made in Kent, fays Mr. Boys in his Survey of that county, this ftands foremoft; fome of the very worft land having been made to produce excellent crops; and poor chalky downs, of fcarcely any value in their original ftate, are by paring and burning made to produce good turnips and clover, and crops of corn, often equal in value to double the fee-fimple of the land. Intead of the land being injured by the operation, as fome theorists imagine, provided it be under a proper fyftem of management and fairly dealt by, it is put into a progrefive ftate of improvement from the time of its furface being burnt. It has frequently happened, that land, after burning, has been fown with corn four or five years in fucceffion, without being folded with fheep, or any part of its produce ever returned in manure; even charlock and other weeds have been fuffered to remain, by which it has been annually burthened with a double crop: hence it has been left in an impoverifhed ftate, and the burning is unjuftly condemned for the mifchief done by the negligence and rapacity of the cultivator. But let the land, when burnt (continues he), be perfectly cleaned from charlock and other weeds, by growing turnips until the weeds are totally eradicated by hoeing, &c.; let the turnips be fed off the land, by fheep lying on the land day and night; then fow it with barley and clover; the latter to be fed off with fheep, folding them on the land for wheat. Laftly, return the ftraw produced upon the land in manure mixed with clay or loam, or any other freft earth that is near at hand, for a fecond Norfolk rotation, which may be repeated; or the land may be fown with fain-foin, to remain till a turf is formed fit for paring and burning again. This plan being purfued, the practice of burning the foil will not give any caufe of complaint, either to landlord or tenant. Theorifts exclaim, that, by paring and burning, the ftaple of the land is reduced, and the foil is wafte; which may

be somewhat true: but all this is very immaterial, if fine crops of corn can be produced where none ever grew before, and the land at the same time be improved.

The method of paring moss in use in that county, he says, is with downshare or breast-ploughs, taking off a turf as thick as the nature of the soil will admit, from half an inch to two inches; the thicker the better, provided there be a sufficient portion of vegetable matter contained within it, to make it burn well; the expence for paring it a moderate thickness, where the land is not very stony, is 20s. per acre; for laying it up in heaps and burning, 10s.; and for spreading the ashes, 3s. A coat of manure is thus produced on the land, of from eighty to one hundred and sixty cart-loads per acre, for the trifling expence of 33s. A hundred cart-loads of dung, purchased from neighbouring towns and villages, at the distance of three miles from the land, would cost, carriage home included, ten times the price of downsharing, and yet would not improve the land more. But, where the land is well covered with turf, it may be ploughed for burning, about two inches deep, with a common plough, drawn by a pair of horses, early in the spring; and as soon as a drying wind sets in, the turf may be laid in heaps, and burnt by labourers for 1l. 1s. per acre; which will produce near two hundred cart-loads.

The ingenious Doctor Anderson also remarks, that it is an undoubted fact, confirmed by the experience of many practical farmers, that on many poor soils a crop may be thus obtained much more abundant than could be obtained without it. This fact, and it is an important one, is admitted even by those who oppose the practice. It is well known by every practical farmer, that an abundant crop of any kind, under judicious management, is one of the most certain means of laying the foundation for future crops; and in cultivating waste grounds, it is a great point gained to obtain a good crop at the commencement of the operations.

Mr. Marshal, in his Rural Economy of West Devonshire, also observes: "From what I have seen in this county of the effects of *sodburning*, I am more and more convinced that in many cases, and under discreet management, it forms a valuable part of British husbandry, and may become an instrument of real improvement in places where it is not at present known; especially in bringing the *waste lands* of the island into a proper course of cultivation."

In order to the improvement of moor land, the first thing to be done is to divide it into proper inclosures; not only to secure the future produce, but also to be a means of procuring rich earth to cover the otherwise insipid usefess mould on the surface, and give root to the plants which may afterwards be cultivated in them. Then, as the natural produce of this earth is of little value, its surface should be pared off, in order to be burnt: but in doing this, the husbandman should be very careful not to make the clods too dry, or light his fires in too dry a season, lest they should extend farther and deeper than was intended. If the depth of the moorish earth be not very considerable, the surrounding ditches, which make the inclosure, will afford the rich strong soil, which should be spread about three or four inches thick all over the surface. When the clods are burnt, their ashes should be mixed with this new soil. If no proper earth can be got from the ditches, sand or gravel may be used with success, as was practised by the ancients, as gravel is singularly beneficial to such lands.

By the Berne Society, who recommended this method of improvement as founded on repeated experience, it is very properly observed, that the good effects of the sand and gravel will be considerably increased by a moderate mixture of dung, and that, especially if the ground be intended for ploughing, this covering should be at least a hand's breadth in thickness. Dung alone would undoubtedly be extremely efficacious on all such

soils, in which it is remarked to be of longer service than in any other; but the farmer can seldom spare a sufficient quantity of it to go far enough unmixed, nor indeed for mixing. In this case, other ingredients must be resorted to; though the sand or gravel will generally do great things without any mixture. Well preserved ashes will be of excellent service, and so will the rubbish of old buildings, or any other similar substance, when mixed with the sand or gravel, even of the coarser kind, and incorporated with this naturally rich earth, which, were its real value known, and the proper method of treating it rightly understood, might claim a preference before any other soil. Loam is still better than either sand or gravel. This should be brought on before the fires are lighted to burn the surface of the moss, and should remain in heaps till it can be equally mixed with the ashes. Lime, where it can be had, will also contribute to the meliorating of mossy grounds. When moorish earth is thus covered, it is fitted for various kinds of crops.

SECT. VII. *Of the most advantageous Course of Crops for different Soils.*

THE articles of culture are commonly divided into two classes: one consists of crops that are said to exhaust and impoverish the land they grow on; the other such as ameliorate and improve it. This must be understood in a comparative sense; for, properly speaking, there are few, if any, vegetables that are carried off the land they grow on to be consumed elsewhere, but in some measure exhaust and impoverish the soil, and render it less fertile and less capable of supporting vegetation.

The first, or those which are supposed to exhaust the land most, are fibrous-rooted plants, as wheat, barley, rye, oats, &c. The second, or the ameliorating, includes all the leguminous and tap-rooted plants, as beans, peas, vetches, turnips, parsnips, carrots, clover, &c. Modern improvements are much increased by a judicious succession of interchanges among those articles. An ameliorating following an exhausting crop, prepares the land for another exhausting crop, and especially if it be a hoeing crop; for by judicious management the land may be constantly cropped for many years in succession, without the intervention of a fallow every third or fourth year, as has been too much the practice till lately.

Doctor Anderson remarks, that no crop succeeds better on harsh unmeliorated soils than turnips. Perhaps it thrives better on these, with a sufficiency of manures, than on those soils that have been long under cultivation. This is therefore the best crop for the *first* on all newly broken-up wastes that are not of too clayey a nature. It not only mellowes the soil, even perhaps more than a fallow, but affords a great deal of dung, which is an article of inestimable value under these circumstances.

In Norfolk, Mr. Kent in his excellent Survey observes, that the management and course of cropping are generally fixed under a six-course shift, viz. wheat the first year—barley or oats the second, without clover—turnips the third—barley or oats, with clover, the fourth—the clover mowed for hay the fifth—and the sixth grazed till midsummer, and then broken up for wheat in succession. The farmers, however, frequently endeavour to contract it to a five-course shift, by sowing their wheat upon clover of one year's lay; and in some of the best parts, some tenants carry on only a four-course shift: thus, wheat, turnips, barley, and clover. This last is similar to the practice of great part of Flanders, where the invariable method is to carry an alternate crop for man and beast; but as land, though ever so good, will grow tired of a too frequent repetition of turnips and clover, some inconvenience is occasionally sustained; to remedy which, they will do well to change the former of these now and then for a vetch crop, and the latter for trefoil or lucern. No course of husbandry can be more profitable than this, where the soil will allow it; and there are many parts of

this county where it may be carried on without doing any injury to the land. He considers the five-course shift to be more unfair than the four; because, in this case, there are three crops of corn to two crops for the animal. This mode of cropping would be better, if the barley crop, after wheat, was sometimes changed for buck wheat or potatoes, which would neither be an unprofitable or exhausting crop; and thus a little varied, the practice of a five-course cropping might be allowed, in the parts where the soil is good in quality; or where any extra-quantity of manure can be procured, which is sometimes the case in the vicinity of towns, or near sea or river navigations, or where a gentleman occupies a park with a farm, or a farmer a large portion of down. But in the great western parts of the county, the course of six shifts ought to be strictly adhered to: and there is something very rational in this six-course husbandry upon a light soil; for though the exhausting and fertilizing crops do not follow alternately, as in the four course shift, yet there is an equal number of each observed in the rotation. He thinks, however, that in the very light parts of the county, a seven-course shift would be an improvement; but he does not mean by letting the land remain three years laid, as some have recommended, because the Norfolk land does not yield much profit from grass seeds after the first year; but he would rather recommend the following course: wheat, vetches, barley, buck, turnips, barley, clover; this would keep the turnips and clover crops at such a distance, that there would be no fear of their success; and, as the buck might be considered as a neutral crop, the alternate advantage would not in fact be lost in its good effect. He believes too, that by means of the vetches, which might be fed off the whole summer, more stock would be kept on very light land, than from the present six course shift; and where a flock is kept, it never can be employed so well, as in penning upon this sort of light land, as soon as the wheat or rye is sown, especially if the sowing be upon one ploughing; in such case, it is best to begin rather early, and sow by degrees as many ridges each time as the breadth of the fold will cover or contain.

The author of the very useful Survey of the County of Kent observes, that the general system or plan of management in the Isle of Thanet, on all the thin light soils, has been, time out of mind, one of four courses, viz. fallow, barley, clover, wheat; but subject to several variations, which have much increased of late. The soil having been greatly improved during the last fifty years by excellent management, it is found that the course may be extended to advantage by substituting pease for fallow, thus: pease, barley, beans, wheat, and then return to a fallow as before: and sometimes, though but seldom (and then generally considered as bad management), a crop of barley is taken after the wheat, thus: barley, beans, wheat, fallow.

But it is to be understood here, that the foundation of all good management, and the system most practised, is the first mentioned of four courses; and it is by this system, with the plenty of manure from the sea weed, that great part of this island, which is naturally as poor land as any in the kingdom, is made to produce such excellent crops of corn of the best kind.

He further remarks, that the deep rich sandy loams, and some of the best of the land at the west end of the island, are cultivated under the round tilth system of East Kent, viz. beans, wheat, barley.

The following is the process under the four-course system: after raking up the stubble of the wheat, and stacking it near the farm yard for littering hog-pounds, thatching, &c. to plough the land five or six inches deep as soon as possible in the autumn, which is cross-ploughed when the land is tolerably dry in the spring, and repeated two or three times during the summer months. Between the times of ploughing, collections of mould, farm-yard dung, sea weed, &c. are formed in conve-

nient situations in the fields, which are turned over in the autumn, and in frosty weather carried out on the fallow, at the rate of from forty to forty-five cart-loads per acre. This manure is spread and ploughed in as soon as opportunity offers; and the barley is drilled in at the rate of three bushels per acre, or sown broad-cast four bushels per acre, the first dry week in February or March; and if for clover or trefoil the next year, those feeds are sown with the barley: the clover or trefoil lies only one year, and is ploughed about five or six inches deep in November, and sown with wheat. But where no seeds are sown among the barley, the stubble is ploughed in about six inches deep in the winter, and harrowed the first dry week in February; and then beans are drilled in furrows eighteen or twenty inches apart, at the rate of four bushels per acre; the furrows are harrowed, and the land generally rolled down smooth. As soon as the beans appear they are horse-hoed, and sometimes immediately harrowed across the furrows; and then, as soon as they have recovered the harrowing they are hand-hoed with a hoe about five inches broad, at each side of the furrow, which operation is repeated in May, or the first week in June. The ground is then stirred with an earthen plate, in order to raise a quantity of mould against the stems of the plants.

When the beans are harvested, the land is scuffled with the broad share, and made perfectly clean by harrowing and burning the weeds, if any, and then ploughed for wheat. In both cases, whether clover-lay or bean-stubble, the wheat is usually sown three bushels per acre, after having been steeped in salt water from five to twelve hours, and mixed with slaked lime. When pease follow the wheat, they are drilled in, and managed in every respect the same as the bean-crop, except harrowing after the horse-hoe. The barley and other crops after pease, are managed the same as if the land had been a summer-fallow, instead of pease. Under the round tilth system, the bean and wheat crops are managed the same as before mentioned; but the barley is usually sown later, in order to give time, by thrice ploughing, to clean the land; and the manure is generally spread on the barley-stubbles for beans.

The chalky lands of East Kent have not yet received any settled plan of management, those that are commonly practised being very bad. The best system of cropping for these Mr. Boys conceives to be

	1	2	3
<i>Down-land, burnt.</i>	Downshare	Turnips	Downshare Turnips
Turnips same year	Turnips		Turnips
Barley	Barley		Barley
Clover	Clover		Sainfoin.
Wheat	Wheat		
Turnips, &c.	Fallow.		

In these the burnt turf produces turnips almost to a certainty; and by folding these off with sheep, much manure is left on the land, and a stout crop of barley and clover obtained; the clover being again folded off, a good crop of wheat is produced, and the land is in a gradual course of improvement.

The loamy soils are usually under the round tilth system of barley, beans, wheat.

Here the barley is a cleansing crop, by being first ploughed in winter, and then twice or thrice more in dry weather in the spring before the barley is sown. Some farmers, whose land is very clean, plough only twice, and then drill the barley in April, in rows from seven to ten inches apart, hoeing and hand-weeding the intervals. Four bushels are sown broad-cast, and from two and an half to three drilled per acre. Barley is mown, and after lying a week or two, is bound in sheaves, and set up into shocks of ten at a place, to be tithed. When the wheat-sowing is over, and the dung intended for beans is carried out, the barley stubbles are then ploughed in.

The beans are put in rows, from eighteen to twenty inches apart; if boxed in, four bushels per acre; if drilled or dropped by hand, three only; the crop is horse and hand-hoed; and the whole, with the succeeding wheat crop, is managed as in the Isle of Thanet.

But the strong cledge soil is generally under a four course system of fallow, oats, clover, wheat; or, fallow, wheat, clover, wheat.

On this land the oats and clover are sown, in a dry season, in March; the clover is generally fed with sheep, and folded for wheat, which is sown early, that the work may be finished before much wet weather sets in. If the fallow is cropped with wheat, it is sown the end of October, or beginning of November; the clover-seed in that case is sown on the wheat in the spring, and covered with a roll only; for this soil is generally too much pulverized with frost to admit harrowing at that time. The clover is fed off by sheep, as before mentioned, and the crops of wheat and oats are harvested as on the other soils which have been described above.

Mr. Boys says, that the hazel mould is under different systems at different places, according to the fancy of the farmer, or situation of his land. Some pursue the Norfolk system of turnips, barley, clover, wheat; others the East Kent, of barley, beans, wheat; and others again peas, barley, clover, wheat: and some sow early pease and turnips the same year. But this sort of soil being dry, and very easy tillaged land, may be managed as well under one course as another. If the occupier has with it a tract of grazing land, he finds turnips and clover convenient, and pursues the Norfolk system; on the other hand, if he has no grass-land, or has the corn-tithes himself, he finds it most advantageous to pursue the East Kent system. The methods used for sowing and harrowing the several crops, are the same as before mentioned.

For the stiff clays on the tops of the chalk-hills a four-course system of fallow, wheat, beans, barley, is pursued; and a very good one he thinks it is for such a soil. The fallow gives an opportunity of getting a fine early wheat season, which is very necessary on this cold backward land. The wheat stubble is ploughed soon in the winter, by which the frost brings the surface into fine order for drilling the beans as soon as the land gets dry in the spring. The beans are horse and hand-hoed to keep the land clean for the barley crop, which is put into the land at two ploughings only. The corn is harvested in the same manner as on other soils, but is much later than on any other kind of land.

The dry loamy soils about Sandwich, Faversham, and Deal, are cultivated in the round tilth system of barley, beans, wheat. And a few oats are sown instead of barley, and pease instead of beans; and sometimes a crop of canary is sown on the bean-stubble instead of wheat. The barley is sown or drilled on the third ploughing, at the end of April and beginning of May: the quantity of seed sown, and other management, the same as on the loamy soils of East Kent. When the land is manured, the dung is generally laid upon the barley-stubble for beans, at the rate of forty or fifty cart loads per acre; when ploughed, the beans are drilled, or dropped by hand, from three to four bushels per acre; the crop is frequently horse and hand-hoed three times each, and always kept perfectly clean from weeds. It is harvested as in other parts; after which the land is ploughed once entirely flat, and sown with wheat chiefly in the month of November; and the crop carefully hand-weeded in the summer months.

But the stiff wet clay of the lower parts of this district is much of it under a two-course system of beans and wheat alternately. The beans are always put in rows, twenty inches apart; they are frequently planted by women dropping them by hand, while a man follows and covers them with the loose

mould which he cuts and draws from the next furrow, with an instrument called a planting-hoe. Wheat is sown broadcast before the rainy season commences in the autumn; and this land is laid in flat ridges of half a rod or a rod in width: after sowing, the ridge-furrows are opened, to let off the water in winter season. And the best of these stiff wet lands are often sown with canary instead of wheat, and garden-beans are planted instead of common ticks; these are the windfor and toker beans, which are dropped by hand, at the rate of six bushels per acre, in rows twenty inches apart. They sometimes produce very abundant crops, and great profit. Both the bean and canary-crops are kept clean by repeated hoeings.

In the Isle of Shepey, Mr. Boys says, the general rotation is beans and wheat alternately; and when the land gets foul, or the farmer thinks it wants rest, he substitutes a fallow for the bean-crop, which is done once in six or eight years. On the gravelly parts they sow a few oats, and sometimes barley. Some turnips are sown; but from the land holding the wet so late in the spring, they are of little use to the grazier. Much clover is sown with great success; and the lay is the farmer's favourite tilth for the wheat. The land is ploughed in the winter for beans. The beans are drilled in rows, about twenty inches apart, as soon as the land will admit of it in the spring; they are horse-hoed twice, and hoed and weeded by hand once. The beans are harvested as in other parts of the county, and the stubbles are ploughed only once, and then sown with wheat in October: the land is laid in flat ridges, with open furrows, to carry away the water in winter. The crops of wheat and beans are generally very fine.

It is necessary to observe that the clover that is sown here is mown twice; the first time for hay, and the second for seed; and this stiff soil, with a good harvest season, frequently produces great crops of very excellent feed.

The chalky soils of the upland farms of West Kent, when under the plough, are cropped with turnips, barley, clover, and wheat, for one, two, or three courses, and then laid to sainfoin or rye-grass for a few years; after which the same course is again followed. On the clay soils, where they have settled systems and favourable seasons which admit the pursuing them, the courses are fallow, wheat, clover and trefoil, wheat; fallow, wheat, clover and trefoil, oats; fallow, wheat, oats, pease.

And on the hill above Wrotham, &c. Fallow, wheat, clover, wheat, oats. But they frequently sow sainfoin or rye-grass for a few years, and then break up with a fallow, and pursue the same course again.

And on the gravel and sandy soils, turnips, barley, clover, wheat; turnips, oats, clover, wheat; turnips, barley, clover, wheat, oats; turnips, barley, clover, pease. This is dry land, and ploughsight.

On the haddock, or stone-shatter soils, one of the following systems is generally practised, turnips, barley or oats, clover, wheat, pease; or turnips, barley, clover, wheat, beans, wheat.

The coomby and pinnacky soils are nearly under the same system as the clay.

But the hazel-mould is frequently managed with four courses: turnips, barley, clover, and wheat, with variations of substituting oats for barley, and pease for wheat; and sometimes after wheat and clover-lay, a crop of pease. And the gravelly soils are often cropped with early pease, then turnips the same year, succeeded by oats, clover, and wheat, in succession. Sometimes rye and winter-tares are sown, to be fed off with ewes and lambs in the spring, and then followed by turnips, &c. But much of the best land of the vallies is under a system of six courses; viz. turnips, barley, clover, wheat, beans, and wheat. And for turnips, on the chalky and other

poor soils, the land is ploughed in the winter, and cross-ploughed in a dry time in the spring, as in many other parts, and generally manured with farm-yard dung, and mould from hedges and ditches, before the third or fourth time of ploughing, unless manure is carried out for the preceding crop of wheat; for without the land is in good heart, the poorest sorts, especially, will not produce good turnips. They are fed off with sheep, and the land, if it is stiff, is sown with oats on one ploughing; and if light and kindly for barley, that grain is sown instead of oats; for which the land is sometimes twice ploughed. The clover-seed is sown on both crops before the last harrowing; a great part of the clover is mown for hay, and then fed off the remainder of the summer, when it is ploughed once and sown with wheat; for which crop a clover-lay is esteemed here on these soils, as well as in other parts, the best tilth that has yet been discovered.

But the stiff red clays and coomby soils are always summer-fallowed for wheat; and when these sorts of land are laid down with seeds, they are sown with rye-grass, clover, and trefoil; they continue two or three years, and are then ploughed in the winter, and made a summer-fallow for wheat, with the same course as before.

Such sandy and gravelly soils as are intended for turnips, are frequently sown with rye, which is fed off with sheep previous to sowing the turnip-feed. This may be of great advantage to the sheep, should there be a scarcity of food in the spring; but it must tend to exhaust the soil, and weaken the turnips, unless the sheep get great part of their food by day on grass-land, or other feed, and go to the rye by way of folding the land at night: or if the land is to be manured for turnips, there is no fear of a crop; in that case, the sowing of rye may be excellent management; and indeed every plan is excellent on these soils that tends to secure good crops of turnips; for that is the very essence and spirit of good husbandry. And not only the manure of the sheep in feeding off the turnips on these loose lands, but the treading of their feet is of great advantage.

As the stone-shatter, loamy soils, and hazel-mould, are of a light dry nature, they may be worked almost at any time. These are made into good tilths for turnips, and frequently produce fine crops without any manure. The sooner the turnips are fed off, and the land sown, the better the produce in general of barley and oats.

Near London, rye and winter-tares are sown in great quantities for spring-feed for early lambs; and they are fed off in good time for a crop of turnips.

When the seasons admit, the following are examples of the rotation of crops in the county of Mid-Lothian in Scotland, as stated by Mr. Robertson in his survey:

1. For a rich loam.

- | | |
|--|---|
| 1st year, summer fallow, without dung. | 5th year, barley, ground thrice ploughed. |
| 2d — wheat. | 6th — clover. |
| 3d — beans and pease, the land dunged. | 7th — oats. |
| 4th — wheat. | 8th — summer-fallow, &c. as before. |

2. For rich heavy lands.

- | | |
|----------------------------------|-------------------------------------|
| 1st year, summer-fallow, dunged. | 5th year, barley. |
| 2d — wheat. | 6th — clover. |
| 3d — oats. | 7th — oats. |
| 4th — beans and pease. | 8th — summer-fallow, &c. as before. |

3. For a hilly district.

- | | |
|--------------------------------|--|
| 1st year, turnip, well dunged. | 4th year, oats. |
| 2d — barley, or oats. | 5th, — turnip, well dunged, &c. as before. |
| 3d — clover. | |

4. For a dry soil.

- | | |
|----------------------------------|---|
| 1st year, potatoes, well dunged. | 4th year, oats. |
| 2d — wheat. | 5th — potatoes, well dunged, &c. as before. |
| 3d — clover. | |

This practice is followed on several farms on a dry soil in the neighbourhood of Edinburgh.

SECT. VIII. Of Wheat.

THIS grain is less particular in respect to climate than most other kinds. It not only thrives in temperate, but also in very hot, and very cold regions. In general, wheat, however, succeeds best upon strong soils, especially if they have been well drained, so that the corn lies dry: but still some sorts of this grain thrive better in some soils than in others.

The most advantageous mode of cultivation for this valuable grain is probably not yet fully ascertained. It may however be profitably sown either after preparing the land by fallowing, or after crops of turnips, potatoes, &c. and on ground from which a crop of clover has been taken.

Various sorts of wheat are cultivated in different parts of the country. But the writer of the Survey of Kent observes, that the old sorts of wheat, cultivated in that county, are the *brown* and *yellow lammas*; the *white straw*, *Fulham*, and the *white* or *egg-shell*. But that the *brown lammas*, which till lately was the sort chiefly grown, is now giving way to a variety of new species, as well as some of the other old sorts. From some experiments made by Mr. Boys, it has been found to be the least productive of the several kinds.

It is the common brown-strawed wheat, which grows with a long jointed ear, the chaff of a dark brown colour; the straw long and apt to fall; the hull or bran thin, the flour very white, and the corn mellow in grinding; for which reasons it is esteemed by the millers as the best of the old sorts for their purposes. The *yellow lammas* resembles the *brown* in every respect, except that the colour of the grain is of a yellow hue, and the chaff of a somewhat lighter colour. And the *white strawed* wheat takes its name from the colour of its ear; in other counties it bears the appellation of the *Kentish white straw*. This kind sends out a greater number of stems from the stool, or plant, than the other sorts; and by that means is often a very thick crop on the land. The straw is generally somewhat shorter than that of many other kinds, and not quite so liable to fall in rainy seasons. It is on these accounts much sown in the eastern part of the county: but, from its dull colour, its having a thick bran, and often grinding very steely, the millers do not seem to approve of it. The *Fulham* also produces a white straw, which grows short and coarse: this kind is very productive, especially on poor land; but the grain is very coarse, and the bran thick: from which circumstances it is by no means so valuable to the millers as the other kinds.

White, or *egg-shell* wheat, is known by its producing a white straw, a smooth white chaff, and very white grain; the bran of which is somewhat thick, but the flour remarkably white. It works mellow in grinding, is very early ripe, and so free in the ear as to blow out in windy weather. This kind, from rich sandy loams, is often a beautiful sample, in which case it brings the highest price of any of the different sorts. He says that the new sorts of wheat, which have been introduced into that county within these last twenty or thirty years, are the *hoary white*, the *nonpareil*, the *pilbeam*, the *square ear*, and the *hoary brown*. The *hoary white*, by some called the *velvet eared*, is by far the most valuable, because it is very productive, and the best for the miller's use. The straw is white and short, the chaff is covered with a thick fine down, somewhat of a brownish hue; the grain is remarkably small, and of a dull white colour; the bran very thin, so that some grains are almost transparent

when held up to the light. It grinds very mellow, and makes a beautiful fine white flour. From the quantity of down upon the chaff, and its small ears binding up very close in the sheaf, this kind, in a rainy season, is apt to vegetate very freely in the field; on which account it is not so proper to cultivate in a moist climate, and in small inclosures, that are not open to the sun and winds.

The *nonpareil* is a kind said to be brought into this country from America; it has a bright straw with a brown ear; and the grain is very white, large, and plump. It is very productive on all soils, thrashes very free, and yields, in that operation, the greater part of its chaff; thereby producing a great quantity of horse-meat. It grinds very mellow, and the millers consider it as a good kind.

The *pilbeam* is a brown wheat, growing very stiff, and generally thick on the land. The grain is small and plump, somewhat of a yellow brown. It is said to be very productive on rich lands, and is a valuable kind to mix with others, but will not of itself make a good loaf of bread, from its not working properly in the act of fermentation. The *square eared* wheat is a very productive kind; but, from its being apt to drop out in the field before it is ripe, and consequently to blow out in gales of wind, is not much cultivated. The *hoary brown* is but lately introduced, and therefore its properties are yet little known. But besides these sorts, Mr. Boys observes, that there are two kinds of *riquet* wheat, the *white* and *brown*; however, neither of them are much cultivated. They both ripen late in the season, and are so very coarse and steely as to be unfit for making bread, unless mixed with a large proportion of a better sort of flour. They, however, produce very abundant crops on strong wet lands.

The best time for sowing wheat would seem to be about the beginning of September, especially if rain has fallen; as it is a general practice among farmers to make choice of a time for sowing their wheat when the earth is moist, and writers on agriculture have also in general recommended the practice. Mr. Boys remarks, with respect to Kent, that the time for sowing wheat on the wet and cold lands is early in October: on stiff cledge and drier clay soils somewhat cold, about the middle of that month; but that the general time for the county is the month of November. It, however, sometimes happens, by badness of weather and other untoward circumstances, that a considerable quantity is sown the first week in December; but that the more early sowings generally produce the strongest crops.

It must also be observed, that early sowings require less seed than late ones, as the plants then rise better, and acquire strength to resist the severity of the winter. More seed should always be allowed for poor lands than for rich, because a greater number of plants will perish on the former. Rich lands, when sown early, require the least seed of any. There is also another circumstance which the husbandman should carefully attend to in sowing, which is, that his estimate of seed be formed, not from the capacity of any particular measure, but from the number of grains which that measure will contain; because the grains of some growths of wheat are much larger than those from other lands, though of the same species, and perhaps equally good. By not considering this, the ground must frequently be sown too thick, or too thin; though farmers are seldom apt to run into the last extreme. Instead of the usual allowance of three bushels of seed-wheat to an acre of land, repeated trials have shewn that half that quantity is generally more than sufficient: It is a common practice to sow more seed upon new broken up ground, than upon that which has been long in tillage. From half an inch to three inches is the usual depth at which wheat is planted, according to the nature of the soil; the stiffest lands requiring the shallowest sowing. The general custom is, to sow it under furrow, which is certainly most adviseable, if the soil be shallow, to prevent the

plants being thrown out by the winter's frosts, or their roots being left bare by the drying winds in the spring. Some sow in broad-cast, either with a single cast, or double bout, harrowing once between; after which the ground is again harrowed several times, till the seed be well covered. In this manner of sowing, however, a great deal of it will become the prey of the birds. And in planting the corn deep, there is great danger of its being eaten off by worms between the grain and the blade of the grain.

In the agricultural Survey of Norfolk, it is observed that wheat there is partly dibbled and partly sown broad cast; but that the former is not in so high estimation as it was some years since. The writer is however of opinion, that when wheat is planted upon clover or on'y one year's lay, it is the best practice, especially if the dibblers are well looked after, for in this case it will admit of a saving of a bushel of corn to an acre, and the corn is generally better bodied, and somewhat heavier.

Mr. Wagstaff, however, dissents from the above writer in respect to dibbling being not in so high estimation as some years since: "It is," says he, "I believe, true, that, in certain districts of Norfolk, dibbling, properly speaking, is somewhat lessened in its manual practice—as, to save the expence by hand, many farmers have adopted spiked and drill rollers, imitative of the pro ess pursued in real dibbling; while this is a confession to and confirmation of the utility of dibbling, its manual practice, where hands are easily procured, doth not appear to be lessened where it hath been long adopted, while it is annually diffusing in an adjoining county, and is become a subject of experiment in other counties. Indeed, what this gentleman has said, that wheat so planted is better bodied, and consequently heavier, is true, in fact, while a saving of seed is acknowledged: these, with the clover or grassy leys, being pasturable to the hour of ploughing, while the inverted turf is a certain manure, and forms, as it were, a matrix for the nourishment of the embryo seed, which, to admiration, dilates its shoots, covers its allotted space, and each shoot has its culm or stem, the ear of which is more replete in number, and with a larger grain than arises in the broadest process: and it may be remarked, that where certain holes have carelessly been passed without seeding, the parallel rows on each side have tillered forth their branches, whereby there hath not been an apparent deficiency, nor, perhaps, much of a real one: certain it is, in general, or with rarely an exception, that lands of the foregoing description, thus dibbled, with a saving, at least, of a bushel of seed per acre, are productive of more than the quantity saved, and that grain specifically weightier than from equal land, after repeated ploughings, when sown broad-cast, produces."

Mr. Varlo also reports, on the authority of many farmers who have employed this method, first, that the produce is more by ten or twelve bushels an acre than by the former method, particularly if the set wheat is hoed. Secondly, that it is less liable to misfortune, such as lodging, after heavy rains, mildews, &c. Thirdly, that the straw is stouter and the grain bolder, consequently would give the best price. Fourthly, that employing so many poor children, parish rates would be less.

"If this method," says he, "was become general, it would save an immense quantity of seed, and keep the poor employed from February to May; and as experience has proved, past contradiction, the great utility of setting wheat in so extensive a manner, might not the scale be extended—even through the three kingdoms?"

Mr. Kent says, that in Norfolk, when wheat is sown upon one year's lay, it never has but one ploughing; and when it is sown upon a second year's lay, it seldom has but two. The old practice was, to break up the second year's lay soon after the spring grass was eaten off; but now it is seldom touched till

after Lammas, and then the best way is just to pare up part of the sward by a sort of half ploughing cross the ridges, just curling the ploughed part over the unbroken part, in an inverted state, and, when the turf is deadened, to cross-harrow it; and at the wheat-seeding to plough it up, in the straight way of the ridges, to its full and proper depth. The turf by this means falls to the bottom, and operates as an assistant manure. In respect to this practice, he thinks that the farmer should take care not to be too late; as it has been remarked, that, as near the time as possible that nature sheds any particular seed, it always grows with more certainty, and therefore less seed is required, when sown early, than when sown late: about Michaelmas is the height of the season in this county; and it never should be delayed above a fortnight after that period.

The best mode of weeding wheat, is probably by the-hoe, which, when used early in the spring, before the ground is covered by the blades of corn, will effectually eradicate all the weeds, especially if done in dry weather; because being small, they then soon wither and die. When the ground happens to be very full of weeds, it may be necessary to go over it a second time, about a fortnight after the first, to cut up those weeds which may have been too small to be noticed. By this means the corn will be kept clean, freed from robbers, which would deprive it of due nourishment, and there will not be time for new weeds to grow so as afterwards to do it any great prejudice: for the ground will be so much shaded by the corn, that the weeds will thereby be kept down in such manner as not to ripen their seeds before the harvest season.

Both M. Duhamel and Mr. Miller justly blame the practice of those who either turn hogs in among their wheat, to destroy part of it when it grows too thick; or sheep to eat it down, when they think it too rank. The absurdity of the former is self-evident: and in regard to the latter, it is well known, from long experience, that the leaves, or blades of corn, are necessary to draw in nourishment from the air and dews, for the increase of the stalk and ear. To be thoroughly satisfied in this, Mr. Miller cut off the leaves of some plants of wheat, alternately, early in the spring, and always found the stalks of these plants much smaller, the ears shorter, and the grain poorer, than those of the intermediate plants whose blades were not cut. Several experiments made by M. Duhamel have also proved, not only that all plants are impeded in their growth, and rendered less perfect in their productions, but often even killed, by stripping them of their leaves: and this is confirmed by Mr. Miller, who adds, that he has frequently observed in gardens, that plants divested only of their lower leaves, plucked off by ignorant persons upon a supposition of their drawing the nourishment from the head, have been greatly weakened thereby. The same will undoubtedly hold good with respect to corn: besides which, cattle, and particularly sheep, often bite so close as to destroy the crown of the plant whence its future growth should proceed.

Wheat may be said to be ripe when its straw is turned yellow, its ears hang, and are destitute of greenness in the middle of them, and the grain is hard on being bitten. It was formerly a custom among farmers, to delay reaping their wheat till it was very ripe. But they now mostly reap it earlier, and do not let it stand to be so ripe as formerly. They indeed find their account in cutting it greener; for such wheat has a better colour than that which is thoroughly ripe, and consequently sells for a higher price. It is also probably heavier in the bushel.

A produce of from four to five quarters an acre is reckoned a good crop: but it can hardly be credited how much beyond this the produce of good ground, thoroughly well cultivated, may be increased. Mr. Miller assures us that he has known

eight and ten quarters, and sometimes more, reaped from an acre, over the whole field, where the corn has stood thin upon the ground; and that he has been informed by persons of great credit, that even twelve quarters have been reaped from an acre of land drilled and managed by the horse-hoeing husbandry.

The most favourable season to get in harvest, is afforded by hot and dry weather; as the quality of the corn is improved, and the grain rendered much fitter to keep, by the sun's having acted powerfully upon it, either towards the latter part of its standing, or just after it has been cut.

SECT. IX. *Of Rye.*

THIS is a kind of grain much cultivated in some of the northern counties. It is distinguished by farmers into two kinds, the *winter* and *spring* rye, and in some parts of the country by the names of *black* and *white*, or *Dantzick* rye.

The *winter* rye is the largest grain, and is what the generality of farmers cultivate. It is usually sown in autumn, or at the same time as wheat; and in some of the northern counties, they are frequently mixed and sown together; but this seems to be bad husbandry, as the rye ripens much sooner than the wheat. Rye is generally sown on poor, lime-stone, dry, gravelly, or sandy soils, where wheat will not thrive, and in such places it does very well. The ground should be dry when it is sown, as in wet seasons it is liable to rot in the earth. It rises in a much shorter time than wheat. If sown upon light land, it ripens much earlier than on cold stiff ground, and by continuing to sow it in such a soil during two or three years, it will be forwarded so much as to ripen a month earlier than that which has been long raised upon strong cold ground. For this reason, those who are obliged to sow rye toward spring, generally provide themselves with this early seed. A little sprinkling of dung or mud, though it be but half the quantity commonly used for other corn land, will, if laid upon the rye ground, greatly advance the crop. The allowance of seed is commonly about two bushels to a statute acre.

The *small* rye is sown in the spring, about the same time as oats, and generally ripens as soon as the other sort: but if the season prove wet, it is apt to run much to straw, and the grain is generally lighter than the other. The chief use of this sort is for re-sowing land where the autumnal crop has failed.

Rye is ripe when its straw turns yellow, its ear hangs, and its grain is hard. If this grain be cut in perfectly dry weather, and be destitute of weeds, it may be housed almost as it is reaped.

The principal use of rye is for bread, either alone, or mixed with wheat, in which it is called *meslin* corn. If sown only for dressing of land, it is of vast service to the ground where it is ploughed-in green and succulent. This plant is likewise sown in autumn to great advantage, purposely for green food for cattle, particularly for ewes and lambs in the spring, before there is plenty of grass. When this is intended, the rye should be sown soon, that it may have strength to furnish early fodder. In this way it supplies the want of turnips where they have failed, or where their season is over: so that in such cases, it is very good husbandry to sow the land with rye, especially where there are flocks of sheep which cannot be well supported without green food early in the spring.

SECT. X. *Buck-Wheat.*

THIS will thrive in any kind of land, even in the poor sandy soils, but grows largest in light dry ground which has been well ploughed. When raised for its grain, a bushel of seed is sufficient for an acre of land; but when it is intended for green fodder, which is the use made of it in many places,

some farmers sow three or four bushels on an acre, in order to have a thick crop. The common time of sowing it is about the beginning of May; it may however be sown considerably later: but if it be sowed somewhat earlier, and a warm season ensues, it will bear cutting twice in the summer. The method of ploughing buck under, and the after management of buck-fallows, is nearly as for wheat, and the harvest process is like that of barley. This grain is an excellent food for pigeons, poultry, hogs, rabbits, &c. and is found to make horses thrive when given among their oats; but for these purposes it should be first bruised in a mill. The flour of buck-wheat is very white, and when mixed with a little wheat-flour, the poor in some countries make bread of it.

In Norfolk, Mr. Kent says, this grain is introduced after the barley that follows the wheat, and is frequently succeeded by wheat; but this is reckoned bad husbandry, and ought not to be allowed, unless it be ploughed under for manure, or unless the wheat-stubble which follows it be turniped.—The best mode of introducing it is after wheat, instead of barley, when it may be housed as a crop, and then to turnip the buck-stubble. This last is good husbandry, as it does no sort of harm to the land, and is an excellent forerunner to turnips, which generally grow kindly after it. If the soil be tolerably clean, and the buck be intended to be ploughed under as a manure, it is sown on one ploughing: but, in general, the ground is broken, as for barley or peas, to forward the fallow, and secure a crop. The seed-process is the same for both intentions; excepting that, for a crop, the seed is sown first; namely, immediately after barley-seed: and that intended to be ploughed under, is sown as soon afterwards as the ground is in a state fit to receive the seed. It is universally sown above furrow. In Suffolk it is usually sown with grass-seeds for laying down land, and for that purpose it is preferred to most other kinds of spring-corn.

SECT. XI. *Of Barley.*

THIS kind of grain is generally sown either after a fallow, or on an ersh or second crop. If after a fallow, the land must be ploughed at least three times; and at the first ploughing, it should be laid in small ridges, and in that manner remain during the winter for the frost to mellow it: but if another ploughing can be given it in January, or in the beginning of February, the ground will be still much better broken and prepared. In March, these ridges should be split, the ground well harrowed and laid as smooth as it can be, and, if possible ploughed again the same day, in order to sow. But in strong wet lands, the best way is to lay it round, and make deep furrows for the purpose of draining off the water.

Some farmers at the time of twifallowing in June, make the land very fine, and sow it with turnips, which they feed sheep with in the winter: and in March plough it up, and order it as before; but others who take this method of sowing turnips, give it only one ploughing in March, just before they sow. And those who sow barley upon an ersh, after wheat, plough up the wheat stubble in as dry weather as they can, as soon as the time of sowing wheat is over. They lay three ridges into one, if they have dung to spread upon it: but if they have not, they plough it in small ridges, that it may be the drier, and the better mellowed by the frost: they then plough it up again in March, and order it as before. Some sow their barley on small ridges, and others on broad lands; when the latter are used they cannot be laid too round.

Clover may sometimes be advantageously sown with barley; but this practice is not suitable for poor light soils. As the clover in wet seasons is frequently liable to overpower the barley, it has been advised to sow the clover a month after the barley, by which means it is prevented from being too rank.

In Norfolk (Mr. Kent observes) the barley, after turnips, is generally sown upon a third ploughing, and the grass seeds with it; and as the ground has been effectually cleaned by five ploughings the preceding year, it is generally in a fine state when laid down in this way.

Different sorts of barley are known, but the *spring barley*, which has a double row of beards or awns standing erect, is the sort principally cultivated in England, of which the farmers make two sorts, viz. the common and the *ratb-ripe* barley: but the latter is only an alteration of the common barley, occasioned by being long cultivated upon warm gravelly lands. The seeds of this, when sown in cold or strong land, will, the first year, ripen near a fortnight earlier than the seeds taken from strong land, therefore the farmers in the vales generally purchase their seed barley from the warm lands; for if saved in the vales two or three years, it will become full as late in ripening as the common barley of their own product: and on the other hand, the farmers on the warm lands are obliged to procure their seed barley from the strong lands, otherwise their grain would degenerate in bulk or fullness, which, by this change, is prevented. This sort of barley is easily distinguished by the two orders of beards or awns, which stand erect; the rind is also much thinner, and consequently better esteemed for malting.

Another sort, the long-eared barley, is also cultivated in many parts of England, and is a very good kind; but some farmers object to it, because they say the ears being long and heavy, it is more apt to lodge. In this sort of barley the grains are regularly ranged in a double row, lying over each other. It has no beards or awns, is very thin in the rind, and esteemed for the process of malting.

The *sprat*, *battledore*, or *Fulham barley*, is a kind which has shorter and broader ears than either of the former sorts; the awns or beards are longer, which tend greatly to preserve it from the birds, and the grains placed closer together. This seldom grows so tall as the other kinds, and the straw is coarser.

Winter-barley, *square-barley*, *bear-barley*, or *big*, is seldom cultivated in the southern parts of this country; but in the northern counties it is frequently sown, as being much hardier than the other sorts. There are two kinds of this barley, the one with four, and the other with six rows of grains. The grain is large and plump, but the rind thicker than that of either of the preceding sorts, which renders it less valuable. These last two kinds of barley are generally sown in the autumn, about the same time with wheat. In Kent only two sorts of this grain are cultivated; the common *long-eared English barley*, and the *short-eared sprat-barley*; the latter is only sown on some of the richest parts of the soil, where the common kind is likely to grow too stout, and fall. The quantity of seed usually sown in the common way is four bushels per acre; but if a drill plough be used, three and a half is enough.

The usual time of sowing barley is in March, April, or the beginning of May. It is generally thought most advisable to sow light lands the earliest, and to embrace the first dry season that offers for the purpose; dry weather being best for most summer corn. Clayey grounds, and lands subject to weeds, generally produce the best crops when sowed late.

The most suitable soil for barley is that which is dry and healthy, rather light than stiff, but yet of sufficient tenacity and strength to retain the moisture. On this kind of land the grain is always the best bodied and coloured, the nicest in the hand, and has the thinnest rind. These are qualities which recommend it most to the maltster. If the land be poor, it should be dry and warm; and when so, it will often bear better corn than richer land in a cold and wet state.

The common method is to sow the barley seed with a broad-cast at two sowings; the first being harrowed in once, and the second

until the seed is buried; the common allowance of seed is four bushels to an acre: however, if the farmers could be prevailed upon to alter this practice, they would probably soon find their account in it; for if a third part of that quantity be sown, there will be a much greater produce, and the corn will be much less liable to lodge. This saving of seed corn is a very considerable object. But if the drill method were employed, it would be still greater, for in that case an eighth part of the seed would only be required.

From the great success which has attended the setting and drilling of wheat in Norfolk, some farmers have been induced to try these methods with barley, which seemed to answer very well on rich lands, and on others they would probably be found equally advantageous, if proper attention were paid to the practice, as the grain is certainly finer when cultivated in this way.

In respect to the choice of seed it is necessary to observe, that the best is of a pale lively colour, and brightish cast, without any deep redness, or black tinge at the tail. If the rind be a little shrivelled, it is the better; for that slight shrivelling proves it to have a thin skin, and to have sweated in the mow. The necessity of a change of seed, by not sowing two years together what grew on the same soil, is not in any part of husbandry more evident than in the culture of this grain, which, if not frequently changed, will grow coarser and coarser every year that it is continued. But in this, as well as in all other kinds of grain, the greatest care should constantly be taken to have the seed full-bodied.

In many counties the *steeping* of barley before it is sown is not practised. It is however supposed by some farmers, that seed-barley may be benefited by *steeping*; though *liming* it is generally prejudicial. A small quantity of foot mixed with the water in which it is steeped, seems of service in preserving the seed from insects.

When the barley is sown and harrowed in, the ground should be rolled after the first shower of rain, to break the clods and lay the earth smooth; which will cause the earth to be closer to the roots of the corn, and be of great service to it in dry weather. This may be done by the *spike-roller* with great convenience. And when the barley has been up three weeks or a month, it will also be a very good method to roll it over again with a weighty roller, which will press the earth close to the roots of the corn, and thereby prevent the sun and air from penetrating the ground, which will be of great service in dry seasons. This rolling of it before it stalks, likewise will cause it to tiller out into a greater number of stalks, and if the plants should be thin, make them spread so as to fill the ground, as well as strengthen the stalks.

When this grain grows too rank, as it sometimes does in a wet spring, mowing is much better than feeding it off; as the scythe removes only the rank tops, whereas the sheep feed upon all indifferently, and are even particularly fond of the sweet end of the stalk next the root, consequently may injure the growth of the plant, by biting it too closely.

This grain is ripe when the red *roan*, as the farmers call it, or the reddish colour on the ear, is gone off, when the ears droop and fall, as it were, double against the straw, and the stalks have lost their verdure. Barley should never be housed till thoroughly dry, lest it mow-burn, which makes it malt worse than if it had sired in the field.

SECT. XII. Of Oats.

This kind of grain is very hardy, and will thrive in almost any soil. There are several different sorts of this grain cultivated in England, as the *white*, the *black*, the *brown*, or *red*, and the *naked* oat. The white is the most common in the southern part of the country; but the *black* oat is more cultivated in the northern, and is esteemed a very good food for horses.

Red oats are much grown in Derbyshire, Staffordshire, and Cheshire. They are a very hardy sort, and yield a good increase, especially on strong lands. The straw of these oats is of a brownish red colour, as is also the grain, which is very full and heavy, and esteemed a better food for horses than either of the other sorts. The *naked* oat is not common in the southern parts of this country.

In the county of Kent, the *large Poland*, the *Bruc*, the *Tartarian white*, the *Siberian*, the *Devonshire black*, the *red* and the *grey* oats are chiefly cultivated.

The time of sowing oats is February or April, according as the season proves early or late, and it may always be right to sow the largest grained sort the earliest.

Oats are frequently sown after a crop of wheat, rye, or barley: in which practice the common method is to turn in the stubble, with one ploughing, about the beginning of February, and sow the seed with a broad-cast at twice, harrowing it in once after the sowing, and five or six times after the second, observing to draw the harrow once or twice across the furrows, to break the clods and cover the seeds: but at the other times to harrow in the same direction as the furrows, lest the stubble should be raised on the surface. But it would probably be much better husbandry to plough in the stubble in autumn, that it may rot in winter, and to give the land another ploughing and a good harrowing just before the oats are sown. This will render the ground finer, and fitter to receive the grain, and the increased produce would amply repay the extraordinary expence of tillage. It is also necessary to observe, that oats, which impoverish the ground, should always succeed some one of the meliorating crops, by which means a more plentiful crop will be produced than in the common way.

When oats are sown upon lay, or on ground newly broken up, as is frequently the case after only one ploughing, given in January, when the earth is moist, to turn down the sward; the harrowing must be in the same directions as the furrows, or but very little across, for fear of raising the turf. But this is bad husbandry: for the ground would be brought to a much better tilth for other grain, as a preparation, for which this sowing is chiefly intended, by giving the sward time to rot before the oats are sown.

Black oats thrive better in a moist soil than the white sort, and being a hardier plant, may be sown a month earlier. The white, which prefer a dry land, and will do well on gravel and sand, are the best of all grain for ground subject to quick-grass or weeds, because it may be ploughed later for them, and they rise sooner, and top the weeds better than black oats. The weather cannot scarcely be too dry when white oats are sown. The red and the white clayey soils, when in good heart, carry moisture enough, and are very fit for this kind of grain. The common allowance of seed oats is four bushels to an acre, but less may probably be sufficient.

In Kent the *Poland* oats are sown, about four bushels and a half per acre, from the beginning of February to the middle of May; and the first sown, if the land be in good order, are constantly the best sample, and generally the largest crop. There are also many white oats cultivated there under different names, as the *Essex*, the *Hertfordshire*, the *Twin* oat, &c. which are probably only different kinds of the *Bruc* oat. It is an early sort, and very productive on deep rich lands, and will yield a good crop on most soils that are not very poor. Four bushels are usually sown per acre, and the produce is generally somewhat greater than the *Poland*.

The *Tartarian* are a very late sort, but very productive; though extremely light, and consequently not much esteemed. The *Siberian black* oat is a very large, long grain, but liable to drop out in the field: It requires as good land as the white oat; but, from its colour, is not quite so valuable. From the

large size of the grain, it is necessary to sow five or six bushels per acre. It is sown early, and is a very forward sort. The *Small*, or *Devonshire Black* oats, are most commonly sown on chalky downs, and being very hardy, will grow on almost any poor soil; though it is the most productive on good land, and such as is in fine tilth. Four bushels per acre is the common quantity sown on the poor lands of this county; but some farmers, on very bad land frequently sow more; that quantity, however, is quite sufficient if the land be perfectly clean. This sort of oat being hardy, and ripening late, cannot be sown too soon, provided the land be dry and in a proper state. The *Red* oats are but little cultivated; when they are, it is chiefly on the poor cold stiff lands: their straw is said to be particularly valuable for cutting into chaff.

The *Grey* oats are a very long, thin, poor, light grain, and are chiefly cultivated on account of their producing a large quantity of straw, on very poor land, for the purpose of cutting into chaff for horses. They must be sown early.

When oats are about four inches high, it is a custom with some husbandmen to run a wooden roller over them, after a shower of rain has softened the clods, by the breaking of which, in this way, fresh earth is laid to the roots of the plants, and their tillering is considerably increased, if they have not been sown too thick. Both oats and barley should be carefully weeded.

This kind of grain is ripe when the straw turns yellow, the corn becomes hard, and the chaff begins to open and shew the feed. Oats may be housed the wettest of any corn, if the weeds among them be but dead. For in very rainy harvests, when other grain is spoiled, this will receive little or no damage, the surface of its straw and ears being so smooth and compact as to turn off water, and of so dry a nature, that, though housed wet, they will not heat in the mow, or become mouldy, as other grain commonly does.

SECT. XIII. Of Pease.

MANY different sorts are cultivated. The small tender sorts are generally improper for a cold soil; and the large sorts, on account of their great haulm, are not proper for strong rich land, as their haulm will increase to too great a length, and not be able to bear pods. They pod best when sown on a mellow mould, rendered light by ploughing.

The *common white* pea is most suitable for light sandy land, or a rich loose soil. It is generally sown with a broadcast, and only harrowed in. Three bushels of these pease are the common allowance of seed for an acre; and the general time of sowing them is about the latter end of March, or the beginning of April, on warm land; but a fortnight or three weeks later, on cold ground. When sown in drills, which is probably the best way, a bushel and a half of seed is sufficient for an acre. When they are thus set regularly, the ground can be stirred with a hoe, to destroy the weeds, and earth up the plants, by which they are greatly improved, and rendered much easier to cut when ripe.

Green and *maple round* pease require a stronger soil than the *white*, and should be sown a little later in the spring, and considerably thinner, as they are apt to grow rank, especially in wet seasons. When sown in drills at the distance of a foot and a half, the ground between the rows should be stirred two or three times with a hoe, which destroys the weeds, and renders the land fitter for whatever crop is put on it the following season.

For *Grey* and other large pease, the best time of sowing is about the beginning of March, when the weather is pretty dry; for if they are sown in a very wet season, they are apt to rot, especially if the ground be cold. When sown by the drill, the distance between the rows should be about three feet, and the pease be sown thin in the rows: for if too thick, their haulm will spread so as to fill the ground, and ramble over each other; by which means many of the plants are rotted, and hin-

dered from bearing. The common allowance of these large pease is two bushels to an acre: but this is certainly more than is necessary. *Grey* pease thrive best on a strong clayey land.

In different parts of Kent (Mr. Boys observes) the *Reading* and *Leadman's Dwarfs*, the *Grey Poll*, *Nutmeg Grey*, and *Early Dun*, are cultivated for breaking and fattening hogs. They have also many varieties of early and marrowfat pease; and all the different sorts are drilled in rows about a foot and a half apart, from the middle of February to the end of March, or even later. During the summer, the crops are cultivated with horse and hand hoes. The *Leadman's Dwarfs* and the *Early Greys* are thought to be the most productive. The *Early Charleston* and *Hopspur* pease in this county are frequently off the land in sufficient time to have a good crop of turnips.

It is evident from all the experiments which have been made in the culture of this kind of grain, that as large pease ripen late, and run much to haulm or stalks, they should be sown as early as the climate will permit; for thereby they will get so forward as to have time to put forth and perfect all their blossoms, &c. before a rainy autumn comes, and hurts their farther vegetation. This sort of pease ought to be sown on a white, or some mixed land, not very full of juice; but by no means on a cold clay: for the moisture of this last will keep feeding the haulm, and thwart the design of sowing them early. The white or mixed mould must be in good condition, otherwise it cannot maintain a great pea. But a small pea, which ripens early, should be sown in a strong feeding land, because such land will nourish it more vigorously, without danger of too great an increase of its haulm, which is naturally short; and notwithstanding the coldness of the soil, there is no fear but that it will ripen. Moderate rains are of great service to pease while they are growing, and particularly at their time of blossoming and filling up their pods; but a continuance of cold rain for some time is perhaps as prejudicial as too much heat or drought. The blueish bloom upon their leaves, and their expanding the two outermost and largest leaves of their blossoms backward, are undoubted signs of great health and vigour.

When the pease are reaped, they are generally laid up in small wads, and left in the field till the haulm and pods are dry: but during this time they should be frequently turned, and raised as much as possible from the earth, that they may lie hollow for the wind to dry them, especially when any rain happens to wet and beat them down. In some counties they set their pease abroad in stacks, being persuaded that they thence acquire a much better colour than when housed in a barn.

SECT. XIV. Of Beans.

THE soils on which beans are most successfully cultivated are of the stiff or strong moist kind. They do not thrive very well on warm dry lands. If the inclosures on which they are sown be open, it is also advantageous. They are frequently sown on land which is fresh broken up, being of considerable use in breaking and pulverising the ground, and also in destroying weeds, so that the land is rendered much better for corn, after a crop of beans, than it would have been before, especially if they are sown and managed according to the new husbandry.

The season for sowing beans is from the middle of February to the end of March, according to the nature of the soil; the strongest wet soil should always be last sown. The usual quantity of beans sown on an acre of land is about three bushels, though this is double the quantity that is necessary when the new husbandry is employed.

The common method of sowing is after the plough, in the bottom of the furrows; but in this case the furrows should not be more than five, or at most more than six inches deep. If the land be newly broken up, it is usual to plough it early in

the autumn, and let it lie in ridges till after Christmas, then to plough it in small furrows, and lay the ground very smooth. These two ploughings will break the ground fine enough for beans; and the third ploughing is for sowing the beans, when the furrows are to be made shallow.

In the common practice many farmers set their beans too close: for as some lay the beans in the furrows after the plough, and others lay them before the plough, and plough them in; by both methods the beans are laid as close as the furrows are made, which is much too near: for when they are generally drawn up to a very great height, they are not so apt to pod as when they have more room, and are of a lower growth. It is a better way, therefore, to make the furrows three feet asunder or more; which will cause them to branch out into many stalks, and bear in greater plenty than when they are closer: by this method less than half the quantity of beans will be sufficient for an acre of land, and, from being more exposed to the air, they will ripen much earlier, and more equally than in the common method.

In planting beans according to the drill husbandry, the ground should be four times ploughed before they are set, in order to break the clods, and reduce it to a proper state. A drill plough is then to be used, to which a hopper is fixed for setting the beans; the drills should be made at three feet asunder, the spring of the hopper being set so as to scatter the beans at three inches distance in them. By this method less than one bushel of seed will plant an acre of land. When the beans are up, if the ground be stirred between the rows with a horse-plough, it will destroy all the young weeds; and when they are advanced about three or four inches high, the ground should be again ploughed between the rows, and the earth laid up to the beans. If a third ploughing about five or six weeks after this be given, the ground will be kept clear from weeds, and the beans will stalk out, and produce a much greater crop than in the common manner.

Various kinds of beans are cultivated in different parts. In Kent the following sorts are chiefly known: The *common ticks*, the large *flat ticks*, or *May-beans*, *small* or *Essex ticks*, and *French ticks*: and of the garden beans, the *Toker*, *Windfor*, *long pod*, *Spanish* or *Lisbon*, and *Mazagan*. They have also a few other varieties, but which are cultivated only in small quantities. The first is however the sort most generally cultivated by the farmers in that county, and is used for fattening hogs, and as food for horses. They are commonly either drilled, dropped by hand, or boxed, in furrows eighteen inches apart, from three and a half to four bushels per acre, in February and March; and in the case they are mostly hand and horse-hoed twice, and sometimes three times, and finally hand-weeded. The *May-beans* are a larger sort of *ticks*, and somewhat earlier ripe: they are sometimes very productive; but, being larger, are in consequence not so heavy, nor so valuable. Sometimes four bushels and sometimes four and a half of this kind of beans are dropped in by hand per acre; but in other respects they are managed in the same way as the *common tick* beans. The *Essex ticks* are a much smaller sort than the *common tick*, and of a rounder shape. They ripen six or eight days later than the first kind, and are not so productive, but more valuable on account of their great weight. The small *French ticks* are a still less sort, being about as big as a moderate sized pea, and nearly circular; this is the latest ripening sort known, and most valuable when dry, on account of their great weight. It is said they will grow on some sorts of poor land, not well adapted for the larger kinds; but they are not very productive. Three bushels per acre of these two small kinds is a sufficient quantity to seed the land when drilled; which is probably the best method of putting them in the ground. The *Toker* is the largest garden-bean, and somewhat of an oval shape. Several of them are

met with of an inch and a half in length. The quantity of seed is commonly about five and a half or six bushels to the acre. The beans are dropped by hand, in rows about twenty inches apart, as soon as the land is sufficiently dry in the spring. They should be kept perfectly free from weeds during the summer, and be pulled up by hand in harvest. The produce is sometimes very abundant. The *Windfor-bean* is rather less than the *Toker*, shorter, and approaches more to a square form. It is managed in the same way as the last kind in every respect, except a little less seed being required.

The *long pod* is only about half as large as the *Toker*, but a more early sort. They are commonly dropped by the hand in rows about a foot and a half apart; and the quantity of seed necessary is about four bushels and a half to the acre.

The *Spanish* or *Lisbon* is a kind of bean which is still smaller, but which ripens about the same time. The *Mazagan* is the smallest of any of the garden beans, but the most early ripe. This sort is frequently drilled in the quantity of four bushels to an acre.

In the vale of Aylesbury it is common to plough two furrows on each outside of the land, without sowing any beans in them; then to drill the three next furrows; then plough two furrows again without drilling beans in them, and so on, sowing three, and leaving two for intervals, till the land is finished. At the time when the beans are about two or three inches high, it is necessary to plough two furrows up each interval, turning the furrows from the beans, so as to make a ridge in the middle of each interval. This is done with a little plough on purpose, which is drawn by one horse. This work should be done after rain. The intervals are now to be harrowed with a triangular harrow, in what is called cross-tining. By this means the land is laid quite smooth, kept clear from weeds, and the beans have a fine loose mould to strike their roots into.

When the beans are ripe they are either reaped with a hook, or mown; and after having lain a few days on the ground, they are turned several times until they are dry enough to stack; but it is a better method to tie them in small bundles, and set them upright.

Beans should lie in the mow to sweat, before they are threshed out; for as the haulm is very large and succulent, it is very apt to give and grow moist; but there is no danger of the beans receiving damage, if they are stacked tolerably dry; because the pods will preserve the beans from injury; and they will be much easier to thresh after they have sweated in the mow than before; and after they have once sweated and are dry again, they never give. The produce by the new husbandry would seem to be much greater than by the old.

Beans form a part of the food of horses, and are chiefly used in mixture with bran or chaff, though by some upon the road with oats. They are however mostly given to coach-horses and such as are constantly in draught. They afford the strongest nourishment of all kinds of grain, and will enable horses to go through a great deal of heavy labour.

SECT. XV. Of Turnips.

THERE are many varieties of the turnip cultivated, as the *round*, *purple*, and *green-topped turnip*, the *yellow turnip*, the *black-rooted turnip*, and the *early Dutch turnip*.

Turnips are most adapted to a light sandy loamy soil that is not very rich, as in a very rich soil they grow rank and are sticky. They will however grow tolerably well on many other kinds of soil.

The general season for sowing of turnips is from the beginning of June to the middle of August, or even later; though it is not advisable to sow them much later; for if the autumn does

not prove very mild, they will not have time to apple before winter, nor will the roots of those which are sown after the middle of July grow very large, unless there be not much frost in the autumn. By those who propagate them in order to supply the markets with their roots, they are sown successively from March to August. There is, however, great hazard of losing those which are sown early in the year, when the season proves dry, by the fly. They should be sown upon an open spot of ground if possible, as they are apt to draw up too much, and be very long topped, without their roots growing to any size, in close situations.

Land for turnips should be ploughed in April, and twy-fallowed in May, that is, once more ploughed and twice well harrowed, to make it very fine: the seed should then be sown rather thin. One pound is the common allowance for an acre. The seed should be harrowed in as soon as it is sown, with a short-tined harrow, and the ground rolled with a wooden roller, in order to break the clods and make the surface even. When the plants have got four or five leaves, they must be hoed in order to destroy the weeds, and cut up the plants where they are too thick, the remaining ones being left about six or eight inches asunder each way. The sooner this is performed, when the plants have four leaves, the better they will thrive. In the second hoeing, which should be performed about a month after the first, they must be cut up, so as that the remaining plants may stand fourteen or sixteen inches distant, especially if they be designed for feeding of cattle. But where they are sown for the use of the kitchen, they need not be left at a greater distance than ten inches or a foot, as large roots are not so much esteemed for the use of the table.

Another method is practised by some farmers in cultivating turnips, which is sowing the seed in rows, with the drill-plough. The rows are sown from three to six feet asunder. In this way much larger crops have been produced than by the broadcast method, though the last is more generally practised, and does very well when the hoeing is well performed.

Turnips, when sown in drills, require to be hoed by hand, to separate and cut out the plants where they are too near together in the rows; and also to cut up the weeds between the plants, where the plough cannot reach them. If this be carefully performed, the ploughing of the intervals will encourage the growth of the roots, by stirring the ground, and render the land much better prepared for the crop of barley, or whatever else is to be sown the following spring. This mode of culture has been supposed by some to be more expensive than that commonly practised; but those who have made trial of both, find the horse-hoeing to be much the cheapest, and by far the best. The most advantageous way of doing this is to plough between every other row, and some time after to plough the alternate intervals; by which method the plants will receive more benefit, from the frequency probably at first only of stirring the ground, than they would do if all the intervals were hoed at one time; and will be in less danger of suffering from the earth being thrown up too high on some rows, while others may be left too bare of earth: but, when the earth has been thrown up on one side of the drill, it may be turned down again soon after the next interval is ploughed. But as the plough cannot be drawn nearer to the drills than two or three inches, the remaining ground should be forked to loosen the parts, and make way for the fibres of the roots to strike out into the intervals: otherwise, if the land be strong, it will become so hard in those places which are not stirred, as to flint the growth of the turnips. This is however the most necessary in stiff strong land. When the ground is stirred in this manner, one ploughing will be sufficient, after the turnips are eaten off, for the sowing of barley or any other crop.

An ingenious farmer (Mr. Wimpey) says it is absolutely ne-

cessary for this crop that the land be very well pulverized. The number of ploughings and harrowings for this purpose must therefore depend upon the nature and condition of the soil. Twice in some land is more effectual than four times in others; but be the labour whatever it may, it must not be omitted. It is also equally necessary that the soil be either naturally rich and good, or made so by a proper quantity of manure. Turnips never arrive to a good and profitable size in poor land, without good manure to promote their growth and push them forward.

It is likewise of great consequence to have seed that is both good in quality and of a good species. He prefers the *large green-topped*, as being the sweetest and most juicy. Some prefer the *red* or *purple-topped*, as being hardier: but whichever sort is sown, the seed from the largest and finest transplanted turnips is greatly to be preferred, even if it cost double or treble the price of the common sort. It may be of advantage also, in this as well as other cases, to change the seed frequently. "As to the quantity of seed (says Mr. Wimpey), supposing it to be good and the season favourable, a few ounces would be sufficient to stock the land; but as the article is so very precarious, it is by far the safest way to allow seed in plenty, and reduce them afterwards by harrowing the ground well. And the greater the success in providing a good plant, the greater is the necessity that the crop be well and carefully hoed: without this, the important advantage to be derived from a good crop of turnips would in a great measure be lost. Twice hoeing, when well performed, is often sufficient for this purpose, especially if the land be pretty clean; but if it be foul, three times is hardly enough."

In the mode of planting, Mr. Wimpey seems to think that the broadcast is the most productive, if the hoeing be properly performed and in good time; but suggests, that the mode of sowing turnips between beans planted in rows, as recommended by some writers, is a much more certain means of insuring a crop.

The sowing of turnips has also been attempted between the drills of wheat with some success.

In Norfolk, turnips are equally cultivated upon heavy and light soils; and with respect to the preparation of the land for them, Mr. Kent observes in his excellent Survey, that the first ploughing should not be later than Christmas, and should be to its full depth, unless the land is foul, in which case it should be ploughed very shallow the first time, in two-furrow ridges, and the second time to the full depth; but it should never be ploughed in wet weather. After the first fallow has received the benefit of the frost and snow, it should be harrowed down in March. The next ploughing should be as soon as the barley sowing is over, and it should have five earths in all: the last ploughing but one, the dung is ploughed in very shallow, and rolled down; and the last should be about a fortnight after, not later, as the muck will about that time begin to ferment. About twelve loads to an acre is a proper dressing. "There is (says he) perhaps no part of husbandry more deserving of imitation by the rest of England than this. Some persons use rape cake for turnip manure; and Mr. Styleman, of Snettisham, a gentleman of considerable fortune, who farms part of his estate upon a large scale, and is trying many ingenious experiments, uses it in a pulverized state, to which he reduces it by means of two mills worked by two women, each mill being formed of two cylinders revolving towards each other. The first breaks the cake into pieces of the size of a walnut, by the operation of cogged cylinders: the second is constructed of plain cast-iron cylinders, similar to those used for grinding clay to make bricks. Thus reduced to powder, he puts it into the very drills, where he had just before deposited the turnip-feed, by means of Cook's machine, which requires no other contrivance or alteration than substituting different cups and funnels. The quantity of cake

used is a quarter of a ton per acre, which has never exceeded 1l. 5s. in its price." He assured Mr. Kent, that this method had never failed to insure him a good crop.

We are also told that river weeds and fedge have lately been used to very great effect, for turnips, by Mr. Coke, and Mr. Branthwaite, of Taverham, who assert that no manure whatever answers better. They are strewed on the ground, in their wet state, as soon as they are taken out of the water. If the land be of a dry nature, Mr. Kent thinks there is no fear of any aquatic seeds taking root in it; but if it be of a cold or wet nature, abounding in springs, he advises this manure to be used with great caution. As this writer suspects that land may grow tired of turnips, he recommends to the English farmer to break the succession of the crops now and then by substituting vetches or potatoes instead of them, which may be done without interruption to the succession of his corn crops: in this way, he is of opinion, this valuable root may be permanently established in our system of agriculture.

Hoeing is an essential part of the culture of turnips, and in this county is performed twice with great care and attention.

The method of raising this valuable root in Suffolk is this: In November, they begin to plough in their wheat stubbles, and give the land four ploughings afterwards, at such times as suit their convenience. Previous to the last ploughing, which should be in the latter end of June, they cart on twenty loads, each of which is as much as three horses can draw, of rotten dung, or muck, from the farm-yard, turned up in April, or early in May. Sometimes, as lime is the readiest and cheapest manure in these parts, it is used instead of dung, but the latter is thought preferable. One quart of seed is sufficient for an acre, and new seed is the best. That which is ploughed for the last earth should be sown the same day; otherwise, unless rain falls, the ground will be too dry for the seed to vegetate. When the turnips are within three days of being fit for hoeing, if the weather be dry, they run a pair of light harrows over the field, in a direction contrary to that of sowing, and before they are hoed the first time. The turnips are hoed with a seven-inch hoe, and left twelve or fourteen inches distant from plant to plant. They constantly hoe them twice, and find great advantage from the practice.

In Gloucestershire the oat stubble is ploughed in autumn or the beginning of winter; in which state it lies till spring-feed time is finished; when, being well dragged, it receives two or more ploughings, if necessary, with sufficient dragging and harrowing between, and allowing as much time as possible between each operation, for the seeds of weeds to vegetate and be destroyed. The dung of the farm-yard is then applied, and the turnips are sown from the latter end of May to the beginning of August, and once or twice hoed as circumstances require.

In Kent (Mr. Boys says) the preparation for turnips is to plough the land in the winter, and two or three times more, as opportunities offer, during the summer months; and to manure before the last ploughing with farm-yard dung, mixed with mould collected from hedges and ditches, unless the land was manured for the preceding crop of corn. For if the land be not in good heart, it does not produce good turnips.

The sorts of turnips chiefly cultivated there, are the *red*, *white*, and *green round*, the *tankard* and *tap-rooted* turnips. The first sort is generally preferred. The *tankard* stands high above ground, and is a good sort to feed off before the frost sets in; after that, they are not so useful, being more liable to injury from frost than other sorts. The *red round* is esteemed a very hardy kind.

On poor lands the time of sowing is about the end of May; but the general sowing is about New Midsummer-day: good crops are, however, often obtained by sowing the last week in

July, and sometimes the first week in August: the latest sown are the sweetest, and stand the frost best. This crop is constantly hoed by hand, once or sometimes twice, as is necessary.

In the General View of the Agriculture of the County of Mid-Lothian, it is observed by Mr. Robertson, that though turnips may be forced to grow on heavy or on damp soils, it is found impracticable in that moist climate to take them off such lands in winter; they are therefore cultivated only on dry soils, and generally as a substitute to summer-fallow. The ground receives commonly a furrow previous to the winter, and care is taken that it be well pulverised in the months of May and June, by frequent ploughings before the manure is laid on, which is generally at the last operation immediately before the seed is sown, which is usually in drills, from two feet to thirty inches asunder. In some cases the dung is laid in the drill below the seed; in others, it is spread equally over the whole field; in which case the land is sometimes laid quite flat, without being formed into drills, the seed being sown, however, in rows at the usual distance; a practice which seems to be judicious, from this, that the principal risk attending this crop is from the seed's not vegetating; a circumstance more apt to occur, when sown on the top of a drill exposed to the drought, than on a flat field, where of necessity there must be more moisture. The kinds of turnip are chiefly the *red*, *white*, and *green*, sometimes separately, sometimes mixed. The *red* is said to be the hardiest; but the cattle, at first, have a greater aversion to it, perhaps from being more pungent to the taste. With respect to the quantity of seed, it is from 1½ lb. to 2 lb. per Scotch acre. The time of sowing is from the middle to the end of June; when more early, the turnips are apt to shoot before winter; when later, there is a risk that the seed does not vegetate, and the crop itself is less in bulk. This crop is hand-hoed once or twice, and horse-hoed as long as the rows do not prevent it by growing together, which generally happens by the beginning of September.

In the growth of turnips, there is a certain period, as in other plants, when they are in the greatest perfection, and most nourishing state for cattle: Those who have occasion to purchase them, observe that an acre of turnips before Christmas will fatten as many sheep as an acre and a half of the same turnips after that time.

It is a custom with some farmers to draw up their turnips late in autumn, and lay them up in store against winter; by which means they are always ready. It is however very difficult, if not impracticable, to preserve them from very severe frosts, unless they have been drawn previous to such frosts. This would not answer the farmer's purpose, as the trouble and expence of housing or stacking them would far exceed the advantage, even in a hard season, and in mild winters would be entirely thrown away.

But to preserve them for late spring-feed is not a task of such little difficulty. Divers methods have been tried; and among the rest, that of drawing and burying them in sand: but this has not answered, on account of the juicy quality of the turnip and the hot nature of the sand quickly promoting their vegetation; after the termination of which they speedily putrefy, and become quite unfit for food.

The best mode of preserving them is probably to stack them up in dry straw; a load of which is sufficient to preserve forty tons of turnips. The method is this: After drawing the turnips in February, cut off the tops and tap-roots, and let them lie a few days in the field, as no weather will then hurt them. Then, on a layer of straw next the ground place a layer of turnips two feet thick; and afterwards another layer of straw, and so on alternately, till the heap be brought to a point. Care is to be taken that the edges of the layers of straw be

turned up, to prevent the turnips from rolling out; and the top is to be well covered with long straw, as a thatch. In this way, as the straw imbibes the moisture exhaled from the roots, all vegetation is prevented, and the turnips are nearly as good in May as when first drawn from the field. Old haulm or stubble will answer the purpose where straw is not easy to be had.

However, in order to prevent this trouble and expence, the method used by the Norfolk farmers may perhaps be advantageously followed; which is, to continue sowing turnips to the latter end of August; by which means their late crops remain good in the field till the latter end of April, and often till the middle of May. But in whatever way accomplished, the advantages of having turnips good till the spring-feed is generally ready, are extremely obvious and important.

The principal use of turnips is in feeding cattle in the winter and spring, when there is a want of grass for their pasture. Oxen and hogs are particularly fond of this food, which is very fattening to them; and when given to cows their milk is much increased by it. Sheep also eat it readily, and thrive upon it, when they have been used to it early; but they do not relish it when it has not been offered them till they are grown old: however, if they are kept fasting two or three days, most of them take to it; and when they have once tasted it, they become very fond of, and feed kindly upon it. In some places, farmers feed their lambs with turnips till the middle of April, when they begin to feed. This is done in order that their clover, sainfoin, lucern, &c. need not be hurt. The practice of turning a flock of sheep at random into a large field of turnips, is very improper; for they will spoil more in a fortnight than would keep them the whole winter. The best methods of feeding them with these roots, are the following:

1st. To portion out the turnip ground, by inclosing with hurdles so much only as the sheep can clear in one day; and advance the folds farther into the field every morning, until the whole be consumed. The sheep, however, in this case, never eat them clean; they only take the leaves and the heart of the turnip.

2d. This differs from the former only in pulling up the turnips so far as they are hurdled off, before the sheep are turned in. In this way they eat them better, and there is not such great waste.

3d. This is to pull up the turnips, and carry them into some other ground, and there spread them every day on a new place, where the sheep will eat them up clean. It is particularly necessary where the land is wet.

In Gloucestershire they are sometimes given in quantity to farm-horses: they keep them very healthy, and induce them to eat the barn chaff and other dry meat with a better appetite.

In Norfolk, on the light soils, they feed the turnips off with stock in the field where they grow; but on the heavy wet lands, they draw them and carry them off in light carts, to be eaten either in some grass or unploughed stubble field, or in the houses or yards at home. "In general (says Mr. Kent) they are drawn, and given to neat cattle, either in cribs or stalls, which is productive of a vast quantity of muck; or else they are scattered before them, as well as the fattening sheep, upon a dry piece of pasture or stubble; and of late years it is become common to strew them before cattle upon the young wheat, and upon light land, and there probably can be no better husbandry; by which means they go much farther than they would if trodden into the dirt, and enrich the land very much upon which they are so thrown; it being understood, in Norfolk, that the land wherein they grow is left in sufficient heart by the manure bestowed upon it for the tur-

nips: so that it is apparent, that by manuring one piece of land they manure two. Indeed, where the land is poor, they draw every other ridge, and feed the other off with sheep, as in other counties; but this is not by any means the general practice."

But Sir Thomas Beever observes, that the best farmers near Norwich, especially where the lands are rich and moist, feed their bullocks chiefly in yards, which have sheds erected in them, under which bins and racks are placed, whereby the cattle, kept dry and warm, thrive faster with less food, and with less waste of hay and fodder. In this Mr. Kent agrees, and thinks the cheapest and best way of fattening a bullock, is to give him plenty of turnips, in cribs, in an open yard, with plenty of barley or oat straw, in a rack under a shed, where he can take shelter when the weather is bad. A beast, says he, treated in this way, will do as well, having his liberty with plenty of turnips and straw, as he will confined in a stall with turnips and hay. In the Survey of Kent it is remarked that the principal, and by far most profitable application of this crop, is to fold them off with sheep. Some few are drawn and carried away for fattening cattle, either by strewing them on grass-land, or stall-feeding; but this is terribly destructive to the land from whence the crop is taken.

The chief evil to which a crop of turnips is exposed, is that of their being destroyed by the fly, which commonly happens soon after the plants come above-ground, or while they are in the seed-leaf; but after they have put out their rough leaves pretty strong, they are past this danger. This always happens in dry weather; therefore, if there should be rain when the turnips come up, they will grow so fast as to be in a few days out of danger from the fly. Another danger of the crops being destroyed is from the caterpillars, which very often attack them, when they are grown so large as to have six or eight leaves on a plant. The surest method of destroying these insects, is to turn poultry into the field, which should be kept hungry, and turned early in the morning into the field: these fowls will soon devour the insects, and clear the turnips.

Mr. Kent, however, thinks that the only precaution against the fly consists in ploughing the land till it is very fine, and filling it full of muck. Rolling in the night has sometimes been used with success on turnips, when in their first leaf. Another powerful enemy of the turnip is the black canker. "Some people (says Mr. Kent) draw a rope over the ridges, two persons holding the opposite ends: this will brush them off, and sometimes save a few acres; but those who can breed ducks now, may save a greater proportion, as they devour them very fast. In some places this insect is said to be gathered by the hand."

Ruta-baga, or Swedish turnip. This turnip has been lately introduced into cultivation, and thrives well. The following account of it is given in Mr. Robertson's Survey of Mid-Lothian: "It is (says he), perhaps, not so beneficial in some respects as the common turnip; but as it admits of being transplanted with advantage, it is surely an object of attention to the turnip farmers, as by means of it they can fill up any vacancies in the drills of the common kind, with very little expence, which is hardly practicable by any other means. Even where the turnip fails altogether, as by the fly or slugs, the crop can be more readily renewed from a seed-bed of *ruta-baga*, than from re-sowing the field, which seldom comes to much good."

The subsequent communication, procured by the Hon. Baron Cockburn, sets the *Swedish turnip* in a still more favourable point of view. "This plant (says he) is the best calculated of any for a northern climate; it stands frost well, keeps wonderfully when headed with straw built in stooks, which becomes in a great measure necessary, as hares resort to

it from all quarters, and will touch no other root, while any of it remains. It eats as well after it is shot and sheds its seed, as it does before. I saw (continues he) the remainder of a stack of it, the end of last May, at the Duke of Buccleugh's farm, which, with several others, had been lifted and stacked the first week of November at Dalkeith, after the winterers had been turned to grafs; one root of which I carried home, and found it, when boiled, eat as well as it would have done in the month of October."

"Cattle are much fonder of them than turnips, infomuch that when put into a straw-yard together, the turnips are never touched until the other is entirely eaten up. Nay, after having been accustomed for some time to the Swedish plant, they have been found to refuse turnips for many hours, and, even when compelled by hunger, to take to them with a seeming reluctance: the superior nutritious quality of the plant is pretty well ascertained from this fact; that, upon a comparative trial of a number of square inches of a single root, against the same of field turnip, the weight was a third more; and that cattle fed upon it, put up at the same time with others upon turnips, advanced more in a month than the others did in six weeks. Upon land prepared for turnips, the proper season for sowing it is about the 10th of May, and not much later. It has been tried in February, when early garden turnips are sown; but it always failed, growing to the stalk only without any root: when sown after May, it seldom ripened to any tolerable size. Hares don't much take to it until the end of October, when the frost commonly begins: but as it can then be stacked, this objection is removed; and likewise the trouble attending the supply of cattle during a storm with turnips, which will not suffer to be kept long after being taken out of the ground. The shaws of this plant, when carefully stripped, are found to be an excellent kitchen green, and a good substitute for spinnage."

We have, in addition to this account, the following circumstances communicated by another gentleman:

"For five years (says he) I have found the Swedish turnip very useful, although less productive than the common Norwich kind; half the quantity will go nearly as far, and nothing will destroy it in winter. As a specimen of its hardiness, I shall mention one fact:—Last winter, which was a severe one, my sheep got into a field, where both species were growing. The smallest bite on the common turnip caused them to rot completely; and although many of the Swedish turnips were half devoured, the remaining pieces continued perfectly fresh and sweet, till the sowing of my barley obliged me to carry them off for my sheep."

In the Survey of Lancashire it is also remarked that the *rutabaga*, or *Swedish turnip*, stood the severe frost of 1794 and 1795, whilst the English turnips of almost every species suffered, and upon the wet lands were totally rotted and destroyed. The tops of the Swedish turnip, it is true, shrunk; but the root stood quite firm. They likewise keep much better than the common turnip when taken up in autumn.

SECT. XVI. Of Potatoes.

THE soil in which potatoes thrive the best, is a light sandy loam, neither too dry nor over moist, but brought to a fine tilth, and ploughed very deep: for the deeper the earth is loosened, the finer and larger the roots will grow. Four eyes of the cluster sort of potatoes being planted by Mr. Townley on four different kinds of soil, produced as follows. In

- 1. A strong rich loam, 34 lb.
- 2. A light rich loam, 29
- 3. A good gravel, 19
- 4. A sandy soil, 15

It seems therefore well ascertained, that dry soils are to be

preferred for potatoes. An old sward or fresh lay is preferred in many places as a preparation for potatoes, and is said frequently to produce large crops without any manure being applied. In Suffolk, an old layer produced 400 bushels without manure: and in Cheshire, old grafs dug, 500 bushels per acre. The culture of potatoes is also highly advantageous for improving waste and mossy soils; and large crops are frequently produced on these kinds of land, particularly the latter, when made dry by draining.

In the Report of the Committee of the Board of Agriculture, we have the following comparative experiments on the advantages of different kinds of manures in the culture of potatoes.

EXPERIMENT, NO. 1.

Manure per Acre	Crop Bushels.
53 Loads (cubical yards) farm-yard dung	400
160 Bushels foot	360
160 Ditto wood-ashes	240
32 Loads of dung	280
42 Ditto	360
No manure	180

EXPERIMENT, NO. 2.

32 Loads dung, and 40 bushels of wood-ashes	400
No manure	280
160 Bushels of slaked lime	380
1½ Ton of barley straw	300
340 Bushels of pot-ash	380
32 Loads of dung	400
32 Ditto, and 160lb. falt added at time of spreading	400
32 Ditto, and 160 bushels lime	480
32 Ditto, and 480 gallons of urine	520

By Mr. Billingsley not less than 20 loads, each 30 bushels, of well rotted horse-dung is recommended, and hog-dung he found next to horse-dung in utility.

In comparing different manures, Mr. Young had the following result:

No.	Manure	Bush. per acre	Second Year
1.	No manure, produced	120	140
2.	Night soil 10 wag. loads	600	640
3.	Ditto 6 ditto	650	500
4.	Ditto 2 ditto	500	300
5.	Bones 10 ditto	650	640
6.	Ditto 6 ditto	640	560
7.	Ditto 2 ditto	560	240
8.	Hog dung 60 one-horse cart loads	480	300
9.	Ditto 30 ditto	480	160
10.	Yard compost 60 ditto	300	240
11.	Ditto 120 ditto	480	300
12.	Ditto 30 ditto	140	140

In Scotland sea weed has been used with success. It is put into the furrows of the drills. The refuse of peat stacks, and peat ashes have likewise been found an excellent manure for potatoes in the same country.

On comparing different manures, Mr. Townly found that

No.	Manure	Produce, lb.
1.	Coal ashes only	211, rather small
2.	Stable dung and coal ashes mixed	344, very fine
3.	Stable dung alone	315, ditto
4.	No manure	134, very small
5.	Compost, dung, lime, and soil	204, middling
6.	Stable dung covered with common yellow moss	438, remarkably fine
7.	Soapers waste	383, very fine
8.	Stable dung and lime	268, tolerable
9.	Lime alone	187, ditto

	Produce, lb.
10. Coal ashes and lime	192, ditto
11. Stable dung and soap's waste	298, very good
12. Soot, soil and coal ashes	271, ditto
13. Salt and soil	200, ditto
14. Saw dust and coal ashes	190, smaller
15. Stable dung and saw-dust	307, very fine
16. Dung of poultry and coal ashes	236, pretty fine
17. Dung of poultry and sand	156, rather small
18. Saw-dust and lime	197, ditto
19. Decayed rushes and lime	203, very good
20. Tanners bark and lime	76, very poor
21. Bark and stable dung	141, rather larger
22. Bark alone	35, very poor
23. Stable dung and lime spread over the land	230, pretty fine
24. Chopped whins, with a covering of lime over them	256, very fine

In these trials the manure was placed in furrows of 5 feet lands.

Stable Dung, when it is used upon sandy or gravelly soils, should be completely fermented, and, if accurately laid into drills above the potatoes, will produce a good effect. Upon clays, however, or tills, what is called long or rank dung will be much more beneficial; not that its nutritive qualities are greater when it is in that state—on the contrary, they are less—but it has one good effect in clay-soils, viz. that of keeping the ground open, and thereby allowing room for the roots to spread and swell in every direction. This idea is so far improved upon in some situations, that broom and furze, and even wheat-straw, are put into the drills by way of manure; and the use of them is certainly attended with considerable advantage; but their effect is completely misunderstood; for in place of supposing that their greatest benefit depends upon their keeping the soil free and open, which is certainly the fact, it is ridiculously imagined that they act as manure. We by no means dispute that furze or broom, when completely rotted, may be converted into manures; but we are perfectly convinced that their benefit in this case will be more completely experienced upon the crop that follows the potatoes; as by that time they will be decayed, and mixed with the soil.

Moss and Turf. On the same principle that long or rank dung is valuable as a manure for potatoes, moss becomes equally so. Upon light soils it will produce good effects, both by enabling the potatoes to resist the drought, and by affording them an excellent nourishment. Upon strong clays or tills, its effects will be similar to rank dung; namely, that of keeping the soil open, and allowing the roots to spread and swell freely. The use of moss in this case will be an advantage not only to the present, but to the succeeding crops. Upon light thin soils it will be a considerable addition to the staple of the land; and if the substratum be chalk or limestone, so much the better, as it will correct its alkalescent quality, and render it more retentive of moisture; by which means it will bear drought better. Upon clay soils, again, it will break their cohesion, and afford a free passage to the water through them: by this means they will be mellowed down, will be much easier laboured, and will be brought in a great measure into the condition of loam. Turf acts in the same way as moss.

New Earth or Soil. From very great crops of potatoes being raised upon new soils, Mr. Somerville was led to suppose that the use of new earth laid into the drills would act as a manure. He consequently made a trial of it upon a crop of potatoes planted about the end of June, on a spot of ground from which a crop of the early kind had just been separated. One of the drills of this late crop was planted without any of the new earth: the effect was very visible; that where the earth was applied, yielding a luxuriant good crop, nearly double of

what was obtained from the drills, where none of it was used. The soil made use of in this experiment, was the sub-soil of a part of the same garden; which was taken out in the following manner: A trench was dug of eighteen inches deep, and the same width. Into this trench the first spading of the earth was thrown, and the next spade-depth of the sub-soil taken out and carried away. In this way the surface remains unaltered, and the ground is equally valuable as it was before the removal of the earth: besides, this earth can be restored at a future period from the field to which it has been carried, by taking away a part of the sub-soil from it in the same manner. It may be remarked that the practice of taking out the sub-soil may be followed with the same success for any other crop, as well as potatoes.

Lime is frequently employed as a manure for potatoes, and, to appearance, with considerable success, especially upon new lands, or deep heavy loams that have been long under tillage. From some observations which Mr. Somerville has lately made, he is disposed to think lime an improper manure. The circumstances which gave rise to this opinion are as follow: A piece of ground (deep loam) was well manured with lime and planted with potatoes: when their plants appeared above ground, near three-fourths of them were curled, while at the same time a few drills immediately adjoining, which had got no lime upon the soil, and planted with the same seed, were entirely free from the distemper. This circumstance attracted notice; and the same experiment was repeated next year, with the same result. Since that time, the author has paid particular attention to those situations in which the curl is most frequent; and he has uniformly found it to prevail most in the districts where much lime or ash-dung is used. He has also observed, that in those parts where the lime-husbandry is but partially practised, such as the hills and uplands, scarce any such thing as the curl is known. There is one circumstance in these upland situations that may operate as a preventive of this disease; that is, the nature of the soil; which is for the most part mossy. This idea gains considerable strength, from observing the practice of the Lancashire planters; some of whom send their favourite kinds to the mossy grounds to recover, after they have caught the disorder.

But at the same time that we are disposed to think that lime in its simple state has a tendency to produce the curl in potatoes, we entertain a very different opinion of it when made into a compost with earth and dung. If the compost has been well mixed, and the quantity of lime not too great, the active qualities of the lime will be exerted upon the substances with which it is mixed: when employed in this way it will be found a good manure, and, in nine cases out of ten, no curl will appear. It ought therefore to be laid down as a rule, That where lime is used for potatoe-crops, it should always be previously mixed into a compost with earth, dung, or some of the putrescent manures. In this way it will afford a valuable nourishment for the crop, and every inconvenience attending its use will be avoided or guarded against.

Quantity of Manure necessary. The quantity of manure necessary for a potatoe-crop, differs according to the nature of the soil and other circumstances. Where stable-dung is used upon sandy or gravelly soils, and it would seem that it should not be employed upon any other, the quantity is generally about thirty loads per acre: in some cases, however, forty loads are laid on.

Where furze, broom, straw, or brown moss are made use of as manures, it should only be upon stiff clays. Their value upon such lands, as we have already observed, depends more upon their keeping the ground open than upon any enriching quality they possess. Where the clay is stiff, the quantity made use of will require to be very considerable. In general, however, an acre may be done with furze, broom, or brown moss, for about

10s. where these articles can be easily got. Heath may also be successfully employed for the same purpose. But where rank stable-dung or wheat-straw is used, the expence will run from 40s. to 3l. per acre. The use of either wheat-straw or long dung is improper, as clay lands will receive the same, nay, perhaps a greater benefit from furze, broom, heath, peat moss, or fog. When stable-dung is put into the earth in an unfermented state, it does little more than keep the soil open; and though it may decay when so applied, the succeeding crops will be very little benefited thereby. Wheat straw is still worse; as the utmost benefit the soil derives from it is the addition of a small quantity of vegetable earth. Besides, the use of these shrubby plants will have one singular advantage, which can hardly be expected from any other contrivance; that is, the drills will act as a kind of drains for carrying off the water, and by that means render the field drier; which, where potatoe-crops are planted upon clay lands, is a very important consideration.

After this statement of the most advantageous manures for producing large crops of this useful vegetable, the different kinds of it may be considered. Those that are principally cultivated in Lancashire, according to Mr. Kirkpatrick, are,

EARLY KINDS.

- Smooth Yellows.
- Red Champions.
- White ditto.
- Lady Queens.
- Drunken Landlord.
- Birchal Golden Yellows.
- Smith's Seedlings.
- Tox's ditto.

- Boskow's Kidneys.
- English Champions.
- Briton's Dwarfs.
- Bates's ditto.
- Mather's Seedlings.
- Kirkham Marbles.
- Donbobin's Seedlings.
- Poor Man's Profit.
- Golden Galleons.
- Invincible.

- Broughton's Dwarfs.
- Hatley's Nonfuch.
- Early Perrins.
- Dwarfs for forcing.
- Early Manleys.

LATE KINDS.

- America White Rangers.
- Ditto Red ditto.
- Derbyshire Reds.
- Late Champions.

- Ditto Kidneys.
- Pink Eyes.
- Pink-nosed Kidneys.
- Ox Noble.
- Lords.
- Seedling Potatoes, containing a variety of kinds.
- Balmer's Seedlings.
- Budworth's Dusters.
- Irish Apples.
- Winter Kidneys.

The *Ox Noble* and *Cluster* are the sorts chiefly planted for cattle.

The *Old Winter Red* is peculiarly good in the spring, when others have lost their flavour, and has never been known to curl as many others do. In some parts of Yorkshire, the *Ox Noble*, *Champion*, and *Surinam* are cultivated; but chiefly the *Kidney*. And the sorts most in use in the Isle of Man are, the *Kidney*, which are tolerably good, but not prolific, nor do they keep well; the *White* and *Apple* sorts are better than most others for the first part of the season; the *Pink Eyes* and *Copperplates* are hardy, strong, and admit of coarse management; the *Blacks* a late sort, also keep well till August, or thereabouts.

On comparing the *Cluster*, *Red-nosed Kidney*, and *Golden Tags*, Mr. Young found the produce per acre, under the same management in the drill method, to be as follows:

Cluster	360 bushels
Kidney	144
Tags	207

In different garden grounds, Sir Thomas Beevor found the following sorts to produce in this manner:

	Wt. of Seed.	Quantity of Land	Wt. of Prod.	Bushels
	lb. oz.	planted.	lb. oz.	pr. acre.
Incomparable, a seedling —	4 9	6 tenths of a rod	13 0	692
Dennes Hill, ditto — —	3 1	8 ditto	16 10	668
Bayley's ditto — —	3 1	5 ditto	8 6	539
Manley White — —	4 12	3 ditto	6 4	670
Kentish Seedling — —	2 10	4 ditto	16 11	1342
Champion — —	3 6	5 ditto	11 1	708
Ox Noble — —	3 11	4 ditto	14 0	1140

In Ireland, Mr. Baker compared various sorts, and found that

	lb.	oz.
Commonwise produced	21	6
Apple	20	2
Red French	15	12
Munster White	16	0
Crones	16	6
Spanish	15	10

And in repeating the experiment the year following, he found the result to be:

Sort,	Barrels per Acre.
Black	111
Quakerwise	108
Red French	88
White ditto	85
Commonwise	103
Apple	76
English White	83
White Munster	79
Spanish	70
Crones	60

Mr. Hassal observes, that the kinds of potatoe, which he has found most useful for family consumption, are the *Apple* and

the *White Kidney*, which are cultivated with great success in the counties of Wexford and Wicklow, in Ireland. These sorts produce great returns, are firm and mealy, pleasant to the palate, and do not acquire that disagreeable taste at the approach of summer, to which many other sorts are subject; and the *Royal*, or *Cum erland Early*, is of a large size, very prolific, of an excellent flavour, and ripens early enough to admit of the ground being employed either in raising another crop of the same potatoes, or a crop of white pease, turnips, cabbages, &c. These circumstances render it very valuable; but what gives it a decided preference is, that it is ready at a time when the price of grain and other necessaries is at the highest, which is between the old and the new crops.

It is generally recommended, that in the spring, just before the last ploughing, a good quantity of rotten dung should be spread on the ground intended for potatoes, and that this should be ploughed in early in March, if the season be mild: otherwise it had better be deferred until the middle or latter end of that month; for, if a hard frost should come on soon after the roots are planted, they may be greatly injured, if not destroyed, thereby; but if they can be planted in the spring, without that danger, it is so much the better. The last ploughing should lay the ground even, and then furrows should be drawn three feet asunder, and seven or eight inches deep. The roots should

be laid at the bottom of these furrows, about a foot asunder, and then be covered in with earth.

The rows of potatoes are placed at three feet distance, in order to introduce the hoe-plough between them, as it greatly improves their roots: for by twice stirring and breaking of the ground between these plants, not only weeds will be destroyed, but the soil will be so loosened, that every shower of rain will penetrate to the roots, and quicken their growth. These operations should be performed early in the season, before the stems or branches of the plants begin to fall and spread upon the ground; as it cannot be done afterwards without hurting the shoots. But as the horse-hoe can only go between the rows, it will be necessary to make use of a hand-hoe to stir the ground, and destroy the weeds in the rows, between the plants. If this is well done in dry weather, immediately after each of the two horse-hoings, it will be sufficient to keep the ground clean until the potatoes are fit to be taken up; which will be soon after the first frost in the autumn has killed the haulm.

It is the method in some places to lay the dung only at the bottom of the furrows in which the roots are planted.

Mr. Kirkpatrick, in his excellent Treatise on the Mode of cultivating Potatoes in Lancashire, observes, that in order to procure a plentiful crop of any thing raised from the earth by human labour and skill, a proper cultivation of the land is previously necessary, and that each different sort of production of this kind requires, in some particulars, a cultivation or management of the land in some manner peculiar to itself. "The land (says he) may be prepared for a crop of potatoes either by the plough or the spade; but the best method of preparing it for every person who keeps a team of horses is certainly ploughing. It is hereby brought into order at much less expense, a third quantity of the dung will be sufficient which digging will require, as profitable a crop will be gathered, and it will be in equally good order for a succeeding crop. The process of this kind of tillage is as follows: The land must be prepared by ploughing and harrowing exactly in the same manner as for barley. This direction will be amply sufficient for all the counties of England. When it is in this state, and harrowed fine and level on the surface, equidistant drills must be opened the length of the field. The plough, after making a furrow up the field, must be drawn down again close by the same, throwing the soil equal heights on each side. These drills are to be made as wide and deep as will make them capable of containing the dung which is to be laid in the bottom of each. For the distance of the drills this plain and easy direction may be observed: Let it be such, that when your horses stand in one drill, each wheel of your cart or tumbrel may be in the middle of the next drills on each side. When you have proceeded thus far, the next operation is to carry in your manure; and as your horses should stand in one drill, and each wheel of your cart be in a similar situation, the neatness and order of your land will be very little injured. The dung is to be thrown out of your cart in small heaps, sufficient to supply the three drills which your horses and the wheels of your cart occupy, a moderate scattering of which is to be put into the bottom of each drill. This will be completed in a very short time by persons with forks of two tines. These will be the most proper tools for this business, if you make use of long strawy dung lately thrown out of the stables or cow-houses, or collected from the farm-yard not having lain a sufficient time to rot. When the drills are thus prepared, the sets are to be put into them upon the dung about six inches distant from each other. The plough is then to be run on both sides of each drill to throw the earth which was raised out of it upon the potatoes. This operation will elevate it in the middle, and cause it to lie sloping on each side like the roof of a house. The business is now completed until the potatoes begin to make their appearance above ground.

The plough is then to be drawn up and down on each side of the potatoes, which will earth them up and destroy the seedling weeds. This should be performed as soon as any of the plants appear; for if you wait until the whole row are above ground, probably those that rose first may be advanced a considerable height, and they will then be in danger of being broken or injured by the mould, or what they may be covered with.

"There is another method of raising potatoes after the plough, which is covering the ground with dung, ploughing it in, making the lands or beds about seven feet broad, then setting the potatoes with a setting-flick, but not quite close to the edge, that a part may be pared off with the spade to throw upon and cover the plants when they are just making their appearance.

"This may also be managed in a different way. Plough the ground in lands of about seven feet broad, then cover the surface with dung, place your sets upon the dung, and then cover them with the soil cut off the sides, which are left unset for this purpose. This will make the space betwixt each bed very broad, or very deep, or both, as it will take a considerable quantity of earth to cover your sets, and a sufficiency must be left for a second covering, which will be requisite when the plants come up.

"Such are the different methods practised for raising a crop of potatoes by the plough, which is certainly the cheapest and best method for persons keeping a team. But drilling he says is to be preferred, as it will produce a larger quantity of potatoes, and, what is very material, takes a much less quantity of manure. With regard to the kind of manures, strawy unrotten dung is recommended as fittest to be used in the drills, and for these reasons, that it is of the least value of any the farmer has upon his premises, will be more expeditiously placed in the drills, and is full as proper, or more so than any other kind. But any sort of manure will give a crop of potatoes. In the vicinity of large towns the scrapings of the streets, or coal-ashes, used either separately or mixed together, will answer very well. Though lime is not supposed to tend much to the increase of this root, yet if it is mixed with either or both of the above-mentioned articles, it will give strength to the ground, increase the succeeding crop, and improve the flavour of the potatoe.

"When *Pusb-ploughing*, or paring and burning, though now almost laid aside, was in use, many acres of potatoes were raised from no other manure than the ashes accumulated from the burnt sods and lime. The quantity of lime used for this purpose was about one bushel and a half to each rod or perch of land containing eight square yards. And upon the moss lands, where this process is still practised, potatoes are frequently raised from the ashes of the burnt sod only.

"In raising potatoes by the spade, the land must be divided into beds of seven feet broad, cut out or pierced two or three inches deep with the spade by a line; the ground will then part on each side where it has been pierced, and an equal breadth will be preserved the whole length. The dimensions of the bed are fixed at seven feet, as this is thought to be the most convenient breadth for covering, or throwing the soil on the plants when they begin to appear; but if it be a moist field it will be better to make them only six feet, and in dry ground they may be made a foot wider. In beginning to dig the bed thus marked out, some earth is first to be thrown out a spade's depth, and about a foot and a half in length. This trench is to be covered level on the bottom with soil dug the same depth from the next solid ground farther on the bed. The dung is then to be spread thinly on this covering; you are then to dig again an equal depth, throwing each spadeful of soil upon the manure. This will form to you a second trench, which is to be filled up in the same manner as the preceding one; and thus you are to go on to the end. And if it be green sward, you are to be careful to throw each spadeful with the grassy end

downward, and on the side of the beds place the green end towards the middle. If you do not proceed in this manner, the turf will be an impediment to you when you pare the edges to cover, and also occasion weeds in those parts. It is necessary to be attentive in throwing each spadeful of soil to break the joints as the workmen here call it, *i. e.* to lay your soil as hollow as you can, so that the middle of your last sod may cover the joining of two, and not lie one exactly upon another of equal dimensions, which, it is evident, will make the ground much harder and more compact than the method here recommended. As you draw near the end of this bed, you must lay each spadeful flatter; which, though it will occasion your bed to be some little lower at the finishing than at the beginning, is in some degree necessary gradually to lessen the size of your trench. The soil you threw out at the beginning may be put into some of the following trenches; or, if it is carted to the end, you may readily dispose of it in finishing the work.

“Potatoes are also sometimes set in this county upon green sward. The beds are marked out in the manner just described, with this difference, that a space is left betwixt each, containing soil sufficient to cover half a bed on each side. The dung is then laid a proper thickness upon the solid ground, and the sets are placed at proper distances upon it; after which they are covered with the intermediate soil left for that purpose. But this method is not now much practised.”

Mr. Somerville, however, observes, that when they are planted on lays or lands that have been some time in grass, the proper management seems to be that of ploughing the land with a plough which only takes off the sod, and lays it flat down into the furrow with the roots uppermost.

The planter is to follow this plough, and place the sets upon the inverted sod; after which a common plough must follow, and cover them with the loose soil. The sod or sward being thus completely inverted soon begins to rot, and, as it progressively decays, furnishes a manure for the crop. If it be preferred to plant the sets with a dibble, it can be done with great facility, the top of the furrow being a sufficient direction for the planter to keep in a straight line, and the compactness of the sod below will prevent him from going too deep. By the time that this crop is ready the turf is chiefly consumed, and by mixing with the soil will afford a manure for a second. It will in this case, however, be of great advantage to have the ridges so measured, as that the second crop may be planted on that part which formed the interspace between the drills of the first, as by attending to this circumstance the sets will not only be put into that part of the soil which has been completely cleaned and is in no degree exhausted, but an opportunity will be afforded of extirpating the weeds upon that space on which the former crop grew.

For planting early potatoes, the best method, according to Mr. Kirkpatrick, is to set them upon ground that has been well manured the preceding year without additional dung of any kind. The part of your garden or field appropriated to this purpose should be carefully dug, and the clods of earth, if there be any, broken fine with the spade. Drills should then be made with a hoe or spade about a foot distant from each other: in these the potatoes are to be placed six inches asunder, and covered with earth about four inches thick. Mr. Kirkpatrick generally makes these drills with a spade, and the soil which comes out of one, covers the potatoes which have been placed in the former one.

He recommends it to persons never to cut the potatoes which they set very early in the spring. They are of a very tender nature, being almost as soon injured by frost as cucumber plants. If only one eye is left in a set, and the shoot which it has made above ground be injured by the frost and caused to decay, though it may apparently revive from the lowest extre-

mity, very little produce can be expected. If the potatoe be set early in February, which is the time he generally sets his earliest crop, at this season it is not improbable but that the frost may be so severe as to reach even the potatoe itself before it rises above ground: should this happen, if it be set whole, part will be left still uninjured, from which as strong shoots will proceed as if the potatoe had received no injury; but if only one eye had been left it would have been entirely destroyed, and no increase from it would have been produced. It is a custom with some persons to lay their earliest potatoes upon a room floor or in some building, and cover them with saw-dust, the husks of oats, or some species of chaff. In this situation they will make long shoots; and as putting them into the ground is deferred until the weather begins to be mild, and severe frosts are not expected, they may be cut with more safety. Mr. Kirkpatrick, however, advises every one who practises this mode to spread them very thin, otherwise the sprits will be very apt to entwine, and break off when they are removed. In taking them to plant they must be handled very cautiously, and it is much safer to place them in drills than to put them in the ground with a setting-stick. If they are brought forward in this manner under cover, and carefully set when the weather begins to be mild, very early potatoes may be produced. They will make their appearance in a few days after they are planted, and their progress in vegetation will be very rapid, provided they have a dry and warm situation, which always should be allotted to this early production of the garden.

“Potatoes are dug out of the earth by a fork with three tines; and in gathering them the largest are selected for family use, the next size are reserved for seed, and the least of all are preserved for the food of cattle, fowls, or pigs. Two wickets are placed upon the bed: into one the larger ones are thrown as they are picked out of the ground; into the other those reserved for planting; and the smallest are cast upon the ground in heaps, and picked up and carted away at the most convenient time. If the potatoe field be large, and many persons are employed, a cart is placed in it; into which the wickets containing the larger potatoes when full are emptied, and sacks are brought to receive the sets that they may be carried off the ground without mixing with the large ones. They are then generally laid upon a barn floor to dry, before they are deposited for winter purposes. Potatoes of a moderate size are generally chosen for planting, and a bushel of these will produce more sets than two of the largest sort. Every person knows that it is requisite there should be an eye in each cutting: if it has more it is not detrimental, but if it have none it will never shoot. Endeavour to make the cuttings nearly of an equal size, and not some very small and others very large: if this is disregarded, and a setting-stick be made use of, the large ones will not reach the bottom of the hole, and will not receive that advantage from the manure which they would have done if in contact with it. When large potatoes are chosen for setting, which some prefer, the eyes must be cut out about an inch deep, making the part taken out about as large as a walnut. It is common to cut the smaller ones into two, and some that are larger into three parts. It is evident, that the eyes near the root or tail of the potatoe put out weaker sprits than those upon the opposite end or crown; and most people throw away these weaker ones, supposing them not so prolific, or capable of producing such strong plants, as sets from the other parts of this root.

“We have a method of raising potatoes for planting which is very easy, and attended with small expence and trouble, though but rarely practised, which is from the apple or crab, as it is here denominated, which grows upon the haulm of the potatoe, and is full of small seeds. Every species of this root indeed does not bear seed; it is produced by none of the earliest kinds, nor by the Ox Noble and many others of a later sort.

But it is to be gathered from so many, that there is no difficulty in procuring as large a quantity of it as you please. If late in the spring you carefully look over the beds where the seed-bearing potatoe grew the former year, you will find abundance of young plants growing in small clusters, which have arisen from the crabs dropt from the last year's crop. These are to be taken up, and, after being carefully separated, planted in rows at the same distance you set potatoes, in a piece of ground prepared by digging and manure for their reception. These plants will produce abundance of potatoes, some equal to a pigeon's egg in size, but the greatest part not bigger than a hazle nut. But the smallest of these, if set the next year, will produce potatoes of the greatest magnitude, and will upon an average yield a more abundant crop than can be attained from any particular species of this root. It is by this method that so great a variety of this root has been produced; and this is probably the only purpose for which trials of this kind have been made. But this mode of propagation is well worth the attention of every person who raises a considerable quantity of this root. Two pounds of these potatoes will set nearly as much ground as a bushel of large potatoes when cut, and two rods of land large measure will furnish sets more than sufficient to plant a statute acre. But though the collecting seedling potatoes from the beds on which the seed-bearing potatoe grew the preceding year has been mentioned, it will be better to gather the crabs and preserve them until next spring for sowing." Mr. Kirkpatrick has not been able to draw plants from the old ground until the middle or latter end of June, and they are then very weak, occasioned by their growing so close together in bunches. If the gathered crabs were to be crushed and mixed with dry sand, and sown in the beginning of February upon a plot of ground properly prepared, they would probably be much earlier fit to transplant, some of them might be taken up for this purpose, and the rest remain in the seed-bed; by which means they would arrive to greater strength and produce larger roots. February has been mentioned as the proper time of planting the first or earliest crop of potatoes, and about the middle of that month is probably the best, without the weather should particularly invite to plant a few days earlier, or should be so unfavourable as to make it prudent to delay this business for an equal space of time after that time. The latter end of April is the properest time to set the later kinds of potatoes: if they are set sooner in the open field they will be in danger of being injured by frosty air, and the best kinds of potatoes planted then, will have sufficient time to attain to full maturity. The potatoe seed-time in Lancashire continues from April to the latter end of June; but those that are planted so late in the year have not sufficient time to grow to perfection, except they be only intended for pigs, cattle, or fowls.

For raising two good crops of potatoes in one year, Mr. Somerville observes, that the method which has from experience been found most successful is, to plant the ground in the spring with the best early potatoe, in the Lancashire method, which will be ready in the beginning of summer: the soil should then be ploughed once, and planted either with the large white kidney or Killimanca, the sets of which should be cut at least six weeks or two months before they are planted: they should be kept in a place where both air and light may have free access to them, by which means their shoots will be strong and vigorous; and as they will then have no frosts to encounter, they will grow immediately when they are put into the earth. The operation of planting should be performed with the greatest care, in order to preserve the shoots from being broken, as in that case the crop will be rendered considerably later. Perhaps, says he, there is no way of doing this so completely as with a flick: in this way the plant is not only placed at a proper depth, but the shoot is preserved and set upright in such a way,

that the top is equal with the surface. It will certainly be objected to this mode of planting, that it requires more labour than the ordinary method of dropping the sets into the furrow; but, when properly considered, this objection will vanish, as three people with dibbles will plant as many in one day as two persons could do in the ordinary way.

If this comparison as to the difference of expence be just, and it will probably be found very near the truth, it will appear that dibbling requires only a third more labour than dropping the sets into the furrow: to balance which the young tender shoots are preserved, none of the plants are liable to be bruised by the horses' feet, and the work is regularly and accurately performed.

The reason for preferring the kidney or Killimanca for the second crop is obvious: both of these are more productive than any of the early potatoes; and as the price at an advanced period of the season is always considerably lower, any potatoe that will produce a greater bulk will be more profitable. There is, besides, another reason of considerable weight; it is found from experience, that when successive crops of potatoes are taken from the same land, the second and succeeding crops are always more abundant when a different kind of potatoe is planted. This circumstance, he thinks, is well worth the attention of farmers, as by a due observance of it they may plant potatoes for years upon the same soil, with profit to themselves and without injury to the property. A crop of this kind of potatoes will be ready to take up about the beginning or middle of October: indeed if the real kidney is planted, they will be ready in September, when sufficient time will remain either for a crop of greens, coleworts, or a broad-cast crop of turnips, to be eaten off in the spring with sheep. These are not matters of conjecture; the author had last year two very abundant crops of potatoes from a patch of ground in his garden, which was afterwards planted with coleworts, which were very large, before the winter set in. No manure was made use of for the first crop of potatoes, and only a small quantity of new earth, part of the sub-soil of the same garden, was given to the second. It is worthy of remark, that the second crop was not planted till the end of June; and though the season was exceedingly dry throughout, the crop was very productive.

This plan of raising two crops in a year upon the same land applies strictly to light free soils, such as sandy or gravelly lands, and the different kinds of loam. These soils, from their want of capacity for retaining moisture, will always be sufficiently dry to allow the first crop to be put in early enough; but upon wet mossy lands or stiff clays this cannot so readily be done, especially the latter, which, if the winter has been wet, is a considerable time before it can be laboured. There is still another circumstance against potatoes planted upon clays; which is, that they are for the most part watery, and very inferior in flavour to those that are produced upon dry free soils. The only kinds upon which clay makes no difference, are the *Yam* and the different kinds of red potatoe. The taste and other qualities of these are nearly the same upon all soils; but what gives them a decided preference for clay-lands, is the circumstance of their growing to a larger size, and being more prolific than upon any other soil: to add to this advantage, they do not require to be planted very early; time is therefore allowed for working and reducing the land in a proper manner.

In Cheshire, the lazy bed method is much practised, the land being ploughed before Christmas, and in April ploughed across and harrowed; then ploughed deeply into beds five feet wide: at the end of April, or beginning of May, the sets are dibbled in eight or ten inches asunder. In three weeks, or as soon as the buds appear, trenches are dug between the beds, and the plants covered with two inches of soil, spread equally;

hoed, and weeded. And on coarse soils, in the Isle of Man, this method is adhered to: the butts, or beds, are from six to ten feet wide; the trenches from two to three feet; the manure is spread on the surface of the beds; the cuttings placed at ten inches asunder, on the dung, and covered with the earth out of the trenches; when the plants appear, a second covering of finer mould is given them; the two, four inches deep: they must be hoed and weeded.

In Wiltshire, it is common to strew the dung in the furrow, and cover it with the plough; then dibble in the sets at six inches asunder triangularly, the rows being four feet apart; then plough between them, from and to. But in Cumberland they plough the land till sufficiently fine, then strike furrows thirty inches distant, and place the sets at the bottom of the furrows, the dung being laid on them and covered with the plough. And in the county of Durham, they are planted in drills from two to three feet asunder, and one foot from plant to plant.

In Kent, Mr. Dann's method is this: To plough the ground in the autumn or winter: as soon as barley-sowing is finished, carry out the dung (twenty large cart-loads per acre) which if rather long he prefers, spreads and ploughs it in immediately with two ploughs following each other, the horses (three in each) single, and on the land, left by walking in the furrow they might destroy or injure the sets; women and children sufficient following to drop the sets; which, as each furrow is ploughed ten inches wide, will be twenty inches, and the sets in the furrow nine or ten inches apart; nine persons are in general sufficient, and, on the average, two and a half acres per day are planted. The expence for spreading dung, ploughing, and planting, is about 14s. per acre; a slight harrowing, and rolling with a light roller, if necessary, is all that is done until the plants make their appearance.

Where the drill method is followed, Mr. Hassal recommends the setting the drills four feet apart, instead of three, as some advise. He has always found the former considerably more productive than the latter.

A correspondent of the Board of Agriculture observes: "In June last, as I was looking at a crop of potatoes of about three quarters of an acre, planted by Mr. Watts, a gardener, near Leicester, I observed an eighth part of the crop to be at least six inches higher than the other part of the field. This naturally led me to enquire the reason of it, by seeing so great a difference. He answered me, that the ground was all of it digged and manured alike, exactly of equal quality all over; that the potatoes were of the same sort, and that most of them were planted the same day, with only this small difference, that on the part which was the most vigorous, drills were made by a hand-hoe, about a foot asunder; the others, by mere accident, were set by a dibble, or setting-stick, at the same distance. I frequently, says he, visited the crop whilst growing, and observed the superiority increasing all the summer, till the drilled crop was fit to take up, when the stems were about a foot higher, and forwarder by nearly a month, as some of the other were taken up the same day to see the difference. During the summer, they were equally hoed alike three times; and on taking up the whole field, and comparing them together, the produce was about one quarter more from the drilled crop than the dibbled or set one. The potatoes were larger, and nearly a month earlier; which is another great advantage, by having the ground at liberty sooner for another crop. The difference, in his opinion, arises from this cause: In drawing a drill with a hoe, the earth is left in a fine pulverized state, and the potatoe set is afterwards covered with similar earth; the roots consequently have very fine earth to strike into. On the contrary, the hole made with a dibbler, or setting-stick, which in general is shod with iron, hardens and glazes the earth

around it, leaves a hole at the bottom, and the earth is hardened on the sides where the roots are to strike into; and if much rain ensues soon afterwards, the hole may probably be filled with water."

In some parts of Essex and other counties, they plough in the manure, and dibble in the seed upon every furrow, ten inches apart and four deep, by which means they produce pretty good crops.

In the Survey of Mid-Lothian, it is observed by Mr. Robertson, that for potatoes the ground is previously well pulverized by frequent tillage; and it is always the driest soil that is chosen, without regard to the preceding crop. The mode of culture is uniformly in drills, from 18 inches to 4 feet distant from one another, and from 9 inches to 12, plant from plant, in the row. The dung is, in some cases, spread over the whole field; in others, it is confined to the rows; and sometimes is applied to the preceding crop, which is thought to make the best eating potatoes, although rather less in quantity. The seed is sometimes raised from the apple, which requires two years to accomplish; the first producing them only as large as nuts: but they are found more prolific, and generally of many kinds from the same apple. The *kidney* potatoe is esteemed the best; but requires the richest soil; and in that case is more prolific than any other, whereas on poor land it will hardly grow at all. The time of planting potatoes is generally in April, but sometimes as late as the 1st of June. There are some early kinds that are ready for the market by the end of July; but it is commonly October before the later sorts are taken up and housed. It is remarked, in general, that the earliest planted make the best or most *mealy* potatoes; but they are more liable to be curled, and always less prolific. Those planted late are *watery*; but the crop is more abundant, and the curl seldom takes place.

The Curl. This (says Mr. Kirkpatrick) is a disease which sometimes appears on the leaves of the potatoe, and is a certain indication that very little produce can be expected from the plants which are infected with it; it has greatly engaged the attention of the cultivators of this root, and many different reasons have been assigned for this unfavourable appearance. But whatever may be the cause of this malady, a pretty certain method of preventing it has been found out. This is, never to set from the same potatoes two successive years; that is, annually change your seed. Procure for seed, potatoes grown at some distance from you, and upon a soil dissimilar to your own: that is, if your soil be stiff and strong, endeavour to procure seed which has grown on light sandy ground, and *vice versa*. Seed procured from moss ground is seldom or ever subject to curl; and procuring sets from a distance, or from soil of as different a nature as possible from that which you allot for this purpose, is the only method known of preventing this disorder. A change of ground as well as seed has been recommended as favourable to the increase of this vegetable; and every person acquainted with land must acknowledge the superior excellence of fresh land as favourable for all kinds of produce.

Mr. Chapple's mode of potatoe management, for the prevention of the curl, is as follows: If dry weather (says he), in March it is proper to begin to till the early crops, known here (Bodmin) by the name of the *red-nose kidney*. The fairest and best-shaped potatoes are carefully picked out from the others, and cut in small pieces about the size of half a walnut; some contain one eye, others two. The ground being in good tilth by often ploughing, is dressed according to the strength of the grounds, from 20 to 60 loads per acre, of a compost of scrapings of the road, head-ridges, and farm-yard dung: when the plants are about four or six inches high, they are hand-hoed; and if any curled ones appear, they are carefully rooted;

out, together with the sets that bare them: when about a foot high, they are again weeded, and the curled plants, if any remain, are carefully rooted out. It is also necessary to look them over just as they are coming into blossom, and root them out if any curled appear.

Mr. Chapple has for twelve years past tilled from six to ten acres for the market yearly. Those intended as seed for his general market crops the ensuing year, are tilled at a distance from any other potatoe crop, and managed as above-mentioned. Since he has practised this mode, which is about seven years, the curled disease has not injured his crops; and his potatoes have been better than those of his neighbours.

The late crops are the *Irisb red*, or *painted Lord*, tilled in April: they produce very plentiful crops, and continue very good from the beginning of December till the kidneys are fit to draw, which is about the first or second week in June. Mr. Chapple has tilled different ways, some by drilling about two feet apart, and twice or thrice earthed up with the double-mould plough; some in ridges five feet wide, leaving between each ridge about 18 inches of ground not tilled, which is thrown between the plants after hoeing: others he has tilled throughout the field, about ten inches asunder between each plant. Many of this last tillage get green and not fit for use. The two former modes answer best with him; if the crops are kept clean about 100 sacks in the average, and in some ground 140 sacks per acre, are produced.

Preserving Potatoes. The method of preserving potatoes not intended for present use, during the winter, as described by Mr. Kirkpatrick, is this: Having lain after they are gathered upon a barn floor, or under cover, a sufficient time to dry on the surface, they are to be deposited in the earth to secure them from rain or frost; to either of which if they are much exposed, they will soon rot and become unfit for any purpose. In order to make these storehouses of safety, a hole is to be dug in the earth; whose whole extent is to be an equal depth, and the dimensions of which are to be regulated by the quantity of potatoes you have to deposit. The store is to be laid in this hole prepared for its reception; and when the first made hollow of this receptacle is filled to the brim, sods are to be dug from the sides of it, and placed firm in their situation round the edge of the hole: this will form a second cavity to be filled; and as you thus advance in height above the level of the surface of the ground, straw is to be placed on the sides betwixt the earth and the potatoes: thus you are to proceed, gradually diminishing the circumference of your heap, until it ends in a point, in form resembling a rick of corn. The earth which covers this must be a considerable thickness, and is to be beat firmly together with the spade, so that no crevices may be left through which rain, snow or frost can penetrate. On the summit of this heap it is common to place one large green sod. As it will take a considerable quantity of earth to cover this deposit, so as to secure its contents from long and intense frost, the surrounding surface of the ground being dug up for this use, it will be lower than the bottom of the hole, which will prevent water from settling in that part; which if it was to remain stagnant there might run in among and injure the potatoes. If, during the winter, frost of unusual severity and continuance should happen, it will be proper to cover your potatoe-hole with some strawy dung, in order more effectually to secure its contents.

In Sussex, the mode of keeping them which has been adopted by General Murray, is to dig holes in the side of a hill, six yards wide, ten feet deep, and of an indeterminate length, into which carts from the field unload at top, and the potatoes are taken out at that end at bottom, which opens to the slope of the hill, where a wall is built with a door. When full, a stack of stubble or straw is built over the hole, wide

and large enough for security against all frosts. In this manner, the effluvia of the roots rising through the stubble does not occasion their rotting from heat. But Mr. Billingsley's method is to dig a trench eight inches deep and four feet broad; a thin layer of straw being put at bottom and sides: he then piles the potatoes in a roof form, four feet high; covers them with straw six or eight inches thick; then earth a foot thick, and thatches over all. By this means they are kept well in the severest frosts. But in the midland counties they preserve them in ridges, and find that there should not be more than four feet wide of potatoes. If some coal-ashes be sifted over the mould, in finishing, they preserve them the better from the frost.

Of all the methods of preparing this root for food, boiling is the most common; and though all instructions on this head may by many persons be deemed superfluous, the appearance and flavour of the potatoe very much depend upon skill and care in this part of cookery. On this head the following directions are given by Mr. Kirkpatrick: Never pare the potatoe like an apple, but scrape off the outer skin with a knife—do not let them boil hastily, nay hardly boil at all, but simmer: when they begin to soften watch them attentively, feel them with a fork, and as soon as they are easily perforated immediately pour off the water; throw some salt upon them, set them again over the fire in the same vessel, until every particle of remaining moisture is exhausted, and bring them hot as possible to the table.

SECT. XVII. Of Carrots.

THE soil most proper for the cultivation of this useful root is a sandy loam; but they may be raised on many other kinds of soil, when rendered fine and mellow by proper ploughing and harrowing.

A Suffolk farmer observes, that he has sown them after turnips, summer-land barley, and pease set upon a rye-grass lay; that the crop upon the first has generally been most productive; next to that he prefers the latter. In the first place he feeds off the turnips by the beginning of February, and then lays the land up on small balks or furrows, in which state it remains until the second week in March, when it is harrowed down, double-furrowed to the depth of about twelve inches, and the seed sown thereon, at the rate of four pounds and an half to the acre. As soon as the plants appear distinctly, they are set out with a small hoe, at the distance of six inches from each other; they are afterwards hoed twice more at different times, according as the crop seems to require it; and it is not unusual to harrow them between the hoeings, which does no injury to the root, and frequently saves the expence of a third hoeing.

When carrots are intended to be sown after pease, he usually ploughs the stubble as soon as the harvest is over, in order that the land may clear itself of weeds; in December it is laid up in small balks to receive the benefit of the frosts; in February it is harrowed down, and manured at the rate of fifteen loads per acre; the manure is ploughed in to the depth of about four inches, and in the middle of March the land is double-furrowed, and the seed sown. By pursuing this method, he says, the manure lies in the centre of the soil, and not only affords nourishment and support to the carrot in its perpendicular progress, but renders it easy to be turned up by a single ploughing, and greatly promotes the growth of the succeeding crop of barley.

In Norfolk it is the practice to sow carrots after a crop of turnips. The manure, after being put on the land in the beginning of March, is first ploughed in with a common plough, and afterwards trench-ploughed about fourteen or fifteen

inches deep, it is then harrowed very fine, and the seed sown about the middle of March, though the latter end of that month is probably better, as the plants come up nearly as soon as the earlier sown, and are attended with fewer weeds. The carrots are generally ready to hoe in the beginning of May, and, when tolerably free from weeds, may be hoed with large hoes. Carrots are also frequently grown with the same preparations on land where potatoes have grown. The manner in which Mr. Billing cultivated his land for these plants is the following: The wheat and clover stubbles he split down with the plough early in the preceding November, and is satisfied, that whether the wheat stubble be, as it is called in Norfolk, flat work, or in ridges, or the carrots are to be sown after clover or rye-grass, the land cannot be ploughed too early, so that the frost and snow may have their full effect in mellowing the ground for the reception of so small a seed; and this is the more necessary to be attended to, the stiffer and tougher the soil is. He ploughs the wheat and clover stubble three times; but the land on which the turnips have been, but twice; the first shallow, but the last as deep as the staple of the ground will permit; and on this ploughing the carrots are sown.

Sometimes the land is immediately dunged for the carrots, but at other times only for the previous crop: the former is probably the better method. Mr. Billing thinks four pounds of seed an acre is sufficient.

It is generally three weeks after sowing, and sometimes longer, before the carrots appear: and they are frequently seven or eight weeks before they are fit for the hoe, which affords the weeds an opportunity to get strength, in this season, as they grow fast: Mr. Billing is therefore of opinion, that it is better to sow them as late as you can with safety to the crop, as he found those sown in April on clover stubble came much the soonest to the hoe, though later sown.

Where the crop of carrots is very clean, once hoeing may be sufficient; but where the weeds are strong it is necessary to hoe them a second time; but about ten days or a fortnight after the first hoeing, they should be harrowed: this will displace the weeds, and prevent their growing again, which many of them will otherwise probably do, especially if it be showery weather: the harrowing does not hurt the carrot plants, but, on the contrary, does them service, by bringing fresh earth to them, as well as by destroying the weeds. About three weeks after harrowing, in case it has not perfectly cleared the ground of weeds, or in case new weeds spring up, Mr. Billing hoes the carrots a second time; and after this, if there still remain any weeds, which will be the case if much rain falls during the time of the second hoeing, a second harrowing is bestowed. But where the weather has been favourable, and those employed in hoeing have done their duty, the carrots once hoed and harrowed have been as clean as those on which two hoeings and as many harrowings have been practised.

An Essex farmer remarks that carrots will amply repay every expence of the *finest* culture; and should, from their extensive utility, on sound, deep, and friable land, be every where attempted. He sows in March, or April; hoes three times, and harrows after each hoeing; sometimes leaves them in the land till after Christmas, and takes them up as wanted; but lately has taken them up in October, in dry days, put them directly into small *upright* cocks of ten bushels each, *entirely* covered, with the tops cut off; they *thus* appear to dry better than in any other mode; and, with very little loss, to bear the weather. If, after being thus dried, they are carried into any barn, or shed, it will be better, if in large quantities, through the hazard of heating, not to pack them *close*, but rather throw them promiscuously into *beaps*, with a little straw over them. Though this writer's produce, with little

ploughing and no manure, was only on an average about 400 bushels an acre, some of my neighbours (says he), who have been induced to try them, on a rather larger scale, with finer culture, and fresher soil, have raised from six to nine hundred bushels per acre, and applied them more profitably, as well as more generally, than any other winter herbage, to deer, sheep, bullocks, cows, and horses. At the lowest calculation they are, from our trials, esteemed to exceed turnips in value one-third, as to quantity of feed; but are far superior in what arises from convenience. For the stable, where to *us* they seem to be a perfect substitute of corn for all horses, at least not used in any quick work; and partially so, for those that are, when corn is joined with them. If they be given when perfectly dry, no washing of the carrots is, in general, necessary for any cattle, except horses *regularly* kept in the stable.

This is undoubtedly a little additional trouble and expence. They are sown in March; and if the weather continue dry, it is some weeks before this plant appears, and so *very delicate*, as to make the first hoeing, or rather weeding, which must be as early as their strength admits, extremely tedious and troublesome. In about a fortnight their root will be sufficiently fixed to bear harrowing, by which their growth will be promoted, and the land cleaned; and the treading of the horses will not hurt the plants. And in about a fortnight more the second hoeing, to set them out at six inches square, will follow, and a second harrowing; the third, if at all necessary, just as the state of the soil and growth of weeds may require; for as to the carrots, their nourishment is drawn from a bed so much deeper than that of weeds, as not to be at all injured in their progress, though disgraced in their appearance, by them. The carrots may be dug out of the ground with a three-tined fork, or be ploughed up with a narrow-shared wheel plough: the latter method leaves the land better prepared for the ensuing crop.

In Suffolk, after the carrots are taken up, they lay them in an out-house, and cover them well with straw, to guard them against the frost; though it is not unusual for some farmers to let them continue in the ground until they are wanted, which is less expensive; and the weather must be extremely severe to injure the crown of the root, which is more hardy than either a turnip or potatoe. When they are taken up, care must be taken of the tops, which are equally good with the roots for cows, sheep and hogs.

SECT. XVIII. *Of Parsneps.*

THESE roots require a rich, mellow, and deep soil, in order that they may have full room to thicken and run downward. The seeds of these plants should be sown in February or March, either alone or with carrots, especially if it be intended to draw these last very young; because parsneps seldom spread much before the latter end of summer, by which time the carrots will, in this case, be gone.

It is necessary that the young parsneps be hoed and weeded, or, if they be sown in rows, that the ground between those rows be dug three or four times in the spring, or whenever weeds appear.

When the leaves of this plant begin to decay, the roots may be dug up for use: but they are seldom well tasted before that time; nor are they good late in the spring, after they have shot out again. In order to preserve them for spring use, they should be dug up in the beginning of February, and buried in sand in a dry place, where they will keep good until the middle of April, or even to a later period.

Mr. Hazzard, however, observes, that in order to cultivate this root so as to make it prove advantageous to the farmer, it will be right to sow the seed in the autumn, immediately after it is ripe, or come to perfection; by which means the

plants will appear early the following spring, and will get strong before the weeds can grow to injure them. Frosts never affect the seed, nor do the young plants ever materially suffer through the severity of the seasons. Not only on this account, but for many other reasons, the autumn is preferable to the spring sowing, as the weeds at this time will keep pace with the parsneps; and often when they are hoed or cleaned, great part of the crop is pulled up, cut out, or otherwise destroyed, as they are (when sown in the spring) so small when they first appear, as not easily to be distinguished from the weeds; and if no rains fall at that season, some of the seed will not vegetate till late in the summer; and the few plants that do appear, will scarce pay the expence of cleaning them: besides, they will never grow to any size, but be sticky or cankered, and consequently will be destitute of nutrimental juice; while, on the contrary, those that are sown in the autumn will be large, free from the defects of the others, and fully answer the cultivator's expectations.

He thinks that the best soil for parsneps is a rich deep loam; next to this is sand, or they will thrive well in a black gritty soil; but will never pay for cultivating in stone-brash, gravel, or clay soils; and they always are the largest where the earth is the deepest. Dry light land is pleasing to them, but wet, stiff, or hide-bound land is destructive. If the soil be proper, they do not require much manure. This writer has obtained a very good crop for three successive years, from the same land, without using any; but when he laid at the rate of about forty cart-loads of sand per acre upon a very stiff loam, and ploughed it in, he found it answered very well, from which he concludes that a mixture of soils may be proper for this root. He says it is most advisable to sow the seed in drills about 18 inches distant from each other, that the plants may be the more conveniently hand or horse-hoed; and that they will be more luxuriant if they undergo a second hoeing, and are carefully earthed so as not to cover the leaves with mould.

He advises those who have not ground to spare, or cannot get it in proper condition to receive the seed in the autumn, to sow at that time a plot in their garden, or the corner of some field, and transplant from thence the latter end of the month of April, or early in the May following. The plants must be carefully drawn from the seed-plot, and the land that is to receive them should be well pulverized by harrowing and rolling; and when it is thus ordered, a furrow should be opened with the plough about six or eight inches deep, in which the plants should be regularly laid at about the distance of ten inches from each other, taking care not to let the root be bent, but for the plant to stand perpendicular after the earth is closed about it, which should be immediately done by means of persons who should for this purpose follow the planter with a hoe; and he must not forget that the plants will be injured if the leaves are covered. Another furrow must be opened about 18 inches from the last, in the same direction, and planted as before; and so in like manner till all the plants are deposited, or the field is completely cropped; and when the weeds appear, hoeing will be necessary, and it will also be right afterwards to earth them up.

He thinks it is wrong to plant parsneps by means of dibbling, as the ground thereby becomes so bound as seldom to admit the small lateral fibres with which these plants abound to fix or work in the earth; on which account they are prevented from expanding themselves, and never attain their proper size. But, says he, if people would in general be attentive to the soil, the season for sowing, the cleaning and earthing the plants, and raising their feed from the largest and best parsneps (which should be selected and transplanted for this purpose), there is no doubt but such a crop would answer

much better than a crop of carrots; they are equal if not superior for fattening pigs, as they make their flesh whiter, and they eat them with more satisfaction. When they are clean washed and sliced among bran, horses eat them greedily and thrive therewith. It is also said, that cows and oxen are fond of parsneps: if so, they are certainly well worth a farmer's attention, especially in countries where there is a scarcity of fodder.

SECT. XIX. *Of Cabbages.*

CABBAGES grow extremely well on any loamy soil which is in good heart and made sufficiently fine. For this last purpose the land should be thrown up in the autumn, that it may enjoy all the advantages of a winter and summer fallow; and as these plants extract their nourishment from a considerable depth, as well as from the surface of the soil, it will also be necessary that it should be double-trenched during the time of fallowing. Immediately after harvest, it is to be turned up, and the workman is to go as deep as he can with his plough: another plough is to follow immediately in the same furrow with a higher earth-board, which will cast the mould over, and bury the stubble, if it was not before, by some other method, destroyed: in this manner the field will, as it were, be turned upside down, double spitted more than a foot deep, and the stubble be sooner rotted. The harrows must then make the ground as fine as the season will admit. After this, when the weather will permit of it, double trench the land, and lay it up till the spring in sharp ridges. By these means the ground is rendered extremely mellow, but the process is probably too expensive for general practice. The land being thus properly prepared, the plants are generally set in rows at the distance of about two feet and an half or three feet, and two feet asunder.

In Staffordshire, Mr. Pitt observes that some farmers plant them on three-foot ridges, manured under the rows, with soil left between the rows for one plough-hoeing; the hoeing being afterwards finished by hand. Others plant them without ridging, spread the manure promiscuously, and do all the hoeing by hand.

Some also think cabbages are best grown on the same spot or flat of ground every year, which should be allotted and inclosed for that purpose: others grow them in the turnip field; and they are followed by barley, as it is generally convenient to reserve them for use late in the spring. Sometimes one part of the field is planted with autumnal plants, and the other with spring plants. This (says Mr. Pitt) is the true system, as the former will be large enough for early use, and the latter will stand the winter for use in spring.

In the vicinity of Edinburgh, Mr. Robertson informs us that in preparing for this crop, the ground is ploughed in November, and again in April following, and well reduced by harrowing, &c. It is then laid out in 3 feet drills, 30 carts of dung per acre being laid in the drills, which are then split with the plough covering the dung, and then rolled lengthways, after which the plants are put in, to the quantity of seven thousand two hundred (long hundreds) per Scotch acre, at two feet distance in the rows.

The seed is sown in garden ground, about the first of September, and transplanted to the field in May, or the first of June. While growing, the earth is taken away from the plants by the plough; they are then hand-hoed, and a few days after the earth is again laid to the plants by the plough; and if any weeds appear afterwards they are again hand-hoed. The crop is ready for use by the end of October, and continues all the winter, till the latter end of March or middle of April.

Mr. Boys observes, that the tillage necessary for cabbage in

Kent, is to plough the land in the winter six or seven inches deep, and to cross-plough it in the spring in a dry season; and then, after manuring with a good covering of rotten dung, before planting in June, to plough it again, turning over a furrow ten inches wide; and then, by planting every third furrow, the rows of cabbages will stand two feet and a half apart. The sort for cattle or sheep is the large drum-head, which in good land will grow to an immense size. The seed should be sown the last week in March, on a rich warm border of light soil, where the plants may remain till a showery season in June, when they should be transplanted with small iron trowels, in the following method:—The plants being ready drawn from the seed-bed, a woman attends in the field to dip the roots of the plants in fine mould and water, beat together to the consistence of batter; two others then carry them in handfuls, and strew them in small lumps along the furrows ready for the planters; seven men will keep these three women fully employed: they thrust their trowels with their right hand into the land, in a diagonal direction, with the point towards them; and then, by pulling the handle of the trowel a little towards them, the earth is lifted so as to leave a space to put in the plant with the left hand; the trowel is immediately drawn out, and the earth pressed close to the root of the plant with the handle. The land being ploughed straight, and left unharrowed, there is no occasion for lines to direct the planter. By rolling the surface, after the plants are in, the work is finished. In July and August the crop must be kept clean by horse and hand-hoeing.

Mr. Baker, who has made many experiments on different kinds of cabbages, and detailed them in the Transactions of the Dublin Society, distinguishes them into summer and winter sorts. The summer cabbages are those raised from seed sown in March, and those from seed sown in August, the winter cabbages. The *Drum-head*, or *great Scotch cabbage*, is probably the most productive and hardy of any of the winter sorts.

It is now fully proved by experience, that cabbages are not only very agreeable food for cattle and sheep, but also that they are very nourishing to them. And cows fed upon cabbages give a great deal of milk, but the butter made from it has been objected to. It is now however known, that the bad taste of butter, when the cows feed upon cabbages, is owing to giving them the decayed leaves: for when these decayed leaves are taken off, and only the sound cabbages given to the cows, the milk and butter are perfectly sweet, and of a rich taste. The quantity of food for cattle that they produce is very great; from twenty or thirty to fifty ton and upwards per acre: and some of them continue sound through the winter; and during the months of March, April, and May. This renders them peculiarly valuable: for in these months the winter provision for cattle is mostly spent, and the grass is not then advanced so far as to supply them, often not till the middle of May.

SECT. XX. *Of the Turnip Cabbage.*

THE mode of culture of this plant is pretty similar to that of cabbage. But the earlier the seed is sown in the spring, and consequently the earlier the plants are put out, the better, especially in poor ground. In strong land, and a favourable season, Mr. Broughton observes a good crop may be procured by sowing the first or second week in May. If sown ever so early, they never run to seed the first summer, unless here and there one which has run from its sort. In good ground the rows may be from three to five feet asunder, and the plants not less than three feet in the rows. Great care must be taken not to plant them too deep; and, when hoed, not to draw the mould too high in their stalks. Strict attention must be paid in selecting bulbs for seed, which should always be the cleanest and handsomest; otherwise they are very apt to sport, as it is

termed, or run from their sort. I have taken them up in the spring from the field (says he), and planted them in my garden when they have been sprouting, and the seed has ripened well; but I would prefer letting them remain where they were first planted. It may, therefore, be prudent to plant a small piece for the purpose of seed, and to pull up any irregular or false ones. Of course none of the cabbage tribe should seed near them. He thinks those intended for seed might be planted closer together, without injury to the crop; by which it will allow for pulling up the bad ones with less loss. If any person should wish to cultivate them in his garden, he will find the method above recommended for the field answer his purpose. The bulbs will be fit for use by October, and may be used till they begin to sprout in the spring, at which time the young shoots are very delicate eating. In preparing for the table, the rind, which is very tough and fibrous, must be entirely taken off, and the bulb cut into small pieces, which must be treated as turnips: they will require to be boiled at least two, and sometimes three hours, before they will be sufficiently tender. He has always found them best when boiled with meat, especially with salt beef; and they give a most agreeable flavour to broth.

In the year 1791 (says he) I planted out between 4 and 5000 of these plants into a field, on the top of a hill, on a thin, worn-out, stone-brash soil. The ground was dragged down to a level, some furrows struck at about three feet distance, and a little dung shook into the furrows, which were afterwards closed with a plough. The first dripping day the plants were put out, at about two feet distance in the rows. They took root very readily, and continued to thrive well, notwithstanding the season was very dry. These plants bore the winter, which was rather a severe one, very well, though many turnips on the adjoining land were destroyed. In the spring they were for the most part given to the sheep, which have always appeared to be very fond of them. Part of them were saved for feed, which ripened and were cut about the middle of July. The land upon which those that were given to the sheep grew, as well as the turnip land, was sown with barley; but the former did not appear to be at all exhausted, more than the latter. I think the average weight of the bulbs was about 5lb.; many reached 8 or 9lb. and some few 14 or 15lb. The next year he again planted out about 4000, in a strong stiff loamy soil, and rather wet and low. Where the ground was driest, the plants thrived well; but where it was wet, they made little progress. These were planted out on two-bout ridges, being nearly five feet distant row from row, and about two feet in the ranks. I expect (says he) that these plants will not stand the winter so well as those on the hill did. They appear to me to affect a dry situation: an opinion which corresponds with the experiments made by others. In the latter situation, they appear to produce more leaves in proportion to the size of the bulb, than in the former. He thinks the lower leaves might be cut off late in the fall, and given to young cattle with advantage; as they are otherwise cast during the winter.

He also thinks that these plants possess some advantages over the common turnip. They have a strong power of resisting putrefaction, and of course endure the frost and wet, but particularly the latter, better than most plants. They are much more nutritive than the common turnip; and being of a closer texture, and less watery, they contain more food in a given space. By standing up above the ground on a foot-stalk, they are more readily come at, when the ground is covered with snow. If the ground be in good proof, and they are intended for spring seed, it will be time enough to plant them out the beginning, or even the middle of July; which will give the farmer a long summer to clean his ground. He imagines that they may be reserved almost as late in the spring as you please. He has found the bulbs nearly as firm and sweet, after the seed

has been cut, as before. Their leaves, not being bitter like those of the turnip, are more readily eaten by cattle. Upon the whole, he supposes that they would prove, upon trial, a very valuable article of fodder to the farmer; and as such he recommends them.

The same ingenious writer has made some farther experiments with respect to the culture of this plant. A piece of wheat stubbs, between two and three acres, lying in a small common field, the soil a free-stone grit, worth about eight shillings per acre, was twice ploughed, cleaned, and dunged. It was then ridged up in two-bout ridges, part having their centres three feet distant from each other, and part only two feet. The plants were all set out on the middle of the ridges, and at the distance of three feet from each other in the rows; but at three different times—the first, seed sown the middle of March—the second, seed sown the beginning of April—the third, the end of April. The season was uncommonly dry; few opportunities offered of planting, or making good the numbers that failed from the drought. On a piece of ground adjoining, he purposed having some common turnips to compare with them; but in spite of all his care, and thrice sowing, the crop was so thin, that the ground was afterwards ploughed up and sown with wheat, to his great disappointment. As soon as the plants had got firm root, and had advanced a little in their growth, a furrow was turned with a plough from *each* side of *each* ridge, and the weeds on the remaining part of the ridge, not touched by the plough, were cut up with a hoe. In a fortnight or three weeks afterwards, these furrows were turned back again into their places; by which means the land was kept clean at a small expence, and the growth of the plants greatly promoted.

On the second of December he caused three square *lug* to be cut in three different parts of the piece, and found the weight to be as follows:

No. I. One square <i>lug</i> , ridges somewhat more than three feet, plants three feet in the rows, seed sown middle of March, weight - - - -	lbs.	230
No. II. One square <i>lug</i> , ridges barely three feet, plants three feet in rows, seed sown beginning of April, weight - - - -		260
No. III. One square <i>lug</i> , ridges about two feet, plants three feet in rows, seed sown end of April, weight - - - -		260

The inferiority of No. I. was not, he believes, owing to early sowing, but more of that plantation failed than of the others; and no opportunity offering to replace them for nearly six weeks, the plants in the seed-bed were stunted in their growth by the drought, and never throve well afterwards: nearly a fourth of the bulbs in the first *lug* were of this description. Had it been otherwise, he believes the first would have been the best. He computes the average weight at somewhat more than eighteen tons per acre. It is remarkable that numbers II. and III. should be exactly equal in weight, the rows

in one case being three feet, in the other two feet asunder: but it is worth observing, that the weight of the leaves, in proportion to that of the bulbs, for he weighed them separately, was greater in those at two feet than in those at three feet.

From the whole of his experience, he recommends this plant very earnestly to the attention of farmers; and thinks that it will be found, under proper management, one of the best hitherto cultivated, especially as a *late spring food*.

He concludes that the earliest season for sowing is the best, if the land can be got ready; but any time in April, or even the beginning of May, will answer perfectly well, if the season be not uncommonly dry at the time of planting: and he thinks three feet square the best distance for the plants. The greatest attention however should be paid to saving seed only from the very best bulbs.

Mr. Robins observes, that the best method he has yet discovered to raise the plants of the *turnip-rooted cabbage*, is to breast-plough, and turn as much old pasture as may be judged necessary for the seed-bed; two perch well stocked with plants will be sufficient to plant an acre. The land should be dug as shallow as possible, turning the ashes in; and the seed should be sown the beginning of April. The land intended for the plantation should be cultivated and dunged as for the common turnip. About Midsummer (or sooner if the weather will permit) will be a proper time for planting, which is best done in the following manner: The land to be thrown into *one-bout* ridges, upon the tops of which the plants are to be set, at about eighteen inches distance from each other. As soon as the weeds rise, says he, I give a hand-hoeing, afterwards plough in the intervals, and fetch a furrow from each ridge, which, after laying a fortnight or three weeks, is again thrown back to the ridges: if the weeds rise again, I think it necessary to give them another hand-hoeing.

Mr. Boys thinks this a most valuable plant, and that every farmer who keeps sheep should have a small piece to eat off in the month of April, after turnips are gone, and before there is a plenty of other herbage. The severest winters do not hurt it; and it produces a great quantity of nutritive and wholesome food: it is however an exhausting crop, and expensive to get out of the ground; but its great value, as a plentiful supply of good food for stock, when, in some seasons, there is nothing else to be had, is more than sufficient to counterbalance every thing that can be said against it.

In order to obviate some of the objections which have been made to these roots, it will be proper to sow them on rich and very light land; and as they are longer after being sown in coming to the hoe, than the common turnips, it will be necessary to sow them much earlier.

Mr. Baker, an ingenious writer on this subject, gives the following table, as the most proper distances for producing the greatest crops, from his own observation and experience of the growth of each sort.

Table of Distances for Cabbage Husbandry.

Kinds.	Season.	Distance used.	Distance recommended.
The long-sided cabbage	winter plants	2 feet by 5 feet	2 feet by 4 feet, or 18 inches by 4 feet
The flat Dutch cabbage	ditto.	2 5	2 feet by 4 feet, or 18 inches by 4 feet
Ditto	spring plants	2 5	18 inches by 4 feet
The Scotch cabbage	winter plants	2 5	2 feet by 4 feet, or 18 inches by 4 feet
Ditto	spring plants	3½ 5	18 inches by 4 feet
The turnip cabbage	ditto.	18 5	1 foot by 4 feet

There is another plant of this kind which may be just mentioned here; it is the *Mowing Cabbage*, which however seems better calculated for culinary uses than for cattle.

SECT. XXI. Of Mangel Wurzel.

THIS plant, though now probably not held in so high estimation as formerly, is certainly very useful in feeding stock.

The land for it should be rendered fine by frequent ploughing and harrowing, and be made perfectly free from weeds. It must then be formed into two-bout ridges, which makes them about three feet wide from the middle of one furrow to that of another; the tops of the ridges about two feet, and the furrow or interval between them one. By this method the mould on the ridges is laid considerably thicker, which is a great advantage to tap-rooted plants of every kind. In the middle of each of these ridges the seed should be dropped eight or nine inches apart, and one good seed only in a hole. Supposing all should grow, then the plants would stand three feet row from row, and at eight or nine inches distance in the rows; but this would be just double the number of plants necessary; for 16 or 18 inches is quite near enough. Sufficient, therefore, might be drawn from these to supply the deficiencies that would necessarily happen from imperfect seeds, &c. and if not wanted might be easily cut up with the weeds in hand-hoeing, for they should by no means be suffered to stand too thick. By being planted in this manner at the distance of three feet row from row, the intervals by horse-hoeing may be kept perfectly clean, and the ground between the plants equally so by hand-hoeing.

The best time for sowing the seed must depend upon the weather; but from the beginning of April to the middle of May seems the most desirable.

In the cultivation of this root Sir M. Martin advises such a preparation of the seed as may make it grow faster than the seeds of weeds latent in the ground, in order to facilitate their first hoeing, which he says at best is troublesome, as the plants grow slow while young; and there are two or three seeds in every little lump, which cannot be separated till the plants are strong enough to stand against the hoe, which they will be at the second hoeing. The most rational means of forwarding the growth of the seed, he observes, is to bury it too deep to vegetate, which is the state the seeds of those weeds are in, which grow as soon as they are brought within the influence of the air. For if they are sprouted before they are sown, and a few dry days should follow, they would probably perish. In this case he thinks it would be advisable to sow them deeper than would otherwise be necessary; for he has had many young plants appear the second year, which he attributes to the seed having been buried too deep the first. He thinks the seed being near the surface contributes to make the roots rise above ground.

Mr. Wimpey, a very ingenious farmer, observes, that though in general he has no great opinion of transplanting tap-rooted plants, especially such whose roots constitute the principal part of the produce, yet he knows not if, upon the whole, this would not be the most profitable method of cultivating this plant. In that case, the seeds should be sown in a nursery-bed as early in March as the season will admit, and in the interim between sowing and transplanting the ridges should be well prepared for the reception of the plants. The advantage of being removed into a clean well-pulverized soil is great indeed, if a favourable season be taken for that business. It is the method he has followed for several years with the turnip-rooted cabbage, and he is well convinced that it is the most profitable and economical of any usage in practice. It may, says he, perhaps, be thought by some too laborious and expensive; but if they would make the experiment, they would soon be convinced of the contrary. A dexterous labourer would set a large piece of ground in a day, and when set they would be done with, all but weeding; for, being planted at due and regular distances, the whole of the operation is finished at once. But if the seeds are sown or dropt, the plants must be set out to a proper distance; which would be found to be as expensive as transplanting, and the ground by no means so clean and in such perfect condition as it must be made for transplanting.

The difficult question is, whether the roots of the transplanted would be equally fine with those which had never been removed. This, from some observations he has made, seems to depend much upon the age and size of the plants when they are removed. The root in its first growth pretty much resembles the carrot; and if it be drawn when not above three or at most four inches long, and the hole in which it is to be planted be made deep enough to receive it without bending or distorting it, the root will receive no injury; but if it be bent, broken, or twisted, it will certainly occasion an unnatural shape, and he fears diminish its size.

Mr. Wimpey's remarks on feeding animals with them are these: The leaves, says he, were cut clean off about an inch above the crown of the root every morning, and given fresh to the pigs two or three times a day. It is not easy to describe how voraciously they ate them. Mr. Wimpey knows of no food they are equally fond of. Even the hogs that were fattening would often leave their pease and barley-meal, to feed on the leaves of the mangel wurzel. The cows also ate them with an exceeding good appetite, and were certainly very desirous of them. After harvest, he observes, the weaned calves were turned into the field, at one end of which they grew: they soon found them out, feasted deliciously upon them, and were manifestly improved by them. During the time the plants were growing, I often, says he, gave a few of the roots and greens together: but neither cows nor pigs were at all fond of the roots in that stage of their growth; they always left the greatest part of them. This circumstance alarmed me; but was entirely done away in the winter, for then both cows and pigs ate them as kindly as they would have done any food whatever. The roots in general were so hard and firm, that he found it necessary to have them cut in slices; which a labourer did with a small bill-hook on a tressel, and could cut several bushels in an hour. The greatest inconvenience that attends them, he observes, is the great quantity of mould that so firmly adheres to them. The roots are covered with innumerable fibres, which embrace the mould too firmly to be easily separated from it. This he says is a matter of no great signification in feeding hogs, who are constantly delving in the dirt; but perhaps it is not quite so clear that in time it might not prove injurious to cow cattle. As his cows and pigs were fed with them promiscuously together with other food, he was unable to ascertain what would be the amount of the produce on any given quantity of land valued in money; but he is pretty certain, that an acre of land planted as above, would well maintain twenty store pigs from six to eight months, and in that time their improvement could not be less than 14 or 15s. a pig. The labour of preparing this article of food would, he thinks, be a considerable deduction from the sum, whatever might be the amount.

It would, however, afford a very large quantity of desirable food for six months out of the twelve; from the beginning of July to the end of December; and in a favourable season, two or three months longer. But in severe winters, he is afraid there can be no dependance upon it after Christmas, unless means similar to those used to preserve potatoes be adopted for its preservation. But still in his opinion, it must be allowed to be a very valuable article of culture, and well worthy the attention of the husbandman.

SECT. XXII. *Of Grasses.*

THESE should be chosen agreeably to the nature of the soil on which they are to be sown. The proper season for sowing these seeds is the latter end of August, and beginning of September, in order that the grass may be well rooted before the frost sets in. The sowing should be performed in moist weather, or when there is a prospect of showers, that the grass

may soon get up. But, where this cannot be performed in autumn, the seeds may be sown in the spring; and about the middle of March will be a good time, should the season prove suitable.

Land on which grass-feed is intended to be sown, should be well ploughed, and cleared from the roots of noxious weeds, such as *couch-grass*, *fern*, *rushes*, *heath*, *gorse*, *broom*, *rest-harrow*, &c. which, if left in the ground, soon get the better of the grass, and over-run the land. Where the ground is low, wet, and of a stiff clayey nature, it will also be necessary to render it dry by proper draining. And before the seed is sown, the surface of the ground should be made as level and fine as possible, otherwise the seed will be unequally buried. The quantity of grass-feed for an acre of land is generally three bushels when the seed is clean, but when otherwise, a much greater quantity must be allowed. After the seed is sown, it must be gently harrowed in, and the ground rolled with a wooden roller.

The kinds of grass seeds that Doctor Anderson recommends for waste lands brought into a state of cultivation are, *white clover*, *yellow clover*, and *rye-grass seeds*, in the proportions of ten pounds of each of the two first, and two bushels of the last per acre. If *yarrow-seeds* are to be had, four or five pounds of these may be added, diminishing the rye grass half a bushel. On spongy, wet, mossy land, six or eight pounds of rib grass may be substituted in the place of so much of the *yellow clover*. Red clover is omitted, because it is a short-lived plant, and its broad leaves' overshadowing other grasses is liable to choke them, and encourage weeds to come up.

The practice of sowing all kinds of rubbish promiscuously, under the name of *hay-seeds*, he considers as justly exploded.

Mr. Boys however remarks, that the only good method, until the best sorts of grasses are cultivated for sale, is to save for seed a piece of fine old meadow hay, that is known to abound in the best sorts of grass, by letting it stand about three or four weeks longer than it should when intended to be mown for hay. When it is mown and ripe, it must be thrashed on a sail-cloth in the field, and immediately sown on the piece of land intended for the new pasture; which should, by a good summer-fallow, be brought into fine tilth to receive the seed. This, with ten or twelve pounds of white clover, he says, will make an excellent meadow.

Rye-Grass. This grass is commonly sown with clover, upon such lands as are designed to be ploughed again in a few years. It is also frequently sown with spring corn. The quantity of seed which is allowed to an acre is about two bushels, with eight pounds of the common clover, which, together, make a very good covering upon the ground.

In some places, rye-grass is preferred to hop clover, as bearing the winter better, and keeping a good head, which clover does not. But although rye-grass will maintain as many cattle on an acre as hop clover; it does not, like it, improve the land for a subsequent crop of corn.

Doctor Anderson however thinks, that besides the recommendation of this grass from the facility of obtaining its seeds, it has so many other valuable qualities to recommend it, that he considers every circumstance which tends to circumscribe its use as a national misfortune. It is a grass, says he, that is liked by almost every domestic animal above all others. It springs up very early in the season, furnishes a vast abundance of herbage, and thrives on almost every soil. On very poor lands, indeed, it produces a much more scanty crop than on such as are richer.

Mr. Peacey observes, that it is very nourishing, and grateful to all kinds of stock; as may be seen where they have a choice of that and other pastures to run in; the natural pastures will be quite neglected, whilst the rye-grass will be pared close to the ground: indeed it requires to be hard stocked; for if suffered

to get a-head, it is neither so palatable nor nourishing: it is equally excellent for hay, if cut just as the ear appears, and before it is fully formed: in the autumn it likewise affords a great deal of keep. It rather improves with age, and has been found particularly advantageous in laying land down to permanent pasture.

Sheep's Fescue Grass. This is an excellent grass, which flourishes best in a dry sandy soil. Cows, horses, and goats will eat it, but it is the favourite food of sheep. They prefer it to all other grasses; and being very succulent, it fattens them sooner than any other. This grass is much esteemed for the food of sheep in Sweden. It abounds in many parts of England and Wales, particularly on all the finest sheep-pastures in Herefordshire, Oxfordshire, Norfolk, &c. It is a very early grass.

Purple Fescue Grass. This grass is frequently met with on the downs and hills in great plenty, where it affords an excellent pasture for sheep.

Creeping Soft Grass. This is a meadow grass, which affords a very sweet and fine herbage.

Clover. Different sorts of this plant are cultivated, as the *red*, the *white*, and the *hop-clover*. *Red clover* is said to thrive best on a firm heavy soil. By the frequent sowing of this seed, the quantity of food for cattle has been much increased, especially on clayey lands, which, before the introduction of this practice, produced very little. At the same time it enriches the soil, and prepares it for a crop of grain; and it is now indeed common, where the land is kept in tillage, to lay down the ground with clover, after having had two crops of corn, whereby there is a constant rotation of wheat, barley, clover, or turnips, on the same land. The clover-seed is generally sown with the barley in the spring; and when the barley is taken off, the clover spreads and covers the ground; and this remains two years, after which the land is ploughed again for some kind of grain.

The roots of this plant decay after they have produced seeds; but by eating the clover down, or mowing it, when it begins to flower, the roots are made to send out new shoots, and the plant continued longer than it usually does. The common allowance of seed for an acre of ground is ten pounds. In the choice of the seed, that which is of a bright yellow colour, inclining to brown, is to be preferred; but the pale-coloured thin seed should be rejected. The clover-seed should be sown after the barley is harrowed in, otherwise it will be buried too deep; and after the seeds are sown, the ground should be rolled, which will press the seeds into the ground: but this should be done in dry weather, for moisture will often cause the seeds to burst; and when the ground is wet, the seeds will stick to the roller. The above is the method generally practiced by most people, in sowing this seed with corn; but it will be much better if sown alone; for the corn prevents the growth of the plants till it is mowed and taken off the ground, so that one whole season is lost; and many times, if there be a great crop of corn upon the ground, it spoils the clover so that it is hardly worth standing; whereas, when it is sown without any other seed, the plants will come up more equal, and come on much faster than that which was sown the spring before under corn. It is therefore sometimes advisable to sow the seed in August, when there is a prospect of rain soon after; for as the ground is at that season warm, so the first shower of rain will bring up the plants, and these will have time enough to get strength before winter: and if the clover be well rolled some time in October, when the ground is not too wet, it will press the ground close to the roots, and cause the plants to send out more shoots: the same should be repeated in March, which will be found very serviceable to the clover. The reason of preferring this season to the spring, for sowing this seed, is, because the ground is cold and wet in

spring; and if much rain falls after the seeds are sown, they are liable to rot in the ground.

However, the most usual time of sowing the *red* or *broad clover* is in the spring; for though it will come up well if sown in autumn, it is, while young, very liable to be killed by frost; and many crops which have come up finely in autumn, have been totally destroyed by the frost in winter, particularly in strong moist soils, where the greatest crops are commonly produced when sown in the spring. Towards the latter end of May, or beginning of June, this grass will be fit to cut, when great care must be taken in making it into hay, as it requires more labour and time to dry than common grass. The proper time for cutting is when it begins to flower.

Some farmers cut two or three crops in one year of this grass; but it is better to cut only one in the spring, and feed it the remaining part of the year.

Great care should be taken of the cattle when they are first put into this grass, lest they eat too much.

When the seeds of clover are intended to be saved, the first crop in the spring should be permitted to stand until they are ripe, which may be known by the stalks and heads changing to a brown colour: it should then be cut in a dry time, and, after being well dried, housed till winter, when the seeds should be threshed out. If, however, seeds be wanted for immediate sowing, it may be threshed before it be housed or stacked.

In Kent, this clover is sown among barley or oats, in the spring, upon land that is clean and in good order. It is sometimes mown three or even four times in the summer, on rich warm soils; but the general custom is to mow the first growth and feed the remainder, or to feed it at first to the beginning of June, and then save it for a crop of seed. Sometimes also two crops of hay are taken, and on poor land farms much clover is fed off with flocks of sheep, entirely folding the land over for wheat; for which crop no tilth whatever is so good and advantageous.

Doctor Anderson thinks, that where any reliance is to be had on broad clover for a *second* year's crop, it is advisable to sow with the clover a proportion of rye-grass. This is a very profitable practice, as it much augments the weight of the first cutting, and makes it come some weeks earlier than otherwise it would have been. It also effectually prevents the *white gozvans* from appearing, which so often render a crop of red clover, sown alone, worth very little. And as the clover afterwards advances much more quickly than the rye-grass, the succeeding cuttings are as good as if no rye-grass had been sown. In order to guard the clover too, in the case of a second year's crop, it should never be cut very late in the season, for this makes the surface so bare as to leave the roots very much exposed to danger; but if it be cut pretty early in autumn, the rye-grass advances again in the end of the season, after the clover has become stationary, so as to afford a close covering that defends the roots pretty well. By these precautions, he has been seldom disappointed in his second year's crop of clover, though it *sometimes* disappears almost entirely. He does not think it possible in Scotland ever to guard against this accident *with certainty*, where broad clover alone is sown: he therefore considers it imprudent in any one, in almost any circumstances, to rely on that *second year's crop*; and holds it as a maxim, that if a man is to depend on red clover alone, he never should think of taking above one year's crop of it. The rule which he has followed to guard against accidents of this sort, is, to sow along with the red clover a considerable proportion of the white or Dutch clover, and some grass. If the broad clover flourishes, these do not retard its growth, and only tend to thicken it; and if it should fail, which it sometimes will do in spite of every precaution, these plants fill the ground, and produce an abundant crop of herbage, which af-

fords a greater weight and finer hay than broad clover alone: though they do not answer quite so well for cutting for green forage.

In Lancashire, Mr. Holt observes, that this sort of grass is cultivated generally with success; being greatly preferred to the white hay, by those who keep horses in the great towns for the draught; containing, it is supposed, more nutriment. If opportunity offers, instead of sending their horses to graze upon a field, which is difficult to obtain, a lot of green clover is purchased, and brought in that state to the consumer, who soils his horses in the stable for a few weeks in the year; and it acts both as food and physic, and enables them to stand work the better. Some few farmers keep their cart-horses in the house throughout the year, and soil them in summer entirely with clover. The lands upon which clovers have been frequently grown, it is said, do not yield such plentiful crops as they did some years past; second crops, in this northern climate, are seldom worth the risque of being made into hay, and, besides, are thought to exhaust the lands, therefore are generally pastured. But marle will always insure clover; therefore when it fails it is the fault of the husbandman, not of the land.

White Clover. This grows naturally in many pastures. Its branches trail upon the ground, and send out roots from every joint; consequently thicken, and make the closest sward of any of the sown grasses.

From these circumstances it is not so apt to be thrown out as red clover; nor is it ever destroyed by any accident, if the earth be rich and firm: frequent rolling makes it flourish abundantly, even on light soils; but without that, on such soils it inevitably perishes. It is a very sweet feed for all sorts of cattle: therefore, when land is laid down for pasture, with intent to continue so, it should be sown with seeds of this kind. The general allowance of this seed is eight pounds to one acre of land: but it should never be sown with corn; for, if there is a crop of corn, the grass will be so weak under it as to be scarce worth any thing. But if this seed be sown in the spring without corn, there will be a crop of hay to mow by the middle, or latter end of July, and a good after-feed for cattle the following autumn and winter. The seed of this sort of clover may also be sown in autumn, in the manner directed for red clover. This autumnal sowing, if the seeds grow kindly, will afford a good early crop of hay the following spring; and if, after the hay is taken off the land, the ground be well rolled, it will cause the clover to mat close under the ground, and become a thick sward. The seed of this kind of clover may be procured by pursuing the same method as is practised for *red clover*.

Hop Clover. This kind of clover is highly advantageous, from its growing and flourishing on almost any kind of soil, and on the most barren sands, and being therefore a very proper grass to cultivate on those unfertile soils where other grasses that are worth notice will not grow at all. It does not swell cattle as the red clover does. In good ground it continues long, and bears very good crops.

Trefoil. This is sown in some places on chalky and other poor dry soils in the spring, with other grains, in the proportion of about two gallons of seed to the acre, and the crop affords a very fine food for sheep to graze in the summer months. In Kent, when it is intended for seed, the crop is mown about the first or second week in July; and is frequently thrashed off the straw in the field on a sail cloth.

Sainfoin. Most dry lands will produce this plant, though it thrives best on a fine rich soil. Mr. Kent says it should be introduced where there is a chalky, marley, or even a gravelly bottom. For this seed, in the Isle of Thanet, the land is always exceedingly well prepared, before the seed is put into the

ground, by frequent ploughings, and the weeds or roots of grafs are carefully picked off. Grafs is a very great enemy to this plant, for without the utmost care it soon chokes and destroys it. The seed is sown in April, according as the season suits: dry weather is best, provided it does not long continue. The quantity of seed allowed to an acre is five bushels: of course it is sown very thick. When it is come up, it is carefully hoed and weeded, to keep the common grafs down.

When this crop takes it is very advantageous, yielding plenty of excellent fodder for many years. It is customary in some places for farmers, when they intend breaking up a sainfoin lay, to seed it the last three or four years.

In Gloucestershire, where this grafs is much cultivated, the usual management has been to sow it with barley, after turnips, three bushels per acre, to which is generally added about five pounds of trefoil; which generally improves the first year's produce, and, by occupying the soil, prevents the weeds from getting a-head till the sainfoin has established its roots. There are some very superior managers, however, who, having been induced from an accidental occurrence to think a different procedure would be more advantageous, tried it with so much success, that they have constantly adhered to it since. The method alluded to, is to sow it on land exhausted by repeated cropping, and full of couch grafs: the sainfoin, rooting so deep, does not draw its nourishment like corn from the surface soil, and therefore is not injured by its impoverished state; whilst its greatest enemy, the black bent, is effectually kept under by the couch grafs. In this practice it is likewise sown with barley, and very thin, not more than a bushel per acre; it having been noticed by the same attentive observers, that, when sown thin, the roots are larger and more vigorous, and in two or three years get full possession of the land, producing greater crops, and lasting longer than the thicker planted. There are other cultivators who object to thin sowing, observing that the hay being chiefly wanted for sheep, although it may produce as much or more in quantity, the stems are much larger, and not so palatable to that animal, occasioning great waste in the consumption. But the method of sowing it on foul exhausted land, has in many instances failed of success. The duration of sainfoin depends a great deal on the management: mowing it before its full blossom is detrimental, the roots bleeding very much and mildewing: for the same reason, feeding of it is accounted beneficial: if wished to last, it should never be fed but in the months of October and November, and then only with cattle, sheep biting too close: the lattermath is, however, excellent food for weaned lambs, and therefore often applied to that purpose. Indeed the farmers in general do not wish it to last longer than seven years; the land being in that time thoroughly rested and fit for corn, whilst other land under the plough wants rest; but if desired, it might, with proper management, last ten or twelve years. The hay, if well made, is, in the fore-part of the season, equal to any meadow hay in this county for most purposes. When worn out, so as not to be worth mowing, it is generally pastured a year or two before it is broken up, for the purpose of thickening the grafs.

Mr. Wimpey observes, that whatever crop precedes the planting sainfoin, the ground should be ploughed in the winter, and laid up in sharp deep ridges by one bout of the plough, to continue till the beginning of April. Then it should be dragged and harrowed level: and if the land be very poor, it should have some light dressing of ashes, foot, or a compost of lime, earth, and rotten dung, well incorporated together. A small quantity of either of these would greatly encourage the plants in their infant state. The beginning or middle of April, as the season may prove, the seed should be sown, and there will be little danger of its succeeding well. He thinks that there can-

not be a better nor a surer means of cultivating this useful plant to great advantage, than by sowing it after potatoes. The horse and hand-hoeing them during their growth, and the ploughing, dragging, and harrowing the ground to clean it of the potatoes, so thoroughly destroy the weeds, and pulverize the soil, that it is made in the most perfect condition for a crop of sainfoin; and though the land may in its nature be very poor, the manuring properly for a crop of potatoes, and that being grown perfectly rotten, the soil is become sufficiently fertile for this plant. One acre of good sainfoin, he says, is of more value to the farmer than two of middling meadow or pasture.

Mr. Boys, in his Survey of the Agriculture of Kent, considers this as the most valuable of all the grasses cultivated in that county. It is, he says, much grown on the chalk-land of the eastern part, and is sown among Lent-corn on clean land, at from four to five and a half bushels per acre. It is mown for hay in June, and its produce is from ten to sixty hundred weight of dried hay, fit to stack, per acre. Those who cultivate this plant should observe, that if it be fed off with sheep, it is very soon destroyed; whereas, if sown on clean dry land, after a good summer-fallow, and preserved from sheep, it will last in the ground ten or twelve years. The aftermath is excellent to feed cattle, and the produce is sometimes very abundant indeed.

Lucern. This will grow on almost any soil, provided it be not too wet; but the strongest land is to be preferred. The ground should be prepared in the same way as for barley, by ploughing, harrowing, and cleaning it from weeds. This being done, the lucern is generally sown broad-cast in fine weather, in the proportion of about fourteen pounds to the acre. This quantity of seed will be sufficient to supply the number of plants that will be wanted to yield a full crop.

Before the last ploughing, the land should be manured, but not with old rotten stuff as is commonly done, but with fresh stable-dung, that has been thrown up in a heap three or four weeks to heat and ferment. The dung in this state is to be laid on the land and ploughed in as soon as possible. The land must then be harrowed and sown, and afterwards harrowed again with a light or bush harrow; and, lastly, rolled to settle the ground and break the clods. This seed may be sown from the beginning of March to the end of May; but April, if the weather be dry, is probably the best season.

Mr. Boys observes, that this is a very valuable plant to cultivate on dry lands, for soiling horses in the summer months; but that in Kent it is seldom made into hay. The tillage required for it, he says, is a well-made summer fallow, ploughed as deep as possible, with a good covering of manure. It is generally sown with a thin crop of barley, from 16 to 20 pounds per acre: coal-ashes or foot are sown over the crop in the spring, and sometimes a covering of rotten dung is spread upon it early in the winter. The produce from dry good land is very abundant, and four crops are usually obtained in one summer.

Lucern evidently requires to be constantly kept clean, and manured now and then. By some it is thought to answer the best when transplanted.

It is preferable to any other grafs for horses, cows, and all black cattle, to be cut and carried to them to eat. It is asserted, that an acre of it in good ground, where it thrives well, will, from early in May to Michaelmas, maintain twice the number of cattle that an acre of good meadow will do.

Burnet. Mr. Pitt says, that in Staffordshire this grafs has been sown by many persons of late years, and by some on a broad scale; and he knows it from experience to be a valuable addition to cow pastures, hardy, and strictly perennial. Cows prefer it to clover, and it is doubtless wholesome for them: sheep and horses prefer clover; and it is by no means so pro-

ductive as the broad-leaved red clover. A very attentive friend and neighbour of mine, says he, who keeps a very large dairy, and has for some years back sown large quantities of this plant, is so very partial to it, that he would this year have sown ten hundred weight of the seed, could he have procured it. It is certainly a good mixture with other herbage, with which it but little interferes, drawing its nourishment deep from the earth by a long tap root. It is a native of some of the midland counties, upon dry calcareous soils, particularly Rutlandshire, where it abounds spontaneously in common-fields, road-sides, and even upon commons wholly uncultivated. It is a very different plant to the meadow burnet, springing out and flowering some months earlier.

Mr. Boys however observes, that it grows naturally on chalky soils, and affords herbage in the winter and spring months, but which is not much liked either by cattle or sheep. When necessary to cultivate it, it is sown, about one bushel and a half or two bushels per acre, among barley or oats.

SECT. XXIII. Of Seeds.

IN some parts of the island plants are cultivated for the purpose of their feed, as well as affording support for a great variety of animals. Where this is the object, very little difference is necessary in their management, except in the manner of reaping or cutting them, and the preservation of their seeds.

Rape or Cole-Seed. This plant is cultivated both for its seed and for the feeding of cattle. Rape will grow well on almost any soil, but succeeds best on those that are deep, with a clayey bottom, and on which manuring and deep ploughing have been practised.

In Essex they generally plough up the fallow early in the spring, and let it lie till the latter end of March; they then plough it again, after which they harrow it down, and lay on a coat of manure. After this is spread, they cross-plough it again in May, and get it in fine tilth by the end of June or thereabouts. In ploughing for the sowing of rape, the plough should go north and south, if the field will admit of it; as in that case the land when sown will lie full-faced to the sun. About the first of July, or the first rain after that time, they sow the seed in the proportion of about half a peck to an acre. It is scattered with three-fingers broadcast, and the land lightly harrowed and rolled. In September they hoe it in the same manner as turnips, setting the plants out at about a foot distance, and clear out the weeds. This hoeing is done at the expence of about three shillings an acre, renders the plants much stronger than they otherwise would be, and makes them produce more seed. If any part of the field misg, they fill it up with plants from the thicker parts in the latter end of October, or beginning of November, which answers much better than transplanting them in January; for in the latter case, should a sharp frost succeed, they would be mostly killed, from not being rooted; otherwise the severest frost in this climate does not hurt them.

In other places, the time of sowing rape broadcast is the latter end of May or beginning of June; the land, previous to sowing, being twice ploughed and well pulverized. About two pounds of clean seed is sufficient for every acre, which should be cast upon the ground as equally as possible. When the plants come up too thick, a pair of light harrows are sometimes drawn length-ways and cross-ways over the land: this thins them equally; and when the plants thus pulled up are withered, the ground is rolled, and a few days after the plants are set out with a hoe, at the distance of 16 or 18 inches.

In some parts of the north of England, the farmers pare and burn pasture lands, and sow them with rape after one ploughing, and by this means have a good crop.

In the Agricultural Survey of Kent it is remarked, that this seed is much cultivated on the poor lands of the eastern part of that county, under the same management as turnips; but that it is seldom hoed, and consequently much over-run with charlock. Sometimes, although rarely, it is sown for feed; but most commonly fed off with lean flocks of sheep. Cattle and sheep, when poor, are however very subject to be destroyed by eating greedily of this plant.

Some writers recommend the transplanting of rape. For this purpose a piece of ground must be sown about the middle of June; and when the plants are ready, the best of them may be collected and set upon lands which have been previously cropped with wheat, &c. One ploughing only is here necessary. The planting should be on ridges about two feet asunder, and a foot and a half apart in the rows. This business is generally done about the middle of August; but if it were done earlier, it would probably be better.

When the young plants are attacked by the flugs, who prey on them greedily, it is a good way to strew over the plants a mixture of slaked lime and wood-ashes; ten bushels of lime, and fifteen of ashes, are enough for an acre. This both destroys the insects, and promotes the growth of the crop.

Rape, when ripe, is cut and laid thin to dry, then threshed in the field on a large cloth spread for the purpose. When the seed is large, black, and without any red, it is said to be good. If it be kept long, it should be laid in a dry place.

This seed is frequently sown merely for the purpose of a winter feed for cattle. It is an extremely fattening food for sheep. They frequently thrive more on rape-feed plants in one month, than on turnips in two, if put in soon after Michaelmas. In this case, when the crop is fed off, the land is ploughed up early in the spring, and a good crop of barley produced. This method is not however generally practised; as it is troublesome to clear the land of the rape-feed plants.

Coriander Seed. This seed is not at present much cultivated in this country. It might, however, be grown with advantage in the neighbourhood of large towns. It should be sowed in autumn on rich land; and when the plants are come up, they should be hoed out to about four inches distance, every way, clearing them from weeds. By this management, the plants will grow strong, and produce a great quantity of good feed.

Canary Seed. In Kent, where this seed is much cultivated, Mr. Boys says there are three kinds of tilths for it, viz. summer-fallow, bean-stubble, and clover-lay; the last he considers the best. If the land is not very rich, a coat of rotten dung is frequently spread for it. Whether manured or not, the tillage necessary is to plough the land the first opportunity that offers after wheat-sowing is done; and, as soon as the land is tolerably dry in the spring, furrows are made about eleven or twelve inches apart, and the seed is sown broadcast, about four or five gallons per acre, and well harrowed in. When the blade appears, and the rows are distinct, the intervals are immediately hoed with a Dutch hoe, and afterwards, in May or June, the hoeing is repeated with a common hoc; carefully cutting up every weed, and thinning the plants in the furrows, if they are too thick. It is cut in the harvest, which is always later than any corn-crop, with a hook, called a *twibil* and a *hink*; by which it is laid in lumps, or wads, of about half a sheaf of each. The seed clings remarkably to the husk; and in order to detach it, the crop must be left a long time on the ground to receive moisture sufficient to destroy the texture of the envelopment, otherwise it would be hardly possible to thrash out the seed. The wads are turned from time to time, to have the full benefit of the rains and sun.

Radish Seed. For this crop the land should be clean, full of manure, and ploughed a good depth in the early part of the winter. In Kent, they cultivate the early *Short Top*, the

Salmon, and the *Turnip rooted*. The seed is sown on furrows, about ten inches apart, in a dry time in the month of March, about two or three gallons per acre. As soon as the plants appear, every other row is cut up with a horse-hoe, leaving the rows twenty inches apart. When the plants get two or three rough leaves, they are hoed out in rows, and are then kept clean by repeated horse and hand-hoeing, when necessary, leaving the plants at about eighteen inches distance. The crop is seldom fit to reap till October, and sometimes is out in the fields till Christmas, without receiving injury from wet weather; it being necessary that it should have much rain to rot the pods, that it may thrash well. The produce is from eight to twenty-four bushels per acre.

Spinach Seed. Two sorts of this seed are cultivated, the prickly and the round: both are sown in furrows, about twelve or fourteen inches apart; the prickly, six gallons per acre, and the round four. Early in March, when the plants have leaves about an inch or two in length, they are hoed out to the distance of four or five inches. When the crop is in full bloom, the greater part of the male plants are drawn out by hand, and given profitably to young pigs; by which operation the female plants have more room to grow, and perfect their seed. The crop, when ripe, is pulled up, and thrashed in the field on a cloth, or carried to the barn for that purpose.

SECT. XXIV. *Of Hemp.*

HEMP is cultivated to the greatest advantage on a soft, rich, loamy soil, which is in fine condition, and well manured.

As it is necessary to have the ground in exceeding fine tilth for this crop, the first ploughing should be given it as early in the autumn as possible; and it should be loosened very deep, and laid rough, that it may be the better mellowed by the winter's frost, especially if the soil be strong. And it should be ploughed again in February, or more early if the season will permit, when the manure is to be laid on. Horse-dung, or the scouring of ponds and ditches, are preferable to cow-dung, though all manures which render the earth light are fit for hemp. In this case, M. du Hamel thinks, that it is best to dung the hemp-ground every year before the winter ploughing, in order that the dung may have time to rot during that season, and that the spring ploughing may afterwards mix it the more thoroughly with the earth.

In order finally to prepare the hemp-ground for receiving the seed, it should be laid as smooth and even as possible by the last ploughing.

The season for sowing hemp chiefly depends on the quality of the soil. In dry light ground, it should be sown as soon as the danger of frost, or other inclemency of the weather, is over, in the latter end of April or beginning of May, that it may get up early, and, by covering the ground, prevent the danger of drought. In wet cold grounds, it should be sown later, as the middle, or even the latter end of May.

If this plant is cultivated principally for the seed, it is probably the best way to sow it thin, in order to give it room to spread and throw out many branches, which will produce much seed; and if the plants are raised on beds or ridges, in rows, and horse-hoed, the seed will be much superior to what is obtained from broad-cast hemp. This plant may also be cultivated to great advantage, in respect of both seed and hemp, by drilling it in equidistant rows, and hand-hoeing; which will improve the land and crop, with less manure than sowing it by hand.

With respect to the seed, it is necessary to have it of the preceding year's growth, and every second or third year it should be had from a different soil. The weather, when this seed is sown, should neither be too dry nor too rainy. The best time is just after a gentle fall of rain. If the soil be deep, and in fine order, it is best to sow this seed thick,

especially if the hemp be intended for fine use, because the plants run most into height when they stand closest together, and their fibres are then by much the finer: but they should not stand so very thick as to choke one another, as this would occasion a considerable loss of plants. The usual quantity of seed is three bushels to an acre. As soon as the hemp-seed is sown, it must be carefully covered with earth, by means of the harrow, and the birds be kept from it.

The profitable culture of hemp and flax is not, however, confined to rich soils alone; for, by proper manuring, they may be made to grow well on poor sandy land. In some counties, where the land is sandy, they first sow it with barley, and the following spring manure the stubble with horse or cow-dung, and plough it under. They then sow their hemp, and harrow it in with a light harrow having short teeth. A good crop destroys all the weeds, and makes it a fine fallow for flax in the spring. As soon as the flax is pulled, they prepare the ground for wheat. Lime, marle, and the mud of ponds, form an excellent compost for hemp lands. A peculiar advantage attending the cultivation of hemp and flax is, that a crop of the former prepares the land for the latter, and therefore a crop of hemp is clear gain to the farmer. That these plants impoverish the soil, is probably a vulgar notion destitute of truth.

It is observed by Mr. Holt, that in Lancashire a crop of hemp is supposed to be an excellent means of destroying *couch*, let it be ever so abundant; and Mr. Fazakerly thinks, that this weed should always be destroyed upon the land by smothering or withering; for, if either carried off the land or even burnt upon it, the ground is injured.

Mr. Kent thinks the cultivation of hemp and flax of great national importance; and that when they are cautiously interwoven with other crops, so as not to come round above once in ten or twelve years, they do no injury to the land. It would be well, he observes, if the cultivation of them were more general in this way.

Mr. Antill's directions for the cultivation of this plant deserve attention. He observes, that whoever would raise hemp properly, and to advantage, should set aside two pieces of ground, of such dimensions each as he shall be able to cultivate every year, and sow the one while he is manuring and preparing the other for the succeeding year's crop; the higher and drier the ground the better, provided it be well dunged, and made strong and mellow. The ground should not be too sloping, lest the good soil be washed away with hard rains: if it droops toward the south, so that it may have the full influence of the sun, it will be an advantage: low, rich, warm, dry grounds will also produce good hemp; but wet land, though ever so rich, will by no means do. The ground, being prepared and made very mellow, some time in May, it being moist and in a vegetating state, but by no means wet, must be well ploughed, the furrows must be close and even, and the soil must lie light and mellow; it must then be sown very even, with two bushels of seed upon one acre. A man with an iron-tooth harrow follows the sower, and harrows in the seed, with two horses, without any balks; for, the less the ground is trampled the better. If harrowing one way be not sufficient to cover the seed, though it would be best if that could be done, it must be cross-harrowed. The ground being thus properly moist, but by no means so wet as to clod, which would ruin the crop, the seed will all start and come up together; which is a sure sign of a good crop, and nothing after that, but too much wet, will hurt it; for, hemp thus come up bids defiance to weeds and grasses of every kind. Its growth is so quick, and it so effectually shades the ground, that nothing below can rise, or shew its head; and it so preserves all the moisture below, that, the hotter and drier the weather, the faster it grows. Whereas, if the seed be sown when the ground is dry, the seed that lies

SECT. XXV. *Of Flax.*

deepest, where the moisture is, will come up first, and these plants will shade and starve those that come up after; by which means the first comers will be too large, and the last will be much too small, so that the crop will be greatly damaged every way: so much depends upon this one circumstance, of sowing the seed when the ground is moist, and fit to receive it. The crop, thus rightly managed, will stand as thick as very good wheat, and be from four to six feet high, according to the strength of the ground, and the stems will not be thicker than a good wheat-straw: by this means the hemp will be finer, it will yield the greater quantity, and it may be plucked from the ground like flax, which will be a great saving. But, if it be sown thin, that is, one bushel to an acre, which is the common practice, it grows large; the hemp is harsh and coarse, and then it must be cut with hooks, which occasions great waste; for, four or five inches above the ground is left by way of stubble, which contains the best and heaviest part of the hemp. When the hemp has got its growth, and is fit to be plucked, which is known by the under leaves of the carle or male hemp turning yellow and falling off, the sooner it is pulled the better. It must then be bound up with straw bands, in single-band sheaves, rather small than large, and each sheaf must be bound in two places; and the sooner it is carried to the water to rot the better. Water-rotted hemp, if it be rightly managed, is every way better than that which is rotted on the ground; there is less waste in it, when it comes to be dressed; it looks brighter and fairer to the eye; it is esteemed to be stronger and more durable, and it always fetches a better price: besides, it is much sooner done, and it is rotted more even and alike, and with greater certainty and exactness. Hemp may be rotted in stagnated or standing water, such as ponds, pools, or broad deep ditches; and, in such water, it is generally four or five days and nights in rotting, and sometimes longer, according to the heat or coolness of the weather. It may also be rotted in running water, as in a brook or river; and, in such water, three or four days and nights are sufficient, according to the weather. To know whether the hemp is rotted enough, in either case, take a middling handful out of the middle row, and try with both your hands to snap it asunder; if it break easily, it is rotted enough; but, if it yet appear pretty strong, it is not, and must lie longer, till it breaks with ease; then it must be taken out carefully, and dried as soon as possible.

He farther observes, that what hemp is intended for seed should be sown on a piece of ground by itself, which must be made very rich and strong. It must be sown in ridges six feet wide; and the seed must be of the largest and best sort, and sown very thin, at the rate of a peck upon an acre, or rather six quarts; for, the thinner it is sown the more it branches, and the more seed it bears. It should be sown some time about the middle of April, and then the seed will not be ripe till some time after the other hemp is done with. If you have no convenient place to sow your seed-hemp by itself, then sow a border, of six feet wide, along the north and west sides of your hemp-field. The reason for sowing your seed-hemp in such narrow ridges or borders is, that when the carle or male hemp is ripe, and has shed its farina on the fimple or female hemp (by which the seed is impregnated), and the leaves of the carle hemp fall off, and the stem grows yellow, you may easily step in along the sides, and pull up the carle without hurting the female, which now begins to branch out, and looks of a deep green colour, and very flourishing; and when the seeds begin to ripen, which is known by their falling out of their sockets, you may, all along both sides, bend down the plants, and shake out the seed upon a cloth laid on the ground; for, as they ripen, they scatter upon being shaken by a hard wind, or otherwise.

THIS plant is cultivated both for its seed and the covering of its stem, the former being used for the purpose of making oil, and the latter for that of linen. The soil most suitable for the growth of this plant, is the same as that for hemp.

When pasture land is broken up in order to its being sowed with flax, it must be made very fine by repeated ploughing, before it will be in a proper state for producing a good crop.

But when the ground on which flax is to be raised has been long in tillage, it should be ploughed deep before winter, and laid up in high ridges, in order that the frosts may the more effectually moulder and loosen it. And if stiff, care should be taken not to till it in wet weather, as it will be liable to clod too much. In February, if the land be not too wet, some very rotten dung should be laid in the furrows, and immediately covered over. And in March, for southern countries, or in the beginning of April where the climate is colder, another ploughing should be given to lay the land smooth, the clods should be broken by hand, or with the spike-roller, and the seed should then be sown, and harrowed in with a light or bush-harrow, so as not to bury it above an inch deep. Wet land should be laid in beds thirty or forty feet wide, separated by deep trenches, in order to drain off the water.

Flax-seed may be sown either in the autumn or the spring; but in cases where the winter is apt to be severe, and where the flax, which is but a tender plant, is in danger of being destroyed by it, almost all the flax is sown about the end of March, or in the beginning of April.

A method of sowing flax, in order to obtain good seed, is to drill it in equidistant rows about a foot distant, and then hand-hoe it; which will keep down the weeds, and improve the crop. But it is still better to drill the rows about twenty inches asunder. For the seed, being smooth and heavy, is very proper for drilling, and in this way a very small quantity of seed sows an acre. The common allowance of seed sown broadcast is about two bushels and a half to an acre, oftener more than less; but drilled in rows at twenty inches distance, half a peck is sufficient for an acre. Flax, when sown thick, runs up in height, and produces fine soft flax; if sown thin, it does not rise so high, but spreads more, and puts forth many side branches, which produce abundance of seed; and such seed is much better filled, plump, and heavy, than the seed produced from thick sown flax. Nothing should be planted or sown between the rows, but the ground should be hoed with a hand-hoe, or small plough, taking care that none of the mould is thrown against the rows; to prevent which the intervals may be hoed with a triangular harrow, having a proper number of iron tines in it, and guided by two handles fixed behind, which make the lines go deeper or shallower at pleasure. The rows must, however, be weeded by hand. Flax cultivated in this way is shorter than common, but stronger, and not so subject to be beat down and lodged in stormy weather. There is also sufficient room to hand-weed the rows, without lying upon or treading down the flax.

In sowing broadcast, the flax and seed are said to be nearly of equal value. But by sowing in the drill method the crop of flax will not be so great, but the quality of the seed will be far superior. Flax being an article of nice cultivation, the soil should not only be frequently changed but also the seed. The quantity of seed necessary is more or less according to the views of the cultivator. If he wants the seed, he must in that case use less seed; but if he wishes to have fine soft flax, a larger quantity of seed must be employed.

Mr. Boys, in his Survey of Kent, thinks that the best tilth for this crop is a summer fallow, and next to that, a clover-lay: it is often sown after wheat and beans. The land is ploughed in

the winter, and harrowed fine in March: the seed is then sown, at the rate of two bushels and a half per acre. It is weeded by hand in the month of May, and pulled up in July; the expence of which, with turning and binding into sheaves, is 16s. per acre: the length is from two to two feet and a half; but it is of little value when of the shortest length. The produce of seed is from eight to twelve bushels; and of flax, from one to two packs of 240 pounds each, per acre. The quality of the flax of this county is like that which is imported from Holland; but somewhat inferior.

The properest time for pulling flax seems to be when its stalks begin to turn yellow, its leaves begin to fall, and when its seeds begin to have a brown colour. When pulled, it is laid together by handfuls, with the seed end turned to the south. These handfuls should neither lie quite in a line with each other, nor directly across, but a little slanting upwards, so that the air may easily pass through them. Some, instead of this method, tie the handfuls of flax loosely at the top, then spread out their roots, and thus set several of them together upright upon their roots. In either of these ways, the flax is commonly left twelve or fourteen days in the field to dry it; but this is much longer than is necessary. Linseed is reckoned good when it is of a bright brown colour, large, oily, and heavy.

SECT. XXVI. *Of Woad.*

THIS plant is grown to the greatest advantage on a light black rich soil, which has a southern situation.

Land intended for woad should be dunged a year before it is sown with this plant, and made first to bear a crop of wheat, &c. This being taken off, three deep stirrings should be given with the plough, the first in November, and the other two in the spring.

Woad is frequently sown so early as the beginning of April when the weather will permit; but when it is too cold at that period, the sowing must be deferred till the beginning of May. In this climate, however, it is often not sown until some time after this.

In some parts of Kent this plant is much cultivated. It is frequently sown on poor, stiff, and some chalky lands, in the proportion of ten or twelve pounds of seed to the acre, and among beans before the last hoeing in the beginning of July. It requires no culture while growing, except the land be foul and full of weeds; in which case the weeds must be drawn out by the hand, or cut up with a narrow hoe. At the time when the plants have produced their bloom up to the top of the stem, they are pulled up, then tied by a single stalk in small handfuls, and set up in a conical form to ripen. When thoroughly dry, the seed is shaken out on a cloth or into a tub, the plants being then bound with rope-yarn into bundles, each weighing thirty pounds. Sixty of these bundles make a load of woad, the price of which is generally from 4l. to 10l. It is chiefly used by the dyers, and the Keynsham growers are said to cultivate and prepare it in the best manner.

SECT. XXVII. *Of Madder.*

THIS is a plant also used by the dyers, which was formerly much cultivated in the eastern part of Kent. I am firmly persuaded, says Mr. Boys, that good crops of excellent madder may be raised in Kent, on soils properly adapted for the purpose; and that it would be a profitable article of culture, if it were never under 3l. per cwt. nor would the buyers be injured by a restriction to this price; but then the legislature must interfere to prevent the importation of the root from Holland, where it can be cultivated cheaper than here. Perhaps, if that country should continue unfriendly to us, it might be good policy to encourage the growth of madder at home. I have ma-

ny years, says he, been in the habit of cultivating it; but, from the low price at market, have been obliged to abandon it. There have been several modes of planting practised; but that which appears to him the best, is to plant it in single rows, about two feet apart. The land should be perfectly clean from weeds, and have been well manured the preceeding year, so that the dung may be well incorporated with the soil; which should be a fine deep, rich, sandy loam, without any redundancy of moisture. In order to prepare the land for planting, it should be ploughed in the autumn, to have the benefit of the winter's frost, and harrowed in dry weather in the spring, and then kept clean by horse-hoeing, until the plants are ready for drawing, which is usually by the end of May, or beginning of June: the proper time is known by the plants having got to the height of ten or twelve inches from the ground, and having produced roots branching out from the bottom of the suckers; which will be perceived by drawing up a few of them. When the suckers are in this state, all hands necessary for this work are to be provided, that the operation may proceed with every possible dispatch. One acre requires about twenty thousand plants. The plants should have about a third of their tops cut off, and then their roots should be dipped in earth, or fine mould and water beaten together to the consistence of batter; which prevents the necessity of watering them. It requires one woman to dip the plants, two others to carry and strew them in handfuls along the furrow, and about seven to follow the plough. The land should be ploughed, with a strong turnwrest plough with six horses, twelve or fourteen inches deep: women attend to lay the plants about eight or nine inches apart in every other furrow, leaning off from the plough; by which, every time the plough returns, the row of plants laid in by women who follow the plough, is covered with the earth of the furrow. The crop must be kept perfectly clean by the hoe and hand-weeding during the summer months, and earthed up with a plough each autumn until the third after planting, when the roots are dug up by trenching the land two feet deep; two children attending each digger, in order to pick out the roots.

The most proper time to take up the roots is when they are about the size of a swan's quill; they then yield most dye, and are of course most proper for use: but the time when they arrive at this proper state depends not only on the nature of the soil in which they have been planted, but also on the good husbandry that has been bestowed on the land.

SECT. XXVIII. *Of Hops.*

THE land most suitable for the cultivation of hops is that which has a rich, deep, mellow, dry soil, rather inclining to sand than clay, and the situation of which inclines to the south.

In the Agricultural Survey of Kent, it is observed, that when a piece of land is intended to be planted, the first thing is to plough the land as deep as possible, early in October, and to harrow it level: it should then be meted each way, with a four rod chain, placing pieces of reed or stick at every tenth link, to mark the place of the hills; which makes 1000 per acre. This is the general method; but some few grounds are planted eight, and some twelve hundred per acre; some are planted wider one way than the other, in order to admit ploughing between the hills instead of digging: but this practice, although it has been tried many years, does not seem to increase, on account of the difficulty of digging along the rows where the plough cannot go: that part, being much trodden with the horses in ploughing, digs so much the worse, that an extra expence is incurred, which in some measure defeats the œconomy of the plan. When the hills are marked out, holes are dug about the size of a gallon, which are filled with fine mould, and the nursery-plants placed in them. Some put three plants, others two, and some only

one good one to each hole. If the land be planted with cuttings instead of nursery-plants, the holes are dug in the spring, as soon as cutting-time commences; some fine mould is provided to fill up the holes, in which are placed four or five cuttings, each about three or four inches in length: they are covered about an inch deep with fine mould, and pressed down close with the hand. When the land is planted with cuttings, no sticks are required; but if nursery-plants are used, they require sticks or small poles, six or seven feet high, the first year: in both cases, the land is kept clean during the summer, by horse and hand-hoeing; the next winter dug with a spade; and early in the spring the old binds are cut off smooth, about an inch below the surface; a little fine mould is then drawn over the crown of the hills. As soon as the young shoots appear, so that the hills may be seen, they are stuck with small poles, from seven to ten feet long, in proportion to the length it is expected the bind will run: these poles are called seconds, and are generally bought in the woods, at from 5s. to 8s. per hundred, and three of them are placed to each hill. As soon as the bind gets about two feet in length, women are employed to tie them to the poles. The land is kept clean during the summer, by horse and hand-hoeing, as before mentioned. The proper time for gathering them is known by the hop rubbing freely to pieces, and the seed beginning to turn brown. They are picked in baskets containing five bushels each, and are carried to the oast in bags, at noon and evening, for drying. Great care and skill are necessary in this branch of the business; the smallest neglect or ignorance in the management of the fires will spoil the hops, and occasion great loss to the planter. When dried and sufficiently cool to get a little tough, so as not to crumble to powder, they are put into bags or pockets; the former containing two hundred weight and a half, and the latter an hundred and a quarter: they are then trodden very close, and the excise-man weighs them.

But the second year after planting, full-sized poles from fifteen to twenty feet in length, according to the strength of the land, which cost from 16s. to 36s. per hundred, are placed to the hills instead of the seconds, which are removed to younger grounds. Here great care is necessary not to overpole; for by that means young grounds are often much weakened; and it is equally necessary not to overdung them, as that will make them mouldy. About fifty cart-loads of well rotted farm-yard dung and mould, once in three years, are generally considered as sufficient for one acre of land.

Some think that a good season for planting hops is from the beginning of March to near the middle of April, the time when they begin to shoot; but in Kent, October is preferred.

SECT. XXIX. *Of Reaping different Kinds of Crops.*

THIS is performed in different ways in different counties, but chiefly either by the sickle or the scythe.

Wheat when weedy should be cut some days sooner than common, that the weeds may have time to wither before the corn become too ripe: for if it be not cut till the grains are full ripe, it will be liable to considerable damage by shedding, loss of colour, and injuries from rain, whilst it remains exposed for the purpose of drying the weeds. A day's gentle rain, or even a single shower, can do much harm: all possible care should therefore be taken to guard against its being much wetted.

Although corn be sometimes bettered by lying a little in *swarth* or *grips*, to take the dews, which contribute to render its grain plump and of a good colour; in hot dry summers, when the corn ripens fully, and its own vigour gives a proper colour and plumpness to the grain, so that the husks readily yield their contents when threshed, wheat need not lie out in grip, before it is sheaved, or in sheaf, unless very full of grass and weeds. When the harvest is wet, small sheaves are best, be-

cause, thin at top, and falling close, the rain does not sink down into the middle of them, and so go through into the bands, as it is apt to do in great sheaves, which lie broader, and take a larger compass. Small sheaves are also best when many weeds are intermixed with the corn; because the air, wind, and sun, have then a greater power to dry them, than they could have if the sheaves were of a large size.

For every purpose, and in whatever way corn has been cut, Dr. Anderson is decidedly of opinion, that it should be bound up into sheaves before it is led, if economy be aimed at, and that the neater these sheaves are done up the better: for, says he, the expediting the loading and unloading, and the saving the waste that would accrue by shaking, and while carrying it about loose in forking, will always do much more than pay for the expence of binding it up, even where the corn has been cut down by the scythe; a slovenly practice, which he says cannot be advisable in any case.

In his Minutes of Agriculture, Mr. Marshall recommends the tying of sheaves but loosely, and not too large: but the extreme must be guarded against; for if they be tied too closely there is danger of their slipping wholly out of their bands; besides their being difficult to load, and worse to stack. He recommends also that they be set up in such a manner, as but just to touch each other at the butts and ears: leaving a space of a foot and a half between each sheaf at the band-place, and that the ears of the bands be turned inward. He observes in general, that the small loose-tied sheaves will dry soon, while the large tight-tied ones, of the same shock, will grow; and that the ears of the bands are the first that will grow; and that those shocks which stand free and open are far better than those of which the sheaves stand huddled together in a close lump, through which neither air nor sun can penetrate. Instead of tying the band at the foot of the butts, he recommends the tying them loosely about the same distance from the tips, and spreading the butts, setting the sheaves up singly in resemblance of sugar-loaves, leaving the insides totally hollow; this will enable them to dry very soon; and then shifting the bands the next day back again to the common banding-places, and opening the ears, they will soon be perfectly dry.

Both in Oxfordshire and several other counties they bind up their wheat in sheaves, though it be full of weeds, and set three sheaves somewhat sloping against three others; after which they cover their tops with two sheaves opened at their ear-ends, which are extended and placed downward. In this situation they let their wheat stand some time in the field before they carry it in.

In forming what they call *wheat pooks* in Wiltshire, the sheaves are set in a circle, with their ears uppermost; another circle of sheaves is placed upon that, and so on, contracting each round, till the pile ends in a point, upon which a sheaf, opened and turned with the ears downward, is placed, like the hackle of a hive. A load or two may thus be put into a pook; which is a good way to secure corn against rain, and to give the weeds among it time to dry.

In Lancashire, though the grain has been generally reaped, some farmers have lately mown their crops of corn. The following is Mr. Harper's method: The wheat is mown *in*, that is, thrown towards the standing corn, immediately gathered and tied up into sheaves: the set consists of two mowers, two women gatherers, and one man binder. The barley and oats are mown *out*, into swathes, and gathered at convenience. The advantages of this method are, a saving of expence about 1d. per acre, less danger of the corn being shook out of the ear, and gaining nearly one-third more straw; no trifling consideration under several heads, especially since it does not appear that what stubble is left in the field is of the least service, but in some instances evidently does harm, as to clover or other young grasses, by retaining moisture through the winter, and starving the ten-

der plants, or injuring the hay when mown, which, when wet, it has a tendency to render putrid. After the corn is gathered, the ground is gone over with a rake, to collect what straggling ears may remain, which are generally the heaviest, and of superior quality. This is done by a *wooden rake*, with teeth about one inch longer than the common hay-rake, which is preferred to the *drag-rake*, and does its work much neater: a woman can rake about two statute acres per day. The scythe for cutting the corn has an addition of a bow, made out of a piece of rod-iron, fastened into the pole, and extending three inches over the scythe heel, from whence it rises about nine inches in height and about two feet in length, and which forms a kind of cradle. This rod is supported by an upright prop from the pole about the centre, and which is further braced and kept tight by a string.

The method of setting up corn in that county, after being reaped, and while it continues in the field, is this: If barley or oats, and in a greenish state, they are set up in four standard sheaves only, with one cover called a *hooder*; that is, a large well-bound sheaf is selected and opened, with which the four standard sheaves, with the grain uppermost, are covered, the grain of the hooder hanging downwards, but free from the ground. This shape is provincially called a *pricket*. The most general method, however, is six sheaves standards placed against each other, spread out in their butt ends, and closed tight at their tops; when a couple of sheaves are opened, each about one-half, clapped over each end of the standards, and meet with their butt ends together in the centre; thus forming a roof or cover for the standards. This form is provincially called *bat-task*, and the cover a *rider*.

In Scotland, Mr. Robertson says, wheat is generally cut with the sickle, and bound into sheaves, and *stooked* in 12 *sheaf stooks* immediately thereafter; but in some cases, particularly in damp weather, it is left *broad-band*, or untied for two or three days, to accelerate the *winning*; and sometimes *gaited*, or tied slack and set on end sheaf by sheaf, for the same reason. In a few cases, however, barley is cut with the scythe, and collected into sheaves with a reaping fork; in which mode of operation one girl forms the sheaves, another makes the bands, while two men cut and one binds; in all five people to two Scotch acres in the day. In the more common method by *shearing* with the sickle, nine people are required to do the same work; but of these eight may be women; one man only for binding being necessary; while the other way takes three men at least, which in the general scarcity of men-labourers in harvest is not practicable to a great extent. Barley is the most difficult of all grain to *win*, requiring generally three weeks standing in the stook before it is fit to be put into the stack, and where, after all, it is more liable to be heated, or *more-burnt*, than any other grain; which renders it sometimes proper to form a funnel up the heart of the stack to keep it cool.

Both the broadcast and drillbean crops are here also laid down loose from the sickle, where they remain eight or ten days (more or less as the weather may be), to *win* before they are bound up. They are sometimes bound with straw ropes, and sometimes with ropes of pea straw.

SECT. XXX. *Of Stacking Grain.*

In order to preserve corn in the straw, it is very common to make it up into stacks. When this is done, it is necessary to make a kind of ground-work, for the grain to rest upon pieces of wood laid across each other, or to put posts into the ground for the same purpose. In Hampshire and other counties, where they have plenty of stone, they make their supporters of them, which is probably the best way.

Mr. Marshall thinks, that a square is the best form of a stack-frame at bottom, as being more pleasing to the eye, tak-

ing less thatch, and standing firmer than any other. The stem, he says, should be carried up as plumb as possible, except in the last course, which should project five or six inches, to form the eaves; for the weight of the roof will press out the upper part of the stem sufficiently. If it overhang in making, its own weight and the weight of the roof will squeeze it too flat. The stem must contain about two thirds, and the roof one-third, of the whole stack. If built on a frame, the stem may contain less, and the roof more; but if on a bottom, the contrary. And the corners of the stem should not be made too sharp. The ends of the roof should have a gentle projection, answerable to the stem; and the sides should be carried up rather convex than flat or concave. Perhaps a roof which is gently convex shoots off the rains preferably to any other. Corn-stacks should not be made too large, as the risk of making and getting-in is much less on small than on large stacks: besides, large stacks do not settle so true as small ones, and consequently do not stand the weather so well.

Doctor Anderson is however clearly of opinion, that the farmer would derive considerable advantages from putting up all his corns under permanent roofs, which, he says, might be constructed at little expence, without having any walls, by means of posts placed perpendicularly on each side and across the building, at the distance of six feet from each other, and then putting a roof upon them.

Now, says he, supposing the corn to be in sheaves, begin to build it up in the corn shade by laying a row of sheaves, with the butt-ends outwards, right across the shade, in a line with one of the rows of posts; and another row of sheaves in the same manner, in a line with the next row of posts, laying the tops of the sheaves towards each other. These ought to be laid in by hand loosely, from a scaffold on each side, and not trod upon. The points of some of the sheaves will reach to the butts of the others, and they will pack thus quite well. A row of sheaves is then to be laid across these, so as that the length of the sheaf may lie *across* the building. The butts of the sheaves of this row should be placed first on the outside, and then another row of sheaves should be placed in the same direction, overlapping the points of the former, and so far from the side as that the middle of the sheaves shall be opposite to the first post; and on the other side of it another row reversed, so as that the points of the one sheaf shall lie towards, and intermix with, the points of the others, and so on across the whole building, in rows, with the butt ends of one row of sheaves to the butt ends of another, leaving a small space between them for the circulation of the air. Above these should be laid another stratum of sheaves across these in the same direction as the first, and so on, crossing each other in alternate layers, the whole way to the top.

One division, of six feet in width, being thus finished, another is to be begun and finished in the same manner, leaving one of the intervals of six feet between the posts free across the whole, and the other filled up alternately throughout the whole. In this way the work is to go on from day to day as the harvest advances. The corn being thus secured, immediately as it is cut, from the possibility of receiving damage from bad weather, and being placed high in the open air in narrow divisions, full of perforations, what sap is in it will be gently evaporated, while the native juices of the plant will be preserved without the danger of heating.

The sheaves being put up loosely, the stack will gradually subside a good deal in consequence of the pressure from above. And as it will be fit in most cases to be packed more closely after a few days, by the time that the whole range of shades are thus filled, and room wanted for more corn to be put into it, the sheaves that are upon the top of the first division, and which are now of course the driest, ought to be thrown down into the first open division, and regularly laid and trampled upon, so as

to make them firm; until, by lowering the one division and raising the other, they come to be of an equal height; when the operators should proceed to another, and so on gradually to others as they are wanted.

The under part of the shade will now be filled close up, and the top be left quite open as at first, so as to admit of a similar operation with the former, the first led corn forming now the base, and so on. The latter cut corn may now be put upon the top of it, exactly after the same manner with the first; and being high in the air, and not so much pressed by the weight above, it will be more quickly dried. In this way you are to proceed, making two or three successive rows, if necessary, until the harvest be finished and all got in.

But for wheat, which is much firmer in the straw than other corn, and generally cleaner and well ripened, less precaution is necessary. The first division may be put up as above described, but it will not be necessary to leave any open divisions for this kind of corn: one division after another can be filled up from the scaffold at the side. In most cases, no precaution will be wanted to prevent it from heating; but when it is greener cut than usual, and it appears doubtful if it will keep well, in laying the sheaves lengthways across the shade, an opening of a few inches in width may be left in the middle between two sheaves, all along in the same line right across the whole, which being covered by the sheaves laid lengthwise across it, will admit a circulation of air: one of these pipes may be made in every second, fourth, or sixth layer, as circumstances may require.

In this way the Doctor thinks that the whole corn of a farm might be perfectly secured against sustaining any damage from the weather in any season; and thus a considerable expence on some occasions, and amazing waste in others, be entirely prevented; while the straw in every case would be nearly as good as hay, and the quality of the grain much better than it ever can be, if subjected to rain after it has been reaped. For, says he, I have found by experiment, that if grain has ever been wetted from the time it is cut down, it never can be brought to the same state of perfection as it would have had if it had never been wetted: nor can any art ever make the same corn, if it has been once wetted, shrink into so small a bulk, or become of course so weighty, as the same corn would have been if it had been thoroughly *winn*, without having been at all wetted. Nor does barley that has been wetted and afterwards dried, ever malt so kindly as it would have done if kept quite dry. This last is probably a fact not very generally known.

SECT. XXXI. Of Making Hay.

WHEN grass is to be made into hay, the farmer should be directed in the season for mowing by its quality. If the crop be very great, it should, however, be cut as soon as the bottom of the grass grows yellow: and in other cases, where nothing prevents, it should generally be when the grass is in full bloom before the stalks begin to harden. But there is not any general rule for this, as in some cases the ripe seeds add a great value to the hay, as in sainfoin and burnet: and in others, the growth of the grass itself is of advantage, as in some kinds of meadow-grass. The process of making hay differs in some respects according to the nature of the grass. But in general, if the weather be quite fine, the grass may be spread out as fast as it is cut down, especially if it lie so thick in the swarth that neither the air nor sun can pass freely through it: but if wet be feared, it should remain in the swarth. At night, make it into grass cocks; and the next day, as soon as the dew is off the ground, spread it again and turn it, that it may wither on the other side; then handle it, and, if it be found dry, make it up into large cocks. Should the weather continue favourable during the second day, the grass will, by that time, be so dry

as to bear being kept in these cocks till the day on which it is to be carted; when it should be spread out again in the morning, to receive a farther drying, if necessary. If the cocks be made as tall and taper as is consistent with their standing safely, the winds, by passing through them, will dry them gently and equally; and though rain should fall upon them, it will not do much hurt, because the greatest part of it will run off directly, and the sun and wind will soon dry that which may have penetrated into the cocks. When made in this way, they have a great advantage over the common small and low cocks: for if a rainy season comes on, these last will be so thoroughly wetted, that the wind will not be able to penetrate sufficiently to dry them.

Where the colour of hay is particularly regarded, the best way of making it, if the weather be fair, is to open it perfectly and spread it thin, immediately after it is cut, and to have hands sufficient to turn and shake it, till the evening, when it should be made up into grass cocks. This method should be pursued every day till it is sufficiently made.

In Staffordshire, Mr. Pitt says, the seasoning or making of clover and rye grass into hay is as follows: After mowing, the swathes are suffered to remain till they are well dried on the upper side; they are then turned over, and the other side dried in like manner, and afterwards turned a second time if necessary; they are then got together, raked, and carried to the stack: the stalks of clover take a good deal of time to dry thoroughly; the time for which is facilitated, as well as the effectual making of it secured, by sunshine and fair weather; and it is supposed to save itself best in the swathe unbroken.

In Lancashire, Mr. Holt says, that Mr. Eccleston's mode is to collect the clover together into small sheaves, which are kept straight; then twisted together in the top part, to admit the sheaf to stand upon its butt or bottom-end, when spread out, in the same manner that horse-beans have been frequently treated. If these little bundles, says he, be not thrown down by the winds, they will resist more rain, if it should fall, than when lying on the surface of the ground; and if the weather be fine, having more surface exposed and open, the clover will cure the faster. Clover for hay requires to be made more dry than grass; for, if the sap is not thoroughly dried up, it often heats too much, and is spoiled. Sainfoin also requires to be well dried, but not quite so much as clover; they neither of them are apt to fire in a stack; but frequently, if carried too green, will burn to a coal.

Mr. Robertson, in the Agricultural Survey of Mid Lothian, observes, that "when hay from seeds, such as clover and rye-grass, is cut down, there are two things respecting it to be considered. 1. The *swath* is laid in pretty regular order, in form somewhat like to the blade of a razor, in which the ears incline to the *edge*, while the bottoms are piled up one above another, in the opposite direction, at the *back*. 2. The stalks, individually, are firm and straight, and like to reeds; naturally unsusceptible of moisture, but very readily admitting a passage through them to the air, or the wind, as it blows over the field. In consequence of these two circumstances, hay, in this situation, is not difficult to be win or *made*; for in dry weather the air readily penetrates through it, and dries it quickly; and in wet weather it is not apt to imbibe the rain, but rather sheds it off along its upper tire of stalks, and of course can stand a considerable deal of rain without receiving much damage, and very readily becomes again dry on the return of fair weather; a fact well confirmed by experience; while, at the same time, its aromatic flavour, as well as natural colour, is very little exhausted or altered, as there is but a small proportion of its bulk exposed to the weather, the greater part remaining sheltered as under a shade, and dries by degrees. But should the hay-makers, in the view of accelerating the process, *turn* it in the

swath, the following circumstances will occur: 1. The swath, instead of presenting a regular inclined surface, naturally adapted to lead the rain off as it falls, will lie expanded, loose and irregular; well adapted indeed to receive the influence of the winds, or of the rays of the sun, in dry weather, but equally ready to catch rain in case of a shower. 2. The hay itself will have become so much bruised, or softened, in the operation, as to retain, and even imbibe, that moisture which in the former case it would have repelled or shed off. The consequence must be (as it is known to be in fact), that hay, in this situation, if once it gets wet, is much more difficult to be got dry again, than if it had not been turned at all.

"There are, however, cases which frequently occur, in which it is proper to turn hay. Thus, if it has received rain, or has been protracted in the making by a long continuance of damp weather, it must be turned in the swath at all hazards; and in most cases it will be proper to turn it in the forenoon of the same day in which it is meant to be put into large ricks in the afternoon: but, in general, the process cannot be greatly advanced by that operation in good weather; and as it really retards it, if followed by wet, the best way is to let it alone till it is finally to be made, which in dry weather will be in about three days after it is cut; when it may be put into ricks of from 40 to 80 stone weight, where it may remain ten or twelve days longer, by which time it will be fit to be put into *rows*, or *stacks*, of any dimensions. There is, however, one fact to be admitted, that in this mode of hay-making the upper side of the swath (exposed perhaps for three days together to the weather) may be *too much win*, while the under side, for want of exposure, may be *too little*. There is, however, another fact equally well ascertained, that by the time the hay is in the rick for 24 hours, the whole becomes one homogeneous mass of the same degree of temperament; that which was too dry imbibing the superfluous moisture of that which was scarce dry enough, so that no distinction can afterwards be observed."

In respect to the making of hay from meadow grass, Mr. Pitt observes, the first operation after mowing, is spreading it all over the meadow, which is called *tedding*; it is then raked into win-rows, and the win-rows farther divided into small cocks, called *grass cocks*: next morning, if fair weather, the grass cocks are cast about into square beds, and the vacant spaces between the beds, if any, raked clean: the beds, after turning, are then put into middle-sized cocks, called quarter cocks; next morning, if fair, the quarter cocks are again spread open, if necessary, and turned over; and then put into large cocks: it is then fit for carrying to the stack. The time for these operations, as well as their effect, is much facilitated and improved, as before remarked, by sunshine and fair weather. But in showery or casualty weather, he thinks the following process is superior: After mowing, and the swathes being somewhat seasoned, rake them clean over: when the other side is seasoned, make them into small cocks: when the cocks are dry on the upper side turn them over, and when dried on the other side, half a dozen of them may be put together into quarter cocks, and so by degrees into large cocks: this process will require more time than the former, but will keep the hay much better protected from the weather. The injury hay sustains from rain is when it is spread all over the ground, in which case if the rain continues the hay will lose its juices and its colour; whereas, if hay be in cock, with the ground bare between the cocks, it will sustain a deal of rain without injury. In the last described process the hay-making will be much facilitated by due attention to hours of sunshine, and by then spreading about the cocks a few at a time, or as many as the continuance of the good weather will permit, getting them up again hastily upon the approach of rain: he believes, that by diligence and due attention to this last process, hay may be preserved from sustain-

ing much damage in almost any season. All the above operations should be performed when the hay is dry.

Mr. Robertson also remarks, that in the making of *natural*, or meadow hay, there are circumstances which make a different and more expensive mode of operation necessary. "In this case the swath is far from being laid down in a regular form, while the hay itself is neither firm nor straight; but, on the contrary, very soft and much interwarp together, and generally so thick at the bottom, that, when turned up by the scythe, it lies so compact and close, as totally to exclude the external air: therefore it becomes necessary, not merely to *turn* this kind of hay from time to time, but to *ted* it very minutely, spreading it like a blanket, as evenly as possible, over the whole surface of the ground, so that no part of it may be much excluded from the influence of the drying winds, or rays of the sun. In this way, when the weather is good, natural hay may be made, in the course of a week, ready to be put into cocks of 20 or 25 stone weight; where it ought to remain, well tied down, and neatly dressed in the sides and at the bottom, for eight days more; when it may safely be collected into larger ricks, and finally into *rows* of greater dimension. In wet weather, this process is no doubt protracted to a longer period; but still it will be found, that to spread it as thinly over the field as the ground will admit of, will be the surest way to preserve it from material injury; for although, in this case, it is exposed to every shower that falls, yet as it is not any where of much thickness, the water is not retained, but sinks through it to the ground; and on the return of the first breeze, in a few hours the upper parts will be dry; and if then turned, the under side in like manner will receive the same benefit."

SECT. XXXII. *Of Stacking Hay.*

ON this subject Mr. Pitt observes, that some people carry tunnels up their hay ricks, either by drawing up a binding of wheat straw, or by actual tunnels of wood: these are meant to discharge a part of the vapour generated in fermentation, and thus prevent any danger of the hay firing: those who practise it remark, that they can carry their hay a day or two the sooner. But Mr. Pitt and many other farmers never use any such precaution; nor is it necessary, says he, if the hay be sufficiently made, and put together in stacks not too wide at bottom. He thinks that a bottom four yards wide at beginning is enough, if the sides be a little sloped outwards, and the stack carried to a sufficient height. The propriety of discharging any part of the vapour arising by fermentation from hay-stacks has been questioned by some, who think it should be smothered and retained in the hay as much as possible, and that no other precaution is necessary than due attention to the hay-making.

Mr. Holt remarks, that in Lancashire Mr. Eccleston cuts gutters in the ground, lengthways, and covers them across in that place whereon a stack of hay is to be built. Through these trenches, in different directions; the outward air may enter, pass through, then ascend the aperture left in the stack; and this continued circulation takes away the generated heat or foul air, which, if confined together without any vent, might produce damage to the hay, or worse effects; and by these useful precautions he is enabled to collect his hay together at a more early period, and in a more juicy state; by which good practice, time is saved, and the quality of the hay rendered better. He has also observed stacks of clover hay made with layers of wheat straw at certain distances from the bottom to the top; which he thinks a good method, particularly when it has had bad weather upon it, and was got in rather damp, as the damp heat is conveyed through it by means of the straw from one side to the other, and a greater circulation of air might still be procured by a chimney in the centre being filled with straw. Hay-barns have of late been erected in many places, standing upon

pillars, and covered with slates; sometimes with a bottom boarded with planks, open in the joints, perforated with holes, and lying hollow a space above ground, to admit a free circulation of air all under the hay. These buildings are useful, cheap, and by their great convenience in bad weather, and the great preservation they afford to the hay, soon repay the expenses which are at first incurred. It is a good practice with hay in buildings, as soon as it is become solid enough to bear the knife, to cut a passage round the walls, about half a yard in breadth. The hay which comes from the passage thus cut, may be put on the top of the mow: by this method, a free circulation of air is obtained, and the tainted smell which is contracted by the hay which lies up to the walls through the winter, is by this method prevented or removed.

Large stacks being apt to heat more than small ones, it is necessary to carry the hay, of whatever kind, so much the drier; and if proper attention is paid, and the weather will admit a large quantity being carried together perfectly dry, there is no occasion for any chimneys being made; but when, from apprehensions of approaching bad weather, it is hurried in too soon, then chimneys made, by drawing up the stack, as it ascends, a basket or a sack stuffed with hay, will certainly prevent any danger of heating.

It is however recommended by Doctor Anderson, as by far the most beneficial practice, for farmers to stack their hay under permanent roofs. By this means there will be less danger of the hay being wet before it is carried.

SECT. XXXIII. *Of Fruits.*

IN many counties the growth of fruit, for the purpose of making liquor from its juice, constitutes a very profitable part of husbandry; it is therefore necessary to consider the methods by which it may be most advantageously cultivated. The fruits chiefly cultivated with this view are, the *Apple*, the *Pear*, and the *Cherry*.

Of Apples. Nature seems to have furnished but one kind of this species of fruit, the *Pyrus malus*, or crab. The great variety of sorts cultivated by those who are engaged in this part of husbandry, are evidently not natural species.

Those, therefore, who are anxious for the improvement of this fruit, should endeavour to procure the best accidental varieties, and, after improving them as much as possible by cultivation, to preserve them in that state by artificial means of propagation. But even this method is limited, for art can only prevail for a time. Thus, most of the old fruits, as the *Red Streak*, the *Stire Apple*, and the *Squash Pear*, are either lost, or very much on the decline.

In raising this fruit, Mr. Marshall observes, that the seed-bed should be adapted to the intention of the planter. Where new varieties of fruit, or the improvement of old ones, is the object, the seed-bed should be made as rich as possible: But on the contrary, where the preservation of varieties is all that is wanted, an ordinary loamy soil is sufficient. In either case, it is proper that it should be perfectly clean, from root weeds at least, and that it should be double dug from a foot to eighteen inches deep. The surface being levelled and raked fine, the seeds are to be scattered on, about an inch asunder, and covered about half an inch deep with some of the finest of the mould previously raked off the bed for that purpose. During summer the young plants should be kept perfectly free from weeds, and the ensuing winter may be taken up for the purpose of transplanting; or they may remain in the seed-bed until the second winter, if not crowded.

And the nursery-ground, like the seed-bed, should be enriched agreeably to the general intention; and should, in common good management, be double dug at least fourteen inches deep, but eighteen or twenty is always preferable. The seedling plants should be sorted, according to the strength of their

roots, that they may rise evenly together. The tap or downward roots should be taken off, and in this operation the longer side rootlets should be shortened. They should then be planted in rows, three feet apart, and from fifteen to eighteen inches asunder in the rows; care being had not to cramp the roots, but to bed them evenly and horizontally among the mould. If the plants be intended merely for stocks to be grafted, they may remain in this situation until they be large enough to be finally planted out. But it is probably a better way to retransplant them into fresh, unmanured, well-dug ground, two years before they are transferred to the orchard or field, and place them together that they may form regular globular roots. In raising or improving varieties, however, the nursery-ground should be naturally deep, well soiled, and highly manured. The plants must also be repeatedly moved at every second, third, or fourth year, that they may grow strong and vigorous by the addition of fresh earth. In pruning the plants, the *leader* should be particularly attended to. If it shoot double, the weaker of the contending branches should be taken off. If the leader be lost, and not easily recoverable, the plant should be cut down to within a hand's breadth of the soil, and a fresh stem trained. The stem boughs also require attention. The undermost of them should be gradually taken off by going over the plants every winter; always, however, cautiously preserving sufficient heads to draw up the sap. A good stem should be pretty tall and well proportioned.

In propagating and improving the varieties of this fruit by cultivation, care should be taken to collect the seeds from those which have the best flavour; and when these have arrived at a proper state in the seed-bed, choose from among them such plants as have the most apple-like appearance. Transplant these into a rich deep soil, in a proper situation, letting them remain until they begin to bear. With the seeds of the fairest, richest, and best-flavoured fruit repeat this process; and, at the same time, or in due season, engraft the wood which produced this fruit, on that of the richest, sweetest, best flavoured apple; repeating this operation, and transferring the subject under improvement from one tree and sort to another, as richness, flavour or firmness may require, until the desired fruit be obtained.

In the planting of fruit-trees, different distances are preferred by different planters. In the grass grounds of Gloucestershire, and the arable fields of Herefordshire, twenty yards is a common distance; but twenty-two yards is probably the best distance. In grounds, the trees should be planted in cross-lines for the conveniency of ploughing; but in orchards, it is better to set them in the *quincunx* manner, that they may have room to spread on every side.

The following are the directions which Mr. Marshall gives for planting, and which he considers as most likely to succeed. The grounds being set out with stakes driven in the centres of the intended holes, describe a circle, five or six feet in diameter, round each stake. If the ground be in a state of grass, remove the sward in shallow spits, placing the sods on one side of the hole. The best of the loose mould place by itself on another side; and the dead earth, from the bottom of the hole, in a third heap. The depth of the holes should be regulated by the nature of the subsoil. Where this is cold and retentive, the holes should not be made much deeper than the cultivated soil. To go lower is to form a receptacle for water, which, by standing among the roots, is very injurious to the plants. On the contrary, in a dry, light soil, the holes should be made considerably deeper; as well to obtain a degree of coolness and moisture, as to be able to establish the plants firmly in the soil. In soils of a middle quality, the hole should be of such a depth, that, when the sods are thrown to the bottom of it, the plant will stand at the same depth in the orchard as it did in the nur-

tery. Each hole, therefore, should be of a depth adapted to the particular root which is to be planted in it. The holes, however, ought, for various reasons, to be made previous to the day of planting. If the season of planting be spring, and the ground and the weather be dry, the holes should be watered, the evening before the day of planting, by throwing two or three pailfuls of water into each: a new, but an eligible practice. In planting, the sods should be thrown to the bottom of the hole, chopt with the spade, and covered with some of the finest of the mould. If the hole be so deep that, with this advantage, the bottom will not be raised high enough for the given plant, some of the worst of the mould should be returned before the sods be thrown down. The bottom of the hole being raised to a proper height and adjusted, the lowest tire of roots are to be spread upon it; drawing them out horizontally, and carefully spreading them in different directions, and pressing them evenly into the soil; covering them, by hand, with some of the finest of the mould; one person steadying the plant, another adjusting and bedding the roots, and a third supplying the mould; which being raised high enough to receive another root, or another tire of roots, they are to be spread out horizontally upon it, and bedded in a similar manner: thus continuing, until every root be bedded, separately, horizontally (or somewhat declining), freely, yet firmly, among the best of the soil; great care being had to work the mould well in, by hand, among the roots beneath the crown, that no hollowness nor false filling may be left: to prevent which, the mould, after the roots are all bedded, and covered some depth, should be pressed or trodden hard (according to the nature of the soil and the state of the season) with the foot; the remainder of the mould being raised into a hillock round the stem, for the triple use of affording coolness, moisture and stability to the plant. In forming these hillocks some skill is requisite. The soil ought not to press against the stem much higher in this situation than it did in the nursery: yet it is proper that there should be a descent for rain water, from the stem; not toward it. To this end a dimple or little dish should be made on the top of the hillock; and, from the rim of this, the slope should be gentle to the circumference of the hole; where the broken ground should sink some few inches below the level of the field."

In the Transactions of the Bath and West of England Society, Mr. Morfe recommends the raising of young apple stocks, from the kernels remaining after apples have been squeezed for cyder, in this manner:

Prepare, says he, a piece of ground by well digging and clearing from weeds, keeping the surface smooth; and in February or March lay the *must* thereon, and shovel-turn it in, that it may be two inches deep: in about six weeks the young plants will appear, and must be kept clean from weeds: let them remain two or three years in the seed-beds, when they should be taken up, and the tap-root cut off, as also some of the spreading branches. There now should be another piece of ground prepared by double digging, wherein to transplant the stocks, laid out in beds four feet wide: plant them in rows across the beds about one foot distance between the rows, and eight or ten inches distance in the rows: let them stand here three years, when they must again be taken up, the roots and tops dressed, and planted in rows about eighteen inches distance in the rows, and three feet between the rows; but four feet is better, as it will leave more room to dig the ground between them, which should be done at least once a year, and kept clean from weeds, &c. by hoeing. Transplanting them twice, and pruning their roots, makes them root better and stronger, and commonly rise with a wig or fibery root. They are to stand in this nursery until of sufficient size to plant in orchards: some may be large enough when ten years old, others not until fourteen or fifteen; for they may be of very different sizes, although

sown and planted at the same time. Here they are to be carefully trained up straight, and pruned every year, by cutting off five or six of the largest knots or sprays each year, and not many more in one year, as it would make the stock grow too heavy and throw out more branches. This pruning should be done in the spring season, as the wounds will heal soonest when the sap is rising; but if pruned in autumn or winter, the wounds will be long in healing, and be very black, and continue so for years. The stocks ought to be strong for planting orchards, that they may the sooner grow out of the way of cattle, which very often do them great injury. The size he chooses to plant is from one inch and a quarter to one inch and a half in diameter at the grafting-place; that is, about five feet six inches from the ground. And the method he pursues in planting orchards is, first to lay out the field by setting up stakes equidistant, 20 or 22 yards from each other, which he looks upon as the best distance. After these are properly arranged, he advises to dig a hole considerably larger than will take the roots of the stock, that the earth may be soft and mellow for them to strike therein more freely; and to have the stock ready with the roots and head pruned, particularly those that are bruised in raising; which must be placed upright in the hole. If some better mould, such as street-shovelings, or a compost made with rotten dung, good mould and lime (lime kills the ants, which are very destructive to stocks and trees), be mixed with the soil to fill the hole, it will expedite the growth of the stock. Care should be taken to fill up every vacancy between the roots, shaking the stock well whilst filling: when filled, tread the earth down to the roots pretty hard: then have a stake four or five feet long driven sideways in the ground leaning against the stock, pointing to the west wind, and firmly tie the stock to the stake with an ozier twig, placing a hayband between the stock and the stake, to obviate galling: this will prevent the wind shaking the stock, which very often injures it, and prevents its taking root. We should then have six or eight black-thorns, pointed and stuck in the ground round the stock, reaching up to the head: these should be tied in two places with twigs, to prevent cattle or sheep from browsing on, rubbing, or peeling the stocks, which they are very apt to do, particularly young sheep. He has had stocks peeled quite round by sheep. The grease of the wool, when sheep rub against them, injures and retards their growth. Where wood is plenty, if three posts be erected triangularly round the stock, and laths nailed to the posts, it is the best fence. The stocks must now stand three years to take full root: at the end of which, those that have made free shoots may be grafted with what sort of apples the planter chooses.

In Kent, the method of planting apple-trees is to dig holes about two feet square, and two spits deep, taking out the stones, and turning down the surface-soil on which the young trees are placed, and the remainder of the earth is trodden down close about the roots: they are supported by stakes until they get sufficient strength not to be hurt by gales of wind. A composition of lime and night-soil is, with a brush, painted on the stems of the young trees; which is said to promote the growth of them very much.

Fruit-trees are injured by various circumstances, as from having too much wood in them, the milletoe, moss, and spring frosts; which can only be prevented by the removal of the different evils, and by promoting their strength and vigour.

Mr. Bucknall observes, in the Transactions of the Society for the Encouragement of Arts, &c. that pruning is an important circumstance in regard to the health of trees and their bearing; and that, if it be judiciously done, they will come into bearing sooner, and continue in vigour for nearly double their common age. In performing this operation, he recommends, that no branches be shortened unless for the figure of the tree, and then constantly taken off close at the separation; by which

means the wound soon heals. The more the range of the branches shoot circularly, a little inclining upwards, the more equally will the sap be distributed, and the better will the tree bear. The ranges of the branches should not be too near each other, as all the fruit and leaves should have their full share of the sun. Where it suits also, let the middle of the tree be free from wood, so that no branch ever crosses another, and all the extreme ends point outwards.

In the business of pruning, he advises all the branches that are any way decayed or galled, or where there are any curled leaves, to be cut out; after which the tree is to be thinned to give it an uniform head, and that the air and sun may be freely admitted. The stumps must then be taken off close to the parts of the tree from whence they shoot out. In doing this, particular care must be taken that they be cut close, smooth, and even, without shivering the bark. The cut ends next the tree, after being smoothed with a knife, must be immediately rubbed over with a substance composed of tar and corrosive sublimate.

When trees are much thinned, they are subject to throw out a great quantity of shoots in the spring, which, he says, should be carefully rubbed off, as cutting increases their number.

With regard to the extent of pruning required by an old tree, the author says: If it be very old, and much incumbered, do not let in the cold winds; but, with care, take off the stumps, with all the decayed, rotten, and blighted branches, leaving the rest to the discretion of each person, who will soon see how much is necessary; self-conviction being the best school for improvement. The truth is, whoever would form orchards to produce credit to himself and profit to his successor, must not suffer the trees to become old before the operations commence, but determine that pruning, cleaning, and rubbing off the rotten bark, should be begun in the nursery, and regularly continued to the extremity of old-age; from which method very little wood need be taken off at a time; and, by using medication, the wounds will heal, without causing any more blemishes than the tree was subject to at the time the limb was taken off; for it is not the first cutting which blemishes the tree, but the corrosion arising from neglect. Let each person therefore, says he, determine that no standard fruit-tree be suffered to remain incumbered with rotten and decaying branches; for these, admitting the water into the tree, and contaminating the balsamic virtues of the sap, lay the foundation of sure destruction to the tree, and furnish to insects a *nidus* under the rotten bark, in which they deposit their eggs.

He also advises, that the rows of trees in a fruit orchard should not stand north and south, but a point of the compass towards the east, as the sun will then shine up the rows soon after ten o'clock, which, in the spring of the year, will serve to dissipate the vapours collected in the night: these vapours stunt the fruit in the early stages of its growth; and, where the shaws are properly attended to, this position will best enable them to divide and blunt the power of the winds, and prevent blights, and the shaw might be a little brought over the south: but, as each situation has a predominant wind, this is only hinted to put the planter upon his guard: the shaw also will greatly protect the fruit from the severity of the autumnal winds, at which season half the crop of fruit is thrown from the tree before it is ripe; and the heads at that time of the year being loaded with fruit and leaves, many trees are actually torn out of the ground, or so lacerated as to be spoiled; which a proper shaw might prevent. Judicious shelter, says he, should be the first object thought of in forming an orchard on a large scale.

It is likewise necessary, he thinks, that nurserymen be attentive to their grafts, for more depends upon it than is imagined; as, from the grafts being full, well wooded, clear, and properly chosen, the fruit will be both larger and higher flavoured.

Though the soil and culture may be the same, the health of the wood of the tree is also most materially affected during the whole time of the tree's existence, by the proper maturity the scion was in at the time it was first put into the stock.

*Blight*s are very detrimental to fruit, the cause of which does not seem to be yet well understood. It is likewise liable to be hurt by insects; for the destruction of which, Mr. Gullet, in the Annals of Agriculture, recommends the following method—after observing that they are deposited in their egg-state by a fly, in the bud of the apple, or blossom, at its first opening, and soon become maggots, which exhaust the nourishment of the blossom, which with the slightest touch will fall off—to set fire to some heaps of wet straw, weeds, or any other like matter on the windward side of the garden or orchard, viz. if the wind be east, let the fumigation be from that point, so that the smoke from the heaps may blow through the tree for some days. The expense attending this, says he, will be very trifling, considering the beneficial effects of it, as it will not only destroy the insects for the present, but prevent them from depositing their eggs.

The fruit should be gathered when full ripe, and will quit the tree by gentle shaking: if gathered before it is ripe, the liquor which is prepared from its juice will be rough, hard, and seldom pleasant or good flavoured. They may be laid on the ground in a fruit-yard; but it is better if upon a gravel walk, as the wet will run from them, and they will lie dry in the bottom; and they should not lie thicker than ten or twelve inches. They are better kept without than within doors. Care should be taken to place fruits of equal ripeness and good qualities by themselves; for if of different ripeness the cyder will be apt to ferment too much, which will cause it to grow hard, and never be rich, full and fine-flavoured.

SECT. XXXIV. *Of Making Cyder.*

THIS is a chemical process, which does not seem to be yet conducted on any fixed or regular plan, as we find different manufacturers recommending different modes of collecting and managing the fruit, as well as of conducting the several processes in the preparation of the liquor. The following is the method recommended by Mr. Morle, which seems to be sufficiently clear and simple:

When the fruit is thoroughly mellow, it must be committed to the mill for the purpose of cyder making, which is formed with a stone-chase and roller, something similar to a bark or a sugar-mill. The roller is drawn round the chase by a horse. Here it should be ground to a pulp, that no bit of apple may be seen, and until you cannot hold it in your hand, if you take a handful and squeeze it: the kernels and rind will then be well broken, and will give the liquor a fine flavour. Let it be put into tubs or hogheads with one head out, and remain there two days; then press it through hair-cloths. I use, says he, fourteen or fifteen, putting about two pails full in each, turning up the sides and corners; then put another on until the whole are filled, when press it with a screw: put the juice into hogheads: after it has been there a few days it will work and throw up a thick substance at the bung hole, somewhat like barn, but of a darker colour: when this appears it generally is dropt fine, and should be immediately racked into a clean cask; for, if the substance be suffered to fall, the grounds from the bottom will rise, and the whole will be in a ferment and very foul, and perhaps must be racked three or four times before it can again be separated and got fine; and will run a risque of making the cyder harsh. So long as it remains fine and free from fermenting, it may remain in the cask; but if it ferments much it should be racked, and the grounds or lees taken from it. These may be dropt through a bag or bags of coarse cloth, made in the form of a jelly-bag, with a hoop sown round the top to hold about a pail-full: by

doing this very little cyder will be wasted, and the droppings added to the cyder will be a mean to keep it from fermenting, and will also help the colour. It often requires four or five rackings. Cyder made with different sorts of apples keeps best by breaking and mixing together; but this should not be done until it is fine, when the proprietor may blend it to his palate. After the whole is done, a bung may be placed over the bung-hole, but should not be close stoppt until February or March, when it will be fit for sale or use. If cyder do not fine, some farmers use itinglafs. For one hoghead of a hundred gallons beat about one ounce and a half and pull it to pieces; add to it about two quarts of liquor, and whisk it together; next day add more liquor, and whisk it again: repeat this until it be dissolved, and beaten fine. Rack your foul liquor, throw in the dissolved glafs, and stir it together with a stick. As soon as it drops fine, rack it off into a clean cask. Cyder should not be bottled until sixteen or eighteen months after it is made, as it will endanger the breaking the bottles, if put into them sooner.

Perry. The same method must be followed in making of this liquor as in that of cyder. The best pears for perry, or at least the sorts which have been hitherto deemed the fittest for making this liquor, are so excessively tart and harsh, that they cannot be eaten as fruit: Of these the *Bosbury pear*, the *Bareland pear*, and the *Horse pear*, are the most esteemed for perry in Worcestershire, and the *Squash pear*, in Gloucestershire; in both which counties, they are planted in the hedge-rows and most common fields. Pear-trees will thrive on land where apples will not even live, and some of them grow to such a size, that a single pear-tree, particularly of the *Bosbury* and the *Squash* kind, has frequently been known to yield, in one season, from one to four hogheads of perry. The *Bosbury* pear is said to yield the most lasting and most vinous liquor. Pears, as well as apples, should be fully ripe before they are ground.

Cyderkin and Perkin. These liquors are prepared by pouring boiling water on the dregs that remain after the making of cyder or perry, in the proportion of about one half the quantity of the liquors that have been previously drawn. After being left to infuse for 30 or 40 hours, it should be pressed very well, and what is thus squeezed out turned up for use.

Cyder Wine. This has been prepared in America, and even in this country, from the juice of apples by *boiling*. For this purpose a browning copper is made use of, in which the fresh apple-juice is evaporated, until one half of it be dissipated; the remainder being then conveyed into a wooden cooler, and afterwards into a proper cask, to which yeast is added, and the liquor fermented in the usual way. The experiments of Doctor A. Fothergill, however, seem to shew that cyder wine thus prepared, contains a slight impregnation of copper.

SECT. XXXV. *Of Cherries.*

IN Kent, they generally prefer for this fruit a situation where there is a deep surface of loam upon the rock. But by some it is said that there is not any necessity for a great depth of soil. In respect to distance apart, cherry-trees require to be planted according to their sorts; a *heart* requiring double the distance of a *duke* or *mcrello*. But when planted by themselves, they are generally placed from twenty to thirty feet distant, and are put somewhat deeper in the earth than apples; but in other respects the management is the same.

Cherry Wine. A cooling and pleasant drink is made from the juice of cherries when properly fermented. For making this liquor the cherries should hang upon the trees till they are thoroughly ripe, in order that their juice may be better perfected and enriched by the sun; and they should be gathered in dry weather. The juice is then to be pressed out, and a quantity of sugar proportioned to the intended strength of the wine is to be

added, and the whole regularly fermented. When the wine is become fine, it must be bottled for use.

SECT. XXXVI. *Of Filberds.*

THIS fruit is much grown about Maidstone in Kent. The soil best adapted for them is the stone-shattery sandy loam, of a quality somewhat inferior; as it is a disadvantage for the trees to grow with great luxuriance, they bearing most nuts when but inoderately strong. If they are planted among hops, without apples or cherries, they are put about twelve feet apart: when the hops are dug up, the filberd plantation is kept clean by repeated digging and hoeing; and great skill is necessary in pruning, to make them bear well. It is indeed entirely owing to skill and management in this operation that the trees are rendered productive upon even a favourite soil. These trees are generally trained in the shape of a punch-bowl, and never suffered to grow above four or five feet high, with short stems, like a gooseberry-bush, and exceeding thin of wood. If suffered to stand till ripe, this fruit will keep good for several years in a dry room or closet; but when gathered, they should be laid thin on the floor of a room where the sun can get in to dry them properly.

SECT. XXXVII. *Of the Cultivation and Management of Timber and other Woods.*

A VERY judicious writer on this subject observes, that it is a truth which has escaped the observation of few, that every kind of vegetable, from the loftiest oak to the minutest plant, thrives better in some soils than in others; and generally the better the soil, the more luxuriant the growth; but that, fortunately, a soil is rarely to be met with which cannot supply nourishment sufficient for the profitable growth of wood of some sort or other. It is not always, or indeed often, that plantations of timber and other wood do not prosper through poverty of soil, as has been commonly imagined; but generally from the situation being too much exposed to the unfriendly chilling quality of strong winds, which are injurious if not destructive to vegetation, in every kind of subject; and nothing suffers more than timber and wood of all kinds, through want of protection and the kindly warmth it affords, as is very evident from numberless instances of strong healthy trees suddenly falling into decay, upon imprudently cutting away the wood growing about them, and too suddenly exposing them to the rigour of a cold and inclement situation. Advantageous, however, as promoting and extending the planting of timber and wood, in every point of view, may appear, it is not to be understood that the immense quantity of waste land in this country should be planted: perhaps one acre in twenty, or at most one in fifteen, would be fully adequate; so that the planting those lands, which in their present state are of very little value, would be so far from diminishing the quantity of pasture and arable land, that it would add immensely to it.

The success of every practice affords the clearest and most satisfactory evidence of the truth and justness of its principles. It is now about eighteen or nineteen years, says Mr. Wimpey, since we began to plant on this spot. Such bits and pieces of land were chosen as afforded no kind of profit whatever; some a quarter of an acre, some a half, some several, but none of any value. As it was meant by way of experiment, every species of pines and firs which are commonly to be met with were planted; as likewise every kind of forest tree that is usually planted in England. The pines and firs run now in general from 20 to 30 feet high, and their circumference in proportion. One of the largest pinasters being measured at two feet above the ground, the circumference was found to be fifty inches; and a spruce fir at the same height was thirty inches; and many silver, Weymouth, and Scotch, considerably more. The forest trees are equally prosperous. A chestnut, planted some years

since the above, is between 20 and 30 feet high, and 25 inches in circumference a yard above the ground; and most of the kinds which were planted have thriven equally well, a few of the softer woods only excepted. He says, poplars, tree willows, and abeles, do not succeed here; they are aspiring trees, and generally shoot up to a great height in a favourable situation; but it seems they cannot bear the rigour of the cold winds in such an elevation, nor do they thrive when protected by hardier trees which shade and overtop them; for it happens to them as to most other plants, when the leading shoot is so much injured as to stop its vegetation, the whole tree soon falls into decay, and seldom thrives afterwards.

It has been found that wherever the plantation is five, six, or more trees deep, the whole has succeeded to admiration; but when they have been planted single, very few indeed have succeeded. It is true, many of them are alive, but never likely to make timber, being stunted in their growth, decrepid and decaying. As the soil, situation, and exposure, are the same for those as the other, the sole cause seems to be the want of that warmth and protection which the other receive from being planted in large numbers. The forest trees succeed no better than the firs and pines if planted single, the beech, hornbeam, and sycamore excepted; these, especially the beech, seem to thrive in every soil and situation, in defiance of all wind and weather. Not so the oak and ash; the first particularly suffers as much for want of warmth and protection, as any tree which is a native of this island. From this account of the success of these plantations, says the author, it evidently appears, that planting such soils with wood would be attended with the greatest advantages; not only as affording a large profit arising out of the thing itself, independent of every collateral consideration; but as the certain means of improving very large tracts of land, which in their present condition are of very little value, and by no means capable of improvement, but by being forced in and planted with wood. The method which he recommends for the planting and improving of such waste grounds is the following:

1st; To dig a broad ditch, and raise a high bank all round them, by way of fencing them off; then to measure out from the inner brink of the ditch, three or four perch or pole on every side, to form a margin, which should be thoroughly ploughed, pulverized, and made ready for planting in the spring. The exterior line should be sown with white-thorn berries in a double row about a foot asunder, row from row. At four feet distance from the same, a shallow furrow should be drawn, and so on at that distance from one furrow to another the whole breadth of the margin. As we advance from the outside, every row of plants will be more and more protected; therefore, the hardiest trees should be planted outermost, which may be in the order following: first, beech, horn-beam, or sycamore; the next may be ash; the third row, chestnut; the fourth, oak; the fifth, cherry; the sixth, pines, firs, or larch; then chestnut again, or a repetition of any of the former, as the planter may judge proper. This would serve as a nursery, and provide plants sufficient to plant all the interior fences. Each interior fence should have ground sufficient for a double ditch, if thought necessary, and a broad high bank. These banks will require three lines of sets to plant them, one on each side about two feet from the bottom of the ditch, and one on the top exactly in the middle. It will also conveniently admit of two rows of trees for timber, to be planted about two feet high in the bank on each side, at the distance of a pole from each other: those on one side to be planted opposite to the intervals on the other.

The most formidable difficulty which occurs in this scheme, is, says he, the time and expence required to establish the outward fence. If the outer line be sown or planted with white or black thorn, with holly, crab, beech, &c. it must be fenced for

several years, to defend it from the bite of cattle, which requires more patience and expence than is usually allowed, though absolutely necessary; but there is an easy method of making an outward fence, which in two, or at most three years, will be very secure, without further expence and with little trouble. This is by the planting of a *witby hedge*, which is a hedge composed of fallows, willows, and osiers, on the brinks of the ditches and banks of the fences.

The manner of doing this is as follows: A sufficient number of strong *witby stakes* are to be prepared, by cutting them from three and a half to four feet long, and from one and a half to three inches diameter: being cut sharp at the lower end, they are to be thrust or driven into the ground about 15 or 16 inches, or till they are firm, at the distance of about 14 or 15 inches one from another in a line: then an equal number of shorter sets must be prepared; these may be 15 or 16 inches long, and from three quarters of an inch to an inch and half diameter, and must be thrust into the ground about 10 inches deep, leaving about six out, to be planted one in the middle of each two of the former, then they will stand in alternate succession. The tall strong stakes must be fastened together by a whale or kind of chain, such as the hedgers weave on the tops of the dead hedges; they are made of three hurdle rods of the same wood. If stakes and sets be cut any time in January or February, and planted in open weather in a few days after they are cut, very few of them will fail of growing, and in two years time the shoots from the stakes and sets will be long enough to be woven flakewise; those from the short sets into the bottom and middle of the hedge, and those from the stakes into the upper part and top of the same. At that age they will be flexible enough to be wrought in without cutting, which is practised in older and larger shoots to the great damage of the hedge. A fence thus managed will be very secure, and stand an age with little expence or trouble.

It is also observed by Doctor Anderson, that waste and barren lands may be very conveniently improved by planting trees on them. There are few fields, he thinks, which might not admit of being brought into culture, under particular circumstances; and there are innumerable tracts of vast extent in this kingdom, which it will be much more profitable to the owner to plant with trees, than to attempt any other mode of improvement. Wherever the soil is dry and infertile; or where its chief or only produce is heath; or where it is full of rocks and stones rising to the surface; or if it be a stiff obdurate clay, having little surface produce; and in general, in most cases where the soil is poor, if not in the very near vicinity of a town, it may be converted into plantations, if it can be freed from hurtful water, with greater profit than any other improvement it could admit of, unless in very particular circumstances; even where it may admit of being brought *in time* into cultivated ground. Where the surface-produce is naturally small, perhaps nothing could be so economical as, *in the mean while*, to fill it with trees; because these, if judiciously chosen, not only yield a greater profit than could be drawn from any other kind of produce, and afford conveniences for houses, and other accommodations for inhabitants and for manufactures, but the ground itself, while the trees continue to grow upon it, undergoes for the most part a gradual amelioration, which it would not have done in its natural state; and admits of being more easily improved when the proprietor can find leisure to overtake it, than it otherwise would have been.

The kinds of trees, he says, which it would be best to cultivate, are the oak, ash, elm, beech, birch, chestnut, Scotch fir, spruce fir, and the larch. Of these the oak is best calculated to thrive on the strongest and deepest clays; the ash loves a rich and mellow loam; and where that is the case it prospers best on rocky banks. The witch elm prefers also a mellow soil, and situ-

ations moderately damp, to such as are drier and more arid. The beech thrives remarkably well on dry gravels, and can bear a pretty exposed situation. The birch loves dry mellow soils, and will prosper well on land that is very sterile. The chestnut delights in deep loam, on a stone shivery bottom, where the roots run no risk of reaching a retentive clay or other stratum that detains the water. The Scotch fir as well as the spruce will grow well on a light moory earth, if dry, though ever so poor, if cold clay does not rise near to the surface, or gravel, or sand. But of all the trees that have been named, the larch prospers on the greatest variety of soils: I have scarcely, says the Doctor, seen it fail on any soil where the water was not permitted to stagnate upon it; but it seems to prefer a mellow loam to either of the extremes of clay or sand. And as this tree is undoubtedly the most useful of the coniferous tribe, as well as the quickest grower, and the most ornamental of that class, it deserves above all others the attention of the rural improver.

Mr. Kent recommends the tall straight-growing pinaster to the attention of all planters upon poor light lands, as it seems to exceed most others in growth. It is frequently planted with Scotch firs; and, when they grow up together, by many incurious people is taken for a Scotch fir. But I have (says he) always remarked its superiority of size when mixed with it, and of the same age. In short, it frequently grows as fast as an alder, or an ash; and therefore, if it be planted merely with a view of being cut down for fuel, it will be found a very profitable tree in many parts of England: but as it will grow to a very large size, it will, in his opinion, be found applicable to many useful purposes, as it admits of being cut into very large scantlings.

He also observes, that when new plantations are made, it is always best to make them in as large a body as the ground will admit of, and, if there be time, to clean the land well. He recommends such plantations to be made from seed in drills, rather than with seedlings, keeping the ground clean till the plants get high enough to protect themselves: but it sometimes happens that single trees are planted with propriety in parks and lawns, upon small swells and eminent spots, where a large plantation would be too heavy. In such cases it is a good practice to open a very large hole, at least six feet in diameter, and full eighteen inches deep, in the spring, and the ensuing winter put three or four plants of different sorts into each hole; guarding them with a triangle frame, which will be more durable than a square, and much cheaper than a circle; and, the stuff being found, this may be erected five feet high, with pales six inches apart, all workmanship and nails included, for 3s. 6d. each. The reason for putting four plants into a hole, is not only to have the greater chance of raising one good tree; but it will sometimes happen, that two or three of them will unite and mix their branches together, and form a most beautiful head of different tints, and, by extending their principal roots different ways, draw sufficient nourishment for a permanent support of their union.

He concludes by reprobating the custom that prevails, in some counties, of pruning up trees, by divesting them of their lower or lateral branches. When a plant is very young (says he), it is sometimes allowable, to a certain distance, but should always be done with great caution; but when trees have begun to form themselves, it is a sort of murder—it stops the growth, and produces extreme deformity; for the sap, in the spring of the year, being checked in its natural diffusion into the number of branches into which it used to flow, becomes distorted.

The following are the judicious observations of Mr. Davis on the management of under or coppice wood, and of the timber grown therein:

Underwood, Nature of its Growth and Cause of its Decay.—The stocks which produce *Underwood or Coppice wood*, being in

fact only *pollard trees growing under ground*; it is obvious that the produce of those stocks must, like the shoots of pollard trees, be the most abundant when the parent stocks are in the greatest perfection; that until they attain that perfection, the produce must be small; and that, when they are past that perfection, they gradually decline; the shoots from them become weaker and fewer every successive cutting, and the stocks finally decay and die. It therefore follows, that to prevent the decay of woods, it is necessary, from time to time, to renew them by raising new stocks, to supply the place of those which from time to time wear out and decay. But besides the constant and regular decay of age, to which all woods are liable, there are many injuries to which they are subject, and which will very speedily and prematurely bring on their decay, unless proper and effectual methods are taken to prevent those injuries.

The first is, the pernicious custom of suffering cattle to feed in woods, under an idea that, after they are of a certain age, (usually seven years) the shoots are grown out of the way, and that the cattle can do no harm. In strong, thriving, flourishing woods, it is possible that cattle may do *but little harm* to the underwood, after it is seven or eight years old; but all the young plants, which either spring up spontaneously or are planted in them, will be liable to be cropped and kept down by the cattle, and few of them can come to perfection. And in weak decaying woods, there is *always* a great deal of the underwood so low, as *never* to get out of the reach of cattle, but continually liable to be cropt and kept down by them, and the decay of the stocks thereby much hastened.

And another cause of early decay of woods, is *the want of draining* such parts of them as are subject to be moist and damp; *nothing being so prejudicial to wood as too much wet*. A third cause of decay, is *the custom of suffering woods to grow too old before cutting*, whereby the strong shoots smother the weak ones, and, by their dropping, kill the stocks on which they grow. To this may be added the practice of permitting the *luyer* to cut the wood, thereby making it *his interest* to destroy every sapling, and *to cut the underwood as close to the stock as possible*—(which in old woods is very prejudicial to the succeeding shoots)—as also the custom of not obliging the buyers *to clear the woods early in the summer*, so as to prevent the new shoots from being injured by their cattle, carriages, and other circumstances.

Of Recovering Decayed Woods.—On this subject it must be observed, that if it be profitable to plant new woods, it is certainly much more so to protect those that are already planted, to fill them up where thin, and to restore them when in a state of decay. The expence is not only lessened by the saving of new fences, but the profit is greatly increased, by the rapid growth of the wood, when planted in situations that are sheltered by other woods already planted. In those woods where saplings spring up in great numbers *spontaneously*, their growth should by all means be encouraged. At the time of cutting the underwood, these saplings will perhaps be 14 or 15 years old; and it might appear proper, after leaving for timber trees such as are straight and handsome, to cut off the rest for underwood. But great part of the saplings so cut off *at that age*, will not be large enough to produce shoots *sufficiently strong* to get up as fast as the other underwood. *These shoots* would therefore suffer, and the stocks would never come to perfection. It is, therefore, more advisable not to cut off such saplings as are intended for underwood, until the *second cutting* of the wood, when (being perhaps near 30 years old) they will throw out shoots *strong enough* to fight their way, and keep pace with the surrounding underwood. But where saplings do not spring up in abundance spontaneously, young trees must be planted; part of which may be preserved for timber, and the remainder left, to be stubbed off at a proper time for underwood.

Of the Kinds of Wood to be planted.—The kinds of wood to be planted in coppices, either in making new ones, or filling up old ones, must be regulated, partly by the demands of the country, but chiefly by the peculiar aptitude of the soil and situation to produce particular sorts. *Let nature be your guide in planting* (says Mr. Davis), *and you will seldom do wrong.*

But particular soils and particular situations (says he) will always favour particular kinds of trees; we need not look for the reason, but only for the fact. The chalk-hills of Hampshire are peculiarly proper for beech; the stony loams and clays of the same county, for oak and ash; the mossy steep sides of the Wiltshire downs, for hazel; and the sands of the same county, for ash; the rugged and almost naked rocks of Mendip, in Somersetshire (near Cheddar), produce the lime tree and the walnut in the greatest luxuriance; and on the highest parts of the same Mendip hills, where no other tree can stand the sea breeze, sycamore flourishes as well as in the most fertile valley. But taking the general demand of countries, and the peculiarities of different soils, into consideration, there is no kind of wood so generally proper for planting in coppices, as ash. The value of ash-poles being at least one-third more, and frequently as much again, per hundred weight, as that of other poles (being applicable at all sizes to some useful purpose or other); the timber being always in request, and saleable at any age or size, at almost the price of oak; and the wood itself being as quick a grower as any, and quicker than most; and above all, there being but few soils, from the blackest and wettest bogs to the highest and most exposed mountains, where it will not grow; are reasons why ash is one of the most profitable woods to plant in such coppices as are favourable to its growth. In soils and situations where ash does not grow kindly, let such other sorts of woods be planted as appear to thrive best in similar soils and situations in the same country. Spanish chestnut, though not so general a grower as ash, is a most excellent wood, either for timber or underwood, and wants only to be more known to be higher in estimation. It partakes much of the properties of oak, but excels it in two points, viz. that it grows faster, and that the sap part of the timber is firmer and less corruptible. To fill up woods that are grown thin by age or neglect, the proper time is one year, or at the utmost two years, after the underwood is cut. The young plants should be eight or ten feet high, and an inch and an half in diameter at the ground, and should be planted without cutting off. If the soil be dry, no other preparation is necessary than barely digging the holes for the plants. If wet, deep drains should be made to take off the superabundant water. The earth dug from these drains should be thrown out on the lower side of them, and upon this new earth the plants should be planted. If land of this latter description be black and peaty, ash is peculiarly proper for it; and will, if planted on the earth thrown from the drains, make a most surprising progress. If it be a stiff yellow clay, it is generally more favourable to the growth of oak than of ash. In such soils, oak for timber, with a mixture of willow, birch, alder, and Spanish chestnut, for underwood, will perhaps be the most proper. All these kinds should stand one round of the underwood, and, if still weak, should stand two, before those are cut off which are intended for underwood, for the reasons before given. Birch plants are indeed an exception to this rule: they should always be cut off the first round of the underwood; for, if they are large when cut off, the stocks frequently decay and die. In all mixtures of kinds of wood for coppices, those sorts should be used which are not unfriendly to each other, and which will come round fit to be cut together at the same periods; and such kinds should be allowed to stand for timber, and that at such distances as to injure the underwood as little as possible. The plants for filling up old decayed woods should be the strongest and best of their kinds. Those which are weak at first will be drawn up by the

surrounding underwood, and become from their increased height still weaker. At the next cutting of the underwood, they will be blown down; or, if cut off, the shoots will be too weak to grow up with the other underwood. Oak, ash, and Spanish chestnut should be kept in a nursery for this purpose: alder and birch plants grow plentifully, spontaneously in some countries, and may be taken up for use: if none such are to be obtained, they may be raised from seed sown on a moderate hot-bed in the open air. Alder is sometimes propagated by taking up old roots, and dividing them into several parts; and hazel may be propagated the same way. Willow is generally planted in cuttings; but a much better way, where there are any old willow stocks, is to plash down the shoots to fill up the vacant places round such old stocks. The wild cherry, which will grow on almost any soil, and is easily propagated, makes an exceeding good underwood, though it yet has been but seldom used for that purpose.

Of making Coppices.—In choosing spots for making coppices, care should be taken to select such soils and situations as are proper for the growth of those kinds of wood intended to be planted; to drain them well if wet, and particularly to fence them well from cattle; and if they be covered with bushes and briars, to let those remain for shelter for the young wood; and if there happen to be a moderate quantity of young oak and ash trees on the spot, to let them stand by all means, always keeping in mind how necessary shelter is, for the growth of wood of all kinds and sorts. But in newly planted woods, where all the plants are of the same age, there is not the same reason for letting them stand before they are set off for underwood, as before directed for young trees planted to fill up old woods. Those which are intended for underwood may, in such newly planted woods, be cut off when planted, or at any age from 8 to 14 years, without any injury: indeed, young woods should not stand too long previous to the first cutting.

Of the proper Age for cutting Underwood.—The periods of cutting underwood must be regulated by the luxuriance of its growth, and by the demand of the country, and the uses to which the wood is to be applied when cut. In the article of underwood, not only the interest of money, but the loss of the succeeding growth, tell against the value of standing wood after it is fit to cut, and make it doubly the advantage of the owner to cut his underwood as early as it is saleable. As soon, therefore, as any kind of wood is fit for the uses of the country, it should then be cut; unless it can be made appear, that it will pay compound interest for standing longer, or, in other words, will pay not only the simple interest of the first value, but also the loss of so many years growth of the wood, as so far advanced towards another crop. Wood merely for fuel can scarcely be cut too young. Hazel is usually fit for hurdles and dead hedges, from 9 to 12 years old; ash for sheep cribs, at the same age; and ash and other woods, for hop poles, from 11 to 14 years old; while ash for carpenters and other large uses, alder, birch, and willow, for rafters, turners' uses, pattens, clogs, coalpit uses, &c. must stand from 16 to 20 years old, before the poles are large enough for their respective purposes.

Of the Time of cutting Woods.—Various opinions have been advanced respecting the most proper time of the year for cutting underwood; but there is one rule which, on the seller's part, is without exception, viz. that the older the wood is, the later in the spring it should be cut. When old wood is cut early in the winter, and a hard winter follows, the damage done to the stocks is very great; young flourishing wood will bear cutting at any time. But on the part of the buyer it is allowed that all woods are more durable, when cut in the most stagnant state of the sap; and in all uses where bending is required, such as hurdles, hoops, and even dead hedges, the wood cannot be cut too early in the winter, being, if cut when the sap is rising, brittle, and

unfit for those purposes. Oak underwood will (at the present price of bark) pay well for standing till the sap is up for barking it, and it seldom happens that the stocks are injured by cutting it so late in the season.

Of the Manner of Disposing of Woods.—In our author's opinion, the best way of disposing of underwood, to answer the purposes of the feller, is to cut it *at the feller's expence before it is sold*; to lay it out in ranges or drifts, according to the custom of the country; to value it in that state, and sell it in such sized lots as the number of buyers will warrant; and particularly to oblige the buyers to clear the whole out of the wood by the 24th of June, and never to suffer them to bring their horses into the woods (after any new shoots are shot out) without muzzling them, or at least tying up their heads.

Of Timber growing in Woods.—In every wood where timber will grow, it should by all means be encouraged, and, if it does not come up spontaneously, should be planted. A proper quantity in woods is so far from hurting the underwood, that it is both *necessary* and *useful*, to shelter the underwood and draw it to a proper height; but that quantity must always be regulated so as to do as little damage to the underwood as possible. Oak and ash timber, and in proper soils Spanish chestnut, are proper for woods. Beech should never be suffered. It is a most un-neighbourly tree, and should not grow with any sort but its own—nothing can live under it. When the woods are cut, it is common and proper to cut such timber *as begins to do damage, by its dropping, to the underwood below*. This is the *proper criterion* by which timber in woods ought to be cut, if it be the *wish* of the owner, as it is his *interest*, to keep up that proper proportion of timber and underwood, by which each shall receive benefit from the other, and the land produce the greatest profit which in a state of wood-land it is capable of yielding.

On this subject Mr. Pitt remarks, that with regard to the proper ground for plantations, every gentleman or land proprietor of prudence and taste, who resides on his property, will furnish himself with a shady retreat from the burning sun, that shall afford at the same time a shelter from the storms of winter. For this purpose he will keep up a sufficient shade near his habitation, in that situation which local circumstances shall direct. Large plantations or coppices for profit should not be made on good land; always of much more value for corn or pasturage; but either on moist land of small value, upon a clay or marle bottom, where timber often grows well; or rather, where such land abounds, upon precipices, and sides of hills impracticable to the plough; and where it often happens the land unplanted is of little or no value. He has often observed, that timber succeeds particularly well in such situations; and that making plantations there is attended with many advantages.—
1. The roots of trees twining and interweaving with the soil, prevent its being washed by torrents into the valleys, which is the cause why many such situations are now bare and almost void of soil. 2. The falling and putrefaction of leaves tend to thicken such soil, and render it by degrees richer, and more capable of

forcing the growth of timber. 3. Such land is often of little value, and incapable of being improved in any other way. And I cannot refrain, says he, upon every occasion, from calling particularly upon all public and patriotic societies to confine their premiums for planting, to land of small value, or impracticable to the plough. The corners of fields, where four unite, are not improper places for small clumps in any land: and in hedge-rows a few oaks, elms, or beeches, are a great ornament, without doing an injury: but ash, always very injurious to arable and pasture land, should by no means be planted in hedges, but reserved for clumps and coppices.

Respecting the sorts of wood, oak is undoubtedly the first forest tree; but being slow of growth, the planter can seldom expect personally to reap the reward of his labour: it should, however, be always plentifully intermixed with other sorts, where it will be ready to supply their place, and fill up the ground when its inferior neighbour shall be cut away. He thinks, without a mixture of oak, no plantation can be improved.

Ash is an extremely useful and valuable wood for many purposes, but not very quick of growth; requiring from fifty or sixty to eighty years, to arrive at tolerable maturity. Elm, the common or narrow-leaved, is very proper for hedge-rows and plantations; it makes a large tree in about the same time as ash. Respecting the fir tribe, he says, planters have certainly been rather too partial here, though many of them are of rapid growth. The larch, or Scotch and other firs, will often measure as many feet of timber as they number years of growth, or even more. He strongly wishes, however, that every gentleman making a plantation of firs would intermix at least an equal number of English forest trees, and not forget oak. As such plantation proceeds in growth, the trees least profitable may be cut away. Beech and fycamore are useful, and of tolerably quick growth, and are therefore a proper mixture with other wood. Many instances may be produced of the rapid growth of poplar; and the same individual has been known to plant and cut down poplars containing from sixty to eighty feet of timber each.

The black poplar succeeds best on a moist soil, or by a brook side. The trees of this sort are apt, however, in some seasons to die in great numbers, even when large trees. But the white poplar, or abele, makes a fine large tree, and will succeed on almost any soil. The Lombardy poplar, he observes, so highly extolled some years back, is a mere weed in comparison of our own native trees before named, and little superior to the aspen, the worst of the species. The Lombardy poplar in this country is a pole rather beautiful to the eye, but of no promise as a timber-tree. The wood of the poplar in general makes very good flooring-boards and packing-cases. Some of the willow species are remarkable for quick growth; and the loppings in the hop countries are useful for poles. He also remarks, that among plantations, perhaps that of fruit-trees has been too much neglected.

P A R T III.

OF THE MANAGEMENT OF LIVE STOCK.

WE must now proceed to consider the different management that is necessary for the purpose of breeding, rearing, and fattening the various kinds of animals that constitute the live stock of those engaged in the business of farming.

The proper management of cattle is unquestionably a matter of the utmost importance to the practical farmer, as a great part of his property must constantly consist of this kind of stock,

and the maintenance of them form one of his most expensive engagements. This sort of stock admits of being distinguished under two different heads, viz. The cattle which can be employed in the business of the farm; and such as are for the purpose of sale. Those of the first kind are chiefly horses, though oxen might probably on many occasions be advantageously employed by the judicious farmer.

Horses.—These are of very different kinds; but it is only those of the draught breed, as being applicable to the purposes of agriculture, with which we have any business in this place.

The ingenious Editor of the Transactions of the Bath and West of England Society makes these very just observations on these animals:

Wherever (says he) horses are used in agriculture, it is of great importance to adapt their shape and size to the business required. It is an object worthy of much consideration. Some particular size and properties of the horse must claim a decided preference. It cannot be right to encourage all, or various growths, for similar purposes in similar situations: and there is too great a difference between the expence of a horse, far too big and heavy, and one of sufficient size to answer the end (whether we consider the *keeping*, the *movement*, or the *casualty* which attaches to large and costly horses), that the prejudice for *show* seems to require much correction. It is a known fact respecting this animal, that strength of bone and sinew is not in proportion to largeness of size; but they are found to be dense and strong as the horse approaches in fineness, even to the racer. And those farmers who have made close remarks on this subject, and have given a fair trial to the lower compact horses, not fifteen hands high, but of good symmetry, have found and must find their account in using them. Perhaps a stronger proof cannot well be urged in favour of a diminished size, than the well known capability for great labour, even of the small horses of the New Forest, when trained to waggon uses. This is a fact which, if duly reasoned from, would remove much prejudice, and do much service to the country. One strong inducement to many capital farmers to breed and train colts of the largest size, is the demand for dray-horses in the capital, and the large prices they bring: but these inducements cannot operate generally; and perhaps, in most instances where they do operate, they influence too far for individual or general advantage.

The kinds of *draught horses* most in use at present seem to be the *heavy-blacks* from the Midland counties, the *Suffolk punches*, and those from *Clydesdale* in Scotland. The *Lancashire* and *Yorkshire horses*, with crosses of different breeds, are also frequently employed in agriculture in different parts of the kingdom. Those of the latter county are in general in high estimation for the purposes of the saddle.

In the breeding of horses, particular attention should be paid to the choice of brood mares and stallions. This is constantly done in those counties which are the most famed for their breeds of horses. Almost every thing, says Mr. Marshall in his *Rural Economy of Yorkshire*, depends upon the mare. What are a few guineas in the first purchase of a good mare, compared with the difference between a race of good and of ordinary horses!

In Norfolk, the horses for agricultural purposes are short and compact, as well as active and hardy, and generally about fifteen hands high. Those of the original standing, and those with the Suffolk cross, in the opinion of Mr. Kent, are equally good.

In the Isle of Shepey, the horses for the plough are bred principally from a sort that has been in the idle time out of mind. The mares are covered by stallions that come over from other parts of the county in the season; they are somewhat of a size smaller than those of other parts of Kent, where the land ploughs much lighter. Whether smaller horses are found to answer best there, it is not easy to determine; but it is natural to suppose, that such very stiff heavy land must require strong horses; it seems, therefore, that the breed of them here is become small from neglect; and it would perhaps be better if more attention was paid to the breeding and rearing the colts in these parts.

In Dorsetshire the farmers pay but little attention to the

shape, size, or symmetry of the cart-horse. The stallions are chiefly working-horses of farmers, and cover mares at half a guinea each for the season; and an average price for a cart-horse, at five years old, is sixteen or seventeen guineas.

In Staffordshire, Mr. Pitt says, the colour of the horses is most generally black or brown, each being equally esteemed, and equally useful; and some valuable stallions are kept of each colour. But in respect to the breed of horses, he thinks this county must yield the palm to the neighbouring ones of Leicester and Derby: indeed, breeding horses is by no means a main object, being carried little farther than to supply the county, and also the neighbouring fairs with a few.

Feeding Horses.—To determine with accuracy what is the most economical and advantageous plan of feeding and managing horses, would be a matter of much utility to the farmer; but it is a subject of considerable difficulty, and which cannot be considered fully in this place.
