The methods of feeding and managing these animals are very different in different counties; but the two principal articles of their food, especially in winter, are mostly hay and corn. If artificial grasses were employed for working horses, cut green, the Earl of Dundonald suggests, that a very few acres would suffice. The plants best adapted for this purpose are red clover, tares, and sainfoin. The same author also thinks, that it is a matter of great importance, that the food intended for working horses should be so prepared, or of such a nature, as to allow them quickly to satisfy their hunger, that more hours may be allotted for rest during the interval afforded from labour. When thus fed in stables or farm-yards with green clover, tares, sainfoin, &c. unless on extraordinary occasions, he thinks they do not require oats or other grain; but in the winter or other seasons, when fed on dry hay or straw, and when occupied in the business of the farm, a supply of oats, other grain, or nourishing food, is found to be indispensably necessary. Oats, mixed with beans or pease, is the grain generally given, although (says he), when barley is at a certain price, it would be an object of economy to make use of it in lieu of oats. The horses in Spain and Portugal are exclusively fed with barley, to which they give a preference. The greater proportion of meal or farinaceous matter contained in barley than in oats is certainly in favour of this practice. By the breaking of grain, by passing it through rollers, or crushing it in a mill, horses, not being ruminating animals, must receive considerable advantage, and the loss or waste, by swallowing their corn whole, be prevented. Barley boiled in sea water, or with a due proportion of sea salt, is also a good support for hard working horses. These economical modes of feeding horses (says this ingenious writer) have been confirmed by several years experience in keeping the horses of a colliery.

It is not, however, the author observes, to be understood that a preference should be given to the feeding of horses with broken or ground corn, instead of potatoes or carrots, which judicious application of these roots is now becoming very general; nothing farther being meant by the above statement, than, that those who may prefer the use of grain should be made acquainted with the best and most economical manner of giving it. This is also equally applicable in the feeding of horses and other cattle on malted corn.

The use of malted instead of raw grain is probably the most judicious way of feeding horses and other cattle. Malted corn, says the same author, tends to open the body and cleanse the intestines, without injury to the health of the animal.

On the principle of a greater utility being derived from substances employed in feeding animals, from their being cut or bruised, as suggested above, Mr. Lawton has lately proposed in a very ingenious Essay the using of different kinds of mixed and compressed fodders; a method which he thinks will be found

highly beneficial for horses as well as other cattle when it becomes in general use. By employing cut and compressed food, he supposes that racks will be nearly abolished in the stables, especially where many heavy horses are kept for the purpose of labour either in the cart or field. By adopting this plan in the feeding of animals, a saving in the consumption of the ordinary food of full one-eighth part will be made, as well as a material advantage arise from the facility of using many coarse kinds of herbage mixed in this way with the common food, such for instance, as the haulm of pease, beans, and potatoes, the tops of carrots, &c. and the young branches of fir-trees, &c. By this means, he therefore imagines that the quantity of cattle herbage may be increased in a very extensive manner.

The Comparative Utility of Horses and Oxen in Husbandry.—This is a matter which has engaged much attention, and which is yet by no means fully determined. Horses are however most generally employed for the purposes of agriculture. The reason of this (says Mr. Pitt) seems to be the great superiority of horses as to dispatch, and with which a less number of servants will do the same business, than can possibly be done with oxen. This, he thinks, is not theory, but the result of experience.

Mr. Kent, however, tells us in his Survey of Norfolk, that if it be a fact, which cannot be disproved, that oxen, in some sort of work, are equal to horses, in these cases they certainly ought to be preferred, because they are kept at considerably less expence, and less casualty attends them. It would evidently be very much for the advantage of this country, if oxen were in higher estimation than they are: upon every farm where three teams are kept, one of them, he thinks, ought to be an ox team; for though oxen would not, perhaps, entirely answer the end, to the total exclusion of horses; there is undoubtedly a great deal of work that they would do as well, particularly in carting and all heavy work. In most instances, they are nearly equal to horses, and, in their support, they are full thirty per cent. cheaper. At present no farmers use them in Norfolk; but Mr. Coke, Mr. Colhoun, and some few other gentlemen, occasionally do; and possibly their example, ere long, will be followed by the farmers in general. It was with infinite satisfaction, says he, that I some time since learned, that Lord Hawke, whose experiments in husbandry are very extensive in Yorkshire, has there set an example of ploughing with two oxen to a plough only, which is attended with complete success, as they plough nearly as much as an equal number of horses; and if the cheapness of their keep, and other circumstances in their favour, are considered, they are certainly preferable to horses. There is, in that country, a strong prejudice against this generous animal, which is the first thing to get over: when that can be removed, the credit of the ox will soon follow. The principal advantage which the farmer would derive from oxen, is in the moderate expence of their keep, and in their being attended with less risk. The best way is, however, not to over-work them; for in that case, they will require rather more hay than a horse, and half as much corn; and if they are suffered to fall into low condition, it will require considerable expence and time to get them up again.

The plan found to answer best he describes thus: Suppose four were called a team, which, in this county, would be enough, and that one man was appointed to attend them; I would advise six, instead of four, to be the team, as one man might attend them at the same expence as four; but I would only work four of them at a time, and let two of them rest two days out of the six; by which means they would, in fact, work only four days out of the seven. In the summer months they should have a leasow or pasture to run in, where there is plenty of water and an open shed, where they should have a bait, the day they were worked, of green vetches, cut grafs, or any thing the farm might furnish. In the winter, they should be kept in

a yard, with the same sort of shed for them to run into at pleasure; and here they should have plenty of barley or oat straw, and offal turnips, and in the days of working, cut hay and straw, mixed in equal proportions, instead of straw, and turnips besides. In this manner they will in general do extremely well, and will at all events earn as much as the value of their keep; so that their work will be had for nothing. Another great advantage is, that in case of falling lame, there is no diminution by that means in their value, for if their shoulders do not return a profit their ribs will; but if a horse falls lame, at least half his value is lost. So far, says he, we shew the advantage of the ox to his employer—but to the public the advantage is superlatively striking. The ox, when labouring, does not consume so much corn as the horse, for, according to my plan, he would not consume any; and when his labour is done, his body goes to the nourishment of men; but the body of the other is good for nothing but to feed dogs. The more the number of horses can be lessened, the better for all ranks of people. The consumption by horses, especially horses of pleasure and luxury, is astonishing; for though a horse, in agriculture, does not consume above three acres of the fruits of the earth in a year, a horse kept upon the road eats yearly, in hay and oats, the full produce of five acres of land;—man, allowing him a pound of bread, and a pound of meat a day, or in that proportion, not quite an acre and a quarter; and as the poor eat but very little meat, it cannot be put at more than an acre to them: so that one of those horses eats nearly as much as five men. The more, therefore, we reduce our number of horses, the more plentiful will be the fruits of the earth for man.

On this subject, however, a Norfolk farmer thinks somewhat differently. He is of opinion that horses are preferable to oxen, and would use them even in farming in Scotland. Horses can do all the work of a farmer of every description, which oxen cannot, at least to the same advantage. For instance, all kinds of land, at certain times, is the better for quick harrowing, to make it ready for sowing grain; the strong lands to break the clods, and the light land to separate the mould from the weeds, which prevents their vegetation. But with oxen you cannot harrow quickly: besides, it is often necessary to travel quickly with empty carts in harvest time; to expedite the business of a farm, or to carry grain to a distant market for sale, or to send for manure, so as to have but one day's journey. On all such occasions horses are preferable; and on an average it may be stated, that two good horses will do as much work to a farmer as four good oxen.

The observations of Mr. Henry Harper, an excellent Lancashire farmer, also merit attention. "I am no advocate (says he) for horses in preference to oxen; but prefer that mode in which business can be done with most ease and least expence.

"I have on my farm some strong heavy land as any in the kingdom, and some as light. Three horses, with the allowance of two bushels of oats per week each horse, are able to plough an acre a day in the heaviest and strongest land (if ever broke up before), and plough it to any depth from four to eight inches at a proper season of the year. When a second ploughing is necessary, two horses will be sufficient to plough one acre and a half per day in the spring or summer months, and by which there is a spare horse for harrowing in the seed, or any other extra work. I plough single, or the horses abreast, as suits the nature of my work the best.

"The average work done upon the heavy and light soils on my farm with a three-horse team, is seven statute acres per week the year through, which, at 7 shillings per acre, is 49 shillings per week, and have a spare horse eight weeks in the year out of this team. My ploughs are the common swing ploughs with cast-iron mould-boards, of different degrees of

strength, according to the nature of their work and land under tillage. Single or double wheels may be used with these ploughs, as occasion requires, and drawn by a chain fixed to the axis of the plough.

“The calculation of the first purchase, and keep of three horses for one year, is this :

	£.	s.	d.
Three horses, at 25 <i>l.</i> each	75	0	0
Harnes for ditto, at 4 <i>l.</i> 4 <i>s.</i> each	12	12	0
Oats, at 6 bushels per week, for 6 months	19	10	0
Oats, at 3 bushels per week, for 6 months	9	15	0
Hay for six months, at 1 <i>l.</i> 1 <i>s.</i>	27	6	0
Grass and green crops for six months, at 15 <i>s.</i> per week	19	10	0
Wear and tear of two ploughs, per annum	3	3	0
Wear and tear of horse gear, per annum	1	5	0
Horse-shoeing, at 10 <i>s.</i> 6 <i>d.</i> each horse	1	11	6
Farrier	0	15	0
	170	7	6
Prime-cost, &c. of ox-team,	147	0	0
In favour of the ox-team, balance	£.23	7	6
My horse-team will earn 49 <i>s.</i> per week per annum	127	8	0
Profit on two young horses each per annum, besides eight weeks rest for one horse, or any extra work	2	0	0
	129	8	0
The ox-team will earn 30 <i>s.</i> per week for nine months	£. 54	0	0
Profit on the oxen	8	0	0
	62	0	0
	67	8	0
Balance in favour of the ox, first purchase	23	7	6
Neat balance in favour of the horse per ann.	£.44	0	6

“The above statement is what a horse team will do on my farm, and I think may be done upon any farm in England, where they have proper implements and properly applied.”

Mr. Boys observes, that the Weald is the only part of the county of Kent where oxen are generally used for draught. Here it is common to see horses and oxen together, both in the plough and on the roads; eight or ten oxen, with a horse or two before, to lead them along: frequently ten oxen, without any horse, are seen drawing a plough; which he thinks would be much more expeditiously done by four horses. An acre a day is the common yoke for eight or ten oxen in wet, heavy land, where four horses would plough an acre and a quarter. On farms having a greater portion of rich meadow than arable, it perhaps may be proper to employ oxen as beasts of draught, because they are in a growing state, and increasing in their value to fatten; and because they are fed at a small expence on good pasture-land: but on farms not having a greater portion of pasture than arable, and that pasture not being rich good land, the expence of supporting the requisite number of oxen exceeds the expence of supporting the requisite number of horses. There is besides another disadvantage attending the use of oxen: the slowness of their pace is apt to lead the ploughmen into slothful habits, which are seldom got rid of. By some it is contended, that oxen are so valuable to fatten when they have worked for five or six years, that, on that account only, they ought to be more used as beasts of draught: but it should be recollected,

that horses, when they have worked the same time, are more valuable than oxen, because they will then sell for more money, and will work eight or ten years longer; during which time they will earn by their labour perhaps double the value of a lean ox at nine years of age; and therefore the value of an ox, after working five or six years, is not a sufficient argument to recommend them for general use. When horses have laboured a great many years, as a great many do, they owe their masters and the public nothing: and therefore they ought not to be condemned as beasts of draught, in favour of oxen, when their labour is done, and because they are only fit for the hounds. In short, neither of these animals is to be generally recommended in preference to the other. Nature has provided situations best adapted for each of them.

Breeding Cattle.—It is a fact at present very well known, that the breeding of cattle is highly advantageous to the farmer. It must not however be supposed, that in order to derive advantage from cattle, it is alone sufficient to have a great number, and to give them the necessary fodder: there are many other circumstances to be attended to, without which it will be in vain to expect much profit from them. They are frequently kept in too narrow cow-houses, whence many inconveniencies arise. Besides being liable to hurt one another in these cases, the most voracious starve their neighbours, from whom they carry off all the fodder within their reach; and the injured cows insensibly decay, become languid, or give little milk. In summer the heat incommodes them; a circumstance which makes them grow lean, and diminishes the quantity of their milk. Care must therefore be taken that they have sufficient room in their stalls; that they be cool in summer and warm in winter. At all seasons they should be kept dry, for that is a material point. Even in summer, wet is disagreeable to them, and in winter it chills them. To prevent this double inconvenience, it will be proper to pave the cow-houses on a gentle descent, and to dig a pit to collect all water and stale. By this means the cattle will lie always dry, and the stale be collected for many useful purposes.

The principles of improvement in breeding cattle in the midland counties, where much attention is paid to the business, as detailed by Mr. Marshall, are the following: The most general principle is beauty of form; a principle which has been applied in common to the different species. It is observable, however, that this principle was more closely attended to at the outset of improvement (under an idea, in some degree falsely grounded, that beauty of form and utility are inseparable) than at present, when men who have been long conversant in practice, make a distinction between a useful sort and a sort which is merely handsome.

The next principle attended to is a proportion of parts, or what may be called utility of form, abstractedly considered from the beauty of form: thus, of the three edible species, the parts which are deemed of use, or which bear an inferior price at market, should be small in proportion to the better parts. This principle, however, appears to have been differently attended to in different species; and will require to be examined, in taking the separate views of each species.

A third principle of improvement, which has engaged the attention of the midland breeders, is the texture of the muscular parts, or what is termed flesh; a quality of live stock, which, familiar as it may long have been to the butcher and the consumer, has not, perhaps, been attended to by breeders, whatever it may have been by graziers, until of late years in this district; where the flesh is now spoken of with the same familiarity as the hide or the fleece; and where it is clearly understood, that the grain of the meat depends wholly on the breed, not, as has been heretofore considered, on the size of the animal.

It appears however, in the practice of Yorkshire, of late years, that circumstances led the breeders of that country to pay some attention to the flesh of cattle; and he has been informed by a gentleman conversant in the Herefordshire breed of cattle, that similar circumstances took place, and probably about the same time, in that quarter of the island.

But the principle which at present engrosses the greatest share of attention, and which, above all others, is entitled to the grazier's attention, is fat, or rather the fattening quality: that is, a natural propensity to acquire a state of fatness at an early age, and, when at full keep, in a short space of time: another quality which is found to be hereditary, or depending, in some considerable degree at least, on breed, or what is technically termed blood; namely, on the specific quality of the parents.

Thus it appears, that the midland breeders rest every thing on breed; under a conviction, that the beauty and utility of form, the quality of flesh, and its propensity to fatness, are, in the offspring, the natural consequence of similar qualities in the parents: and, what is extremely interesting, it is evident from observation that these four qualities are compatible, being frequently found united, in a remarkable manner, in the same individuals.

Without admitting, or endeavouring to confute, in this place, that the four qualities here explained are the only ones necessary to the perfection of the several species of live-stock now under review, we pass on to the means whereby those principles have been applied, in attaining the degree of perfection at present observable in the district under survey.

The means of improvement, in the established practice of the kingdom at large, are those of selecting females from the native stock of the country, and crossing with males of an alien breed; under an opinion, which has been universally received, that continuing to breed from the same line of parentage tends to weaken the breed.

Rooted, however, as this opinion has been, and universally as that practice has prevailed, there is little doubt of the fact, that the superior breeds of stock of this district have been raised by a practice directly contrary; that of breeding, not from the same line only, but the same family: a practice which has now been so long established, as to have acquired a technical phrase to express it. Breeding *in-and-in* is as familiar in the conversation of midland breeders, as *crossing* is in that of other districts. The sire and the daughter, the son and the mother, the brother and the sister, are, in the ordinary practice of superior breeders, now permitted to improve their own kind; and through the assistance of this practice, the bold leader of these improvements evidently produced his celebrated stock.

The argument held out in its favour is, that there can be only one best breed; and if this be crossed, it must necessarily be with an inferior breed; the necessary consequence of which must be an adulteration, not an improvement.

How far this novel practice may, in a general light, be considered as superiorly eligible, would be improper to be discussed in this place. To this intent, it must be understood, that although much has probably been done by breeding *in-and-in*, much also has been done by crossing; not, however, by a mixture of alien breeds, but by uniting the superior branches of the same breed.

The degree of excellency obtained, however, through these means, is not more remarkable than the rapidity with which the improvement of the several breeds has been carried on and extended, not over this district only, but to various parts of the island.

But these circumstances likewise have arisen principally out of a mere point of practice, which, though not peculiar to this

district, is no where, he believes, equally prevalent (except in Lincolnshire), and enters not, in any degree, into the practice of the island at large, in which breeders of every class rear or purchase their male stock.

Here, on the contrary, breeders mostly hire them by the season, of a few leading men in the line of breeding males for the purpose, returning them at the end of the season to their respective owners, who, during the time of letting, have their shows or exhibitions, to which dairy-men, graziers, and stallion-men repair, to choose and hire males for the coming season.

The breed of the midland counties is the long-horned kind.

Feeding and Fattening Cattle.—For the purposes of fattening, cattle are generally bought in the spring, and about Michaelmas. Those which are bought at the former period will be ready for the butcher in the summer, according to circumstances; but those that are purchased at the latter season are either to sell in winter or in spring: they ought to be forward in flesh to be improved the beginning of winter, and kept up during that hard season, either with burnet, hay, turnips, carrots, &c. in order to be fit for a good market whenever it offers; or they may be young lean cattle, which by their growth may pay for their wintering, and be fit to fat the next summer. Some farmers upon ordinary land buy in young Welch heifers, which, if they prove with calf, they sell in spring, with a calf by their side, for the dairy; and those that are not with calf they fatten: all which ways may turn to good account; but most commonly meat is one-third dearer in winter and spring than in summer, as the convenience either of hay, turnips, &c. to fatten cattle with in winter is but in few places.

In the wintering of cattle, it is necessary about September to turn out those you design to keep up for a winter or a spring market, and the cows that give milk, into rough pastures, till either snow or a hard frost comes on, as by that means they will need no fodder: but when either snow or frost comes, hay must be given to such cows as are near calving, or those that have lately calved, or that give a great deal of milk, and also to your fattening cattle. This must be done every morning and evening, in proportion to the quantity of rough grass, &c. that there may be upon the ground. But for the lean cattle, those that give but little milk, straw will do well enough to fodder them with; only you must observe to give barley-straw first, and the oat-straw last, except you value your milk: if you do, give such cows your oat-straw, provided the quantity of milk they give do not deserve hay, or hay be scarce; for barley-straw will take away the milk they have, though it is good food for dry cattle. When hay and carrots fail, scalded malt-dust and grains are frequently given to cows in winter, which makes them give a great deal of milk; the latter is, however, apt to rot them, if given in too great quantities, and continued too long.

When the pastures are eaten up, the milch-cows must be housed, and hay be given them in the cow-house, and to the other cattle in the yard; for which purpose two yards are necessary; one for the cattle which eat straw; with racks and other conveniences to fodder them in. They should be fed often, and not have too much at a time. The yards ought to be well sheltered, and made as dry as possible, and a good deal of straw given them to lie dry and warm in; which is equally advantageous to the cattle and the increase of dung.

For the feeding off land, beasts and horses may be introduced together, or beasts first, and horses afterwards; and after both, sheep. But the grass should not be too rank before it be fed.

Cattle are frequently fed in winter with rye straw, mixed with a little hay; with the straw or haulm of buck-wheat; with the leaves of white beet; with turnips, the turnip-cab-

bage, carrots, cabbages, burnet, and the bruised tops of furze, &c. as has been already mentioned.

All fattening cattle, whether lambs, sheep, barren cows, or oxen, require a proportionable progression from coarser to better food, as they grow more and more into good flesh; otherwise when half fat they will go back, and are with great difficulty raised again, which is obviously a great loss to the farmer.

Farmers in some parts of the country are in the habit of fattening oxen, and other cattle, in stalls, on potatoes and hay, or straw; others on turnips and cabbages, and hay or straw; and likewise on oil-cake and hay. By these means the cattle are frequently made very fat: but it is generally observed by the most experienced men, that this system is not profitable, the chief advantage being that of raising a supply of good manure for the arable lands: a consideration which by some is not thought to be of sufficient importance to pay for the risk and trouble of attending stall-fed oxen. This practice therefore seems to be on the decline.

Cattle when fed with cabbages dung more, and make less urine, than when fed with turnips, and drink little water, which seems to prove that they are a better food for them than turnips. All cattle fed in this manner should have about seven pounds of hay a day allowed to each.

In Kent, some graziers buy Welch calves in the autumn, put them out to keep in farm-yards for the winter, and in the spring place them among their sheep, where they get fat in a few months, and weigh from eighteen to twenty-two score each.

The cattle which are fatted in Wiltshire consist chiefly of long-horned cows, turned off from the dairies, and of oxen brought from different counties, particularly from Devonshire. They are usually bought in very early in the spring, so as, if possible, to be finished with grass; but the largest and latest are taken into the stalls, and finished with dry meat, chiefly hay. Corn is but little in use for fattening cattle in this district; of late, potatoes have been introduced for winter fattening, dressed with steam, and mixed with cut hay or straw, and found to answer very well.

Mr. Pitt, in his Survey of Staffordshire, observes, that all good stock must be both bred with attention and well fed; and perhaps it is necessary that these two essentials in this species of improvement should always accompany each other; for without good resources for keeping, it would be in vain to attempt supporting a capital stock, and with such resources it would be absurd not to aim at a breed somewhat decent in quality. He coincides in opinion with Mr. Miller, that gentlemen of fortune should procure, for the use of their tenants, the best bulls, rams, stallions, &c. This, says he, if they did not choose to do *gratis*, might easily be thrown upon a plan to indemnify expences, and would tend very much to facilitate the improvement of the stock of the smaller farmers. The great object in the produce from horned cattle being, first, milk; second, beef; the uniting of these two products in the greatest quantity from the least food or produce of land, seems the ultimatum of breed. It has often been observed, that cows with the best disposition to fatten, not only give the least milk, but soonest go off their milking; whilst a loose, open, ill-made cow will both give a larger quantity, and continue it longer; but it is not so easily fatted, nor without much more time: the uniting of these two qualities in the highest degree is therefore the true desideratum of breeding.

The cow-stock of Mr. Princep, an excellent Derbyshire breeder, is of the long horned breed, and by long attention have been brought to a very high degree of superiority; large, thick, heavy, and well-made, with a pretty good show for milking, and such a disposition to fatten, that he says the young stock are obliged to be almost starved by short pasturage,

otherwise they run fat and never stand the bull: the cows give upon the average about eight quarts of milk each, a day, which the owner thinks equal, from its superior quality, to a much greater quantity from inferior breeds.

A Norfolk farmer says, that from all the experience he has had, he prefers the Argyll or west Highland breeds of cattle. He considers them to be the most profitable cattle in Great Britain, for fattening. If bought at about four years old, they both grow in size, and fatten at the same time, and make a very quick return of profit. They are horned, generally black, and weigh, when fattened, about 560lb. or 40 stone, at 14lb. to the stone (16 ounces to the pound). That medium size is always sure to fetch the best price at market.

And Sir John Clerk, whose attention to rural improvements is well known, is decidedly of opinion, that the Galloway breed is by far the best species of cattle for the greatest part, if not of Scotland in general. The Highland cattle are certainly excellent, both in regard to shape and hardiness; but they are of so wild a nature, and so untameable, that they cannot be fattened half so quickly. Poll'd animals, of every species, are always of a tamer and more quiet disposition than the horned, and consequently are more easily fattened, and at less expence. Poll'd cattle, it is well known, are also much better calculated for working, and for being driven in droves, or great numbers at once; and it is well known, that no sort of cattle sell better in England than the Galloway.

In Lancashire, Mr. Holt remarks, that amongst the cow-keepers all varieties are found: they change so frequently, that when a cow, likely to be useful, and at the point of dropping calf, is brought to the market, they purchase it, without paying much regard either to the species or country. Some farmers have introduced upon their farms the Suffolk polls; and they have been found to stand the climate, although they have a thin skin and fine coat; and they have, upon proof, been found to answer so well in milking, that frequent applications have been made for the purchase of them. These stock seem well calculated for the spongy soft lands, being lighter upon the surface than the long-horn. But others have hitherto preferred the Holderness. But the long-horn of the true Lancashire breed is the prevailing stock, and seems in general well adapted to the soil; doing less damage to the clay lands than the heavy Holderness, and being much esteemed by the feeder and butcher for their carcase. Mr. Orme of Derbyshire tried nine Holderness cows against nine Derbyshire cows of the improved sort: the former gave the greatest quantity of milk, but that of the latter was considerably more productive of butter and cheese. By the improved Derbyshire cow is meant such as was bred by crosses from the Lancashire, Warwickshire, &c. and what the Leicestershire breeders and others call the old-fashioned sort, before delicacy of flesh, and the feeding properties, were so much attended to. This sort of cow is generally the home-bred stock of Derbyshire.

In West Kent, where the dairies are small, the cows are home-bred, between those of Staffordshire, Wales, and Sussex; but some of them, which consist not of more than three or four cows, have the Welch sort only.

Lately indeed some cows have been brought from the islands of Alderney and Guernsey, for the use of the dairies of gentlemen's families. These are a small ill-made kind of cattle, but remarkable for giving milk of a very rich quality, which yields a greater portion of cream, and makes more butter from a given quantity than that of any other kind of cattle: the butter too is of a beautiful yellow colour, and highly esteemed for its fine flavour. Whether, however, these kinds of cows will preserve their superiority in this respect many years, if bred and kept in this country, time only can discover; but it is most probable, that soil and climate will operate in the course of

time, so that there will be no perceptible difference in the quality of the cream and butter between these and common English cows.

Mr. Robertson, in his able Survey of Mid Lothian, says, he has found good and bad milch-cows of all different shapes, sizes, and complexions, without a single circumstance to discriminate them, but one only, and even that not uniformly certain, which is the size of the neck, as all good milkers in general have the neck small. I have, continues he, just now two, that in every circumstance, of colour, height, and shape, are as unlike to one another as a bull-dog is to a spaniel; but yet in respect to milk and butter, they are similar to a fraction; having frequently caused their milk to be measured, kept separate, and churned each by itself; and have always found the same quantity in both, viz. from 8 to 12 Scotch pints of milk, and from 20 to 24 ounces of butter in the day. They are very large, and have a reserve of the best grafs to themselves. From their size, they require a longer time to get fat than the smaller sorts: they usually weigh from forty-five to seventy score each.

In the Survey of Wiltshire, it is observed, that many attempts have been made lately to supplant the long-horned cows, by introducing the Devonshire kind into this district. The comparative merits of the two species are very warmly contested: the Devonshire cow, undoubtedly, gets ripe at an earlier age than the long-horned cow, and, being a smaller animal, is less liable to tread and poach out the wet lands; and being disposed to get fat at an early age, and when fat of a greater comparative value to the butcher than almost any other kind, is much better calculated than the long-horned cow, for those who breed for the purpose of fattening.

How far these properties, particularly that remarkable disposition to get fat at an early age, may answer the general purpose of a dairy, where milk alone is required, remains to be proved. It is possible, that each of the two kinds of cows may be most proper for the particular purposes for which they are kept. But the supporters of the Devonshire cows say, that they are equally good milkers with the long-horned species; and yet, that they are so much smaller, and eat so much less food, that three of these may be kept on the same land as will keep two long-horned cows. If this can be proved, the question is decided at once.

Thus there seems an increasing opinion of the merits of the Devonshire kind; and, perhaps, if half so much care and attention had been paid to the breed of the Devonshire cows, as has been bestowed on the long-horned kind, it is probable that the former might have been still more improved, and that the comparison might have been much more in their favour. Whatever may be the real comparative merits of the two kinds of cows for the dairy, there is not a doubt but the Devonshire kind are the most proper for fattening; and as to the oxen bred from the two kinds, it would be injustice to the Devonshire oxen, even to make a comparison between them.

The ingenious Doctor Anderson seems to think it probable, that in feeding of cattle, the progress which they make will be nearly in proportion to the quantity of nourishing food that they can be induced to take, above that which is necessary merely for their support. But, says he, I know of no fact that has been yet brought forward, which clearly ascertains whether the degree of melioration is exactly in proportion to the *surplus* food of any sort that an animal can be brought to eat in a given time, though the probabilities are greatly on that side. Neither do I know if it be an universal rule, when animals of *different kinds* are compared with each other, that those kinds which can be made to eat, in a given time, the greatest quantity of food, can be the soonest fattened.

The same author also thinks, that *condiments* might be employed in feeding animals, with great advantage. In the fat-

tening of calves, some attention has been paid to this matter. I have met, says the above author, with few persons who have had an extensive practice in this department, who are not sensible that the profit is in proportion to the quantity of milk that the creatures can be induced voluntarily to take in a given time. The vast importance of studying the taste of the creatures they feed has, he observes, been seen by many, that they may not only furnish them with the kinds of food they like best, but also to vary these from time to time, and to give them exactly in the quantities, and in the way that they find will induce the creatures to eat the most. In this branch of rural economics, continues he, I have met with no person who has made greater progress than a plain practical farmer at Hope, in the neighbourhood of Manchester, who spares no trouble or expence in procuring such kinds of food and condiments as he finds best calculated to induce his cows to consume, in a given time, the greatest quantity of food possible. The consequence is, that this man makes much money, where his neighbours, who are not in the secret, and more niggard in their outlay than he is, sustain a loss. Among other condiments, this man has discovered, that *pure water* stands pretty high in the scale; on which account his beasts are never suffered, far less obliged, to taste a drop of water that has ever been sullied by any animal setting a foot into it. With this view, they are always served with running water, which is, for their convenience, received into a long wooden trough, through which it passes while they are drinking.

Common salt may also be used with advantage in the way of condiment. There is no substance yet known, says the same author, which is so much relished by the whole order of *graminivorous* animals as common salt. It has been found by those who have made the experiment, that salt given along with the food of domestic animals (except fowls, to which it is a poison) tends very much to promote their health and accelerate their feeding. The way in which this substance is supposed by the author to produce its beneficial effects, is by acting as a condiment, thereby whetting the appetite, and giving the creature to which it is properly administered, a strong relish for its proper food, so as to induce it to eat a greater quantity than it otherwise would have done *in a given time*, and thus greatly augmenting, as has been just explained, its feeding quality beyond what it otherwise could have had. In this way, the same author thinks, it is not an extravagant position to say, that by a proper use of common salt, the same quantity of forage might, on many occasions, be made to go twice as far as it could have gone in feeding animals, had the salt been withheld from them.

We must however observe, that the salt laws as they stand at present operate very much against any improvement in fattening animals on this plan.

For *fattening* of cattle, *hay* should be of the very best quality, as one stone of hay of an exceeding fine quality will go as far in *feeding* beasts, as four of an inferior quality. Indeed no hay but that of the best quality will fatten beasts at all. But for this purpose, the Doctor says, it may frequently be necessary to mix the *hay* with grafs; but for rearing young beasts, or other purposes, it will be highly economical to make use of straw for this purpose; for straw of oats or barley, when thus mixed with grafs, will be equally good as ordinary hay. If economy were duly studied by farmers, perhaps not one particle of those kinds of straw should ever be employed in any other way. Nor could the possessor of *corn* farms ever be at a loss for making such an intermixture, as he will find it profitable always to have as much ground under clover, as would be sufficient thus to mix the whole of his straw, if he were inclined.

Mr. Henry Harper's *Method of feeding Cows* is deserving of the attention of those who are engaged in dairying. There are,

says he, seasons in which it is so very difficult to make good hay, that much will be damaged although the greatest attention be paid; the consequence of which is, the milk given by the same cows is less in quantity, and of inferior quality; the butter both loses its natural colour and good flavour; to remedy which, this ingenious farmer takes the following method: He provides some sort of provender for his cows; that is, some species of ground grain; and to mix with it, he procures some hay of the best quality, and from the most fertile lands, which he treats in the following manner: This rich hay is to be used as an ingredient for tea, by pouring boiling water upon it; and the infusion he makes use of to scald his ground grain, chopping the hay, before it is infused, with an engine designed for the purpose of cutting straw; and this hay, so cut to the size of one inch long, is to be mixed with scalded provender, to the amount of two or three quarts to every beast. This mixture of bruised grain, scalded with the infusion of rich hay, and the addition of the hay to the amount of two or three quarts to each beast, improves the flavour of the butter, and restores it to its proper yellow colour.

The same attentive farmer made the subsequent trial, which we shall give in his own words: "I had, says he, one year six cows that I house-fed, all at one time, and nearly all of an age; and by way of experiment, I fed two with turnips and ground corn; and two with boiled potatoes and ground corn; and two with raw potatoes and boiled corn: they were all put to feed at one time; and when I thought them fit for the market, I sold three, one from every lot, and went to see them dressed. In those two fed with ground corn and turnips, and ground corn and boiled potatoes, there was little or no difference; but that which was fed with raw potatoes and boiled corn, was better in flesh, and more fat within side, than the other two, by a fortnight's keep; and this was not only my opinion, but the butcher's who killed them: the other three I kept three weeks longer; and when killed, they were proportionably nearly in the same state with the others, but better by being kept the longer: so I prefer boiled corn to any sort of grain, and think it more forcing, either for milk or feeding. They had all one and the same quantity of corn, &c."

Boiling corn has been practised by some others, with good success. A little linseed improves the quality. Hay feeds, that drop out of the hay, should be carefully preserved, and worked up in mixtures of potatoes or oats, either scalded or boiled. Mr. Holt has experienced the good effects of hay feeds upon his cattle, for many years. An ingenious farmer, lately talking upon this subject, observed, that the seeds of many weeds might be converted to good use; and spoke with confidence of the feeding quality of some of them.

Instead of oil-cake, the linseed boiled, and instead of spent grains from the breweries, barley boiled and mixed together, with the addition of chopped straw, hay-feeds or chaff, have been tried by Mr. J. Balmer, both upon milch and feeding cattle; and with more profit than with either of the residuums.

On the cow management of Lancashire Mr. Holt observes, that those who are supposed to follow the best system, with a proper capital, seldom keep the same cow more than one calf, except some particular favourite. They are purchased at the time of calving, and the calf is immediately sold to feeders for the market, and who keep cows for that purpose, and dispose of their milk, and procure a livelihood that way. The cows, when they fail of yielding a certain quantity of milk (about six quarts per day), are, if in proper condition, disposed of to the butcher: and, if properly kept, to advantage, *i. e.* for more than the first cost.

Some, who regularly change their cows, do it however frequently at the loss of two guineas per head. A cow at drop-

ping calf is generally worth, *cæteris paribus*, two guineas more to the cow-keeper than she would be to the butcher.—If she can be sold after nine months milk, for the first cost, or any advance, it must depend upon the beast being well bought, the season of the year when sold, or extra keep to promote feed.

By Mr. Henry Harper we have also the following statement of the expence of keeping, and produce, of a cow per ann. averaged out of a flock of twenty-five cows, kept upon his farm.—The sales of produce, and expence of keep, are estimated according to the price of the different articles in 1794.

Average butter of one cow for 52 weeks is			
4lb. per week; 208lb. of butter, at	£.	s.	d.
11d. per lb.	-	-	9 10 8
Milk of all kinds, 52 weeks, at 3s. 3d.			8 9 0
Price of calf			0 4 0
Three tons manure, at 4s. 6d.			0 13 6
Cartage saved, by the dung on the premises			0 7 6
			<hr/>
			19 4 2
Expence of grafs for the summer	-	2	5 0
Hay, 160 stone, at 8½d.	-	5	13 4
Provender, 26 weeks, at 3s. 6d.	-	4	11 0
After-grafs or eddish	-	1	10 0
I.ofs in cattle 5 per cent. 9s. per head	-	0	9 0
Cart-horse and keep (to carry the produce to market)	-	0	2 6
Dairy-maid	-	1	0 0
Attendance to milk	-	1	2 6
Wear and tear, mugs, &c.	-	0	1 6
Salt for 208 lb. butter, 16lb.	-	0	1 9
			<hr/>
			16 16 7
			<hr/>
Profit per ann.	-	£2	7 7

The provender, to which the above statement alludes, consists of two feeds, morning and evening, each day, half a peck of potatoes or turnips cut and given raw, value one penny halfpenny; one pint of oats and one pint of barley mixed together, and boiled with chaff, cut straw, bran, or malt-dust, mixed with the potatoe or turnip, value one penny halfpenny, or three pence each meal. The corn is boiled in plenty of water till it bursts, and the water is used in the mixture.

The average milk of the stock of this farmer is seven quarts of milk per day the year through; although some prime cows in their full perfection, and in the height of grafs, may yield when fresh calved eighteen, twenty-four, or even thirty quarts of milk in a day; but this superabundance is but of short duration.—From every twelve quarts of milk is produced one pound of butter, of 18 ounces to the pound.

On the advantages of feeding milch-cows in the house, in preference to keeping them out of doors, Baron d'Alten, an intelligent Hanoverian nobleman, has communicated some observations to the Board of Agriculture, from which the following are extracted.

He remarks, that milch-cows are infinitely more profitable, kept in the house than out of doors; but they must be early trained to it, otherwise they do not thrive. The best kinds of food for them are clover, lucerne, potatoes or yams, turnips, carrots, honey grafs (a German grafs not known in England), cabbages, pease and beans. Such cows as those in the neighbourhood of London, kept in the house, and properly fed, ought to yield nine gallons per day, for the first four months after calving. Afterwards the quantity will become less and less. But on the supposition that such cows yield, at an average, only 6 gallons for 9 months, or 252 days, that at 6d. per gallon produces 3s. per day, or in 9 months, 37l. 10s.

If, from any circumstance, the milk cannot be sold fresh, the profit will be much less, but is still very considerable. Each 5 gallons of milk should produce a pound of butter. Hence, in all, 302lb. worth, at 1s. per pound, 15l. 2s. The butter-milk, for the purpose of fattening swine, should be worth 7l. 11s. Total 22l. 13s. An English acre of a middling soil should produce 20,000lb. weight of green, or 5000lb. of dry clover. A large cow requires 110lb. of green, and 27½ lb. of dry clover per day; consequently in 365 days 40,150lb. or a trifle more than the produce of two acres. Whereas the same cow, fed entirely out of doors, summer and winter, would require the pasture of four acres, the ground would be injured by being poached by their feet, the grass hurt by being bruised instead of cut, and the manure would not be half so useful. According to the first calculation, each acre should produce in milk 18l. 18s.; and by the second, (in butter and butter-milk) 11l. 6s. 6d. besides the value of the manure. It has been found, that carrying cattle, fed within doors, and keeping them as cleanly as horses in a stable, is attended with the best consequences, both in regard to the milk they yield, and the rapid improvement of the carcase.

Management of the Dairy.—This is a matter of considerable nicety and importance, and with which every one engaged in this branch of husbandry should be well acquainted, as considerable advantages may be made by a judicious management of the different processes.

Butter.—Where the object of the farmer is the making of butter, Doctor Anderson observes, that it is necessary to choose cows of a proper sort. Among this class of animals, says he, it is found by experience, that some kinds give milk of a much thicker consistence, and richer quality, than others; nor is this richness of *quality* necessarily connected with the smallness of the *quantity* yielded by cows of nearly an equal size; it therefore behoves the owner of a dairy to be peculiarly attentive to this circumstance. In judging of the value of a cow, it ought rather to be the quantity and the quality of the *cream* produced from the milk of a cow in a given time, than the quantity of the milk itself. This is a circumstance that will be shewn by and by to be of more importance than is generally imagined. The small cows of the Alderney-breed afford the richest milk hitherto known; but individual cows in every country may be found, by a careful selection, that afford much thicker milk than others: these therefore ought to be searched for with care, and their breed reared with attention, as being peculiarly valuable.

Few persons who have had any experience at all in the dairy way can be ignorant, however, that in comparing the milk of two cows, to judge of their respective qualities, particular attention must be paid to the time that has elapsed since their calving; for the milk of the same cow is always thinner soon after calving than it is afterwards; as it gradually becomes thicker, though generally less in quantity, in proportion to the time the cow has calved. The colour of the milk, however, soon after calving is richer than it afterwards becomes; but this, especially for the first two weeks, is a faulty colour that ought not to be coveted. In order to make the cows give abundance of milk, and of a good quality, they must at all times have plenty of food. Grass is the best food yet known for this purpose, and that kind of grass which springs up spontaneously on rich dry soils is the best of all. If the temperature of the climate be such as to permit the cows to graze at ease throughout the day, they should be suffered to range on such pastures at freedom; but if the cows are so much incommoded by the heat as to be prevented from eating through the day, they ought in that case to be taken into cool shades for protection, where, after allowing them a proper time to ruminate, they should be supplied with abundance of green food

fresh cut for the purpose, and given to them by hand frequently in small quantities fresh and fresh, so as to induce them to eat it with pleasure. When the heat of the day is over, and they can remain abroad with ease, they may be again turned into the pasture, where they should be allowed to range with freedom all night during the mild weather of summer.

Cows, when abundantly fed, should be milked three times a day during the whole of the summer season, in the morning early, at noon, and in the evening just before night fall. For if they be milked only twice in the day, while they have abundance of succulent food, they will yield a much smaller quantity of milk in the same time than if they be milked three times. In the choice of persons for milking the cows, great caution should be employed; for if that operation be not carefully and properly performed, not only the quantity of the produce of the dairy will be greatly diminished, but its quality also will be very much debased; for if all the milk be not thoroughly drawn from a cow when she is milked, that portion of milk which is left in the udder seems to be gradually absorbed into the system, and nature generates no more than to supply the waste of what has been taken away. If this lessened quantity be not again thoroughly drawn off, it occasions a yet farther diminution of the quantity of milk generated; and so on, it may be made to proceed in perpetual progression from little to less, till none at all is produced. In short, this is the practice in all cases followed, when it is meant to allow a cow's milk to dry up entirely without doing her hurt.

After stating some facts respecting the properties of milk, which seem to be founded on experiment, such as that the first drawn milk is always thinnest, but continues to increase in thickness to the last; that the portion of cream which first rises to the surface of the milk is thicker, of better quality, greater in quantity than that which rises in a second equal length of time; that thick milk throws up a smaller quantity of cream than such as is thinner, but the cream is richer in quality; that milk carried to any distance in vessels, thereby suffering considerable agitation, never throws up so rich or such a quantity of cream as when it is put into the milk pans without any agitation; the same writer draws the following conclusions: 1st. That it is of importance that the cows should be always milked as near the dairy as possible, to prevent the necessity of carrying and cooling the milk before it be put into the dishes; and as cows are much hurt by far-driving, it must be a great advantage in a dairy farm to have the principal grass fields as near the dairy or homestead as possible.

2dly. That the practice of putting the milk of all the cows of a large dairy into one vessel, as it is milked, there to remain till the whole milking be finished before any part of it is put into the milk-pans, seems to be highly injudicious, not only on account of the loss that is sustained by agitation and cooling, but also, more especially, because it prevents the owner of the dairy from distinguishing the good from the bad cow's milk, so as to separate them from each other, where necessary. He may thus have the whole of his dairy product greatly debased by the milk of one bad cow, for years together, without being ever mixed with any other.

3dly. That if it be intended to make butter of a very fine quality, it will be advisable in all cases to keep the milk that is first drawn separate from that which comes last; as it is obvious that, if this be not done, the quality of the butter will be greatly debased, without much augmenting its quantity. It is also obvious, that the quality of the butter will be improved in proportion to the smallness of the proportion of the last-drawn milk that is retained; so that those who wish to be singularly nice in this respect, will do well to retain only a very small proportion of the last drawn milk.

4thly. That if the *quality* of the butter be the chief ob-

jeet attended to, it will be necessary not only to separate the first from the last drawn milk, but also to take nothing but the cream that is first separated from the best milk, as it is this first rising cream alone that is of the prime quality. The remainder of the milk, which will be still sweet, may be either employed for the purpose of making sweet milk cheeses, or it may be allowed to stand to throw up cream for making butter of an inferior quality, as circumstances may direct.

5thly. That butter of the very best possible quality can only be obtained from a dairy of considerable extent, when judiciously managed; for when only a very small portion of each cow's milk can be set apart for throwing up cream, and when only a very small proportion of that cream can be reserved as of the prime quality, it follows, that, unless the quantity of milk were upon the whole very considerable, the quantity of prime cream produced would be so small as to be scarcely worth the while for manufacturing separately.

6thly. That it seems probable that the very best butter could only be with economy made in those dairies where the manufacture of cheese is the principal object. The reasons are obvious: if only a small portion of the milk should be set apart for butter, all the rest may be made into cheese while it is yet warm from the cow and perfectly sweet; and if only that portion of cream which rises during the first three or four hours after milking is to be reserved for butter, the rich milk which is left after that cream is separated, being still perfectly sweet, may be converted into cheese with as great advantage nearly as the newly-milked milk itself.

But, says the author, as it is not probable that many persons could be found, who would be willing to purchase the very finest butter made in the manner above pointed out, at the price that would be sufficient to indemnify the farmer for his trouble in making it; these hints are thrown out merely to satisfy the curious in what way butter possessing this superior degree of excellence may be obtained, if they choose to be at the expence: but for an ordinary market, he is satisfied, from experience and attentive observation, that if in general about the first drawn *half* of the milk be separated at each milking, and the remainder only be set up for producing cream, and if that milk be allowed to stand to throw up the whole of its cream, even till it begins sensibly to taste sourish; and if that cream be afterwards carefully managed, the butter thus obtained will be of a quality greatly superior to what can usually be obtained at market, and its quantity not considerably less than if the whole of the milk had been treated alike. This, therefore, is the practice that he thinks most likely to suit the frugal farmer, as his butter, though of a superior quality, could be afforded at a price that would always insure it a rapid sale.

Milk-House.—No dairy, however, can be managed with profit, unless a place properly adapted for keeping the milk, and for carrying on the different operations of the dairy, be first provided. The necessary requisites of a good milk-house are, that it be cool in summer, and warm in winter, so as to preserve a temperature nearly the same throughout the whole year; and that it be dry, so as to admit of being kept clean and sweet at all times. This structure ought, if possible, to be erected near to a cool spring or running water, where easy access can be had to it by the cows, and where it is not liable to be incommoded by stagnant water.

And when cheese is the principal object, a building constructed for that purpose is necessary.

The precise degree of heat that is the most favourable for the different operations of the dairy, is not yet determined; but until farther experiments shall have ascertained this point, the author thinks we may take it as a safe rule, that the heat should be kept up, if possible, between the 50th and 55th degree; and to ascertain this point, a thermometer, graduated by

Fahrenheit's scale, should be hung up perpetually in the milk-house, to give notice to the owner of any alterations in the temperature that might affect his interest.

Utensils.—With respect to the utensils of the dairy, they must in general, from the nature of the business, be made of wood. But of late many persons, who affect a superior degree of elegance and neatness, have employed vessels made of lead, or of common earthen-ware. But, as the acid of milk very readily dissolves lead, brass, or copper, and with these forms a compound of a poisonous nature; such vessels must be accounted highly pernicious in the dairy, and therefore ought to be banished from it. The same may be said of vessels of any of the common kinds of earthen ware, which being glazed with lead, and the glazing soluble in acid, are equally improper.

The creaming dishes, or vessels in which the milk is placed for throwing up cream, when properly cleaned, sweet, and cool, are to be filled with the milk as soon after it is drawn from the cow as possible, having been first strained carefully through a close strainer, formed of a large wooden bowl with a hole at the bottom covered with a very close sieve of fine wire (silver wire is best, and most durable and cleanly) or hair web woven for that purpose; or thin cloth of any kind, so as to keep back hairs, &c. that may accidentally fall from the cow. These dishes should never exceed three inches in depth, whatever be their other dimensions; and if the plan recommended above of separating the milk into two parts, and of keeping each cow's milk by itself, shall be followed, it would be convenient to have them made of such dimensions as to contain about one and a half or two gallons. As soon as they are filled they are to be placed on the shelves in the milk-house, where they should be allowed to remain perfectly undisturbed till it be judged expedient to separate the cream from them; which will depend upon the degree of heat at the time, and the particular views of the owner of the dairy. In a moderately warm temperature of the air, if very fine butter be intended, it should not be allowed to stand more than six or eight hours; but for ordinary good butter it may safely be let stand twelve hours, or more.

The cream, being carefully separated, must be deposited by itself in a vessel suitable for the purpose, and kept until a sufficient quantity be collected. A firm neat-made wooden barrel, with a lid fitted to it, is probably as well calculated for this use, as any vessel. Its size must depend on that of the dairy.

The length of time which the cream must remain in this vessel must depend on circumstances; but it should always have acquired a certain degree of acidity, without which it cannot be made into butter with facility. With regard to the operation of churning, it is only necessary to say that it should be carefully performed, whatever kind of churn be employed.

The butter when made must be immediately separated from the milk; and being put into a clean dish (the most convenient shape is that of a shallow bowl), the inside of which, if of wood, should be well rubbed with common salt, to prevent the butter from adhering to it, the butter should be pressed and worked with a flat wooden ladle, or skimming-dish, having a short handle, so as to force out all the milk that was lodged in the cavities of the mass. On this being well performed, much depends with respect to the goodness of the butter. When butter has been thus prepared, it is to be preserved by means of common salt when necessity requires it, and kept from being too soft by means of cold water.

And in every part of the above process it is of the utmost importance that the vessels, and every thing else about the dairy, be kept perfectly clean and sweet; for without this precaution there neither can be pleasure nor profit derived from it.

In Lancashire, according to Mr. Holt, the management of milk for butter, in many respects agrees with the above,

though he suspects it to be peculiar to that district. The mode is, dividing the milk into two parts; the first drawn being set apart for family use, after being skimmed; the cream of which goes into vessels appropriated to receive it; as also the whole of the second, or last, drawn milk, provincially called *afterings*; about one half from each cow, each meal; but the quantity taken first in some measure depends upon the consumption of milk in the family. These two being mixed together, are stirred, but not a great depth, to prevent the bad effects of foul air accumulating on the surface: and kept, according to the season of the year, exposed to the fire, to bring on fermentation and founness; which is accelerated by that which may remain in the pores of the vessels: to prepare this fermentation, they are not scalded, except after having contracted some taint: and then to accelerate it (the quicker it is the better) the vessels are sometimes rinsed out with sour butter-milk; in which state the milk is ready for the churn; and, in consequence of this treatment, more butter is obtained, and of a better quality, than if the milk was churned sweet. And the butter-milk, as it is called, after the butter is extracted, instead of being given to the hogs, as is generally the practice in many counties, becomes, under this process, an excellent food for man.

In Mr. Robertson's Survey of Mid-Lothian, we have the following observations on this important subject: A gentlewoman in the vicinity of Edinburgh, who has been much accustomed to the management of a dairy, states, that she has always been used to churn the whole milk in a plunge churn, with a *sauce* (a lever applied to the end of the churn-staff), which she thinks is much preferable, on account of its greatly facilitating the operation. In warm weather the milk is fit for churning in 48 hours, keeping it from the churn till it is cool; but in cold weather it must be put in warm, to make it thicken sooner; for it is not fit to be churned till it is thick; and in great cold, it is even necessary to set it in a warm place, to promote the coagulation, as the sooner this is accomplished, both the butter and the butter-milk are the better; for when the milk is long kept, it contracts a disagreeable rancid taste; on which account, chiefly, she prefers churning the *whole milk*; for in making butter from *cream*, the milk must be kept long, in order to obtain all the cream from it: but whether churning milk or cream be most profitable, is not yet ascertained in that neighbourhood; though it is held, that the milch-butter is most palatable, at least will keep much longer sweet. In warm weather, cold water is put in during the operation of churning; and in cold weather, boiling water in proportion to the degree; but in temperate weather none at all. It generally takes from one to two hours to churn: but that depends much on the temperature of the milk; for, if it is either too warm or too cold, it requires a longer time.

In the management of his own dairy, Mr. Robertson seems, however, chiefly to have followed the methods which have been recommended by Doctor Anderson, and the quantity of butter which he procures is generally in the proportion of a pound of 22 oz. to every five gallons of milk.

Making Cheese.—In the making of cheese many circumstances are to be attended to; such as the preparation of the rennet, the coagulation of the milk, the management of the curd, &c. These operations are differently conducted in different dairies, and different parts of the country. The following is the method of preparing the rennet, and making cheese, which Mr. Marshall employed:

“Take a calf's bag, maw, or stomach; and, having taken out the curd contained therein, wash it clean, and salt it thoroughly, inside and out, leaving a white coat of salt over every part of it. Put it into an earthen jar, or other vessel, and let it stand three or four days; in which time it will have formed the salt and its own natural juices into a pickle. Take it out of the jar, and hang it up for two or three days to let the pickle drain from it;

refalt it; place it again in a jar; cover it tight down with a paper pierced with a large pin; and in this state let it remain until it be wanted for use. In this state it ought to be kept twelve months: it may however, in case of necessity, be used a few days after it has received the second salting; but it will not be so strong as if kept a longer time.

In preparing this substance for use, it is the custom in some places to mix with it various aromatic and spicy ingredients, such as rose-flowers, cinnamon, mace, &c. but in others this is not at all attended to, yet very good cheese is made.

From the experiments and observations of the same writer it appears, that curd of a good quality may be obtained from milk heated from 87 to 103 degrees of Fahrenheit's thermometer; provided the rennet be so proportioned, that the time of coagulation be from three quarters of an hour to two hours and a half; and provided the milk be kept properly covered during the process of coagulation. From the same trials it also seems, that from 85 to 90 are the proper degrees of heat; that from one to two hours is the proper time of coagulation; and that the milk ought to be covered so as to lose in the process about 5 degrees of its original heat. But climate, seasons, the weather, and the pasture, may, says this writer, require that these bounds should sometimes be broken.

“In my dairy, (continues he) the practice has been uniformly this: As soon as the curd is come at the top, firm enough to discharge its whey, the dairy-woman tucks up her sleeves, plunges her hands to the bottom of the vessel, and, with a wooden dish, stirs the curd and whey briskly about: she then lets go the dish, and, by a circular motion of her hands and arms, violently agitates the whole; carefully breaking every part of the curd; and, at intervals, stirs it hard to the bottom with the dish; so that not a piece of curd remains unbroken larger than a hazel nut. This is done to prevent what is called slip-curd (that is, lumps of curd which have slipped unbroken through the dairy-woman's hands), which, by retaining its whey, does not press uniformly with the other curd, but in a few days (if it happen to be situated toward the rind) turns livid and jelly-like, and soon becomes faulty and rotten. This operation takes about five or ten minutes; or, if the quantity of curd be large, a quarter of an hour. In a few minutes the curd subsides, leaving the whey clear upon the top. The dairy-woman now takes her dish, and lades off the whey into the pail; which she empties into a milk-lead to stand for cream, to be churned for whey butter. This is a practice peculiar to the cheese counties, and forms no inconsiderable part of the profit of a dairy in those counties. Having laded off all the whey she can, without gathering up the small pieces of the loose curd floating near the bottom of the vessel, she spreads a straining-cloth over her cheese tongs, and strains the whey through it, returning the curd retained in the cloth into the cheese-tub. When she has got all the whey she can, by pressing the curd with her hand and the lading-dish, she takes a knife and cuts it into square pieces, about two or three inches square. This lets out more of the whey, and makes the curd handy to be taken up, in order to be broken into the vats.

“A dairy should be plentifully furnished with vats, and some of them of different sizes; for when three or four cheeses are made at each meal, a number of vats become actually in use; and if there are not still a number empty, the dairy-woman becomes confined in her choice, and cannot proportion exactly her vats to the quantity of curd she happens to find in her cheese-tub; and keeping a little overplus curd from meal to meal frequently spoils a whole cheese.

“Having made choice of a vat or vats, proportioned to the quantity of curd, so that the cheese, when fully pressed, shall neither over nor under fill the vat, she spreads a cheese-cloth loosely over the vat; into which she re-breaks the curd; carefully squeezing every part of it in her hands; and, having filled

the vat heaped up and rounded above its top, folds over the cloth, and places it in the prefs.

“ Much depends on the construction and power of the prefs. The excellency of construction depends upon its pressing level: if it has too much play, so as to incline and become tottering or leaning one way or another, and do not fall perpendicular upon the cheese-board, one side of a cheese will frequently be thicker than another; and, what is still worse, one side will be thoroughly pressed while the other is left soft and spongy. Its power may be given by a screw, by a lever, or by a dead weight, and ought to be proportioned to the thickness of the cheese.

“ In autumn, when the weather got cool and moist, the curd was scalded, to make the cheese come quicker to hand, (that is, sooner saleable) and to prevent a white woolly coat from rising. It is done thus: If from new milk, scalding water (boiling water with a small quantity of cold whey mixed with it) is poured over the whole surface of the curd as it lies at the bottom of the cheese-tub: if from skimmed or other inferior milk, the outsides only are scalded, after the curd is in the vat, by first pouring the scalding water on one side, and then, turning the cheeseling, pouring it on the other. For if in this case the curd were to be scalded, it would render it hard, and spoil the taste and texture of the cheese. In the scalding the cheeseling, the curd is first put into the bare naked vat, and the upper part scalded: the cheese-cloth is then spread over it, and the vat being turned, the curd falls into the cloth: the curd, with the cloth under it, is then put into the vat; the outer edges pared off; the paring broke, and rounded up in the middle; and the scalding water poured upon it as before; the folds of the cloth laid over, and the vat set in the prefs.

“ The whey being pretty well pressed out, and the cheeseling (whether it has been scalded or not) having got firm enough to handle, which it will be in about half an hour, the dairy-woman takes it out of the vat; washes the cloth in a pail of clean cold water; spreads it over the vat; turns the cheeseling upon it; squeezes it gently into the vat; folds over the cloth; tucks in the corner with a wooden cheese-knife, and replaces the vat in the prefs.

“ Supposing the cheeseling to be made in the morning, it now remains in the prefs, untouched, until the evening; when it is taken out, salted, put into a fresh dry cloth, and left in the prefs all night.

“ The method of salting is this: The salt being well bruised, and the lumps thoroughly broken, it is spread plentifully on each side of the cheeseling, so as wholly to cover it, about one-tenth of an inch in thickness, more or less, in proportion to the thickness of the cheese. If this be of a considerable thickness, as suppose three inches and upwards, some salt is put into the middle of it, by stopping when the vat is half filled with curd, strewing on the salt, and on this putting the remainder of the curd.

“ Next morning, if the curd be rich, or has been cold run, the cheeseling is turned into another dry cloth, and left in the prefs till evening: but if on the contrary the curd be from poor milk, or from milk which before setting had acquired any degree of sourness, or if it has been run hot and quick, the cheeseling should in the morning be bare-vatted; that is, be put into the vat without a cloth round it, and be put again into the prefs until evening.

“ The use of bare-vatting is to take out the marks of the cloth, and thereby evade a waste of labour in bringing the cheese to a smooth glossy coat. The reason for the above distinction is, therefore, obvious; for, the harder the curd, the longer the marks of the cloth are in pressing out.

“ In the evening, that which was turned into the dry cloth in the morning, is now bare-vatted; and that which was bare-vatted in the morning, is now turned in the vat; and, having

stood in the prefs until morning, the process is finished. The cheeses are taken out of the vats, and placed upon the shelf.”

Mr. Holt tells us that “ the farmers about Leigh make their cheese of two meals of milk, the night's milk and the morning's; sometimes the night's milk is skimmed, and part of the cream taken from the cheese; but this not every where, for the best dairies put all in: in the morning when the cheese is to be made, the night's milk is to be heated till it is just as warm as from the cow, and then mixed with the new milk as soon as it is milked;—into this is put a small quantity of rennet just sufficient to come the curd, and no more; for on this just proportioning of rennet and milk, they tell him, the mildness of the cheese greatly depends. The rennet is made from the stomach-bag of a calf, salted and dried, which they call a bag-skin: a piece of this, no bigger than a much worn sixpence, is put into a tea-cup full of water, with a little salt, about twelve hours before it is wanted; and this is sufficient for 18 gallons of milk, which it will come in about an hour and a half, if the bag-skin be good: then the curd is broke down, and, when separated from the whey, is put into a cheese-vat, and pressed very dry, and after that broken very small, by squeezing it with the hands: the new curd used is mixed with about half its quantity of yesterday's, and which has been kept for that purpose; and a part of this new curd is put by for to-morrow, if it can be spared; if not, all to-morrow's is put by to mix with new, as convenience suits, for the best cheese is always made with part old curds. Some mix the old and the new together, after both have been worked very small: others put the old curds in the middle of the cheese; either of which ways will do very well. When the curds have been thus mixed, and well pressed and closed with the hands in a cheese-vat, till they become one solid lump, it is put into a prefs for four or five hours; then taken out of the cheese-vat and turned, by means of a cloth put into the cheese-vat for this purpose, and again put into the prefs, where it stands till night; then taken out, well salted, and put into the prefs again till morning, when it is taken out, and laid upon a flag, or board, till the salt is quite melted, which will be in a day or two; then it is wiped, put into a dry room upon a turning board, and turned every day, till it becomes dry enough for the market.”

Excellent cream cheeses are made in Lincolnshire, by adding the cream of one meal's milk to milk which comes immediately from the cow: these are pressed gently two or three times, turned for a few days, and are then disposed of at the rate of one shilling per pound, to be eaten while new with radishes, sallad, &c.

Cheeses of various kinds and qualities are made in different parts of the country; but cheese of the first quality (says Mr. Marshall), that which comes as near perfection as the nature of it admits of, or as art can probably approach, is of a close even contexture; of a firm but unctuous consistency; of a mild flavour, while young; acquiring, by age, an agreeable fragrance. If a cheese of this quality be ironed, it has somewhat the appearance of firm butter; or of wax moderately warmed. If the plug be gently rubbed, the substance of the cheese seems to melt under the finger, which wears it down as it would fine clay duly moistened. If the end of the plug be pinched, it yields to the pressure without crumbling; grinding down, between the fingers, to an impalpable matter. Cheese of this description, improves, by age, in mellowness and flavour.

The following is the account which Mr. Pryce has given of Signor Vitabni's process of making Parmesan cheese. At ten o'clock in the morning, says Mr. Pryce, five *brents* and a half of milk, each *brent* being about forty-eight quarts, were put into a large copper, which turned on a crane, over a slow wood-fire, made about two feet below the surface of the ground. The milk was stirred from time to time; and, about eleven o'clock, when just luke-warm or considerably under a blood heat, a ball

of rennet, as big as a large walnut, was squeezed through a cloth into the milk, which was kept stirring. This rennet was said to have been purchased of a man at Lodie, famous for the composition; but that it was principally made of the same part of the calf as we use in England for that purpose, mixed up with salt and vinegar: it appeared to the writer to be also mixed with old cheese. He much doubts whether there was any great secret in the composition: but it seemed to him that the just proportion of rennet was a matter of consequence, which is not in general sufficiently attended to. By the help of the crane, the copper was turned from over the fire, and let stand till a few minutes past twelve; at which time the rennet had sufficiently operated. It was now stirred up, and left to stand a short time, for the whey to separate a little from the curd. Part of the whey was then taken out, and the copper again turned over a fire sufficiently brisk to give a strongish heat, but below that of boiling. A quarter of an ounce of saffron was put in, to give it a little colour; but not so unnaturally high as some cheeses in England are coloured; and it was well stirred from time to time. The dairy-man (this is not women's work in Italy) frequently felt the curd. When the small, and, as it were, granulated parts felt rather firm, which was in about an hour and a half, the copper was taken from the fire, and the curd left to fall to the bottom. Part of the whey was taken out, and the curd brought up in a coarse cloth, hanging together in a tough state. It was put into a hoop, and about a half-hundred weight laid upon it, for about an hour; after which the cloth was taken off, and the cheese placed on a shelf in the same hoop. At the end of two, or from that to three days, it is sprinkled all over with salt: the same is repeated every second day, for about forty to forty-five days; after which no further attention is required. Whilst salting, they generally place two cheeses one upon another; in which state they are said to take the salt better than singly.

The whey is again turned into the copper, and a second sort of cheese is made; and afterwards even a third sort, as the writer was informed.

Sheep.—This kind of stock is highly advantageous in different points of view. Sheep are important both as supplying food and clothing, and as a mean of improving the farm. Therefore in the breeding of these animals attention must be had to these circumstances. The sheep of different counties excell in these different properties, and in some parts they have been lately much improved by crossing the breeds. Mr. Kent in his Survey of Norfolk observes, that there ought always to be some affinity or similitude between the animals which are crossed. It is, says he, a manifest incongruity to match a Norfolk and a Leicester sheep; or a Norfolk and a South Down; or any long woolled sheep with a short-wooled; but a Leicestershire sheep may be matched, with some degree of propriety, with a Cotswold; and a South Down sheep with a Berkshire or a Herefordshire Ryland.

In the Survey of Staffordshire, Mr. Pitt says, the Wiltshires crossed by a heavy ram have produced sheep, at little more than two years old, of forty pounds per quarter, and which have been sold to the butcher at three pounds ten shillings each. The Dorsetshire breed, which are well made and compact, have often answered well here, and are, in the opinion of some experienced farmers, equal to any other breed; and the fact is, that any breed of sheep, if sound and healthy, may be enlarged and improved by good keeping, and by crossing with rams selected with due attention.

The best sort of sheep for fine wool are those bred in Herefordshire and Worcestershire; but they are small and black-faced, and consequently bear but a small quantity. Warwick, Leicester, Buckingham, and Northamptonshire, breed a large-boned sheep, of the best shape, and deepest wool. The marshes of Lincolnshire also breed a very large kind of sheep, but their wool is not so good. The northern counties in general breed sheep with long, but

hairy wool: and Wales breeds a small hardy kind of sheep, which has the best tasted flesh, but the worst wool of all.

The farmer should always buy his sheep from a worse land than his own, and they should be big-boned, and have a long greasy wool curling close and well. These sheep always breed the finest wool, and are also the most approved of by the butcher.

Mr. Pitt in his Survey of Staffordshire tells us, in that populous manufacturing county the considerable demand for lamb, as well as mutton, has induced a great proportion of farmers to keep none other than an annual stock of sheep, consisting of ewes bought in at Michaelmas, from *Cannock Heath, Sutton Coldfield*, the commons of Shropshire, and sometimes even from Gloucestershire, Wiltshire, and Dorsetshire. These ewes are immediately put to a ram, and the lambs in spring suckled till they are fit for the butcher: they are then sold, and the ewes kept in good pasture, fatted, and sold after them, and the whole flock generally cleared off within the year. And many people think the profits in this are equal to those in any other way: the lamb and wool will generally pay the original purchase of the ewe, and sometimes more; and the price of the fat ewe remains for keeping and profit.

He also observes that the rams of Mr. Fowler, a celebrated breeder of this kind of stock, are stout, broad-backed, wide on the rump, and well made, with fine wool to the very breech: the largest of them would, he believes, fatten to more than thirty pounds the quarter; and the smallest would be considerably more than twenty. Great attention has been paid for several years past to improving this breed both in wool and carcass. But Mr. Fowler himself thinks the breed is now pushed rather too far in bulk and weight, for the pasturage of the common, or even of the neighbourhood, unless they are driven into better land for fattening. But he is clearly of opinion, that pushing or increasing the size or bulk of sheep, by improving their pasturage, or removing them to a better pasture, does not at all tend to injure the staple, or degenerate the fineness of clothing wool, provided due attention be paid to selecting the finest-wooled rams.

The Leicestershire breeds, says he, are of two kinds, the old and the new. The old Leicesters are well known, as large, thick, heavy sheep, with long combing wool: the new Leicester breed is a refinement upon the old, by crossing with a finer-boned and finer-wooled ram. These are now established in various parts of Staffordshire, and increasing in other places. The old Leicester breeds are crossing with the new, which bids fair to produce a very good breed; there being many instances in which the old breed were become too coarse, and the new too fine. The flock of Mr. Dyott, of Freeford near Lichfield, a gentleman who has attended much to this subject, is closely bred from the new Leicester breed, by means of rams for many years procured from the best breeds. His farming is upon a considerable scale, to the extent of 800 acres or more; and the main object, sheep. His flock of breeding ewes is two hundred and sixty, and he never sells a lamb, which upon the average rearing, are about three hundred. He informed our author, that his annual sales from sheep and wool amounted upon an average to 650l. that his *shear bags*, or yearling wethers, generally go to the butcher at two guineas each; and the *culls* of this age make thirty-five shillings each; and by keeping to the month of February following, he has sometimes sold them at fifty shillings each, being then less than two years old. This is a proof that this breed of sheep will make a profitable and quick return into the farmer's pocket: he has several times killed sheep when kept to a greater age, that have weighed forty pounds per quarter.

Mr. Pitt says, that there are some other flocks, such as those of Lord Bagot's tenants, and particularly some belonging to Mr. Harvey, his lordship's steward, that deserve attention. This breed, introduced into that neighbourhood a few years back, is

gaining ground fast, and is supposed by many, with whom Mr. Pitt is disposed to concur, to be the best pasture sheep-stock in the kingdom. The superiority consists, or is supposed to consist, in this: that the pastures may be stocked much harder with these, than with any other stock of equal weight; as they are always fat, even when suckling lambs. The ewes full grown will weigh from 20 to 25 pounds per quarter; wethers at two years old, at which age they generally go off, about the same; but when kept another year, they will rise to thirty pounds per quarter. The fleeces weigh from seven to ten pounds. He has observed this year, that the lambs from a ram of this breed were lambéd much easier than many others, particularly than those from a ram of the old Leicester breed the preceding year. This our author attributes chiefly, or wholly, to the form, as the ram is finer in the neck and shoulders than a coarse made sheep. These sheep he describes to be fine and light in the bone; thick and plump in the carcass; broad across the loin, with the back bone not rising into a ridge, but sinking in a nick, and, as it were, a double chine of mutton rising on either side; fine and clean in the neck and shoulder; not too short in the leg; and of a sufficient bulk in the carcass to rise to the weight above-mentioned; which bulk in this breed will be apparently less than in any other. But, says he, many other crosses of sheep of considerable merit are to be found in the pastures of different farmers; and perhaps the great superiority of this, or of any breed over all others, has been over-rated by those who have made the comparison. The difference in natural ability and attention of different sheep-masters cannot be supposed so great as to influence the result of their endeavours, in a manner so very superior. Accidental causes may have first raised the attention of those who by assiduity have since contrived to keep the lead. But others will closely press upon them: and as the different breeds of sheep are but different varieties of the same species, to record the idea that any one individual has carried his breed of sheep to a pitch of excellence so much superior to all others, is a libel upon all other sheep-masters. This idea, says he, strikes me more forcibly, since, taking an extensive yet particular view of the sheep of Staffordshire, I have found distinct breeds, each having its peculiar merit; so that it is not very easy to decide the superiority. He who begins with a good breed has doubtless an advantage; but he believes no breed has yet arrived at its *ne plus ultra* of perfection, but remains to be improved upon by future attention.

In Norfolk, those who keep ewe-flocks, Mr. Kent observes, find them answer extremely well; for, besides the fleece and manure, the average price of the lambs is, at this time, twelve shillings. Those who buy the wether lambs at that age, with a view of bringing them up for fattening stock, after keeping them eighteen or nineteen months, generally sell them at an average of thirty shillings; which may be considered as a very handsome profit, as they are only kept as store sheep the first twelve months, and when fattened, in general, an acre of turnips will do for eight; from which however a deduction must be made of about ten sheep, out of a hundred, for casualty.

Mr. Boys informs us, that the management of sheep in the different parts of Kent is as follows: In the eastern part, the flock farmers buy-in lambs at Romney fair the twentieth of August, at from 12s. to 14s. each; and when they have kept them two years, they either sell them lean to the fattening grazier, or make them fat themselves on turnips, and pea or bean-straw. Sainfoin and clover hay are generally too valuable at the watering places to be used for that purpose. Oats, and cullings of garden beans, are sometimes given to finish them in the spring. When these two yearling sheep are sold in the autumn to the graziers, the price is from 24s. to 28s. each; and when made fat, they produce from 34s. to 42s. according to their size and fattening. But these prices have lately considerably advanced.

VOL. IV.

The few sheep bred in the marshes are of the same sort, except some small parcels of Dorsetshire and South-Down ewes, which are bought to make early fat lambs; and the ewes are made fat in the autumn. But almost the whole of the sheep kept on the upland farms of East Kent, are the true Romney marsh breed; whose carcases and bones being large, and wool long and heavy, they require rich land and good keep to make them fat. It seems quite contrary to reason and nature that they should be equally adapted to rich marsh-land and poor chalky downs; and consequently they are not so fit for this district, at least the chalky part of it, as the South-Down sort, whose natural soil is a fine turf on chalk-hills. Impressed with this sentiment, Mr. Boys has himself, for these seven years past, kept no other than South-Down-sheep, and has every reason to be satisfied with them; his flock is about 1000;—400 of which are breeding ewes.

In the Isle of Shepey, the sheep are of the Romney marsh sort, true *Kents*. The soil being much inferior to Romney marsh, the sheep are somewhat smaller; and, from the same cause, their wool is lighter and finer. Some graziers get rams from Romney marsh; others prefer their own sort; and but very few, if any, pay that attention which it is their interest to do, to the wool of the rams they use. The wethers are fattened at three years old, then weighing from twenty to twenty-four pounds per quarter.

The sheep mostly kept in the district of West Kent, are the South-Down sort, bought-in wether-lambs, at the autumnal fairs on the Downs, chiefly at Lewes, the second of October. They are kept the first winter on stubble-land, with grass and a few turnips, and on grass and seeds in summer; and frequently are fattened on turnips the next winter, before they are quite two years old: this is become the favourite sort within these few years, and increases annually in this district. The other sorts of sheep kept there, are the West Country, from Wiltshire and Dorsetshire; the wethers are bought-in at all ages, to be fattened on turnips. But there are hardly any sheep bred in the Weald of Kent, excepting a few for early fat lambs, of the Wiltshire and South-Down sorts.

Some of the Wiltshire wethers are bought-in to fatten on turnips; and a few South-Down wether-lambs are bought in the autumn, and kept on the driest parts until they are two years old, and then made fat for sale on turnips or meadow-lands.

The principal system of management in Romney marsh is that of breeding, rearing, and fattening sheep; and the modes of doing these are the following: The rams are usually put to the ewes, allowing one to forty or fifty, and sometimes sixty, from the twelfth to the sixteenth of November, and stay with them about five weeks. The ewes live entirely on the grass, without any hay, during the winter: in deep snow they scrape with their feet, and obtain a subsistence, although they then lose flesh, and sometimes become very poor by their yearning-time. This marsh produces many twins; but a great number are lost: so that most graziers consider their crop not a bad one, if they wean as many lambs as they put ewes to ram. The lambs are weaned the first or second week in August, and very soon after put out to keep to the upland farmers of the county, where they remain till the fifth of April, at from 2s. to 3s. per score, per week. When they return to the marsh, they are put on the poorest land, or such fields as the grazier thinks want improvement by hard stocking; which is there called *tegg*ing a field, and is held to be of great service. These young sheep are placed in the fields in proportion to what it is judged each will maintain, from the fifth of April until August, which is at the rate of from four to eight per acre. The *wether-tegs* in the autumn are removed to the fattening, and the *ewe-tegs* to the breeding grounds, among the two and three

yearling ewes. The wethers remain till July or August following, when, as they become fat, they are drawn out and sold to the butchers at the marsh markets, or are sent to Smithfield. The two yearling wethers, when fat, at this season weigh from twenty to twenty-eight pounds per quarter; and some of the largest and best fed, a few pounds more. The old ewes, there called *barrens*, are put to fattening as soon as their milk is dried after the third lamb, which is at the age of four years, on some of the best land; where they are placed from two to three per acre for the winter. These, in favourable winters, are sometimes made fat, and sold in the spring, soon enough for the same field to take in a fresh set of wethers, and make them fat by the autumn; but this can only be done by light stocking.

The practice of fattening sheep on turnips, assisted by oil-cake, corn, hay, sainfoin, &c. is greatly in use among the upland farmers of this county; not so much for the profit by feeding with those articles, as for the great improvement of the soil where the turnips are fed off. The manure from sheep fed on oil-cake and turnips, is reckoned very enriching to the land. A great number of fold-flocks of lean sheep are kept by the farmers of the eastern part of the county, of from eight to twenty score in number. These are each attended by a shepherd, who removes the fold every morning to fresh ground, at six o'clock in summer, and at break of day in winter: the flock is then driven away to the most inferior keep at the first part of the morning, and is returned into the fold for two or three hours in the middle of the day, while the shepherd goes to dinner: in the afternoon it is gradually led to the best keep on the farm, that the sheep may return full fed to the fold in the evening. Great caution is necessary in feeding sheep on clover in summer, and on turnips in the first part of the winter.

Mr. Robertson has inserted the following account of feeding ewes with early lambs in his Survey of Mid-Lothian, as stated by an accurate observer. The number in all was sixty, fed off in four weeks, the expence as under:

	£.	s.	d.
"To 2 bolls of grains per day, at 2s. per boll, 28 days,	5	12	0
To 2 pecks of oats, ditto, 1s. per peck, ditto,	-	2	16
To 3 stone of hay, ditto, 6d. per stone, ditto,	-	2	2
To 1-4th acre of turnips;	-	1	10
	£.	12	0

" Thus each lamb cost 4s.

" Feeding with turnips, oats, and hay, takes five weeks to feed off.

	£.	s.	d.
" 20 ewes will eat 1-half-acre of turnips in 35 days,	3	0	0
ditto, a peck of oats daily, hence,	-	1	15
ditto, a stone of hay per day,	-	0	17
	£.	5	12

" This comes to 5s. 7½d. each lamb.

" Feeding on grafs takes six weeks to feed off. The average rent of good grafs may be two pounds per acre, which will feed off four ewes with lambs. He considers six weeks from the middle of April, the usual time of laying on, to be full 1-half of the value of the grafs for that season; hence the lambs cost 5s. each in that time. In turnip-feeding sheep, by flaking them on the field, 20 sheep eat an acre in 14 weeks. If they be led off to a grafs field, ten score will *take* or dung an acre in seven days, worth 2l. 10s.

" As to feeding in the house, he finds the dung worth the trouble of carting, and the value of the straw it takes for litter. He finds also the lambs fed on grains, not only sooner ready, but more white and firm in the flesh; the ewes are also in better

condition. He likewise found, that, at times, to mix a little salt among the grains, was of great service; but it was necessary to avoid, above all things, giving them grains when sour, or old kept; and of importance also to feed them regularly, and to give them fresh clean litter every day."

A sheep will consume about twenty pounds of turnips in twenty-four hours, provided it be allowed as many as it can eat, which should always be allowed to fat sheep; but as sheep vary in size, so they will consume more or less food.

Hogs.—In general, those kinds of hogs which are the best for feeding, are wide made, plump, and round in the carcase, light of bone, with short legs and soft hair.

In Staffordshire, Mr. Pitt says, the breed of hogs most esteemed is not the large slouched-eared breed, but a cross between them and a smaller dwarf breed. They should be fine in the bone, thick and plump in the carcass, with a fine thin hide, and of a moderate size; large enough to fat, at from one to two years old, to the weight of from three hundred to four hundred pounds each. These, if well bred, will keep themselves in good plight with little feeding, and will soon grow fat with a plentiful allowance of proper food. Hogs of the large breed have been fattened there, to from six hundred to eight hundred pounds weight, exclusive of the entrails; but, requiring much time and food, have pretty generally given way to a smaller-sized, finer-boned, thick, plump animal. Hogs are generally fattened there by farmers with the refuse of the dairy, boiled potatoes, and barley meal, and peas either whole or ground: by millers, with what they call *sharps* and *gurgeons*, that is, with the husk or bran of wheat ground down, but not wholly divested of its flour; also with other sorts of grain, and pulse ground down: by butchers, with the refuse or offal of slaughtered animals. The best way of managing the potatoes, is to boil them in their own steam, and put them afterwards into a large oven when the bread is drawn, to evaporate the watery parts: they will then go nearly as far as chestnuts or acorns in feeding.

In Lancashire, Mr. Holt observes, that Mr. Eccleston has a breed between the wild boar and the Chinese, which have very light and small bellies. Upon the same food, this gentleman thinks they will yield one fourth more flesh than either the large Irish or Shropshire breeds. Their size is but small, weighing only from ten to fifteen score, generally about twelve score.

In Kent, a great number of pigs are reared and fed on the corn-stubbles for the butchers, which are killed in the autumn for roasting-pork, at the age of three or four months, then weighing as many score pounds each. Some are also fattened and killed at from six to twelve months old, and sold to small families in the neighbouring towns and villages, or to pork-butchers, who retail them in sides and quarters to those families. The business of rearing and fattening hogs for sale, is generally considered as a bad one in this part of the country. In the western part of this district, there are a few farmers who have the larger kind, or Berkshire-breed of hogs; but in general they are mixtures of many different sorts. Little attention, says Mr. Boys, is paid to this animal, though the breed might, doubtless, be very much improved with proper care. Many hogs, says he, are likewise kept in the woods of the Weald of Kent in the autumn, on acorns, and fattened on corn in the winter.

Pigs, in the opinion of Mr. Holt, should, during the stage of their growth, be regularly turned out to graze, where there is a conveniency. This, besides the advantage of grafs, which is nutritious and helps digestion, by the fresh air and exercise, causes a disposition to take their rest, and sleep after a meal, contributes to their cleanliness, and renders their flesh of superior flavour.

The best way of managing hogs, is probably to feed them so as to keep them in middling plight, till you design to fat them; for if you keep them too fat, it will endanger their health; and too lean will render them too ravenous. It is proper to give them such swill as you have, every morning and evening, to make them come home to their sty. The rest of the day, let them graze, and get such food as they can. Moist sedgey grounds are good for them, the roots of which they will eat; and all sorts of haws, haws, haws, haws, acorns, chestnuts, &c. with which if you have plenty enough to fat them, the flesh will eat much better and sweeter than if fattened in a sty. Some, indeed, say their fat will not be so solid, nor so profitable, and therefore they commonly shut them up for a week or ten days, and feed them with dry peas; but this is a mistake, experience having shown, that hogs fattened with acorns only, have their fat as solid as those fattened with peas. In fattening hogs in styes, it is necessary to give them meat often, and but little at a time, that it may be always fresh; and likewise to give them as much water as they will drink, and to keep them very clean; which will help their fattening, and improve the taste of their flesh. However, the common mode of fattening them is, in styes, with peas, if cheap; but when dear, the meal of barley, rye, or offal corn, according as they are cheapest, which is mixed with water, whey, or skimmed-milk: with these they are fed till fat, which is commonly in about a month's time: they are then fed with peas for a little time before they are killed.

On the best means of rearing and fattening of hogs, the following observations and experiments by Mr. Young, are given in the Transactions of the London Society of Arts, &c.

The importance of this animal to the farmer, says he, is not sufficiently known in every part of England; there are many dairies that do not maintain one-tenth of the swine they might, with proper management. Several garden-roots are raised in large quantities, without being applied to feeding hogs; and clover is cultivated in many countries, upon the largest scale, without its utility for the same use being the least known. No person who has tried many experiments in this part of rural economy, can fail regretting, that so many farmers should neglect a conduct that adds so much to the good of the public, as well as to their own profit.

There are two principal objects in the rearing and fattening hogs; first, to make the greatest advantage of a dairy; and secondly, to substitute some other food, in the place of that which arises from cows, where none are kept.

It is the practice of several counties to use the skim-milk, butter-milk, and cheese-whey, in fattening hogs. This is a most pernicious custom: that food, for such a use, it is every where known, has twenty substitutes, viz. peas, beans, buck-wheat, barley, &c. &c. but it is not so generally known that pigs may be reared without cows. It is agreed that the dairy food is excellent for the latter purpose.

For this reason, says he, I shall venture to propose a different conduct, and with the greater readiness, as I have found it, by experience, to be more profitable than the common management. The dairy upon this improved system should be applied only to rearing pigs, and feeding sows which have young. But this at once opens a larger prospect of the whole management of a farm.

The sows and weaned pigs should evidently be proportioned in such a manner to the number of cows in milk, as to consume all the dairy-food without waste; and other sorts of food provided for the keeping sows that have no pigs; hogs half, three-fourths, full grown, and fattening ones.

The practice of some counties, as well as the annexed experiments, proves that clover is a most capital object in keeping all these sorts of swine; but those writers who assert that it will completely fatten them, go much too far. There is no sort

of cattle in a farm that requires more attention than hogs: any method, therefore, that simplifies the management must be peculiarly valuable. Hogs that are a quarter (or upwards) grown, continues he, may be absolutely confined to a clover field until it is necessary to sow wheat.

Here Mr. Young relates several experiments made on feeding and fattening hogs with different sorts of food.

Experiments on feeding Hogs.—Exp. I. The first week in March, 1765, thirty pigs, just weaned, were drawn from forty-three, that they might be all of a size; they were then distributed into five lots, equally divided (I do not think there was half a crown difference in the value of them), and then fed with distinct sorts of meat. Each lot had a sty to themselves, and all were kept clean and littered with straw.

Lot No. 1. was fed with pollard mixed with water.

2. with pollard mixed with skim-milk.

3. with boiled turnips, and pollard mixed with the turnip liquor.

4. with boiled potatoes and water.

5. with skim-milk.

They were kept with this food thirty days. He then turned them out of their styes (none had died), and viewed them with a person particularly skilled in hogs: the result was,

No. 2. the best—pollard and skim-milk.

5. the next best—skim-milk.

1. next—pollard and water.

3. and 4 equal.

It appears from hence that pollard and milk are the best food, milk alone very good; the other articles advantageous (for none of the pigs were in bad order), though not equal to the former.

Exp. III. January 1, 1766, forty pigs, that had been weaned about a fortnight, were draughted very equally into eight lots, and confined each to a sty; they were cleaned out and littered on the same day, and equally. Their food was as follows:

No. 1. Raw carrots.

2. Boiled ditto.

3. Boiled potatoes.

4. Pollard mixed with skim-milk.

5. Pollard mixed with boiled turnips.

6. Malt dust mixed with skim-milk.

7. Skim-milk.

8. Ditto and half carrot-water boiled.

They continued upon this food the month of January, and were then viewed: the result was as follows:

No. 4. the best—pollard and milk.

7. next—skim-milk.

2. ditto—boiled carrots.

3. ditto—boiled potatoes.

5. ditto—pollard and boiled turnips.

8. ditto—skim-milk and carrot-water.

1. ditto—raw carrots.

6. the worst—malt-dust and skim-milk.

Two dead.

Pollard and milk hitherto maintain the superiority, boiled carrots excellent, the rest almost equal, except the malt-dust, which is evidently bad.

Exp. IV. In the beginning of June, 1766, he confined sixty hogs, half and three-fourths grown, in his hog-yard, (a pond's mouth in it) and fed them fourteen days with clover, mown fresh every day: it was given in their troughs, with racks across to prevent the soiling it. They fell off in their looks in about four days, and grew worse and worse, several dying. At the end of that time, he gave them some malt, grains, and wash every day for a few days longer; but the effect was no better, more dying. They were then all

turned into the clover-field whence it had been taken, and confined constantly to it for some time. Not one more died, for all throve greatly. It will not perhaps be impertinent here to add, says he, that I never found any method of using clover more beneficial than thus applying it to the feeding of hogs.

Exp. V. At the time of the preceding experiment, eight hogs of equal size were divided into two lots, and confined to two styes. Four were fed fourteen days on clover mown, and the other four on lucerne mown; they were given at the same time, and in the same styes. At the end of that time the same were viewed attentively: both were bad, the clover ones much the worst, one near dying.

Exp. VI. In the month of December, 1766, twenty pigs, that had been weaned a month, were draughted into four parcels, and kept that month separately in the following manner:

- No. 1. Boiled carrots.
- 2. Boiled potatoes.
- 3. Boiled turnips.
- 4. Boiled cabbages.

At the end of the month they were turned out and viewed attentively. The result was,

- No. 1. the best—boiled carrots.
- 2. next—boiled potatoes.
- 3 and 4 equal—all nearly dead.

Carrots continue, in every trial, superior to all common vegetable food. I am, says he, not at all surpris'd at the ill success of turnips and cabbages.

Exp. VII. In June, 1767, he draughted from his hogs twenty that were of a perfect equality in size and appearance; they were even half grown; marked them into four lots, and turned

- No. 1. into his clover field.
- 2. lucerne ditto.
- 3. sainfoin ditto.
- 4. burnet ditto.

In another month they were drove up and viewed: the result was,

- No. 2. the finest—lucerne.
- 1. next—clover.
- 3. next—sainfoin.
- 4. very indifferent—burnet.

The result of this experiment he thinks decisive in favour of lucerne, and likewise in the proportionable merit of the other articles: but it must be farther enquired into by future experiments.

The result of these trials is thus given:

Milk mixed with pollard appears to be, of all food, the most proper for rearing pigs. Milk alone is good. Boiled carrots excellent, and fully proved to be sufficient for any farmer to depend on who does not keep a good dairy. Potatoes boiled to a batter, also a very good food. Turnips, cabbages, and malt-dust very bad. Of green food, that which is growing is clearly the best; mown, and given in styes, it is pernicious. In the field, lucerne is superior to all the rest. Clover comes next, then sainfoin: all these three are good. Burnet last and bad.

He then instituted a set of experiments in order to discover what kind of food was most proper for fattening hogs, when given to them separately, and the best mixtures of them for that purpose.

Exp. II. In January, 1766, he drew from the herd ten hogs, as equal in size as possible, and weighed them alive in five lots.

No. 1. weighed stone lb.
13 4

No. 2. weighed	stone lb.
3.	12 6
4.	13 0
5.	12 11
	13 1

A nearer quality than this, in matters that can neither be added to nor diminished, can scarcely be expected.

No. 1. was fatted with white pease, that weighed 56lb. per bushel; the price 30s. per quarter.

No. 2. with pollard that weighed 22lb. per bushel; price 9d. per bushel.

No. 3. with buck-wheat 47lb. per bushel; price 2s. 3d. per bushel.

No. 4. with boiled potatoes 54lb. per bushel; price 2s. per bushel.

No. 5. with boiled carrots 55lb. per bushel; price 1s. 1d. per bushel.

He thought it best to fix on a given sum, as proper to fat each hog. The people he consulted were of opinion that eight bushels of white pease were necessary to fat one such hog well. This he accordingly fixed on as his criterion. The account of the expence therefore stood thus:

		£.	s.	d.
No. 1.	Pease, 16 bushels	-	-	3 0 0
2.	Pollard, 80 bushels	-	-	3 0 0
3.	Buck-wheat, 27 bushels	-	-	3 0 0
4.	Potatoes, 28 bushels at 2 16 0	2	16	0
	Labour and coals - 0 4 0	-	4	0
5.	Carrots, 49 bushels - 2 13 2	2	13	2
	Labour and coals - 0 6 10	-	6	10
		3	0	0

Each lot was weighed as soon as the food was done. The result was as follows:

No. 1. weighed	stone lb.
2.	27 6
3.	27 9
4.	29 13
5.	25 7
	31 0

It is evident from this experiment, that carrots boiled are superior to any other food. He did not expect that potatoes would be so much inferior; but he has found, from divers other trials since, that it is requisite to mix the meal of some kind of corn with them. Pollard in this trial, as in the last, is superior to pease.

With respect to the comparative fattening quality of carrots and potatoes, it appears by this experiment that lot No. 5. gained 17 stone 13 pounds weight in flesh, fed upon carrots; and lot No. 4. fed upon potatoes, gained but 12 stone 10 pounds. The difference was 5 stone and 3 pounds of flesh gained by feeding on carrots, more than was gained by their feeding on potatoes; a great superiority when viewed in this light. But on the other hand, to gain this greater weight there was a consumption of 49 bushels of carrots, and but 28 of potatoes. But 49 bushels of potatoes (the same quantity as the carrots) would, in the above proportion, advance such a lot of hogs to the weight of 22 stone and 4 pounds; that is, to 4 stone 5 pounds more in weight, than the same quantity of carrots did advance them; by which it appears that potatoes are really more fattening than carrots, of the same measure or weight. The hogs seem to relish carrots much, and they eat a great quantity of them; but taking an equal quantity of each, the potatoes go farthest in fattening hogs: a circumstance that merits the farmer's attention; for it is much more difficult to find a soil that is proper for carrots than for potatoes, and the produce from an acre of potatoes is nearly as great, and frequently greater than the produce of carrots; nor is there much difference in the expence. This however is certain, that in most farms, there

is much more land proper for potatoes than for carrots. The price of the potatoes, in this instance, is indeed much higher than the carrots; but that is a circumstance merely local, it is not so in all places; as the farmers may, in general, raise potatoes as cheap as they can carrots, and in much greater quantities.

The other experiments in Mr. Young's paper, were made in order to discover the fattening quality of several sorts of food, when mixed together; pollard, bran, and of beans, pease, buck-wheat, and barley ground into meal; upon which he makes the following observations. It appears from these experiments, that pollard alone, at the preceding prices, is a cheaper food than pease alone. That boiled carrots is much the most profitable food that has been tried. That buck-wheat is a more profitable food than pease. That several kinds of food mixed are better than given alone. That the meal of any one, or various kinds of grain is better, and more profitable, than the whole grain mixed or alone. That pease and barley are a much sweeter food than beans.

Rabbits.—Mr. Marshall, in the Rural Economy of Yorkshire, observes, that in situations where the ground, as well as the soil, is suitable to rabbit-warrens, and where an extent of it sufficiently large can be collected together in one property, there is a very strong reason why it may be profitably stocked with rabbits.

And in his Minutes on Norfolk, he says, a level country is unfit for rabbit-warrens, but convenient for the plough: on the contrary, rabbits delight in the sides of sandy hills; which, where turnwrist ploughs are not in use, are extremely inconvenient for tillage; and, when cultivated, are generally unproductive. The rabbit, on level ground, finds it difficult to make its burrow; the excavated mould is all to be dragged upward to the surface: hence a piece of ground altogether level can seldom be stocked successfully with rabbits, unless it be first laid up, by art, at a great expence, into inequalities. On the contrary, against the side of a steep hill the rabbit has no difficulty to encounter: the declivity affords him a ready vent for his mould; his work is all down hill: and unless the soil be too stubborn, or too rocky, for the rabbits to work freely among, a broken hilly country may generally be stocked with advantage; provided a tolerable market for the carcasses can be had within reach. There are, says he, perhaps, few sandy or other loose foiled hills, which would not pay better in rabbit-warrens than under any other course of husbandry.

Those who keep rabbits tame for profit, breed them in hutches; but these must be kept very neat and clean, otherwise they will be always subject to diseases. Care must be taken also to keep the buck and does apart, till the latter have just kindled; then they are to be turned to the bucks again, and to remain with them till they shun and run from them. The best directions for the choosing of tame rabbits, are to pick the largest and fairest: but the breeder should remember, that the skins of the silver-haired ones sell better than any other. The food of the tame rabbits may be colewort and cabbage leaves, carrots, parsnips, apple-rinds, green corn, and vetches, in the time of the year; also vine leaves, grass, fruit, oats, and oat-meal, milk thistles, sow-thistles, and the like; but with these moist foods they must always have a proportionable quantity of dry foods, as hay, bread, oats, bran, and the like; otherwise they will grow pot-bellied, and die. Bran and grains mixed together have been also found to be very good food. In winter they will eat hay, oats, and chaff, and these may be given them three times a day; but when they eat green things, it must be observed that they are not to drink at all, as it renders them dropical: and at other times a very little drink serves them, which should always be fresh. When any green herbs or grass are cut for their food, care must be taken that there is no hem-

lock among it; for, though they will eat this greedily among other things, when offered to them, it very soon destroys them.

These animals are subject to two principal infirmities. First, the rot, which is caused by the giving them too large a quantity of green food, or from the giving it fresh gathered, with the dew or rain hanging in drops upon it. It is over moisture that always causes this disease; the greens therefore are always to be given dry, and a sufficient quantity of hay, or other dry food, intermixed with them, to take up the abundant moisture of juices. On this account, the very best food that can be given them, is the shortest and sweetest hay that can be got, of which one load will serve two hundred couples a year.

The second disease to which these creatures are subject, is a sort of madness: this may be known by their wallowing and tumbling about, their heels upwards, and hopping in an odd manner into their boxes. This distemper is supposed to be owing to the rankness of their feeding: and the general cure is the keeping them low, and giving them the prickly herb called tare thistle to eat.

The general computation in respect to males and females is, that one male rabbit will serve for nine does: some allow ten to one buck; but those who go beyond this, always suffer for it in their breed.

Poultry.—Under this head are comprehended a great variety of birds, which are objects of attention to the farmer.

Fowls.—The farm-yard cannot be said to be complete until well stocked with fowls; the advantage of which will be most considerable in situations where the farmer is best supplied with grain, and has the best means of preserving the birds. In choosing this kind of stock, it is necessary to prefer the best breeders and the best layers; the oldest being always reckoned the best sitters, and the youngest the best layers; but no sort will be good for either, if they are kept too fat. The best age to set a hen for chickens, is two years old, and the best month to set them in is February; though any month between that and Michaelmas is good. Hens sit twenty-one days, during which time they should constantly have meat and drink near them, that they may not straggle from their eggs, and thereby chill them. If fowls are fed with buck or French wheat, or with hemp-seed, it is said they will lay more eggs than ordinary; and buck-wheat, either whole or ground, made into paste, which is the best way, is a grain that will fatten fowls very speedily; but the common food used is barley meal, with milk or water, but wheat-flour moistened is probably the best. A good hen should be working, vigilant and laborious, both for herself and her chickens, and the larger the better. The elder hens are rather to be chosen for hatching than the younger, because they are more constant, and will sit out their time; but if you choose for laying, take the youngest. Those eggs that are laid when the hens are a year and a half, or two years old, are the best; at that time you must give the hens plenty of victuals, and sometimes oats, with fenugreek to heat them, if you would have large eggs.

In setting hens, take care that the eggs be new, which may be known by their being heavy, full and clear.

While sitting, a hen should not be taken off or disturbed from her nest, for that will make her utterly forsake it.

A hen-house should be large and spacious, with a pretty high roof and strong walls, in order to keep out thieves and vermine; there should likewise be windows on the east side, that they may enjoy the benefit of the rising sun; and round about the inside of the walls, upon the ground, should be made large pens of three feet high, for geese, ducks, and large fowls to sit in; and near unto the covering of the house long perches, reaching from one side of the house to the other, should be fixed, on which cocks, hens, capons and tur-

keys may fit. At another side of the house, at the darkest part of the ground pens, fix hampers full of straw for nests, in which hens should lay their eggs; but when they sit to hatch chickens, they should be on the ground: there should likewise be stakes tuck in the walls, that the poultry may climb to their perches with the greatest ease; and the floor should not be paved, but made of earth smooth and easy. The smaller fowls should also have a hole made at one end of the house, to go in and come out at when they please, or else they will seek out roosts in other places. It would likewise be of great advantage to have the hen-house situated near some kitchen, brew-house, bake-house, or kiln, where it may have the heat of the fire, and be perfumed with smoke, which is very grateful to pullets.

In order to fatten chickens, you must put them into coops, and feed them with barley-meal; put likewise a small quantity of brick-dust into their water, which they ought never to be without: this last will give them an appetite to their meat, and fatten them very soon; for in this case it must be considered, that all fowls and birds have two stomachs, as they may be called; the one is their crop, that softens their food, and the other the gizzard, that macerates the food: in the last we always find small stones and sharp sand, which help to do that office; and without them, or something of that kind, a fowl will be wanting of its appetite to eat; for the gizzard cannot masticate, or, as it may be said, grind the food fast enough to discharge it from the crop, without such sand or stones: and in this business the brick-dust assists them.

The following method will probably be found still more advantageous; for a very short time is necessary for this purpose, as chickens, if not fattened in a week, become distempered. In order to promote this end, poultry should be fattened in coops kept *very clean*. They should be furnished with gravel, *but with no water*. Their only food barley meal, mixed so thin with water as to serve them for drink. Their thirst makes them eat more than they would, in order to extract the water that is among their food. This should not be put in troughs, but laid upon a board, *which shoud be clean washed every time fresh food is put upon it*. It is foul and heated water which is the sole cause of the pip.

This kind of flock is liable to be affected with different disorders, such as the *pip*, the *roup*, the *flux*, *stoppage* in the bowels, and *sores* eyes.

The first of these complaints is occasioned by eating foul meat, and drinking dirty water, and is known by the fowl having a thin white scale on the tip of the tongue. The remedy of this disorder is, the removal of the scale, and slightly rubbing the part with salt.

The second is merely a swelling on the rump, which is known by the feathers of the affected part standing out in an unnatural manner. The cure is to be attempted by *opening* the sore, and forcing out the *core* after the feathers have been plucked out.

The *flux* is caused by eating too much moist food, and is to be removed by an opposite kind of diet.

The removal of the disorder in the eyes of this kind of fowls, must be attempted by changing their situation and food.

Ducks.—These are very necessary for the farm-yard of the husbandman, as they require no charge in keeping, but live on lost corn, worms, snails, &c. for which last reason they are very good in gardens. Once in a year they lay very well, especially that sort of duck that turns up the bill more than the common kind; when they sit they need little attendance, except to let them have a little barley, or offal corn and water near them, that they may not straggle far from their nest, and thereby chill their eggs. In general it is found more profitable to set a hen upon the duck's eggs, than any kind of duck whatever, because the old one leads them when hatched too soon to the water,

where, if the weather be not very mild, some of them will be lost. Put by means of the hen, they remain a good while upon the land, and get hardy before they venture into the water. About thirteen eggs is the proper number to let a duck sit upon. When the ducklings are hatched they require no care, if the weather be tolerably good; but if they happen to be produced in a very rainy season, it would be right to keep them under cover a little, especially in the night; for, though the duck naturally loves water, it requires the assistance of its feathers, and, till they are grown, is easily hurt by the wet.

It may here be observed, that the fattening of ducks at any age is very easy; and that whether it be the duckling, or the grown duck, the method to be used is exactly the same. They are to be put in a quiet dark place, and kept in a pen, where they are to have plenty of corn and water: any kind of corn will do; and with this single direction they will fatten themselves extremely well in fifteen or twenty days.

The manner of fattening these birds in Languedoc in France, is this: When the ducks are pretty fat by the usual modes of feeding, they are shut up eight by eight in a dark place. Every morning and evening, a servant puts their wings across, and, placing them between his knees, opens their bill with his left hand, and with his right fills the craw with boiled maize: they sometimes die suffocated; but they are not a bit the worse for it, provided care is taken to bleed them directly. These unfortunate animals pass there fifteen days in a state of oppression and suffocation, which makes their liver grow large, and keeps them always panting, and almost without breathing. When the tail of the duck spreads out like a fan, they know that it is fat enough; they are then turned out to bathe in water, after which they are killed and dressed for use.

Two ducks being opened, of which the one had not, and the other had been crammed; the first had a liver of the natural size, the skin equally thick in all places, and the lungs perfectly sound. That which had been crammed, had an *enormous liver*, which, covering all the lower part of the belly, extended as far as the *anus*. (The ducks are generally suffocated, when, by the pressure of the liver, the *anus* is opened, and the liver appears at its orifice.) The lungs were small, and loaded with blood. The skin of the belly, which covered the liver, was of the thickness of a shilling. When the ducks thus crammed have been plucked, they seem balls of fat, and none of their members are discernible.

Geese.—These are advantageous both for food, feathers, and grease. They will live upon commons, or any sort of pasture, and need little care and attendance; only they should have plenty of water. The largest geese are reckoned the best; but there is a sort of Spanish geese that are much better layers and breeders than the English, especially if their eggs be hatched under an English goose. Geese in general lay in the spring, the earlier the better, because of their price and of their having a second brood. They commonly lay twelve or sixteen eggs each. You may know when they will lay, by their carrying of straw in their mouths, and when they will sit, by their continuing on their nest after they have laid. A goose sits thirty days; but if the weather be fair and warm, she will hatch three or four days sooner. After the goslings are hatched, some keep them in the house ten or twelve days, and feed them with curds, barley-meal, bran, &c. After they have got some strength, let them out three or four hours in a day, and take them in again, till they are big enough to defend themselves from vermine.

For fattening *green* geese, they should be shut up when they are about a month old, and they will be fat in about a month longer. The fattening of older geese is commonly done when they are about six months old, in or after harvest, when they have been in the stubble-fields, from which food some kill

them; which is a good way: but those who have a mind to have them very fat, shut them up for a fortnight or three weeks; and feed them with oats, splitted beans, barley meal, or ground malt mixed with milk: the best thing to fatten them with, is, however, probably malt mixed with beer. Geese will likewise feed on and fatten well with carrots, when cut small, and given them.

But the method of fattening them in Languedoc, in France, is thus stated by Doctor Anderson, in his valuable Essays: "After the bird is got into full flesh (*i. e.* by being well kept upon green food), it is necessary not to delay the fattening of them too long, lest you lose the season entirely. About the end of December they enter into rut, *after which time they will not fatten at all.* As soon as the frost has set in (usually towards the end of November), they are shut up, to the number of ten or twelve (never more), in a dark still place, where they can neither see light, nor hear the cries of those which are kept for laying. They remain in that prison till they have attained the greatest degree of fatness, and are ready for killing: that moment must be seized, otherwise they would very soon turn lean, and at last die. There are two ways of fattening them. The first is, by giving them a trough filled with grain which they call *farde*, so that they may eat whenever they please. The geese fattened on this grain are very delicate. Others put into the trough grains of maize boiled in water. They take care to give them plenty of that food, and to keep the coop clean. At the end of two or three weeks, the geese are all fully fattened. They are then taken out of the coop, and allowed to go at large into the water for twenty-four hours. Without that precaution, their flesh would have a disagreeable flavour. The above, says the Doctor, may be called the natural method of fattening, by enticing them to eat food enough of their own accord. The second may be called the artificial method, and is as follows: The geese are put up in the same manner as before, and are crammed twice a day, by putting into their craw, by means of a tinned tube, as much as it will hold of maize boiled in water. The tube is used, because, the bill of the goose being furnished with teeth, the person who should attempt to perform that operation by hand, would soon have it scratched and torn to pieces. By this means, the geese acquire a prodigious fatness, so that a pair sometimes weigh from fifty to sixty pounds. Their liver weighs from one pound to a pound and a half,—is white and delicate;—but has a slight bitterness to the taste, which the liver of a duck has not. The *beards* are large like a small apple, and when dressed on the gridiron they are excellent eating. The feet are boiled, after which they are fried the same as the tongue."

In some countries they shear the geese for their feathers, and in others they pull them once or twice a year; but the latter way is more injurious to them.

Turkeys.—These are fowls that prosper very well in open countries, where there is not much shelter to harbour vermine to destroy them, as they are naturally inclined to ramble. The hens are so negligent of their young, that, while they have one to follow them, they never take any care of the rest; and therefore great care must be taken of them while they are young, to watch them, and to keep them warm, being birds that cannot bear the cold. Some, however, where they have the conveniency of a small cover near the house, let them take their liberty, and seek their own nests; but it is only in some particular places that they do well with such management.

When kept with corn, they are very great feeders; but if left to their liberty when grown up, they will get their own living, without either trouble or expence, by feeding on herbs, seeds, &c. Turkeys, being very apt to straggle, will often lay their eggs in secret places; therefore the common sort of them must be carefully watched, and made to lay at home. They

begin to lay in March, and will sit in April. Eleven or thirteen eggs are the most they sit on. They hatch in between twenty-five and thirty days. The young ones may be fed either with curds, or green fresh cheese cut in small pieces. Their drink may be new milk, or milk and water. Some give them oatmeal and milk boiled thick together, into which they put wormwood chopped small, and sometimes eggs boiled hard, and cut in little pieces. They must be fed often, as the hen will not take much care of them herself; and when they have got some strength, feed them abroad in a close walled place where they cannot stray; they must not be let out till the dew is off the grass, taking care to have them in again before the night, because the dew is very prejudicial to them.

In the fattening of turkeys, *sodden* barley is very excellent, or *sodden* oats for the first fortnight, and for another fortnight it may be necessary to cram them as is done with capons.

From some of the various facts which have been stated above, respecting the feeding of poultry, Doctor Anderson draws the following conclusions: Not only do they, says he, confirm the general position, that the more food an animal can be made to take in a given time, the quicker it will be fattened; but this rule seems to hold, when it is given even in a *hurtful* quantity, beyond what the animal would naturally have taken; and farther, that by certain modes of feeding, when well understood, the size of particular parts of the body can be augmented at pleasure, far beyond their natural proportions. Could the quantity of tallow in quadrupeds be augmented nearly in the same proportion to the liver; in this case, it is evident the profit to the owner would be greatly augmented.

Pigeons.—These, Mr. Pitt observes, can hardly in general be considered as an article of profit to the occupier of a farm; though there are instances in Staffordshire, where something handsome is actually made of them by tenants; yet these instances are rare, and too seldom occur to be reckoned upon in a general account. But few farm-houses are indeed furnished with the necessary accommodations for them: and the increase of pigeons beyond a certain degree must doubtless, he thinks, be injurious to the cultivation of grain: within due bounds, says he, they do little harm; but increased beyond it, they prove pernicious vermine, both to the new-sown crops and the early part of harvest. They are particularly voracious in early pease; he has therefore no wish to see them much increased, conceiving the advantage arising from their increased numbers, for consumption as food, to be more than counterbalanced by the mischief occasioned by their depredations. And Mr. Kent says, that pigeons are much fewer in Norfolk than formerly, as many of the pigeon-houses have been dropt, on account of the injury which the pigeons do to thatched buildings.

Bees.—For the advantageous culture of these industrious insects, the situation of the farm should be suitable; and also well supplied with their proper food. The ingenious Mr. Bonner, who has paid much attention to the cultivation of bees in Scotland, lays down the following plan and directions for the speedy increasing of bee-hives in that country:

If a gentleman of property, says he, has a proper situation for bees, and be inclined to commence the cultivation of bees with spirit, let him apply to some person tolerably skilled in that branch of science, and let him purchase one hundred or more bee-hives, in the month of August, and place them properly, according to the directions which shall be laid down hereafter. Let him next rear a sufficiency of turnips in their neighbourhood, that they may blossom next spring; and in the month of February let him sow some mustard seed, and some furze and broom upon dykes or waste ground. Gentlemen of property, who have any ground proper for planting, should by all means plant a number of plane-trees and fallows. They should likewise sow a good deal of white clover, sweet residu, or

mignonette, &c. with any other flowers that will grow upon the ground, either by nature or art. In winter, particular care should be taken to preserve the bees from cold; in spring, from famine, and robbery by other bees. And when they are ready to swarm, great care must be taken to lodge them in proper habitations. With such attentive management, he can venture to assure all who will make the experiment, that one hundred well chosen stock-hives will, in a tolerably good season, produce from one hundred and eighty to two hundred or even two hundred and twenty hives, or more.

Supposing, says he, that there are, in May 1795, twenty stock-hives in each parish in Scotland, the amount in eight hundred parishes would be sixteen thousand. Then, supposing each of these hives to throw one swarm, which would probably keep through the winter, in September we should have thirty-two thousand stock hives. At this period, let every gentleman who rears bees, keep all his hives, young and old, for stock hives, that are fit for it; let the poor, who are able, do the same with theirs;—and let those who are not able to lie out of the produce of their bees, sell them to those who are inclined to purchase them for stock-hives. By doing this, they will raise as much honey as if they killed all the bees and sold the honey and wax, and with far less trouble. On these principles, by keeping thirty two thousand stock-hives, with proper management, during a tolerable season, and always preserving all that will preserve, for the space of seven years, the stock would, he thinks, increase as follows, viz.

	Hives.
In the 1. year, Sept. 1795, there would be	32,000
----- 2. ----- 1796, -----	64,000
----- 3. ----- 1797, -----	128,000
----- 4. ----- 1798, -----	256,000
----- 5. ----- 1799, -----	512,000
----- 6. ----- 1800, -----	1,024,000
----- 7. ----- 1801, -----	2,048,000

Thus, he concludes, that within the short period of seven years, the number of our bee-hives would be increased to no less than *two millions and forty-eight thousand hives*. But allowing the forty-eight thousand to be discounted for dead hives, there would still remain two millions of stock hives. Although this number may appear large, yet there is no reason to suppose that the calculation is either impossible or improbable. But even dropping the one-half of this number, upon the supposition of losses by bad seasons, &c. there would still remain, at the lowest estimate, a clear *million* of stock-hives; which next year might produce *four millions* of pints of honey, and *one million* of pounds of wax, and still keep the stock entire. With such a quantity, indeed, of these useful animals, and valuable commodities, we might rest contented; as such a quantity, besides every other advantage, would afford employment to hundreds of old and poor people to watch them in swarming time, and to make hives to receive the young colonies of these animals.

Situation of the Apiary.—As a general rule, place your hives where they will be least exposed to the wind, and enjoy as much of the influence of the sun as possible; for wind always retards the bees in their work, while the sun's beams invite them to it. Although it is well known, that bees will thrive well in high and windy situations, yet a low one is always to be preferred. In the neighbourhood of the apiary, there should be abundance of flowers, from which the bees may collect their wax and honey. Were a choice allowed me, says Mr. Bonner, where to place my bees, it would be in an early situation,—a hollow glen by the side of a rivulet, surrounded with abundance of turnips in blossom, in the spring,—mustard and clover in summer,—and heath in the latter end of summer and harvest; with a variety of other garden and wild flowers in their seasons. However, he would not be understood as if he

hinted that bees will not thrive unless they be placed in such an advantageous situation, as the contrary can be proved: for bees have thriven amazingly well in places where they were not within reach of many of the above-mentioned flowers: but although they will do well in most situations, and fly far for food, yet they will thrive far better when situated among or near good pasture, and surrounded with abundance of food.

Food of Bees.—Among the great variety of flowers, which wise Nature has so profusely laid before our noble insects, from which they may abundantly supply themselves with food, we shall, says the same author, in the first place, give some particular account of those five principal ones in this country, from which bees extract vast quantities of honey;—viz. turnips, rape, mustard, clover, and heath; and then some account of many other excellent flowers which bees feed on. Turnips, in particular, blow early in the spring, and continue long in flower; and they also yield both honey and farina, by which the bees are greatly excited to go abroad, and work upon them; when perhaps, in late situations, they have scarcely any other flower to work upon. In such places, therefore, it is highly proper that turnips be sowed, and allowed to remain in the ground during winter. These, yielding their flowers from the middle of March to the end of April, will afford the bees six weeks good pasture, and thus render them equal to those in more favourable, or earlier situations; whereas they would perhaps have scarcely had any other flower to work upon, that could do them much good. He, therefore, strongly recommends to all proprietors of bees, particularly those in late situations, if they can by any means, to let always as many turnips run into blossom in the spring, as may be sufficient to afford plenty of early pasture for their bees to work on. *Ruta-baga*, or Swedish turnip, would answer well for this purpose, as it is equally good for cattle after it has blown, as before. Thus the rich may supply themselves with that feed for sowing, and the poor will have it to sell to those who need it, which will enable them to pay the rent of the ground they grow upon. The rape in blossom answers the same end to bees as the turnips; and as it is a little later of flowering, it will yield the bees a fresh and seasonable supply, when the turnips begin to fade, and thereby keep them constantly at work till the latter end of May, when all the herbs of nature will, as it were, vie with each other, which shall contribute most to supply this noble and virtuous race with abundance of the sweetest nectar. Then, at this season, the balmy plane-tree regales them in the morning, before the drowsy herd ascends the hill to relieve his imprisoned bleaters; and the gold-like furze, mustard, and broom, invite them to feast till the day decline. Garden and wild mustard, with bunches of all kinds, bees are very fond of, and work keenly thereon; and these flowers are attended with this advantage, that by sowing their feeds at different times in the spring, their flowering may be so protracted as to afford the bees a sufficiency of pasture during the whole working season. In June the white clover comes, which continues long in blossom, and also yields abundance of the finest of honey: and wherever the proprietor of bees has it in his power, he should be particularly attentive to raise it in his pasture lands. So fond are the bees of this flower, that, whenever it appears, they will desert and overlook many other excellent flowers, as unworthy of their attention, and eagerly dart upon it, and work and sing thereon all the day long, until the cold evening chase them with reluctance home to rest. But as all nature's beauties fade, and thereby give way to their successors, so does this beloved herb, as, about the end of July, they begin to blacken, and the balmy dew to forsake their sweetest lips; then our heroes go in search of fresh provisions, and in their rambles, as they skim over our lofty mountains, are attracted by the blue heather bells, which are here in great numbers. Heath is attended with this advantage, that it needs no culture nor rearing;

but, on the contrary, grows spontaneously, in too great abundance, in many places; as most certainly the greater half of Britain is covered with it: but, like the clover, it yields also vast quantities of the finest honey; and, when the month of August is favourable warm weather, no thriving hives of bees, placed near it, need fail, in a short time, to enrich themselves with plenty of honey. The flowers of furze, broom, and plane tree, as formerly hinted, are also highly grateful to bees, as all of them afford abundance of matter to collect their honey and wax from. Furze in particular generally flowers early, and continues long in blossom. But besides the flowers above mentioned, there is a great variety of others, which, in their different seasons, afford employment and materials for the bees; such as lilies, rose marys, yellow gowans, and the blossoms of crocuses, snow-drops, oziers, fallows, vetches, alders, poppies, beans, gooseberry bushes, and fruit-trees of all kinds. In short, he knows no flower that they will refuse, when they are at a loss for variety. *There is one thing very observable, that whatever flower a bee first pitches upon, she always continues to work upon the same species till she is loaded, although she should be obliged to fly over better kinds, and even to some considerable distance for them:* but, if the bees cannot obtain a full loading from those flowers which they prefer, they sometimes make up the remainder from other flowers which they meet with.

Method of choosing a Stock.—Those who intend to erect an apiary, must take particular care to have it filled with proper inhabitants. They must be peculiarly attentive to this, as all their future profit and pleasure, or loss and vexation, will, in general, depend upon it. They must therefore pay the utmost attention to the choice of their stock hives; for the man who takes care to keep good stock hives will soon gain considerably by them; but he who keeps bad ones, will, besides a great deal of trouble, and little or no success, soon become a broken bee-master. In September every flock hive ought to contain as much honey as will supply the bees with food till June following; and as many bees as will preserve heat in the hive, and thereby resist the severity of a cold winter, and act as so many valiant soldiers, to defend the community from the invasions of foreign enemies in spring. Therefore the bee-master should purchase a proper number of hives in August, or September, when they are at the cheapest rate. They should be full of combs, and well stored with bees and honey; and should weigh at least 30lb. each; if heavier, so much the better; for light hives run a great risk of perishing by famine, unless the bees are supplied with food; which will cost as much expence, and a great deal more trouble, besides a considerable risk of their dying at last, after all this extraordinary trouble and expence. Whereas, a well chosen hive of 30lb. weight, allowing 12lb. for the empty hive, bees, combs, &c. will contain 18lb. of honey, which will supply the bees with food till next June; a time when, it may be presumed, they will find abundance of provisions for themselves among the flowers. When a choice can be obtained, the youngest hives should always be preferred, because old hives are liable to vermine and other accidents. However, although a hive should be four or five years old, it should not be rejected, if it possesses these two essential qualities, plenty of bees, and abundance of honey; but if either of these be wanting, the purchaser will have much cause of regret, when too late to repair the injury he may sustain.

Cover for Hives.—The same writer observes, that the best of all covers for hives that he has yet seen or heard of, are such as he ordered a potter to make for him, of burnt earthen ware. They are made in the form of a hive, pretty strong, about 21 inches wide, and 12 deep; with a circular edging turned up at the skirts, and a spout about an inch in length. These, being placed above the pob tow, or straw, keep it close to the hive, and may easily be taken off or put on at pleasure. The spout

being placed behind, all the water runs off at the back of the hive. The hives, when thus covered, may be compared to a man's head with a wig and hat upon it; the pob tow resembling the wig, and the earthen cover the hat. The only objection to these covers is, that they are brittle and easily broken; but the care that every good bee-master will readily bestow upon his hives in any case, is sufficient to preserve them from accidents of this kind.

Mr. Bonner also observes, that with regard to the profit arising from bees, one consideration should not be overlooked, viz. that almost the whole produce, arising from the sale of both honey and wax, is in a great measure clear profit; as bees and bee-hives are, particularly in Scotland, equally free from rents and taxes; and the culture of them does not in the least injure or impede any other improvement in any respect. Nor do they require a constant attendance, as most other articles of improvement do; for a proper person might easily oversee, with a little assistance in swarming time, at least 500 bee-hives. And as Nature has amply supplied them with food, and with powers to provide it for themselves, they put their owners to little or no expence for that article; which cannot be said of any other of our servants whatever. Thus, says he, by following the above plan, with a little attention and exertion on the part of our landed gentlemen, such a number of bee-hives would soon be raised all over the kingdom, that the quantity of honey and wax would be increased to such an extent, as to produce the greatest advantages to the nation at large, as well as to the private proprietors of the hives. All the money sent to foreign markets for these commodities would be kept at home; which would be a saving of perhaps no less than 50,000l. a-year; and honey would be produced in such abundance at home, as to supply the poor, as well as the rich, not only with a delicious luxury, but also with an excellent substitute for some necessaries of life. It might, for instance, be converted into mead, a fine well-tasted wholesome liquor, which would prove an excellent substitute for strong ale and porter, and could be sold at a very moderate price. A weaker kind of mead, called *bragwort*, could also be made of it. This is an agreeable, wholesome liquor, much esteemed by many, who use it as a substitute for small beer. When properly made, it will keep long; and when of a proper degree of strength, it is highly exhilarating. The increase of the quantity of honey would also reduce the price of it so much, that, instead of paying 10d. or 1s. per pound for it, as at present, it might be sold so low as 3d. per pound, in which case it would prove an excellent substitute for butter to the poor. Even at the present prices, it is already used by many persons mixed with butter. As to the wax, almost every person knows the great uses made of that article, in medicinal preparations, wax candles, sealing wax, &c. &c. as well as the high esteem in which wax candles and wax tapers are held by persons in the higher ranks of life, on account of their clear light and odoriferous smell, as well as their freedom from all danger of greasing, as tallow candles do, when a drop falls from them upon any thing.

Mr. Pitt's opinion, however, differs materially from the above. Some sanguine writers, says he, have conceived that very large products are to be obtained from the labours of these industrious insects. But of this I have great doubts: the climate of this island is not sufficiently steady even in summer; storms and showers often interrupt their labours, and at the end of the season it often happens that all their industry has not been sufficient for a winter's subsistence. They succeed best, he thinks, in straw hives, neatly hooded over with an upper coating of straw. In the autumn, those who have not raised a sufficiency of food for winter, it is doubtless humanity to destroy, as sudden suffocation is better than a prolonged but certain starvation; and sometimes a good hive or two are destroyed with the rest

for the sake of profit. But though the average annual profit of bees may be small, their cultivation, says he, is doubtless commendable, and ought to be encouraged.

On the most economical Consumption of the Produce of a Farm.

THE hints which have lately been thrown out by Doctor Anderson on this subject, in the third volume of his excellent *Essays on Agriculture*, are so ingenious and philosophical that we cannot refrain from laying a few of them before the reader in concluding this treatise.

After observing that nothing of this nature has yet been attempted in any work on rural economics, he says, "It may be admitted as a maxim, that agriculture can never be said to have been carried to its ultimate degree of perfection, so long as there is to be found one inch of ground that could be made to yield a single grain of greater or more valuable produce; so long as a single ounce of vegetable matter is allowed to go waste, or that has not been applied towards the sustenance of some useful animal, in the way in which it could produce its most beneficial effect; and while a single particle of dung or other manure is suffered to be misapplied, or so employed as not to afford the greatest possible resource it is capable of yielding, for the reproduction of additional crops of the most valuable kinds. That the highest degree of possible perfection should, in every case, be attained, is not to be expected in this imperfect state: but the nearer we approximate to it the better; and the more steadily we keep these objects in view, and the more strenuous our exertions are to attain them, we shall doubtless approach the nearer to these desirable attainments. So far, says he, are these objects, however, from being steadily held in view, in the present age, that one who attends to general practice in Britain, would be induced to believe they were scarcely ever adverted to, unless by a very few persons, and in regard to a small number of particulars only. Economy in the expenditure of the produce of a farm, like economy in the expenditure of capital in family affairs, seems indeed to be despised by many men, as indicating *poverty* of spirit, rather than wisdom, and is therefore studiously, as it should seem, avoided. There are, however, a few individuals, who have showed themselves to be above these prejudices, and who have not been ashamed to attempt to make some progress in different departments referable to this head of useful enquiry.

He observes further, in respect to economical arrangements, that was the subject to be considered in its utmost extent, as affecting the management of a farm, it would take a much wider sweep than that to which he means to confine himself in the present disquisition; which he tells us is solely meant to relate to the consumption of the crude produce of a farm by animals. He does not pretend, in what follows in this essay, to give absolute directions to the farmer what he ought to do, even on that part of the subject now under view. At the mere outset, in a business of such magnitude and intricacy, he remarks, the person who first attempts to open up the view, can do little more than act in the humble station of a pioneer, who clears away a few obstructions that may enable others, with less labour, to penetrate farther than he has done.

Dung much wasted under the common Practice of Pasturage.—The author says, that it is stated in the *Agricultural Survey of Gloucestershire*, that one acre of rye-grass, which had been sowed from Michaelmas to May, kept nine ewes and lambs *one month*. We may therefore, he says, safely conclude that the produce of the same field, from May till Michaelmas, would have been double to that it yielded during the winter half-year; consequently it could have sustained eighteen ewes and lambs *one month*. At this rate the acre of ground, tak-

ing the whole year round, would have afforded food for twenty-seven ewes and lambs for *one month*. These were large sheep, weighing about 25 pounds per quarter on the average.

And it is remarked in the *Survey of Wiltshire*, that 500 such ewes and lambs are sufficient to dung an acre each day when folded upon it: at that rate, says the Doctor, 27 of them should dung an acre in a little less than 19 days; consequently, in thirty days, somewhat better than half an acre more. He is however inclined to think this would be but a very moderate dunging; but should double the quantity of dung, or more, be required for certain purposes on particular occasions, it will not, he says, affect the conclusions deducible from these facts in *kind*, only in *degree*. Hence, in his opinion, it follows, that if none of this dung were suffered to go to waste, *an acre* of good land laid down to grass, in high order, should afford as much dung as would be sufficient to dress each year *an acre and a half* of other land.

And further, in the *agricultural account of Suffolk*, it is stated, that the rich marsh lands there keep at the rate of six sheep for seven summer months, and four for the five winter months per acre: that is, a little more than five sheep on an average per acre throughout the whole year. These are very large sheep, of which 800 would be equal to the 500 ewes and lambs above mentioned, and consequently would be sufficient to dung an acre in one day. But 5 times 365 makes 1825, the number of sheep kept for *one day*. At this rate, one acre of these rich grass lands would afford as much dung, in the course of one year, as should be sufficient to dung somewhat more than *two acres and a quarter* each year, if husbanded with due economy and attention.

But as the sheep in neither of these cases are folded, the dung is suffered to drop in a scattered manner over the pastures, throughout the whole year. In this manner, the influence of the dung must either be nothing, or it must produce *certain* effects upon the grass. If the last, what will these effects be? To this he says, it is well known that when sheep are folded upon grass ground, so as to deposit their dung upon it in considerable quantities all *about one time*, as in folding, the effect is, that a flush of grass is quickly produced over its whole surface, which is much more luxuriant and abundant than it would have been, had it not received this dressing. But it is equally well known, that the animals, whose dung has occasioned that flush of grass, nauseate it; nor can they be brought to taste it, unless they be compelled through hunger to do so; although animals of another kind are seen to eat that kind of grass (called in some places *goss*, in other places *toth*), not only without reluctance, but even with avidity and much eagerness.

He adds, that the extra flush of grass raised on the two acres and a quarter, that might be thus manured by the sheep fed on one acre, would be sufficient, on a moderate computation, to keep at the rate of two sheep per acre. By consequence, the extra grass produced by the dung of the sheep kept on one acre of this rich grass land, would be sufficient to keep four sheep and a half. But to keep within bounds, say *three* sheep only could be kept by the grass produced from the dung of the sheep fed on one acre. If the dung be supposed to have the same effect in producing extra grass, when dropped from the animals as they pasture on the field, as it has when laid upon ground closely, by means of folding, it must follow from these premises, that as much grass will grow from that dung upon each acre as would feed three sheep. But as the sheep will not eat this kind of grass without constraint, the ground must either be so hard stocked as to compel them, through hunger, to eat that nauseous food, or that portion of the grass which is produced by the dung, will be suffered to run to waste; so that, in either case, a considerable loss must be sustained by the owner.

This loss, he observes, may indeed be avoided, in as far as respects the consuming of the grass only, by mixing different kinds of stock on the same field, while in pasture. For if these animals can be made to associate together, so as not to disturb each other in the field, the one set of animals will eat up the rank grass produced from the dung of the others, and thus the whole will be eaten up without waste. This practice is indeed sometimes adopted in Suffolk to a certain degree, where the farmers are in use to put among their sheep a certain proportion of calves, or horses, which, in some measure, answer this end. But as the general practice there is to stock with sheep only, the loss to the stock itself, which must arise from this cause, would be very great, were it not obviated by a circumstance which indeed diminishes the evil, though this is in consequence of its producing another evil of nearly an equal magnitude and equally detrimental.

For, says the Doctor, if the dung, which is scattered about on the field, in small quantities, as it drops from the animals when pasturing upon it, were supposed to be incapable, in that state, of producing any sensible effect as a manure; or if that effect were very inconsiderable, in comparison of what it would otherwise have been, if applied all at one time, as in folding; in either of these cases, the nauseating quality of the grass would not be experienced by the animals; or in such a degree only, as not to prove considerably hurtful to them: for, in this case, the dung proving inert, it would do little or no service to the ground, and in consequence of that, would prove not in any sensible degree hurtful to the sheep in feeding.

But that the above supposition is literally true, seems to be proved by the very fact which gave rise to these observations. If the dung thus dropped produced a melioration in any degree proportionate to what it would have done, if collected together, as in folding, its effects must have been extremely obvious in two respects; *first*, in augmenting the quantity of grass produced on the field; and, *second*, in increasing its nauseating quality; neither of which, at present, are very obviously perceptible. In regard to the *first* particular, says he, every person knows, that if a dunging equal to more than double what is given by a good folding were laid upon even ordinary grass ground, it would at once make the produce nearly equal to that of the rich grass lands in question. And though it be true, that the effect of such a dressing upon poor ground would not be equally perceptible during the second year as the first, yet it would still be very considerable; inasmuch that, although no other dunging were given to it, and the crops were constantly cut and carried off from the field, it would not return to its former state, but would continue to afford much better crops than before it received the dressing, even for the third, and many succeeding crops. If the same dunging, then, were annually repeated, and if a similar effect were to result from each repetition, the quantity of produce must go on continually augmenting in a very rapid degree from year to year. But as no such rapid melioration is here perceived, we are, says he, forced to conclude, that the dung which is *thus* applied produces not the effect it might, under good management, be made to do; and that consequently an unnecessary waste is thus incurred.

But further, if it should be alleged, that when land is once brought to a certain degree of productiveness, it can be made to yield no more produce, were it to be dunged ever so often; and that its richness could not be augmented even by folding itself, no more than it is observed to be by pasturing upon such land;—the want of economy, in suffering the dung to be thus applied, would be even perhaps still more obvious than in the case before stated. For if the dung produces *there* no good effect whatever, there can be no doubt but it would produce a very powerful effect, if properly applied to ground of a poorer

quality: so long, then, as such ground is to be found, those who suffer their dung to be so applied, must be held guilty of very great mismanagement, and of course should make haste to correct such a practice.

And the other circumstance above noticed is a corroborative evidence, that the dung thus laid on the field is allowed to waste itself in a great measure without effect: for, had the nauseating quality of the grass been *nearly* as great as we know it must have been, if such a proportion of the grass had been forced by the dung of the animal which is set to consume it, this dislike in these creatures must have been so great as to be at once perceptible to every person; and must have *compelled* the farmers *universally* to adopt strong and decisive measures to guard against it: but as no such peculiarity is generally recognised, we are forced to conclude that, if it does exist at all, it is felt but in a very inconsiderable degree; and consequently that the great quantity of dung which is dropped upon these fields, operates not upon them in any sensible degree as a manure. If these observations be well founded, says the Doctor, what an amazing waste is sustained through the whole nation, by the loss of the dung that is thus uselessly scattered on the surface of pasture fields every where!

He tells us, that he is aware of the prejudice that is very generally entertained in favour of the benefits that grass land derives from the dung which is dropped by the animals that pasture upon it. But although he has searched diligently for a fact, or an argument grounded upon facts, to support this opinion, he is forced to declare that he has not been able to find one in support of it; but, on the contrary, many, besides those above stated, which militate against it. He is therefore compelled to rank this as one of that numerous class of opinions which have been at first casually adopted, and afterwards cherished, by a prejudice derived from habit rather than from reasoning of any sort.

For, says he, had this opinion been well founded, it must necessarily have happened, that in every case where grass-land has been long pastured upon, without folding, the quantity of its annual produce must have been sensibly augmented. That this has not been the case, we need only to open our eyes to be convinced of. It is only necessary to notice the immense numbers of poor grass fields in every part of this kingdom, which have been pastured from year to year without interruption, perhaps for ages past, and which discover not the smallest tendency to melioration of any sort, whether the quantity of produce within the utmost stretch of the memory of man, or the rent that has been paid for them (the alteration in the value of money being adverted to), be considered as the standard. He himself knows many fields which, under certain circumstances, have grown evidently less productive than before, though perpetually pastured upon. The forest of Dartmoor in Devonshire, and other such extensive moors of a barren nature, in many other parts of England, though every year stocked in summer with more beasts than the produce can properly sustain, do they discover the smallest tendency to melioration even till this hour? But there can be no doubt, that if all the dung which has been dropped upon these wastes had been properly husbanded, a great and sensible melioration on them must have been effected many ages ago.

But, says he, taking the converse of the proposition above stated,—Were it true, that the dung which is dropped upon pastures tended sensibly to meliorate them, it must follow that those pastures from which the dung is constantly abstracted by folding, as on Marlborough downs in Wiltshire, and many other places, must either have grown worse in the course of ages, even where it had not been touched by the plough; or at least must have advanced much more slowly in their melioration, than other grass lands, equally untouched by the plough,

from which no dung has been abstracted. Is this the case? I have not met with a single fact which tends to show that the present produce of the parts of those fields which have never been ploughed, when compared with that of former times, differs in any respect from that of other fields of a similar nature, from which no dung has ever been carried away by folding. He is therefore forced to conclude, that in all cases where animals are allowed to feed on pastures of any sort, the dung which is dropped from them is, in a great measure, lost as a manure; and a rigid economy would require that measures should be adopted for preventing this waste, if it can be done without occasioning evils greater than that which it is intended to correct or prevent.

The Folding of Sheep economical.—The Doctor here observes, that the remedy which first presents itself in this case, is that of folding; and that, if properly managed, there are perhaps few cases in which it might not be put in practice, not only without detriment to the stock, but even perhaps in some cases to their advantage.

All animals, but especially those that ruminates, choose to feed and rest by turns. Ruminating animals require much time for rest; and the more quiet they are allowed to be during that period, the better they will thrive. If these then are withdrawn from their pastures after they have properly filled their belly, and when they become necessarily disposed to ruminate, they can sustain no damage from being then put into a place where they can have no access to food. And if they be only as long detained there as till they have rechewed the food they had swallowed, and begin to feel an inclination to eat more, they will even be benefited by this confinement, rather than otherwise. And they will thus all feed and rest at the same time.

Penning, however, under injudicious management, may tend to retard the feeding of the animals subjected to it. If the creatures be driven to a great distance from their pastures to the pen, it must subject them to a hurtful degree of fatigue; and this will be increased if they must be made to pass through narrow lanes, where they may be crowded and incommoded by passengers; or where they cannot avoid being at times mired in dirt, or drenched in wet: or if they be neglected too long in the pen; or put up at improper times, &c. Therefore, says he, to derive the full benefit from folding, it would seem, that where the pastures are of a great extent, there ought to be two or more folds placed close by the pasture, at convenient distances from each other; so that the flocks being gently conducted from one towards the other, feeding all the way, might find themselves, when full, just at the place into which they might retire for rest. There they should be suffered to remain just so long as is found by experience to be necessary to complete their ruminating process, and to prepare them for feeding afresh: they should then be suffered to rise and stretch themselves, when they naturally void their dung and urine on the spot. Thus will the dung be preserved, and the pastures be kept clean and sweet. They ought then to be led gently to the fresh pasture which they had not lately breathed upon, or trampled with their feet, and which of course will be to them sweet and inviting; they should thus be slowly conducted to their next resting place, feeding all the way; and so on till they go over the whole in a regular succession. If experience shall discover that diseases are produced by suffering the animals to eat their food when covered with hoar frost, or dew, or mildew, or at certain times of the day or night, when snails or other creatures are abroad, which they may swallow with their food; in all these cases, when observed, the evil may, by an attentive economist, be avoided by means of a judicious use of the fold. He may, also, by the same contrivance, withdraw the creatures from the pastures at those times

when they become restless and refuse to feed. In short, a judicious economist, by having folds properly situated, respecting the circumstances of shelter, coolness, water, and other conveniences, may avail himself of these for greatly promoting the health and enjoyment of the animals, and thus accelerating their feeding; so that, independent of the benefits he shall derive from their dung, he will in other respects reap considerable emolument.

Here the Doctor enters into some reasonings and calculations respecting the greater progress and improvement that might be produced on land by these means, under a judicious system of management, than by suffering the produce to be consumed by animals allowed to pasture at large, for which we must refer the reader to the Essay itself.

From the whole he however concludes, that dung dropped upon a field in pasture either produces no effect whatever, or an effect far less considerable than it might be made to afford under a more judicious system of management; and that, if it has any effect at all upon the pasture, it must be that of rendering the food yielded by these pastures less palatable, and less nourishing to the animals that feed upon it, than it otherwise might have been.

The Utility of hard or light Stocking of Pasture Ground.—The Doctor observes, that some persons contend that the pastures ought to be stocked very lightly; alleging, that although much of the produce is thus allowed to run to seed, which the beasts will not eat, and which of course is trod under foot, and rotted by rain, and thus wasted; yet experience, they say, proves, that a greater profit will be thus derived from it, upon the whole, on account of the superior thriving of the animals, than by any other practice. Others pretend, on the contrary, that light stocking of grass land is a practice highly to be condemned; as it tends not only gradually to diminish its produce, but also to encourage the growth of coarse and unprofitable grasses, which greatly deteriorate the pastures; and that hard stocking of grass lands, especially those of a rich quality, is an indispensable requisite of good management. These two opinions, so diametrically opposite to each other, and which are equally maintained by sensible men, he thinks clearly prove the embarrassment to which they are subjected, in consequence of their not having adverted to the circumstances stated above, and many other particulars that require still to be developed, as affecting the economical consumption of the produce of lands in grass.

He further remarks, that a third party, who approach perhaps nearer to the truth than either of the above, advise that a mixed stock should be always kept upon the same field; and that were the consumption of the foul grass produced by the dung of the animals, the only article to be adverted to, it might be, doubtless, so managed as to correct this evil. But there are so many other circumstances to be adverted to, that it is not easy by this means to get them all remedied. In every field, a variety of plants spontaneously spring up, some of which are disrelished by one class of animals, while they are eaten by some others; and some of which plants, though eaten readily by some animals at a particular period of their growth, are rejected by them entirely at another age. Thus it becomes necessary, not only to have a vast variety of animals in the same pasture; but also a very particular attention is required to augment or to diminish the proportion of some of these classes of animals, at particular seasons of the year; otherwise some part of the produce will be allowed to run to waste, unless it be hard stocked to such a degree as to retard their thriving. But if a great variety of animals be allowed to go at large in the same pasture, they are never suffered to feed with that tranquillity which is necessary to insure thriving in the highest degree. One class of these wishes to feed, or to play, while the others

would incline to rest. They thus mutually disturb and tease each other; and this inconvenience is greatly augmented, if penning of any sort be attempted. From these considerations, the practice of intermixing various kinds of stock very much together, is found to be productive of evils, in many cases, greater than those which result from the waste of food they were intended to prevent. And though there can be no doubt that by hard stocking the grafs will be kept shorter, and consequently will be more palatable in general to the animals who eat it, than if it were allowed to run to a great length, and that thus even unpleasing patches may be consumed; yet as animals which are to be fattened must not only have sweet food, but an abundant bite at all times, to bring them forward in a kindly manner, it seems to be nearly impossible to obtain at the same time both these advantages in the practice of pasturage.

Of cutting and consuming the Produce in the House.— Might not these evils, says the Doctor, be greatly diminished, if not entirely remedied, in many cases, by having the produce cut by the scythe, and given to the animals fresh in the house; rather than to suffer them to go at large and eat the produce on the field, even under any system of management whatever? Many arguments, he thinks, tend to show, that this practice would be, in general, highly economical and advantageous. In the first place, says he, if the consumption of the plants be the object principally attended to, it is plain the benefits will be great: for experience has clearly proved, that there are many plants which are greedily consumed by beasts, if cut and given to them in the house, which never would be touched by them when growing in the field. Of this nature is the dock, cow-parsley, thistles, nettles, and many other plants. Upon what principle it should happen that these plants should be so readily eaten, when thus given, while they are totally rejected when in the field, he cannot say: but that they are thus eaten, without reluctance, even when the animal is not hurtfully hungry, is evident from this circumstance, that the beasts often fall greedily to these at the moment they are brought in from the field, even before they have had time to become hungry after they had come in. Fewer plants would be rejected or suffered to go to waste on this plan.

And in the second place, It is well known that many of even the best kinds of grasses, which when young form the most palatable food for the creatures, if once suffered to get into ear, are disrelished so much as never to be tasted by them unless to prevent starvation; and as, in most pasture fields, many of these grasses get into ear from various causes, all the produce of these plants is inevitably lost to the farmer. But if cut down by the scythe, in proper time, not one of these is ever suffered to get into that nauseating state; and consequently no waste is sustained.

Thirdly. But when animals are suffered to go upon the field, many of the plants are trodden under foot by the beasts, and bruised or buried in part in the earth; in which state they are greatly disrelished by animals, and are suffered to run to waste; which never could take place were the practice of cutting adopted generally.

Lastly. It may be observed that those few plants which are totally disrelished by one class of animals, so as to be rejected by them even in the house, will not, from this circumstance, become less acceptable to others, but much the reverse. Food that an animal has breathed upon, for any considerable time, becomes unpleasant to other animals of the same class; but not so to those of another species: it seems indeed thus to acquire for them a higher relish. Even greater defilement by one animal, seems to render food more acceptable to others: for straw, that in its clean state has been rejected by cattle, if employed as litter for horses, acquires a relish for cattle that

they search for with avidity. Hence it happens, that the sweeping of the stalls from one animal, furnishes a dainty repast for those of another kind; which can easily be shifted from one to the other, if the plants are consumed in the house, but which must have been lost in the field.

If, says our author, *the health and the comfort of the animal* be chiefly adverted to, the balance will be clearly in favour of the cutting system, when compared with that of pasturing. It is well known that when animals are exposed to the sun, in the open air, they are not only greatly incommoded on many occasions by the heat, but also are annoyed by swarms of flies, gnats, and hornets, as well as the terrible gad-fly, which drives them into a state of perturbation little short of fury, which must obviously tend to retard their thriving. At other times they are hurt by chilling blasts, or drenched by cheerless rain, which renders their situation very unpleasing, and greatly retards their feeding, as is well known. Under proper management, in a well constructed stall, all these evils would be alike removed, and they would be kept perpetually in a proper state of coolness, tranquillity, and ease, so as to make the same quantity of food go farther than it otherwise could have done in nourishing them. They would also be prevented from licking up snails, worms, and other noxious creatures, among their food, which they are by pasturing apt to do, when they feed at those times of the day, or night, when these creatures crawl abroad. This would be entirely avoided by cutting the grafs at those times of the day when none of these are to be found. Thus lingering diseases might often be avoided, which always retard the thriving, and often prove totally the destruction, of the animal. And by giving an opportunity of administering dry and nourishing food, along with the soft and succulent, where circumstances require it, in any requisite proportions, and by varying the tastes, so as to provoke an appetite, not only the health, but the thriving of the creatures, would be greatly augmented beyond what they could have been in any other way.

But if *manure is to be chiefly* attended to, there can be no comparison between the two modes of consumption. This is so greatly in favour of stall-feeding, that it would be idle to spend time in searching for proofs of a proposition that may be considered as self-evident and certain.

And lastly, If the *quantity* of herbage produced from the same field be adverted to, it will be found to be equally in favour of the cutting system. It is well known, that all animals delight more to feed on the young fresh shoots of grafs, than those that are older. Hence it invariably happens, that those patches in a pasture field that happen to have been eaten once bare, in the beginning of the season, are kept very short ever afterwards throughout the whole of that season, by the creatures delighting to feed upon them in preference to the parts of the field that have got up to a greater head; so that these last are suffered to remain in a great measure untouched throughout the season. It is not however in general known, that grafs, even the leafy parts of it, when it has attained a certain length, becomes stationary; and, though it will retain its verdure for some months in that state, makes no sort of progress whatever; whereas, if it had been cropped down frequently, it would have continued in a constant state of progress, advancing with a rapidity in a great measure proportioned to the frequency of its being cropped. For experimental proofs of this fact, (see our author's *Essays on Agriculture and Rural Affairs*, Vol. II. Disquisition V.) From his own experiments and observations, the Doctor is satisfied that, in some cases, the actual produce of the same field, by a judicious management *in this respect*, compared with bad management, may be augmented *fourfold* in the same season. It is owing to this circumstance, though the reason of the fact has not been understood, that

hard stocking of pasture lands has been found to enable the same field to sustain a much greater weight of stock than it could do when lightly stocked. But under no system of management can the evil of unequal cropping of land under pasturage be avoided, unless it be by a destructive degree of hard stocking; which must be avoided where the animals are expected to thrive. By cutting with the scythe frequently, so as to keep the grass always short, and therefore in a state of continual vigorous vegetation, all these evils are avoided. The quantity of produce will be raised to the *maximum* that the land, in its present state, is capable of producing, while the stock to be fed by that produce needs not be in the smallest degree stinted in point of food. Therefore, under every point of view that this question can be considered, we are forced to conclude that the practice of cutting grass, and consuming it green, in all cases where the ground is in a state that can admit of it, when compared with that of pasturage, appears to be so greatly economical, that the particulars under which that mode of management can be practised, and the peculiarities affecting it, deserve to be much more minutely investigated than has ever yet been done.

He adds, that in confirmation of the justness of this conclusion, it is now universally admitted as a fact, confirmed by innumerable experiments, that a crop of red clover, when cut, and consumed in the house green, goes in all cases much farther in feeding beasts, than when it is consumed by pasturage upon the field. The lowest estimate that he has ever seen made on this head, from actual experiment, is, that it will go at least twice as far when cut, as when pastured upon: some go as high as to say it will go *four times* as far. As every person who has tried the experiment agrees that the saving, by cutting this crop, is very great, that practice has of late years begun to prevail very much; though reason has not yet been able so effectually to stem the torrent of ancient prejudice, as to render it general.

However, the practice of cutting other grass grounds, and consuming their produce green, seems not yet to have been deemed even practicable, and has not of course been ever thought of being experimentally tried, although he has reason to be satisfied, from some experiments that he has made, and the considerations above stated, that the benefits to be derived from consuming the produce of rich grass lands *of any sort*, in this way, will be even greater than that which takes place in the case of the red clover, as just stated. The circumstance, says he, that made me first advert to those benefits that might be derived from consuming grass land by cutting, in preference to pasturage, was merely accidental. It was from the experiment of frequently cutting a grass walk, and giving the produce to his cows.

This experiment, he tells us, first suggested doubts in his mind, as to the propriety of consuming *rich* grass lands by pasturage; and every observation that he has since made, has tended so strongly to add to his conviction, that he has now not a doubt remaining upon this head: and he conceives that the loss which is annually sustained by the nation at large, from an inattention to this circumstance, is so great as, in some measure, to call upon him to publish these remarks, with a view to direct the attention of others to investigate the subject with greater care than it has hitherto obtained.

After suggesting the means of determining this point by actual experiment, for which we must refer the reader to the work itself, the Doctor proceeds:

Grass lands, when constantly cut, are not deteriorated.—The Doctor observes, that what the changes would be, both in regard to the quantity and the nature of the produce from the same field, if annually cut, and the produce carried off, or if consumed by suffering beasts to pasture upon it, cannot at pre-

sent be told with certainty; but there are not wanting *facts*, that may enable us to have some idea of the probable result. It has been rendered probable, at least, from facts already stated, that dung, when dropped upon land by cattle pasturing upon it, does not tend to enrich it perhaps at all; or, if it does so, it is only to a very small degree. Whether rich grass land, if constantly cut, and the produce carried off from it, will thus, in time, come to produce crops less abundant than the same land would have done, if kept under pasturage, will not, with many persons, seem to admit a doubt. Yet there are considerations, says the author, which so strongly operate upon my mind for doubting if this be the case, that nothing short of actual experiment can remove them. I have often, says he, seen lawns around gentlemen's houses that have been under a course of continued shaving for time immemorial, that discovered no symptoms of exhaustion, nor any sensible diminution of luxuriance or of verdure, though no manures of any sort had ever been laid upon them. This fact struck him as an important one; and that he might not be mistaken with regard to it, he applied for information respecting this particular, to a gardener who had had charge of very extensive lawns of this sort, belonging to a gentleman of large property. He assured him, that for the space of upwards of thirty years, that he had had the care of these lawns, some parts of them which had been laid down long before he knew them, and were originally, as he supposed, of a rich quality, had never received during all that time the smallest quantity of manure of any sort; and that the lawn continued to be equally close in the pile, equally verdant at all seasons in the year, and required to be as often cut as ever; and that, in short, he had no reason to apprehend that the quantity of its produce had diminished in the smallest degree. This seems to our author a strong presumptive proof that grass land, when once of a rich quality, may be continued for an indefinite length of time under the scythe, without being at all deteriorated, even where it gets no return of dung that is annually made from the produce of it. And as the Doctor has shewn that rich grass land, under pasturage, produces as much dung as ought to manure each year more than double its own extent of surface; it follows, that if the same quantity of grass land will only nourish as many beasts in the house, as if it were pastured upon (and there are strong reasons for thinking it will do much more), there can be annually obtained from each acre of land kept under the scythe as much dung as might manure two acres more, which might be abstracted from that grass land without deteriorating it. Of course, if the land be such as that it can admit of being made richer, a dressing of that dung, now and then returned upon itself, would give it the richness wanted, without any extraneous aid. In this point of view, then, it seems to be impossible to deny that rich land, if kept under the scythe, can never become poorer, if none of the dung made by the beasts fed upon it be abstracted from it; but that, on the contrary, it can thus be made to afford a large annual supply of dung for the purpose of enriching poorer land, while it still continues to be fertile itself in the same degree.

He also remarks, there seems to be no doubt but that the *quality* of the grass must continue to improve while under the scythe, much more than while under pasturage. Every person, says he, who has bestowed the smallest attention to objects of this sort, must have remarked that the worst kinds of grasses grow most freely upon those parts of rich grasslands that are the most open and spongy in their texture; and that they are in general much sweetened in the pile where they chance to be much trod upon. Hence the finest grasses on such fields are always found to abound most upon those paths which are moderately trod upon; white clover and the sweetest grasses being seen there in abundance, while they are less frequent in the

spongy parts of the field. But frequent rolling tends to produce this effect more universally and equally than any kind of treading by beasts (a practice frequently recommended by the best farmers) can ever accomplish.

In confirmation of his opinion, the Doctor quotes the observations of Mr. Davies, as given in his account of the Agriculture of Wiltshire, who says, that "the sweetness of the feed depends much more on its being kept close, and eaten as fast as it shoots, than on any peculiar good quality of the grass itself: for there are many downs that, when close fed, appear to be a very sweet pasture, but which, if suffered to run a year or two without a full stock on them, will become so coarse, that sheep will almost as soon starve as eat the grass: and even in those parts of the downs, where the finer and sweeter grasses abound, the soil is frequently so loose and porous, that nothing but constant treading will prevent them from dying out, or being choaked by the larger and coarser grasses." They also, he observes in another place, say, "that this new kind of sheep being so much nicer in their food, and rejecting the feed of the downs, on which the chief dependence for sheep food is, have suffered the herbage to grow gradually coarser and coarser; and that the farmers, in attempting to remedy this evil by shortening their stock of sheep, have made it worse; it being a well known fact, that *the closer the downs are fed, the more stock they will keep.*" It is likewise farther remarked by Mr. Davies, that in consequence of too light stocking, heath, in some cases, comes in the place of the better grasses. But, says the Doctor, it is very evident that all the purposes of hard stocking, that is, keeping the grass short, and in a continual state of vegetation, and consequently sweet, and preventing the coarser grasses from running up to stalk and overpowering the others, together with the consolidating of the ground by treading, would be obtained with much greater certainty by the practice of mowing; while the animals that consumed the produce could in no case be subjected to a stint of food, which they necessarily must sometimes be, where reliance is had upon hard stocking alone for preventing this evil. From these considerations, he says, there seems to be good reason to believe, that not only an equal quantity of produce would go farther, if cut and given green to beasts in the house, than if it were pastured upon, but that, by a continuation of this practice for years, the ground kept under the scythe would gradually improve, so as to produce a greater quantity of food, and that also of a richer quality, than if it had been kept under a course of pasturage; while, at the same time, a great quantity of dung might thus be acquired for the purpose of fertilizing other soils of a poorer quality. The reader, however, says the Doctor, will please never to forget, that though this reasoning be very *probable*, it amounts not as yet to a *certainty*; nor can it ever do so, until some decisive experiments shall be made to ascertain with precision the facts that are as yet but very imperfectly understood.

Sweetness of Pastures, what.—The Doctor observes, that the term, *sweetness of pastures*, used above, and *sweet kinds of grass*, frequently occur in agricultural writings: yet it is doubtful, he thinks, if ever they have been properly defined, so as to convey a precise and accurate meaning to the reader, or been so much adverted to as their importance deserves. He therefore here attempts to supply these defects. Those pastures which animals choose to feed upon in preference to others, and which in general are eaten down close to the ground, are said to be *sweet pastures*, in contradistinction to those where the grass, being disrelished, is suffered to grow to a greater length, and often to wither in part, without being touched; which are called *coarse*, or, if tending to dampness, *four pastures*. Without entering into a disquisition concerning the circumstances that tend to produce this sweetness of

pasturage, which are various, he observes, that from whatever cause it originates, it is in as far as he knows an universal rule, that in every case the younger the grass is, the sweeter and more palatable it will be to beasts of every sort; and that the same weight of food will go much farther in nourishing or fattening an animal, if it be very pleasing to the palate of the animal to which it is given, than if it had been less toothsome. For, as a certain quantity of food is required for the mere sustenance of every animal, if that quantity be daily administered to it, and no more, the creature will barely subsist, and neither grow better nor worse, if fattening alone be considered; and of course will never return, in the way of fattening, any profit to the farmer for that portion of its food, however long it may be continued upon it. But if the beast shall get a greater quantity of food than this portion which is barely necessary for subsistence, that surplus food then goes to augment the size, and to *fatten* the animal, and of course yields a profit to the farmer in proportion to its quantity. If this fact be admitted, he thinks it will necessarily follow, that the greater the proportion of this surplus food the creature can be induced to eat in a given time, the more quickly it will be fattened, and, of course, the greater will be the profit of the farmer.

From some calculations here introduced, the Doctor concludes that the same quantity of food, which would sustain no more than *one* beast, if it were so sparingly administered as to require a whole year to fatten it, would be more than sufficient to fatten *four*, if they could be induced to take it in such quantity as to fatten in six weeks only. But as it is hunger alone that can induce any animal to eat such kinds of food as are unpalatable to that creature, it is impossible to get the animal to eat more of coarse unpalatable kinds of grass, than what is necessary for bare subsistence only; so that such fields must be appropriated to breeding only, because, in the way of feeding, they can return no profit whatever to the farmer, by a kind of stock which disrelishes that food. If it be a little sweeter, they may get on a little; but the profit, in this case, will be very small. Render the grass more sweet and palatable, they will fatten the more quickly, and the farmer's profit be thus augmented: and so on almost in a geometrical *ratio*, in proportion to its augmented sweetness. Under this point of view, whatever tends to render the produce of fields more sweet and palatable to the animals which feed upon it, is a very great national improvement; because it answers the same purpose that a large augmentation in the quantity of the produce would do. But if the *quality* can be improved at the same time that the *quantity* can be augmented, it will be a twofold gain, and the greatest national benefit will thus be obtained. But as it has been already shown that every kind of grass will be rendered as palatable as it is possible to be, by being cut and given to them in the house, while the quantity of its produce will, at the same time, be thereby augmented, it seems to be impossible to doubt that the practice must be highly economical. He here says, it is well known that very rich land in general produces the sweetest pile of grass; and that calcareous manures in particular have been remarked as being peculiarly calculated for producing this effect. It hence follows, that it is the best economy to lay lands down to grass while they are still in the most fertile state, before they have been exhausted by frequent corn crops, especially after liming. Land may certainly be made too rich for corn crops; but he does not know if that can be the case with grass land, under proper management.

Here the Doctor, after guarding the reader against the possible error of his *illustrative* calculations, observes, that he knows of no fact that has been yet brought forward, which clearly ascertains whether the degree of melioration is exactly in proportion to the *surplus* food of any sort that an animal

can be brought to eat in a given time, though the probabilities are greatly on that side. Neither does he know if it be an universal rule, when animals of *different kinds* are compared with each other, that those kinds which can be made to eat in a given time the greatest quantity of food, can be the soonest fattened. The subject has never as yet, that he knows of, been properly attended to.

The Importance of Condiments on Domestic Economy.—Little attention has hitherto been bestowed on the subject of condiments as affecting animals. Hitherto, says the Doctor, the greatest part of mankind seem to forget that mere animals have the sense of tasting in as great perfection as man; and are disposed to indulge their appetite for sensual gratifications, without any restraint, wherever circumstances put it in their power. The uses that may be made by man, for his own emolument, of this natural propensity of animals, are very obvious when adverted to. Yet I know, says he, no case in which the general attention of men seems to have been strongly turned to that point, unless it be in respect to the fattening of calves: for I have met with few persons who have had an extensive practice in this department, who are not sensible that the profit is in proportion to the quantity of milk that the creatures can be induced voluntarily to take in a given time. This solitary fact is known by thousands, who never once think of extending it to any other case of animal existence. But there are not wanting a few persons, who, in consequence of accurate observation, have discovered the vast importance of studying with care the taste of the creatures they feed, that they may not only furnish them with the kinds of food they like best, but also to vary these from time to time, and to give them exactly in the quantities, and in the way that they find will induce the creatures to eat the most; having the full experience, that the profit to be drawn from feeding beasts is always proportioned to the increased quantity of food they can get each individual *coaxed* to consume in a given time. The cramming of poultry is also another instance of the economy that arises from the principle here alluded to being adhered to even by *force*. In this branch of rural economics, our author has met with no person who has made greater progress than a plain practical farmer at Hope, in the neighbourhood of Manchester, who spares neither trouble nor expence in procuring such kinds of food and condiments as he finds best calculated to induce his cows to consume, in a given time, the greatest quantity of food possible. Among other condiments, this man has discovered that *pure* water stands pretty high in the scale; on which account his beasts are never suffered, far less obliged, to taste a drop of water that has ever been sullied by any animal setting a foot into it. With this view, they are always served with running water, which is, for their convenience, received into a long wooden trough, through which it passes while they are drinking. Such poor beasts as are compelled through necessity to drink out of those muddy stagnant pools, in which other cattle have waded for days together to cool themselves in hot weather, which are fully impregnated with their dung and piss, feel the inconvenience of this nauseating draught; and the farmer of course suffers an abatement of his profit to an astonishing degree.

Value of common Salt in feeding Beasts.—Our author remarks, that there is no substance yet known which is so much relished by the whole order of *graminivorous* animals, as common salt. The wild creatures of the desert are so fond of it, that wherever they discover a bank of earth impregnated with a small proportion of salt, they come to it ever after regularly to lick the saline earth, as they would to a pool of water for drink, were there none other near; so that when a hunter in America discovers such a *lick*, as such places are there called, he reckons himself sure of obtaining plenty of game, by lying in

wait near it and shooting them as they approach it, until the whole beasts that have discovered it are destroyed. It is also admitted by all those who have tried the experiment, that salt given along with the food of domestic animals, except fowls, to which it is a certain poison, tends very much to promote their health and accelerate their feeding; and although some persons, who have been at a loss to account for the manner in which this stimulant could act as a nutritious substance, have affected to disregard this fact, yet no one has been able to bring the slightest show of evidence to invalidate the strong proofs that have been adduced in support of it; though, unfortunately for this country, few experiments of this kind have been tried in it. In fact, we have no reason to suppose that salt acts in the smallest degree as a nutritious substance, or, *of itself*, tends to fatten any animal; but that, merely by acting as a condiment, it whets the appetite, and gives the creature to which it is properly administered a strong relish for its proper food, so as to induce it to eat a greater quantity than it would have done *in a given time*, and thus greatly to augment, as has been above explained, its feeding quality beyond what it otherwise could have had. In this way, it is not perhaps an extravagant position to say, that by a proper use of common salt, the same quantity of forage might, on many occasions, be made to go twice as far as it could have gone in feeding animals, had the salt been withheld from them. If so, we have here laid open to our view an easy mode of augmenting the produce of our fields to an amazing extent: for, if the same quantity of forage can be made to go, not twice as far, but *one-twentieth* part only farther than it now does, it would be the same thing as adding one-twentieth part to the aggregate produce of meat for beasts, throughout the whole kingdom. But, according to the estimate of the President of the Board of Agriculture, there are upwards of fifty millions of acres of *cultivated* land in this island; the value of the forage produced by which cannot, on an average, be rated so low as twenty shillings per acre; but even at that low rate, the addition of one-twentieth would amount to 2,550,000*l. per annum*; a sum so great, that, when viewed in the aggregate, it is difficult to bring the mind to believe that such an improvement is actually practicable: yet, when the particulars are considered in detail, it seems to be impossible not to admit that the amount of the improvement must be greatly above the statement here given. The salt laws however operate very strongly against improvements in this way.

Best Mode of obtaining Hay of a fine Quality.—As in this climate, where grass does not continue to vegetate luxuriantly throughout the whole year, a provision must be made for winter food for beasts; and for this purpose, on grass farms, it becomes necessary, in all cases, to appropriate a proportion of the land for hay; it becomes then a consideration of some importance, to enquire in what way hay of the best quality can be obtained in the greatest quantity, and at the least expence that the nature of the case will admit of.

From the considerations above stated, it is evident that it is a matter of much greater consequence than has been generally imagined, to take care that the hay shall be of the very best quality possible; because one stone of hay of an exceeding fine quality may probably go as far in *feeding* beasts as four of an inferior quality will do. So little attention is in general bestowed upon this subject, that few farmers have even an idea of the circumstances that chiefly tend either to improve the quality of their hay, or to make it worse. For the most part, all that seems to be aimed at is, to get the grass as quickly dried as possible, so as that it may admit of being kept, when put up in a large mass together. And as grass, that is already withered before it be cut, can be more easily dried than that which is very green and succulent, it is too general a practice

to allow it to advance too far before it be cut ; in consequence of which the hay is rendered of a quality much inferior to what it might have been. The judicious remarks of Mr. Davies, in his account of Wiltshire, are here introduced.

“ The dairy farmers (he observes) in North Wiltshire, and in particular the graziers, are much more attentive to the quality than the quantity of their hay. It has been already remarked, that they make a point of mowing up their meadows as early as possible in autumn, and of course are able to mow early in the summer.

“ It is not uncommon to see grass mown, not only before it is in blossom, but even before it is *all in ear* ; and to this it is owing that it is more common to fat cattle with *hay alone*, in North Wilts, than perhaps in any county in the kingdom.

“ And by this the dairy-men are able to keep up the milk of those cows that calve early, and from which calves are fatted, which would otherwise shrink before the springing of the grass, and never recover. And the advantage they get by early after-grass, and by the duration of that after-grass to a late period in autumn, fully compensates for the loss of quantity in their hay crop.”

Doctor Anderson observes, that nothing is here said as to the mode adopted for *winning* the hay ; by which is meant the process of converting succulent herbage into a state of hay that can be kept in quantities, on which its quality must always greatly depend. It is in general understood, that if hay can be made so as to retain some tinge of its green colour, it is better than if it were bleached white, or rotted : but precautions are seldom thought necessary to be adopted for guarding against the effects of scorching sun-shine, which, by too quickly exhaling its natural juices, renders it sticky, brittle, and unpalatable to a certain degree ; and, what is of still more importance, the effects of rain, or even dew if abundant, if they are suffered to fall upon the grass after it is cut and before it be made into hay, are seldom adverted to ; so that if dry weather comes soon to exhale that wet, while the grass lies spread out upon the ground, the farmer feels little anxiety about the consequences ; though it is a certain fact that no hay, which has been in the least wetted during the process of hay-making, can ever be made to have that sweet palatable taste it would have had without it. Nor has our author ever seen that beasts, when allowed to choose between hay so made and that which has been carefully guarded from moisture, ever hesitated to make choice of the last, or committed a mistake, even where he himself could not distinguish a perceptible difference. But in order to obtain hay in all cases of the very best quality the circumstances will admit of, the following process, he says, may be safely conjoined with the practice of cutting and feeding beasts with grass in the house, as above recommended. Where the produce of grass land is to be cut, as above described, and used green, it will be proper in general to reserve a part of it for hay. In this case the cutting for grass and for hay should be carried on together ; but with the following variations, depending on the uses it is to be applied to. That part of the grass which is intended to be used green, as it will suffer no damage by being cut when wet, must continue to be cut regularly each day as it is wanted, without regard to the weather ; whereas that part of it which is intended for hay, ought on no account to be cut while wet ; and therefore that part of the operation must be discontinued, unless when the weather is dry and fine ; nor should it ever be cut either in the morning or the evening, while dew is upon it. And as the hay, in the mode proposed, ought to be made day by day, for a continuance, as the grass comes forward for the scythe, while the weather is in a proper state for it ; and not all at one time, as in the usual mode of hay-making, the cutting both grass and

hay from the same field may be very economically combined together. For this purpose the grass which is cut in the morning, while the dew may perhaps be upon it, and in the afternoon, ought to be appropriated to the beasts green ; and that part of the grass only which is cut from nine till two o'clock, while the weather is dry and fine, should be made into hay. If the mower begins to cut down for hay about nine o'clock in the morning, and goes on in that operation till one or two in the afternoon ; and if the persons who are to put up the hay begin to that operation about one, the grass will thus be allowed to lie between three and four hours in the swath, exposed to the sun, which will exhale some part of its moisture, and deaden it enough for the purposes required, though it still retains the whole of its nutritious juices without abatement. After being allowed to lie thus long, it should be raked clean up, and carried off the field in the same cart that is employed for taking in the grass, and immediately put into the stack, so as that the whole grass that was cut that day, shall be put up before evening ; and thus regularly each good day throughout the season. But as grass, while in this green and succulent state, would not keep if put up by itself, care must be taken to provide some dry forage to mix with it. For this purpose nothing can be so proper as good dry hay ; but for want of that, at the beginning, good straw may be very safely employed. The Doctor once saved a great quantity of clover hay, being a late third cutting, when the season was too far advanced to admit of its being made in the usual way, by putting it up when new cut, thus intermixed with a large proportion of good straw. It kept perfectly well ; and when cut down and given to the beasts, was relished by them better than any other hay he had, and was equally valuable for every purpose. Our author's method of *stacking* hay is noticed under that article.

The Doctor further observes, that for the purpose of *fattening* beasts, it may be necessary to mix the hay with the grass ; but for rearing young beasts, or other purposes, it will be highly economical to make use of straw for this purpose : for straw of oats or barley, when thus mixed with grass, will be equally good as ordinary hay. If economy were duly studied by farmers, says he, perhaps not one particle of these kinds of straw ought ever to be employed in any other way : nor could the possessor of *corn* farms ever be at a loss for making such an intermixture, as he will find it profitable always to have as much ground under clover, as would be sufficient thus to mix the whole of his straw, if he inclined. If the proportion of wheat straw be more than enough for litter, it may be cut and profitably applied in the same manner. The Doctor adds, that as much saving may arise from the proper distribution of buildings, and as this would become an object of much greater importance than it now is, were the system of stall-feeding in summer, as well as in winter, to become universal, a few words on that head may not be deemed superfluous or improper.

On the proper Construction of Farm Buildings.—Here our author remarks, that whatever diminishes the quantity of labour required of one man, produces a saving to the farmer that will be in proportion to that diminution of labour. In houses ill arranged, and of course inconvenient, it will require one man to feed and clean from ten to twenty stall-fed cattle ; but in houses properly constructed, he has known one man be able to feed and clean fifty head of beasts with great ease. The arrangement which admitted of this economy, was as under. The house was divided by a foot-way of six feet wide, running along the middle from end to end. On each side of it was a range of stalls for cattle, placed with their heads towards each other, of such a length as to admit of twenty-five to stand on a side, which at three feet for each will give seventy-five feet. At each end of this walk was a door, by one of

which the hay or other dry food was introduced; and at the other turnips or other food recently brought home were laid down, so as not to mix with or foul the hay. Along each side of the walk was placed a wooden trough running the whole length without interruption, a section of which was of this shape U, the bottom being about six inches wide. Between each beast there was a small division by means of a board, perforated below, and the whole trough was placed in an exact horizontal position, the bottom being raised about six inches from the ground. Behind the troughs were placed the stakes to which the beasts were fastened. The floor on which they stood was paved, sloping a little backwards; and at a length just sufficient to allow the beasts to stand easily and no more, it was lowered at once about three inches, so that the dung which was dropped from the beasts, when they stood right, fell into the lower division. This part of it, and indeed the whole, was made very smooth, so as to admit of the dung being easily swept off by a broad-mouthed flat shovel or rake occasionally, and put into a wheel-barrow as often as was necessary, and thus carried off. The upper part of the structure was supported by stout posts placed at proper distances, and a passage of three feet left clear behind the cattle. This house had been originally intended to be left open without walls; but as it was found to be too cold for winter-feeding, to which it was solely appropriated, the spaces between the pillars had been walled in. For a house to be used the whole year round, it would best answer the purposes of this climate to have these intervals closed in winter, by boards that join to each other quite close, which could be removed during the summer so as to keep the cattle quite cool at that season. At one end of the stalls, where the situation will admit of it, should be a pipe of water, which could, by means of a stop-cock, be let into the troughs at pleasure. In this way the whole troughs could be filled at pleasure with pure water; and when the beasts had drunk as much as they inclined, the water that remained could be let off by opening a plug in the bottom, and carried clear away by a channel prepared for that purpose. In feeding, the attendant fills a barrow properly constructed for that purpose, and wheels it along the middle walk, giving to each beast, as he goes along, a small quantity only of that kind of food; and so on till he goes over the whole. As soon as that is eaten up (or if any part of it remains in the stall of a particular beast, he takes it first away), he gives each beast in the same manner another small quantity of a different kind of food. In this way he goes over them three or four times successively, varying the food at each time if he can; and always reserving to the last the sweetest and most palatable kind of food by way of dessert. Then sweep their troughs clean; and if they have got much dry food, especially if salt has been administered, the trough ought to be filled with water, at least four times a-day; which will keep it always sweet and clean, and induce them to eat much more than they would have done without such attention.

Sheep may be Stall-fed.—Hitherto, says the Doctor, I have supposed that stall feeding can only be employed with regard to beasts that have been usually kept in the house, viz. cattle, horses, and swine: but it will be presumed, that sheep must be thrown out of the list of domestic animals, if ever the mode of stall-feeding, on green food above recommended, should come into general practice. So far is this, however, from being the case, that he is inclined to believe, that if sheep should be fed after this manner, the improvement will be greater on them than any other class of animals. It is true, says he, we have never yet been accustomed to see sheep fastened to a stake, and thus fed by hand, like what has been done with cattle: but this only proves that we have not hitherto considered the subject with the attention it requires, and no more; for he knows of no instance where it ever has been tried and proved abortive.

It behoves us then to enquire what reasons we have for believing that it would not succeed; and if we can find none which tend to that point, but rather the reverse, we ought at least to suspend our ultimate decision on that point, until the fact shall be clearly ascertained by fair experiment. We know, says the Doctor, that the sheep is an animal as gentle in its nature, and as susceptible of domestication and controul, as any creature whatever; and therefore we have no reason to believe that it would make any violent struggle, or such efforts as might tend to retard its thriving, if tied up; but much the reverse; for it delights in ease and quiet: so that in this state it would meet with an indulgence in this respect entirely suitable to its nature. And we farther know, that no domestic animal suffers so much from wet as the sheep: for, on account of the thickness of its fleece, it becomes so weighty when wet, as to overload the poor creature so as to oppress it. And as it is long before it can be dried, especially in winter, the animal is chilled by the cold while thus drenched in wet, so as greatly to retard its thriving. But if the sheep were put into a stall *when dry*, and never suffered to go from under cover to be wetted, it must be totally freed from both of those inconveniencies; in consequence of which it could not fail, as one would think, says he, to thrive much better under this mode of management, than that to which it has hitherto been commonly subjected.

In answer to this, says he, it may perhaps be alleged that we do not observe that sheep thrive in general better in those districts, where they are usually put up under cover all night in cots, than in those districts where they are never housed at all, but rather the reverse. He believes indeed that they always thrive worse where they are cotted than where they are suffered always to lie without doors: but this, he says, seems not at all to militate against the practice recommended, because the cases differ from each other in an extreme degree. When put up into a cot, while the sheep are yet wet, as must often, indeed usually, be the case in winter, and there stowed very close together, as they usually are in these circumstances, they must soon become extremely hot, and a copious steam arise from their wet skins, under which they must be stewed for the greatest part of the night: but it is well known that the sheep delights rather in a cold than a hot climate; and if it be dry, this animal never seems to enjoy such perfect health as during the coldest weather we ever experience, provided it have at all times abundant food. This kind of stewing heat thus produced can scarcely fail to prove highly detrimental to the creature; and when it is considered that the vapour that rises from its own dung, on which, to a great depth, it is usually obliged to lie in these cots, mixes plentifully with the warm aqueous vapour, it can scarcely fail but that diseases of various sorts will be the consequence. Nor is this all: after being stewed all night in this close place, and put into a state of high perspiration, the poor creature is turned out hungry in the morning, perhaps amidst frost and snow, which soon freezes the water in its fleece, stops all the pores in the skin, suddenly checks all perspiration, and chills the poor creature almost to death during the whole day. Under this kind of management it would be wonderful indeed if diseases innumerable were not to be the consequence. But where the creature is put up while dry, and is kept continually so, and at rest ever afterwards in a cool airy place, where it never can be so much crowded as to suffer any extraordinary degree of variation in regard to heat or cold, and at the same time receives abundance of nourishing food, none of these evils can be experienced; and the diseases which originate from that source can never be expected to be seen. From these considerations there seems, he thinks, to be good grounds for believing that sheep will admit of being stall-fed, with perhaps greater benefit to the person who adopts that mode of management, than that which is to be drawn from any other animal.

whatever. Those then who would wish to fatten sheep under the system recommended, in preference to other kinds of domestic animals, have no reason to think that they will be under a necessity of laying aside the scythe on that account. It will be easy to contrive low apartments under the hay-ricks, properly divided by stakes and alleys of a proper size, bounded by stakes, as for cattle, of a proportional size, to which the sheep may be fastened, and thus to be regularly fed by hand throughout the season.

On the Consumption of Turnips by Sheep.—Turnips, says our author, are an article of such vast importance to the farmer, and the economical modes of consuming them have been so little adverted to, that I cannot omit offering a few short hints on that head. There are three modes in which turnips have been hitherto chiefly applied; viz. 1st, eating them by sheep on the field in which they grew; 2d, drawing them and giving them to cattle *in the house*; or, 3d, drawing them and giving them to beasts in the field. To these practices he does not object; but there are some circumstances respecting the management of each, that do not seem to him as yet to have obtained all the attention they deserve. In consuming turnips where they grew, by sheep, much waste is incurred over most parts in Britain, by letting them have access to too great a quantity at once. It is not uncommon to hurdle off as much ground at once, as is intended to keep the sheep for a week at least; and sometimes as much as will serve them four weeks without moving the hurdles. The sheep have thus at one time too much food; in consequence of which they range at once over the whole, and break during the first day almost every turnip in the field, all of which broken turnips begin instantly to rot; so that many of them become so putrid and stinking that no creature will taste them, and a large proportion of wholesome food is thus inevitably wasted. Nor is this the only waste sustained by this practice. As the pulp of the turnip is more palatable to the sheep than the rind, they naturally scoop out the pulp from the whole, before they ever think of eating any more of the rind than is necessary to give them access to the pulp. When that pulp is all consumed, however, they must either eat the rind *alone*, or the whole of it will be lost; so that the farmer finds himself constrained either to keep his sheep so long upon that part of the turnips, as to compel them through hunger to eat the turnip-peel (in which case the creature must cease to thrive, if not fall back into a worse condition than before), or he must resolve to abandon the turnip skins to waste also, although he knows that these, under proper management, are a very wholesome kind of food. A good economist will think it necessary to adopt such a mode of management, as to sustain no sort of waste in this case.

In this view, says the Doctor, he will not blindly adopt the notion which seems to be but too common, that turnips can only be beneficially employed for *fattening* of sheep; but he will examine with attention, whether under certain circumstances he might not be more benefited by *rearing* sheep by the aid of turnips than by *fattening* them. Every considerate man knows that the market for fatted sheep is extremely limited, in many remote situations, which are peculiarly adapted for sheep-rearing; but that if he can contrive to keep his breeding sheep always in high condition, he will find abundance of markets for these at good prices, where sheep in worse order could not be sold at all. When turnips were first introduced into the remote parts of Britain, they were invariably considered as being in a manner exclusively adapted for the fattening of beasts; and that was the use to which they were solely applied: but, by degrees, experience taught the farmers in some remote situations, that a much greater profit could be derived from applying them to the sustaining of milk cows, and the rearing of young cattle, than to the feeding of them; and these are the

uses to which this valuable article is now chiefly applied. But the use of turnips for keeping on a breeding stock of sheep, though it is known in some districts in Britain, is far less generally understood than it deserves to be. By this mode of applying turnips, however, it would seem to be a very easy matter for an attentive economist to avoid the waste above pointed out, and to derive the full benefit from all his turnips with much improvement to his flock.

What is therefore required for keeping a young flock in a constant state of growth through the whole year round, is, to prevent them from being ever stinted for food, especially of the tender and succulent sort. It must happen, however, that during the winter, when the days are short and the weather severe, very little succulent food of any kind can be found on their common pastures; so that they are pinched for hunger, and greatly decline during that season, if they do not die entirely. What is wanted then is a small addition to their ordinary food, administered so equally throughout the winter season, as to give them each day enough to prevent them from shivering, though not so much as to fatten them for the butcher. This will be best done by giving them a snap of turnips each night, that shall in quantity be just sufficient for this purpose, without being so much as to prevent them from seeking and relishing their ordinary food throughout the day. With this view, let us suppose that a row of hurdles is run along one side of a field of turnips, so far only as is just sufficient to allow the whole flock to get access to the turnips with their heads at one time. Let this row of hurdles be moved just so far back every day, as to leave access to as many turnips as shall be judged sufficient for this purpose, and no more. The consequence will be, that when the sheep come in from their pastures at night, after having picked up as much through the day as they could there find, they will eat their turnips by way of dessert; and then lie down to repose during the night in a comfortable state, with their bellies full. If the food throughout the day has been scanty, the turnips will be all eaten up at night, skins and all: If the food has been more abundant, perhaps a few of the skins may be left till the morning, when they will be clean eaten up. In general, it will be advisable to set off rather fewer turnips at one time than the sheep could easily eat up, in order that none may be wasted. By this practice the sheep will be kept in perfect health and high condition, throughout the whole year, and will grow, nearly, as much during the winter as the summer months. The ewes in particular will be kept strong and healthy, so as to produce stout lambs, and afford milk in much greater quantities when they yearn, than they otherwise would have done; as is known to be invariably the case with cows that have been kept up by means of turnips during the winter; and being in high health in the spring, the whole flock will advance with the first spurt of early grass, so as to be at all seasons more forward for market, and consequently bring much higher prices than otherwise could have been expected.

And by moving the hurdles regularly forward, as proposed, and leaving the field open behind them, the area in which the sheep are confined will become larger every day as the season advances, so as to give them better room to choose their bed where they find it most convenient. A necessary consequence of this will be, that if the field be uneven in its surface, the sheep will naturally choose to lie most upon the high and dry patches, which are usually the poorest parts of the field, so that these patches will thus get a more than ordinary share of the dung, which is precisely what they stand in need of to make the crop equal over the whole. To admit of this, it will be proper to begin in all cases at the higher parts of the field, and advance downward to the lowest extremity.

The Doctor also suggests that turnips might be advantageously employed for various other purposes, particularly for dairy

cows, which under a judicious management can be fed by them without affecting the taste of the milk in the smallest degree, and of course requiring no process for removing that taste; and for rearing young horses, to which use turnips can be applied with singular economy; as well as for various other uses, which the attentive economist will discover when his attention is steadily directed to the matter.

The Doctor concludes by observing, that it would give

him great pleasure, if he could indulge a hope, that in consequence of these hints the reader should be induced to think for himself in all cases; to reflect upon the objects he sees; to examine the foundation of popular opinions, and then to draw his own conclusions from the whole. It is thus he will acquire sound knowledge, says he, much better than by relying on the instructions he shall receive from any writer whatever.

H U S

Virgilian HUSBANDRY, a term used by authors to express that sort of husbandry, the precepts of which are so beautifully delivered in Virgil's Georgics. The husbandry in England is Virgilian in general, as is seen by the method of paring and burning the surface, of raftering or cross-ploughing, and of the care in destroying weeds, upon the same principle, and by much the same means. In those parts of England along the southern coast, where the Romans principally inhabited, not only the practice, but the expressions, are in many respects the same with those of the ancient Romans; many of the terms used by the ploughmen being of Latin origin, and the same with those used by those people on the like occasions. And on a strict observation, more of Virgil's husbandry is at this time practised in England than in Italy itself. This change in the Italian husbandry is, however, much more to the credit of that people, than the retaining the Virgilian scheme is to ours. Tull, who has established a new method of husbandry, observes, that it is upon the whole so contradictory to this old plan, that it may be called the *anti-Virgilian husbandry*; and adds, that no practice can be worse than the Virgilian.

HUSK, the same with what botanists call the *calyx* or *cup* of a flower. See CALYX.

HUSO, in ichthyology. See ACCIPENSER.

HUSS (John). See HUSSITES.

HUSSARS, are the national cavalry of Hungary and Croatia. Their regimentals consist in a rough furred cap, adorned with a cock's feather (the officers either an eagle's or a heron's); a doublet, with a pair of breeches to which the stockings are fastened, and yellow or red boots: besides, they occasionally wear a short upper waistcoat edged with furs, and five rows of round metal buttons; and in bad weather, a cloak. Their arms are a sabre, carbine, and pistols. They are irregular troops: hence, before beginning an attack, they lay themselves so flat on the necks of their horses, that it is hardly possible to discern their force; but being come within pistol-shot of the enemy, they raise themselves with such surprising quickness, and begin the fight with such vivacity on every side, that, unless the enemy is accustomed to their method of engaging, it is very difficult for troops to preserve their order. When a retreat is necessary, their horses have so much fire, and are so indefatigable, their equipage so light, and themselves such excellent horsemen, that no other cavalry can pretend to follow them. They leap over ditches, and swim over rivers, with surprising facility. They never encamp, and consequently are not burthened with any camp equipage, saving a kettle and a hatchet to every six men. They always lie in the woods, out-houses, or villages, in the front of the army. The emperor, and king of Prussia, have the greatest number of troops under this name in their service.

HUSSITES, in ecclesiastical history, a party of reformers, the followers of John Hus. This person, from whom the Hussites take their name, was born in a little village in Bohemia, called *Hufs*, and lived at Prague in the highest reputation, both on account of the sanctity of his manners and the purity of his doctrine. He

H U S

was distinguished by his uncommon erudition and eloquence, and performed at the same time the functions of professor of divinity in the university, and of ordinary pastor in the church of that city. He adopted the sentiments of Wickliffe, and the Waldenses; and in the year 1407 began openly to oppose and preach against divers errors in doctrine, as well as corruptions in point of discipline, then reigning in the church. Hus likewise endeavoured to the utmost of his power to withdraw the university of Prague from the jurisdiction of Gregory XII. whom the kingdom of Bohemia had hitherto acknowledged as the true and lawful head of the church. This occasioned a violent quarrel between the incensed archbishop of Prague and the zealous reformer; which the latter inflamed and augmented from day to day, by his pathetic exclamations against the court of Rome, and the corruptions that prevailed among the sacerdotal order.

There were other circumstances that contributed to inflame the resentment of the clergy against him. He adopted the philosophical opinions of the Realists, and vehemently opposed, and even persecuted the Nominalists, whose number and influence were considerable in the university of Prague. He also multiplied the number of his enemies in the year 1408, by procuring, through his great credit, a sentence in favour of the Bohemians, who disputed with the Germans concerning the number of suffrages which their respective nations were entitled to in all matters that were carried by election in this university. In consequence of a decree obtained in favour of the former, which restored them to their constitutional right of three suffrages, usurped by the latter, the Germans withdrew from Prague, and, in the year 1409, founded a new academy at Leipsick. This event no sooner happened, than Hus began to inveigh with greater freedom than he had before done against the vices and corruptions of the clergy, and to recommend, in a public manner, the writings and opinions of Wickliffe, as far as they related to the papal hierarchy, the despotism of the court of Rome, and the corruption of the clergy. Hence an accusation was brought against him, in the year 1410, before the tribunal of John XXIII. by whom he was solemnly expelled from the communion of the church. Notwithstanding this sentence of excommunication, he proceeded to expose the Romish church with a fortitude and zeal that were almost universally applauded.

This eminent man, whose piety was equally sincere and fervent, though his zeal was perhaps too violent, and his prudence not always circumspect, was summoned to appear before the council of Constance. Secured, as he apprehended, from the rage of his enemies by the safe-conduct granted him by the emperor Sigismund, for his journey to Constance, his residence in that place, and his return to his own country; John Hus obeyed the order of the council, and appeared before it to demonstrate his innocence, and to prove that the charge of his having deserted the church of Rome was entirely groundless. However, his enemies so far prevailed, that, by the most scandalous breach of public faith, he was cast into prison, declared

a heretic because he refused to plead guilty against the dictates of his conscience, in obedience to the council, and burnt alive in 1415; a punishment which he endured with unparalleled magnanimity and resignation. The same unhappy fate was borne by Jerome of Prague, his intimate companion, who attended the council in order to support his persecuted friend. Jerome, indeed, was terrified into temporary submission; but he afterwards resumed his fortitude, and maintained the opinions, which he had for a while deserted through fear, in the flames in which he expired in 1416.

The disciples of Hus's adhered to their master's doctrine, after his death, with a zeal which broke out into an open war, that was carried on with the most savage and unparalleled barbarity. John Ziska, a Bohemian knight, in 1420, put himself at the head of the Hussites, who were now become a very considerable party, and threw off the despotic yoke of Sigismund, who had treated their brethren in the most barbarous manner. Ziska was succeeded by Procopius, in the year 1424. The acts of barbarity that were committed on both sides were shocking and horrible beyond expression: for notwithstanding the irreconcilable opposition between the religious sentiments of the contending parties, they both agreed in this one horrible principle, that it was innocent and lawful to persecute and extirpate with fire and sword the enemies of the true religion; and such they reciprocally appeared to each other. These commotions in a great measure subsided, by the interference of the council of Basil, in the year 1433.

The Hussites, who were divided into two parties, viz. the Calixtines and Taborites, spread over all Bohemia and Hungary, and even Silesia and Poland; and there are some remains of them still subsisting in all those parts.

HUSTINGS, from the Saxon word *Hustinge*, i. e. *concilium*, or *curia*, a court held in Guildhall before the lord-mayor and aldermen of London, and reckoned the supreme court of the city. Here deeds may be inrolled, outlawries sued out, and replevins and writs of error determined. In this court also is the election of aldermen, of the four members of parliament for the city, &c. This court is very ancient, as appears by the laws of Edward the Confessor. Some other cities have likewise had a court bearing the same name, as Winchester, York, &c.

HUSUM, a town of Denmark, in the duchy of Sleswick, and capital of a bailiwick of the same name, with a strong citadel, and a very handsome church. It is seated near the river Ow, on the German sea; and is subject to the dukes of Holstein-Gottorp. E. long. 9. 5. N. lat. 54. 55.

HUTCHESON (Dr. FRANCIS), a very elegant writer and excellent philosopher, was the son of a dissenting minister in the north of Ireland, and was born on the 8th of August 1694. He early discovered a superior capacity; and having gone through a school-education, began his course of philosophy at an academy, whence he removed to the university of Glasgow, where he applied himself to all the parts of literature, in which his progress was suitable to his uncommon abilities.

He then returned to Ireland; and entering into the ministry, was just about to be settled in a small congregation of dissenters in the north of Ireland, when some gentlemen about Dublin, who knew his great abilities and virtues, invited him to take up a private academy there. He complied with the invitation, and met with much success. He had been fixed but a short time in Dublin, when his singular merits and accomplishments made him generally known; and his acquaintance was sought by men of all ranks, who had any taste for literature, or any regard for learned men. The late lord viscount Moleworth is said to have taken great pleasure in his conversation, and to have assisted him with his criticisms and

observations upon his "Inquiry into the Ideas of Beauty and Virtue," before it came abroad. He received the same favour from Dr. Synge, lord bishop of Elphin, with whom he also lived in great friendship. The first edition of this performance came abroad without the author's name, but the merit of it would not suffer him to be long concealed. Such was the reputation of the work, and the ideas it had raised of the author, that lord Granville, who was then lord lieutenant of Ireland, sent his private secretary to enquire at the bookseller's for the author; and when he could not learn his name, he left a letter to be conveyed to him: in consequence of which he soon became acquainted with his excellency, and was treated by him, all the time he continued in his government, with distinguished marks of familiarity and esteem.

From this time his acquaintance began to be still more courted by men of distinction either for station or literature in Ireland. Archbishop King, the author of the celebrated book *De origine mali*, held him in great esteem; and the friendship of that prelate was of great use to him in screening him from two several attempts made to prosecute him, for daring to take upon him the education of youth, without having qualified himself by subscribing the ecclesiastical canons, and obtaining a licence from the bishop. He had also a large share in the esteem of the primate Bolter, who through his influence made a donation to the university of Glasgow of a yearly fund for an exhibitioner to be bred to any of the learned professions. A few years after his "Inquiry into the Ideas of Beauty and Virtue," his "Treatise on the Passions" was published: both these works have been often reprinted; and always admired, both for the sentiments and language, even by those who have not assented to the philosophy of them, nor allowed it to have any foundation in nature. About this time he wrote some philosophical papers, accounting for laughter, in a different way from Hobbes, and more honourable to human nature: which papers were published in the collection called *Hibernicus's Letters*.

After he had taught in a private academy at Dublin for seven or eight years with great reputation and success, he was called, in 1729, to Scotland, to be a professor of philosophy in the university of Glasgow. Several young gentlemen came along with him from the academy, and his high reputation drew many more thither both from England and Ireland. Here he spent the remainder of his life in a manner highly honourable to himself and ornamental to the university of which he was a member. His whole time was divided between his studies and the duties of his office; except what he allotted to friendship and society. A firm constitution and a pretty uniform state of good health, except some few slight attacks of the gout, seemed to promise a longer life; yet he did not exceed the 53d year of his age. He was married, soon after his settlement in Dublin, to Mrs. Mary Wilson, a gentleman's daughter in the county of Longford; by whom he left behind him one son, Francis Hutcheson, doctor of medicine. By this gentleman was published, from the original manuscript of his father, "A System of Moral Philosophy, in three books, by Francis Hutcheson, LL. D. at Glasgow, 1755," in two volumes 4to.

HUTCHINSON (JOHN), a philosophical writer, whose notions have made no inconsiderable noise in the world, was born in 1674. He served the duke of Somerset in the capacity of steward; and in the course of his travels from place to place employed himself in collecting fossils: we are told, that the large and noble collection bequeathed by Dr. Woodward to the university of Cambridge was actually made by him, and even unfairly obtained from him. When he left the duke's service to indulge his studies with more freedom, the duke, then master of the horse to George I. made him his riding surveyor, a kind of sinecure place of 200l. a year with a good house in the Meuse. In 1724 he published the first part of *Moses's*

Principia, in which he ridiculed Dr. Woodward's Natural History of the Earth, and exploded the doctrine of gravitation established in Newton's *Principia*: in 1727, he published the second part of *Moses's Principia*, containing the principles of the Scripture Philosophy. From this time to his death, he published a volume every year or two, which, with the MSS. he left behind, were published in 1748, in 12 vols. 8vo. On the Monday before his death, Dr. Mead urged him to be bled; saying pleasantly, "I will soon send you to Moses," meaning to his studies: but Mr. Hutchinson taking it in the literal sense, answered in a muttering tone, "I believe, Doctor, you will;" and was so displeas'd, that he dismissed him for another physician; but died in a few days after, August 28, 1737. Singular as his notions are, they are not without some defenders, who have obtained the appellation of *Hutchinsonians*. The reader may find a distinct and comprehensive account of the Hutchinsonian system in a book entitled, *Thoughts concerning Religion*, &c. printed at Edinburgh 1743; and in a letter to a bishop, annexed to it, first printed in 1732.

HUXING of pike, among fishermen, a particular method of catching that fish. For this purpose, they take 30 or 40 as large bladders as can be got; blow them up, and tie them close and strong; and at the mouth of each tie a line, longer or shorter according to the depth of the water. At the end of the line is fastened an armed hook, artfully baited; and thus they are put into the water with the advantage of the wind, that they may gently move up and down the pond. When a master pike has struck himself, it affords great entertainment to see him bounce about in the water with a bladder fastened to him: at last, when they perceive him almost spent, they take him up.

HUY, a town of the Netherlands, in the bishopric of Liege, and capital of Condras. It is advantageously seated on the river Maese, over which there is a bridge. E. long. 10. 22. N. lat. 52. 31.

HUYGENS (CHRISTIAN), one of the greatest mathematicians and astronomers of the 17th century, was the son of Constantine Huygens, lord of Zuylichem, who had served three successive princes of Orange in the quality of secretary; and was born at the Hague in 1629. He discovered from his infancy an extraordinary fondness for the mathematics; in a little time made a great progress in them; and perfected himself in those studies under the famous professor Schooten, at Leyden. In 1649 he went to Holstein and Denmark, in the retinue of Henry count of Nassau; and was extremely desirous of going to Sweden, in order to see Des Cartes; but the count's short stay in Denmark would not permit him. He travelled into France and England; was, in 1663, made a member of the royal society; and, upon his return into France, M. Colbert, being informed of his merit, settled a considerable pension upon him to engage him to fix at Paris; to which Mr. Huygens consented, and staid there from the year 1666 to 1681, where he was admitted a member of the academy of sciences. He loved a quiet and studious manner of life, and frequently retired into the country to avoid interruption, but did not contract that moroseness which is so frequently the effect of solitude and retirement. He was the first who discovered Saturn's ring, and a third satellite belonging to that planet, which had hitherto escaped the eyes of astronomers. He discovered the means of rendering clocks exact, by applying the pendulum, and rendering all its vibrations equal by the cycloid. He brought telescopes to perfection, made many other useful discoveries, and died at the Hague in 1695. He was the author of several excellent works. The principal of these are contained in two collections; the first of which was printed at Leyden in 1682, in quarto, under the title of *Opera varia*; and the second at Amsterdam in 1728, in two volumes quarto, entitled *Opera reliqua*.

HUYSUM, the name of several Dutch painters; the most celebrated of whom was John, whose subjects were flowers, fruit, and landscapes. According to Mr. Pilkington, this illustrious painter hath surpassed all who have ever painted in that style; and his works excite as much surprise by their finishing as they excite admiration by their truth. He was born at Amsterdam in 1682, and was a disciple of Justus van Huysum his father. He set out in his profession with a most commendable principle, not so much to paint for the acquisition of money as of fame; and therefore he did not aim at expedition, but at delicacy, and, if possible, to arrive at perfection in his art. Having attentively studied the pictures of Mignon, and all other artists of distinction who had painted in his own style, he tried which manner would soonest lead him to imitate the lightness and singular beauties of each flower, fruit, or plant, and then fixed on a manner peculiar to himself, which seems almost inimitable. His pictures are finished with inconceivable truth; for he painted every thing after nature; and was so singularly exact, as to watch even the hour of the day in which his model appeared in its greatest perfection. By the judicious he was accounted to paint with greater freedom than Mignon or Brueghel; with more tenderness and nature than Mario da Fiori, Michael Angelo di Campidoglio, or Segers; with more mellowness than De Heem: and greater force of colouring than Baptist. His reputation rose to such a height at last, that he fixed immoderate prices on his works; so that none but princes, or those of princely fortunes, could pretend to become purchasers. Six of his paintings were sold at a public sale in Holland for prices that were almost incredible. One of them, a flower piece, for fourteen hundred and fifty guilders; a fruit piece for a thousand and five guilders; and the smaller pictures for nine hundred. The vast sums which van Huysum received for his works, caused him to redouble his endeavours to excel: no person was admitted into his room while he was painting, not even his brothers; and his method of mixing the tints, and preserving the lustre of his colours, was an impenetrable secret, which he never would disclose. Yet this conduct is certainly not to his honour, but rather an argument of a low mind, fearful of being equalled or surpassed. From the same principle, he would never take any disciples, except one lady, named Haverman; and he grew envious and jealous even of her merit. By several domestic disquiets his temper became changed; he grew morose, fretful, and apt to withdraw himself from society. He had many enviers of his fame, which has ever been the severe lot of the most deserving in all professions; but he continued to work, and his reputation never diminished. It is universally agreed that he has excelled all who have painted fruit and flowers before him, by the confessed superiority of his touch, by the delicacy of his pencil, and by an amazing manner of finishing; nor does it appear probable that any future artist will become his competitor. The care which he took to purify his oils and prepare his colours, and the various experiments he made to discover the most lustrous and durable, are instances of extraordinary care and industry as well as capacity. From having observed some of his works that were perfectly finished, some only half finished, and others only begun, the principles by which he conducted himself may perhaps be discoverable. His cloths were prepared with the greatest care, and primed with white, with all possible purity, to prevent his colours from being obscured, as he laid them on very lightly. He glazed all other colours except the clear and transparent, not omitting even the white ones, till he found the exact tone of the colour; and over that he finished the forms, the lights, the shadows, and the reflections, which are all executed with precision and warmth, without dryness or negligence. The greatest truth, united with the greatest brilliancy, and a velvet softness on the surface of his

objects, are visible in every part of his compositions; and as to his touch, it looks like the pencil of nature. Whenever he represented flowers placed in vases, he always painted those vases after some elegant model, and the bas-relief is as exquisitely finished as any of the other parts. Through the whole he shows a delicate composition, a fine harmony, and a most happy effect of light and shadow. Those pictures which he painted on a clear ground are preferred to others of his hand, as having greater lustre, and as they demanded more care and exactness in the finishing; yet there are some on a darkish ground, in which appear rather more force and harmony. It is observed of him, that in the grouping of his flowers, he generally designed those which were brightest in the centre, and gradually decreased the force of his colour from the centre to the extremities. The birds-nests and their eggs, the feathers, insects, and drops of dew, are expressed with the utmost truth, so as even to deceive the spectator. And yet, after all this merited and just praise, it cannot but be confessed, that sometimes his fruits appear like wax or ivory, without that peculiar softness and warmth which is constantly observable in nature. Besides his merit as a flower-painter, he also painted landscapes with great applause. They are well composed; and although he had never seen Rome, he adorned his scenes with the noble remains of ancient magnificence which are in that city. His pictures in that style are well coloured, and every tree is distinguished by a touch that is proper for the leafing. The grounds are well broken, and disposed with taste and judgment; the figures are designed in the manner of Lairesse, highly finished, and touched with a great deal of spirit; and through the whole composition, the scene represents Italy, in the trees, the clouds, and the skies. He died in 1749, aged 67.

HUZZOOR, a Hindoostan word signifying *The presence*; applied, by way of eminence, to the Mogul's court. According to polite usage, it is now applied to the presence of every Nabob or great man. The appellation *Huzzoor Neves* denotes the secretary who resides at court, and keeps copies of all *firmans*, records or letters.

HYACINTH, in natural history, a genus of pellucid gems, whose colour is red with a mixture of yellow. The hyacinth, though less striking to the eye than any other red gem, is not without its beauty in the finest specimens. It is found of various sizes, from that of a pin's head to the third of an inch in diameter. They are harder than quartz-crystals; transparent, and formed into prisms pointed at both ends. These points are always regular with regard to the number of facets; being four on each facet, but with some exceptions: the sides of the main body are also very uncertain, in regard both to their number and shape: being found of four, five, six, seven, and sometimes of eight sides; sometimes being so compressed as almost to resemble the face of a spherical faceted garnet. Sometimes they are of a dodecaedral form like the garnet, but with more obtuse angles. The specific gravity of the hyacinth, according to Dutens, is 2.631; but Romé de l'Isle says that Brisson found it to be 3.6373; and the European hyacinths to be 3.760.

The hyacinth, as well as all other gems, is divided into oriental and occidental; the former being very hard and brilliant, so that they are frequently ranked among the topazes; but when soft, they are supposed to belong to the garnet kind, as mentioned under that article. The hyacinths, however, may generally be distinguished from the garnets by losing their colour in the fire, becoming white, and not melting. There is a kind of a yellow-brown hyacinth, resembling the colour of honey, which is distinguished from the rest by the remarkable property of not being electrical, and being likewise inferior in hardness.

Our jewellers allow all those gems to be hyacinths or jacinths that are of a due hardness with the mixed colour above men-

tioned; and as they are of very different beauty and value in their several degrees and mixture of colours, they divide them into four kinds; three of which they call *hyacinths*, but the fourth, very improperly, a *ruby*. 1. When the stone is in its most perfect state, and of a pure and bright flame-colour, neither the red nor the yellow prevailing, in this state they call it *hyacintha la bella*. 2. When it has an over-proportion of the red, and that of a duskier colour than the fine high red in the former, and the yellow that appears in a faint degree in it is not a fine, bright, and clear, but a dusky brownish yellow, then they call it the *saffron hyacinth*. 3. Such stones as are of a dead whitish yellow, with a very small proportion of red in them, they call *amber hyacinths*. And, 4. When the stone is of a fine deep red, blended with a dusky and very deep yellow, they call it a *rubacelle*. But though the over-proportion of a strong red in this gem has made people refer it to the class of rubies, its evident mixture of yellow shows that it truly belongs to the hyacinth.

The hyacinth *la bella* is found both in the East and West Indies. The oriental is the harder, but the American is often equal to it in colour. The rubacelle is found only in the East Indies, and is generally brought over among the rubies; but it is of little value: the other varieties are found in Silesia and Bohemia.

HYACINTHIA, in antiquity, feasts held at Sparta, in honour of Apollo, and in commemoration of his favourite Hyacinth. This Hyacinth was the son of Amyclas king of Sparta, and was beloved both by Apollo and Zephyrus. The youth showing most inclination to the former, his rival grew jealous; and, to be revenged, one day as Apollo was playing at the discus, i. e. quoits, with Hyacinth, Zephyrus turned the direction of a quoit which Apollo had pitched, full upon the head of the unhappy Hyacinth, who fell down dead. Apollo then transformed him into a flower of the same name; and as a farther token of respect, they say, commanded this feast. The Hyacinthia lasted three days; the first and third whereof were employed in bewailing the death of Hyacinth, and the second in feasting and rejoicing.

HYACINTHUS, **HYACINTH**, in botany; a genus of the monogynia order, belonging to the hexandria class of plants; and in the natural method ranking under the 10th order, *Coronariæ*. The corolla is campanulated, and there are three melliferous pores at the top of the germen. There are six species; of which the most remarkable is the orientalis, or eastern hyacinth. Of this there are a great number of varieties, amounting to some hundreds, each of which differs from the rest in some respect or other. This plant hath a large, purplish, bulbous root, sending up several narrow erect leaves eight or ten inches long; the flower stalk is upright, robust, and succulent, from 10 to 15 inches in height; adorned upward with many large funnel or bell shaped flowers, swelling at the base, and cut half-way into six parts; collected into a large pyramidal spike of different colours in the varieties; flowering in April or May.

These plants are cultivated with the greatest success in Holland, from whence great numbers are annually imported into Britain. Each variety is by the florists distinguished either by the name of the place where first raised, or the person who raised them, or the names of illustrious personages, as of kings, generals, poets, and celebrated ancient historians, gods, goddesses, &c. They are sold by all the seed dealers. The prices are from three pence per root to five or ten pounds or more; and some varieties are in such high esteem among the florists, that 20*l.* or 30*l.* will be given for a single bulb. They are hardy, and will prosper any where, though the fine kinds require a little shelter during the winter. They may be propagated either by seeds or offsets from the roots.

The properties of a good oriental hyacinth are, a stem perfectly upright, of moderate length, and so strong and well-proportioned that it will sustain the weight of the florets without bending: the florets should be large, swelling below, expanded above, and numerous, 10 or 15 at least, but are often 20 or 30 in number; and should be placed equally round the stem, the pedicles on which they grow longer below than above, diminishing gradually in length upward in such a manner as to represent a pyramid, and each pedicle sufficiently strong to support the florets without drooping. The curious in these plants are careful never to plant the fine sorts two years together in the same bed of earth; for, by planting them every year in a fresh bed, the beauty of the flowers is greatly improved.

HYADES, in astronomy, are seven stars in the bull's head, famous among the poets for the bringing of rain. Whence their name *Ἰαδῆς*, from the Greek *εἶναι* "to rain." The principal of them is in the left eye, by the Arabs called *aldebbaran*. The poets feign them the daughters of Atlas and Pleone. Their brother Hyas being torn to pieces by a lioness, they wept his death with such vehemence, that the gods, in compassion to them, translated them into heaven, and placed them in the bull's forehead, where they continue to weep; this constellation being supposed to presage rain. Others represent the Hyades as Bacchus's nurses; and the same with the Dodonides, who fearing the resentment of Juno, and flying from the cruelty of king Lycurgus, were translated by Jupiter into heaven.

HYÆNA, in zoology, see **CANIS**.

HYÆNIUS LAPIS, in natural history, the name of a stone said to be found in the eyes of the hyæna. Pliny tells us, that those creatures were in old times hunted and destroyed for the sake of these stones, and that it was supposed they gave a man the gift of prophecy by being put under his tongue.

HYBERNACULUM, in botany, **WINTER-QUARTERS**; defined by Linnæus to be part of the plant which defends the embryo herb from injuries during the severities of the winter. See **BULB** and **GEMMA**.

HYBLA, in ancient geography, or **MEGARA**; which last name it took from the Megareans, who led thither a colony; called also *Hybla Parva* and *Galeotis*. In Strabo's time Megara was extinct, but the name *Hybla* remained on account of its excellent honey named from it. It was situated on the east coast of Sicily, between Syracuse and the Leontines. *Galeotæ*, and *Megarenses*, the names of the people, who were of a prophetic spirit, being the descendants of Galeus the son of Apollo. *Hyblæus* the epithet.—The *Hyllæi colles*, small eminences at the springs of the Alabus near this place, were famous for their variety of flowers, especially thyme; the honey gathered from which was by the ancients reckoned the best in the world, excepting that of Hymettus in Attica. By the moderns it was called *Mel Passi*, for the same reason, namely, on account of its excellent honey, and extraordinary fertility, till it was overwhelmed by the lava of *Ætna*; and having then become totally barren, its name was changed to *Mal Passi*. In a second eruption, by a shower of ashes from the mountain, it soon reassumed its ancient beauty and fertility, and for many years was called *Bel Passi*: and last of all, in the year 1669, it was again laid under an ocean of fire, and reduced to the most wretched sterility; since which time it is again known by the appellation of *Mal Passi*. However, the lava in its course over this beautiful country has left several little islands or hillocks, just sufficient to show what it formerly was. These make a singular appearance in all the bloom of the most luxuriant vegetation, surrounded and rendered almost inaccessible by large fields of black and rugged lava.

HYBLA-Major, was situated in the tract lying between mount *Ætna* and the river *Symethus*. In Pausanias's time de-

folate. **HYBLA-Minor**, or *Heræa*, was an inland town of Sicily, situated between the rivers *Oanus* and *Herminius*; now **RAGUSA**.

HYBRIDA PLANTA, a monstrous production of two different species of plants, analogous to a mule among animals. The seeds of hybrid plants will not propagate.

HYBRISTICA, of *ἵβρις* *injury*, in antiquity, a solemn feast held among the Greeks, with sacrifices and other ceremonies; at which the men attended in the apparel of women, and the women in that of men, to do honour to Venus in quality either of a god or a goddess, or both. Or, according to the account given by others, the *hybristica* was a feast celebrated at Argos, wherein the women, being dressed like men, insulted their husbands, and treated them with all marks of superiority, in memory of the Argian dames having anciently defended their country with singular courage against Cleomenes and Demaratus. Plutarch speaks of this feast in his treatise of the great actions of women. The name, he observes, signifies infamy; which is well accommodated to the occasion, wherein the women strutted about in men's clothes, while the men were obliged to dangle in petticoats.

HYDATIDES, in medicine, little transparent vesicles or bladders full of water, sometimes found solitary and floating about, and sometimes in clusters, upon the liver and various other parts, especially in hydropical cases. Each is a distinct animal possessing life. Hydatids are frequently met with in quadrupeds; especially in the brain in sheep.

HYDATOSCOPIA, called also **HYDROMANCY**, a kind of divination or method of foretelling future events by water.

HYDE (EDWARD), earl of Clarendon, and lord high chancellor of England, was descended from an ancient family in Cheshire, and born at Dinton near Hindon, in Wiltshire, in 1608. He was entered of Magdalen-hall, Oxford, where, in 1625, he took the degree of A. B. and afterwards studied the law in the Middle Temple. In the parliament which began at Westminster April 10, 1640, he served for Wotton-Ballet in Wiltshire. But that parliament being soon after dissolved, he was chosen for Saltash in Cornwall in the long parliament. His abilities were much taken notice of, and he was employed in several committees to examine into divers grievances; but at last being dissatisfied with the proceedings in the parliament, he retired to the king, and was made chancellor of the exchequer, a privy-counsellor, and knight. Upon the declining of the king's cause, he went to France, where, after the death of Charles I. he was sworn of the privy-council to Charles II. In 1649, he and the lord Cottington were sent ambassadors extraordinary into Spain, and in 1657 he was constituted lord high chancellor of England. The year before the restoration, the duke of York fell in love with Mrs. Anne Hyde, the lord chancellor's eldest daughter, but carefully concealed the amour both from the king and chancellor. As it was by a promise of marriage, however, that he had gained upon her, he was afterwards induced to fulfil his engagement, and the ceremony was performed after the restoration. Upon the restoration, her father was chosen chancellor of the university of Oxford; and soon after created baron Hindon, in Wiltshire, viscount Cornbury in Oxfordshire, and earl of Clarendon in Wiltshire; and on the death of Henry lord Falkland, was made lord lieutenant of Oxfordshire. He took care neither to load the king's prerogative, nor encroach upon the liberties of the people; and therefore would not set aside the petition of right, nor endeavour to raise the star-chamber or high-commission courts again: nor did he attempt to repeal the bill for triennial parliaments; and when he might have obtained two millions for a standing revenue, he asked but one million two hundred thousand pounds per annum, which he thought would still put the king upon the necessity of having recourse to his parliament. In this just conduct he

is said to have been influenced by the following incident, which happened some years before. When he first began to grow eminent in the law, he went down to visit his father in Wiltshire; who, one day as they were walking in the fields together, observed to him, that men of his profession were apt to stretch the prerogative too far, and to injure liberty; but charged him, if ever he came to any eminence in his profession, never to sacrifice the laws and liberty of his country to his own interest or the will of his prince: he repeated his advice twice; and immediately falling into a fit of an apoplexy, died in a few hours: and this circumstance had a lasting influence upon him. In 1662, he opposed a proposal for the king's marriage with the infant of Portugal, and the sale of Dunkirk: however, the following year, articles of high treason were exhibited against him by the earl of Bristol; but they were rejected by the house of lords. In 1664, he opposed the war with Holland. In August 1667, he was removed from his post of lord-chancellor; and in November following impeached of high treason and other crimes and misdemeanors by the house of commons: upon which he retired into France, when a bill was passed for banishing him from the king's dominions. He resided at Rouen in Normandy: and dying there in 1674, his body was brought to England and interred in Westminster-abbey. He wrote, 1. A history of the rebellion, 3 vols. folio, and 6 vols. octavo; a second part of which was afterwards given to the public by his lordship's descendant the late lord Hyde and Cornbury. 2. A letter to the duke of York, and another to the dukes of York, upon occasion of their embracing the Romish religion. 3. An answer to Hobbes's Leviathan. 4. A history of the rebellion and civil wars in Ireland, octavo; and some other works.

The following character of this nobleman is given by Mr. Walpole: "Sir Edward Hyde (says he), who opposed an arbitrary court, and embraced the party of an afflicted one, must be allowed to have acted conscientiously. A better proof was his behaviour on the restoration, when the torrent of an insatuated nation entreated the king and his minister to be absolute. Had Clarendon sought nothing but power, his power had never ceased. A corrupted court and a blinded populace were less the causes of the chancellor's fall, than an ungrateful king, who could not pardon his lordship's having refused to accept for him the slavery of his country. Like justice herself, he held the balance between the necessary power of the supreme magistrate and the interests of the people. This never-dying obligation his cotemporaries were taught to overlook and clamour against, till they removed the only man, who, if he could, would have corrected his master's evil government. Almost every virtue of a minister made his character venerable. As an historian, he seems more exceptionable. His majesty and eloquence, his power of painting characters, his knowledge of his subject, rank him in the first class of writers; yet he has both great and little faults. Of the latter, his stories of ghosts and omens are not to be defended. His capital fault is his whole work being a laboured justification of king Charles. If he relates faults, some palliating epithet always slides in; and he has the art of breaking his darkest shades with gleams of light that take off all impression of horror. One may pronounce on my lord Clarendon, in his double capacity of statesman and historian, that he acted for liberty, but wrote for prerogative."

HYDE (Dr. Thomas), professor of Arabic at Oxford, and one of the most learned writers of the 17th century, was born in 1636; and studied first at Cambridge, and afterwards at Oxford. Before he was 18 years of age, he was sent from Cambridge to London to assist Mr. Brian Walton in the great work of the Polyglot Bible; and about that period undertook to transcribe the Persian Pentateuch out of the Hebrew cha-

acters, which archbishop Usher, who well knew the difficulty of the undertaking, pronounced to be an impossible task to a native Persian. After he had happily succeeded in this, he assisted in correcting several parts of Mr. Walton's work, for which he was perfectly qualified. He was made archdeacon of Gloucester, canon of Christ-church, head keeper of the Bodleian library, and professor both of Hebrew and Arabic, in the university of Oxford. He was interpreter and secretary of the Oriental languages, during the reigns of Charles II. James II. and William III.; and was perfectly qualified to fill this post, as he could converse in the languages which he understood. There never was an Englishman in his situation of life who made so great a progress; but his mind was so engrossed by his beloved studies, that he is said to have been but ill qualified to appear to any advantage in common conversation. Of all his learned works (the very catalogue of which, as observed by Anth. Wood, is a curiosity), his *Religio Veterum Persarum* is the most celebrated. Dr. Gregory Sharpe, the late learned and ingenious master of the Temple, has collected several of his pieces formerly printed, and republished them, with some additional dissertations, and his life prefixed, in two elegant volumes quarto. This great man died on the 18th of February, 1702. Among his other works are, 1. A Latin translation of Ulug Beig's observations on the longitude and latitude of the fixed stars; and 2. A catalogue of the printed books in the Bodleian library.

HYDNUM, in botany; a genus of the natural order of fungi, belonging to the cryptogamia class of plants. The fungus is echinated or prickly on the under side. One of the species, named the *imbricatum*, is a native of Britain, and is found in woods. It hath a convex hat, tiled, standing on a smooth pillar, of a pale flesh-colour, with white prickles. It is eaten in Italy, and is said to be of a very delicate taste.

HYDRA, in fabulous history, a serpent in the marsh of Lerna, in Peloponnesus, represented by the poets with many heads, one of which being cut off, another immediately succeeded in its place, unless the wound was instantly cauterized. Hercules attacked this monster; and having caused Iolaus to hew down wood for flaming brands, as he cut off the heads he applied the brands to the wounds, by which means he destroyed the Hydra. This hydra with many heads is said to have been only a multitude of serpents, which infested the marshes of Lerna near Mycene, and which seemed to multiply as they were destroyed. Hercules, with the assistance of his companions, cleared the country of them, by burning the reeds in which they lodged.

HYDRA, in astronomy, a southern constellation, consisting of a number of stars, imagined to represent a water serpent. The stars in Hydra, in Ptolemy's catalogue, are twenty-seven; in Tycho's, nineteen; in Hevelius's, thirty-one.

HYDRA, in zoology; a genus of the order of zoophyta, belonging to the class of vermes. There are several species, known by the general name of polypes. See POLYPE and ANIMALCULE.

HYDRAGOGUES, among physicians, remedies which evacuate a large quantity of water in dropsies. The word is formed of *ὑδρ* water, and *αγειν* to draw or lead; but the application of the term proceeds upon a mistaken supposition, that every purgative had some particular humour which it would evacuate, and which could not be evacuated by any other. It is now, however, discovered, that all strong purgatives will prove *hydragogues*, if given in large quantity, or in weak constitutions. The principal medicines recommended as hydragogues, are the juice of elder, the root of iris, soldanella, mechoacan, jalap, &c.

HYDRANGEA, in botany; a genus of the digynia order, belonging to the decandria class of plants; and in the natural

method ranking under the 13th order, *Succulentæ*. The capsule is bilocular, birostrated, and cut round, or parting horizontally. There is but one species, viz. the arborefcens, a native of North America, from whence it hath lately been brought to Europe, and is preserved in gardens, more for the sake of variety than beauty. It rises about three feet high; and hath many soft pithy stalks, garnished with two oblong heart-shaped leaves placed opposite. The flowers are produced at the top of the stalks in a corymbus. They are white, composed of five petals with ten stamina surrounding the style. It is easily propagated by parting the roots; the best time for which is the end of October. The plants thrive best in a moist soil, and require to be sheltered from severe frosts.

HYDRASTIS, in botany; a genus of the polygamia order, belonging to the polyandria class of plants; and in the natural method ranking with those of which the order is doubtful. There is neither calyx nor nectarium; there are three petals; and the berry is composed of monospermous acini.

HYDRARGYRUS, a name given to quicksilver. The word is formed of *ὕδωρ aqua*, "water," and *ἀργυρος argentum*, "silver;" q. d. *water of silver*, on account of its resembling liquid or melted silver.

HYDRAULICS, the science of the motion of fluids, and the construction of all kinds of instruments and machines relating thereto. See **HYDROSTATICS**, Part II.

HYDRENTEROCELE, in surgery, a species of hernia, wherein the intestines descend into the scrotum, together with a quantity of water.

HYDROCELE, in surgery, denotes any hernia arising from water; but is particularly used for such a one of the scrotum, which sometimes grows to the size of one's head, without pain, but exceedingly troublesome to the patient. See **SURGERY**.

HYDROCEPHALUS, a preternatural distension of the head to an uncommon size by a stagnation and extravasation of the lymph; which, when collected in the inside of the cranium, is then termed *internal*; as that collected on the outside has been termed *external*. See **MEDICINE**.

HYDROCHARIS, the **LITTLE WATER-LILY**; a genus of the enneandria order, belonging to the diœcia class of plants; and in the natural method ranking under the first order, *Palmeæ*. The spathe of the male is diphyllous; the calyx trifid; the corolla tripetalous; the three interior filaments styliferous. The female calyx trifid; the corolla tripetalous; the styles six; the capsule has six cells, and is polyspermous inferior. There is only one species, a native of Britain, growing in slow streams and wet ditches. It hath kidney-shaped leaves, thick, smooth, and of a brownish green colour, with white blossoms. There is a variety with double flowers of a very sweet smell.

HYDROCOTYLE, **WATER-NAVELWORT**; a genus of the digynia order, belonging to the pentandria class of plants, and in the natural method ranking under the 45th order, *Umbellatæ*. The umbel is simple; the involucreum tetraphyllous; the petals entire; the seeds are half round and compressed. There are several species, none of which are ever cultivated in gardens. One of them, a native of Britain, growing in marshy grounds, is supposed by the farmers to occasion the rot in sheep. The leaves have central leaf-stalks, with about five flowers in a run-dle; the petals are of a reddish white.

HYDROGRAPHY, the art of measuring and describing the sea, rivers, canals, lakes, &c. With regard to the sea, it gives an account of its tides, counter-tides, soundings, bays, gulphs, creeks, &c.; as also of the rocks, shelves, sands, shallows, promontories, harbours; the distance and bearing of one port from another; with every thing that is remarkable, whether out at sea or on the coast.

HYDROLEA, in botany; a genus of the digynia order, belonging to the pentandria class of plants; and in the natural

method ranking with those of which the order is doubtful. The calyx is pentaphyllous; the corolla rotaceous; the filaments at the base are cordate; the capsule is bilocular and bilvalved.

HYDROMANCY, a method of divination by water, practised by the ancients. See **DIVINATION**.

HYDROMEL, honey diluted in nearly an equal weight of water. When this liquor has not fermented, it is called *simple hydromel*; and when it has undergone the spirituous fermentation, it is called the *vinous hydromel* or *mead*.

Honey, like all other saccharine substances, is susceptible of the spirituous fermentation. To induce this, nothing is necessary but to dilute it sufficiently in water, and to leave the liquor exposed to a convenient degree of heat. To make good mead, the best tasted honey must be chosen; and this must be put into a kettle with more than its weight of water: a part of this liquor must be evaporated by boiling, and the liquor scummed, till its consistence is such that a fresh egg shall be supported upon its surface without sinking more than half its thickness into the liquor; then the liquor is to be poured into a barrel, and exposed to a heat as equable as is possible, from 20 to 27 or 28 degrees of Reaumur's thermometer, taking care that the bung-hole be covered, but not closed. The spirituous fermentation will appear in this liquor, and will subsist during two or three months, according to the degree of heat; after which they will diminish and cease. During this fermentation, the barrel must be filled up occasionally with more of the same kind of liquor of honey, some of which ought to be kept apart on purpose to replace the liquor which flows out of the barrel in froth. When the fermentation ceases, and the liquor has become very vinous, the barrel is then to be put in a cellar and well closed. A year afterwards the mead will be fit to be put into bottles.

Mead is an agreeable kind of wine: nevertheless it retains long a taste of honey, which is displeasing to some persons; but this taste it is said to lose entirely by being kept a very long time. The spirituous fermentation of honey, as also that of sugar, and of the most of vinous liquors, when it is very saccharine, is generally more difficultly effected, requires more heat, and continues longer than that of ordinary wines made from the juice of grapes; and these vinous liquors always preserve a saccharine taste, which shows that a part only of them is become spirituous.

HYDROMETER, an instrument to measure the gravity, density, velocity, force, &c. of water and other fluids. See p. 12, and **HYDROSTATICS**.

Though this instrument is incapable of determining the specific gravity of liquors with perfect accuracy, yet in the way of public business it has undoubtedly the advantage of every other, on account of the ease and expedition with which it can be used; and for this reason it has been adopted by government, in order to determine the strength of spirituous liquors. Dr. Blagden (*Phil. Transf.* vol. 80. p. 342.), who was lately employed to make experiments on this subject, is of opinion, that glass is the most proper material for the construction of an hydrometer. Its sensibility depends on the size of its stem. In the old areometers the stem was made so large, that the volume of water displaced between its least and greatest immersions was equal to the whole difference of specific gravity between water and alcohol, or perhaps more; whence its scale of divisions must be very small, and could not give the specific gravity with much accuracy. On this account weights were introduced, by means of which the stem could be made smaller; each weight affording a new commencement of its scale; so that the size of the divisions on a given length was doubled, tripled, &c. as one or more weights were employed, the diameter of the stem being lessened in the subduplicate propor-

tion of the increased length of the divisions. This method, however, in our author's opinion, has been carried to excess; and the following is recommended as a proper mean betwixt these extremes, to determine the specific gravity of spirituous liquors to three places of decimals.

In this method the weight of water is supposed to be unity, or 1 with any number of cyphers annexed: "the whole compass of numbers, therefore, from rectified spirit to water, at 60 degrees of heat, would be the difference between 825 the weight of rectified spirit, and 1000 the weight of water, which is 175. To make allowance for the lightest spirit and heaviest water, however, at all the common temperatures, the difference may be supposed 220. The stem might show every twenty of these divisions, and thus ten weights would be sufficient for the whole. Hence the inconvenience of shifting the weights, which has always been complained of, would in a great measure be avoided; as people versant in that business would seldom err so far as to the whole amount of the difference previous to making any trial. Hence also the stem may be made small enough, and the scale graduated so nicely as to make the instrument sufficiently accurate.

According to this arrangement, it would be proper to have the weights adapted to the hydrometer marked with the different specific gravities which they are intended to indicate; zero on the top of the stem without a weight being supposed to mean 800, and 20 at the bottom to signify 820, which number the first weight would carry; the successive weights being marked, 840, 860, &c.; and the division on the stem cut by the fluid under trial, would be a number always to be added to that on the weight; the sum of the two showing the true specific gravity. The weights should undoubtedly be made to apply on the top of the stem, so as never to come in contact with the liquor; and in using the hydrometer, its stem should always be pressed down lower than the point at which it will ultimately rest, that by being wetted it may occasion no resistance to the fluid. The instrument itself should be of as regular a shape and with as few inequalities as possible, that all impediments to its motions may be avoided.

HYDROMPHALUS, in surgery; a name given to any tumor in the navel, that contains water.

HYDROPHANES, **OCULUS MUNDI**, or *Lapis Mutabilis*, a kind of precious stone highly esteemed among the ancients, but little known to the moderns till M. Boyle made his observations upon it. Its specific gravity is about 2.048; its colour of an opaque whitish brown; it is not soluble in acids nor affected by alkalis, but is easily cut and polished. Sometimes it gives fire with steel, sometimes not. It is infusible *per se*; but when urged by a blow pipe, changes to a brownish brittle substance. It is found in beds over the opals in Hungary, Silesia, and Saxony, and over the chalcedonies and agates in Iceland. These stones in general are either of a yellowish green, milky grey, or of a yellow like that of amber.

The most remarkable property of this stone is, that it becomes transparent by mere infusion in any aqueous fluid; but gradually resumes its opacity when dry. There are three of these stones in the British museum at London; the largest of them about the size of a cherry stone, but of an oval form. It is opaque and coloured like a common yellow pea; it may be scratched, though not without difficulty, by a common knife, notwithstanding which it seems to leave a mark upon glass. It does not ferment with nitrous acid. When it has lain some hours in water, it becomes transparent, and of a yellow amber colour. The change begins soon after the immersion, and at one end in form of a little spot; but in a small one of the same kind, the transparency begins round the edges. By degrees the spot increases, until the whole stone becomes uniformly clear throughout: when out of the water it loses its transpa-

rency, first at one end, and then gradually over the remainder, until the whole has become opaque; which change happens in less time than it takes to become transparent. This change is not entirely peculiar to the hydrophanes. Bergman informs us, that some steatites produce the same effect; and M. Magellan, that the crull of chalcedonies and agates frequently exhibits the same appearance.

Messrs. Bruckman and Veltheim were the first who particularly enquired into the nature of this stone, and investigated its properties, many of which were brought to light by their endeavours. Their account is to the following purport: As soon as the stone is put into water, it exhales a musty smell, several air-bubbles arise, and it becomes gradually transparent. Some of the stones become colourless as soon as they are thoroughly transparent, others have a more or less deep yellow colour; some acquire a beautiful ruby colour; and, lastly, others gain a fine colour of mother-of-pearl, or of a blueish opal. Whatever be the colour of the liquor in which the hydrophanes is immersed, it gains only its usual degree of transparency with the colour peculiar to it. When we look at it in its moist state, we perceive a luminous point, varying its situation as the position of the eye is altered. This luminous point is not, according to Mr. Bruckman, the immediate image of the sun, but a reflection of that image refracted in the substance of the stone itself, a phenomenon which probably gave rise to the name of *oculus mundi*. Mr. Bruckman left a piece of this stone weighing 35 grains seven hours in water, the space requisite to make it perfectly transparent; and in that time he found that it had gained three grains in weight. The hydrophanes becomes much sooner transparent when put into hot water; and the same happens if it be dipped in a very dilute acid, or rather a very dilute solution of alkali. When dipped in oil of vitriol, it becomes very quickly transparent, and will continue so, on account of the strong attraction of that acid for moisture, which takes as much from the atmosphere as is necessary to keep the stone transparent; but its opacity will return if it be dipped in an alkaline liquor and afterwards dried.

HYDROPHOBIA, an aversion or dread of water: a terrible symptom of the *rabies canina*; and which has likewise been found to obtain in violent inflammations of the stomach and in hysteric fits. See **MEDICINE**.

HYDROPHYLACIA, a word used by Kircher and some others who have written in the same system, to express those great reservoirs of water which he places in the Alps and other mountains for the supply of rivers which run through the several lower countries. This he makes to be one of the great uses of mountains in the economy of the universe.

HYDROPHYLLAX, in botany; a genus of the monogynia order, belonging to the tetrandria class of plants. The calyx is tetrapartite; the corolla funnel-shaped; the fruit two-edged and one-seeded.

HYDROPHYLLUM, **WATER LEAF**; a genus of the monogynia order, belonging to the pentandria class of plants; and in the natural method ranking with those of which the order is doubtful. The corolla is campanulated, with five melliferous longitudinal stria on the inside; the stigma is bifid; the capsule globose and bivalved. There is only one species, *viz.* the *Virginianum*, or water-leaf of Morinus. It grows naturally in Canada and many other parts of America on moist spongy ground. The root is composed of many strong fleshy fibres, from which arise many leaves with footstalks five or six inches long, jagged into three, five, or seven lobes, almost to the midrib, indented on their edges. The flowers are produced in loose clusters hanging downward, are bell-shaped, and of a dirty white colour. It may be propagated by parting the roots; which ought to be done in autumn, that the plants may be well rooted before spring, otherwise they will require a great deal of water.

HYDROPS, in medicine, the same with DROPSY.

HYDROSCOPE, an instrument anciently used for the measuring of time. The hydroscope was a kind of water-clock, consisting of a cylindrical tube, conical at bottom: the cylinder

was graduated, or marked out with divisions, to which the top of the water becoming successively contiguous, as it trickled out at the vertex of the cone, pointed out the hour.

H Y D R O S T A T I C S ;

THE science which treats of the nature, gravity, pressure, and equilibrium of fluids, and of the weighing of solids in them: that part of the science of fluids which treats of their

motions being included under the head of *Hydraulics*. In conformity with what is customary in books of philosophy, we shall treat these subjects in two distinct parts.

PART I. H Y D R O S T A T I C S.

SECT. I. *Of Fluidity.*

THE late Mr. George Adams, of whose estimable writings we propose to avail ourselves in the following treatise, defines a fluid to be a body whose parts are so loosely connected together, that they easily yield to any force impressed upon them, and move freely amongst each other. In this sense, fire, air, mercury, water, &c. are considered as fluids. In almost every physical speculation, wherever experiment can reach, the subject will admit of some illustration; where that is denied, the reasonings are in general vain and conjectural. We do not know the form of the parts of which fluids are composed, and can make no experiments to reduce them into their primary particles.

There is nothing more different in accuracy and truth, than that apprehension which is adequate to the purposes of the vulgar, and that which ought to satisfy the investigation of a philosopher. Thus there is nothing more obvious to the vulgar than *fluidity*, yet the philosopher finds it a property difficult to be conceived, and which he could not give credit to, if it was not rendered familiar to him by custom and experience; it is a physical phenomenon which has not yet been explained, and of which it is very difficult to give a clear account. How, indeed, can we comprehend, that a material and incompressible substance can be composed of parts so elementary, so moveable among themselves, and yet with so little adherence, as to assume immediately the form of any vessel into which it is poured; that its surface is always parallel to the horizon, or perfectly level; that in syphons, or when agitated by the wind, it makes isochronic vibrations, or undulations like a pendulum; that it runs off where favoured by the smallest descent? &c. &c.

Fluidity is caused by a certain degree of fire, which, when employed for this purpose, disappears with respect to any other sensible or perceptible effect. It does not dilate the volume, but resists the particular attachment of the parts. Some have endeavoured to give mechanical ideas of a *fluid body*, by comparing it to a heap of sand; but the impossibility of giving fluidity by any kind of mechanical comminution, will appear by considering two of the circumstances necessary to constitute a fluid body: 1. That the parts, notwithstanding the greatest compression, may be moved, in relation to each other, with the smallest conceivable force, or will give *no sensible resistance* to motion within the mass in any direction. 2. That the parts shall gravitate to each other, whereby there is a constant tendency to arrange themselves about a common centre, and form a spherical body; which, as the parts do not resist motion, is easily executed in small bodies. Hence the appearance of drops always takes place when a fluid is in proper circumstances.

Let us now see how far these qualities may be procured by mechanical operations, even executed without those imperfections that necessarily attend human performance. A body of

sand, the particles of which should be perfectly spherical and polished, or smooth, would only imitate a fluid in being able to spread itself upon a smooth plane, instead of lying in a heap, but would possess neither of the two qualities essential to a fluid body. For a heap of spherical bodies, if compressed, could not move by relation to each other, except by a force sufficient to balance that by which, in this case, they are necessarily retained in their places. Neither can the parts of the supposed body of sand cohere, either to themselves or to other bodies, in the manner of fluids, as in each particle the mass of gravitating matter must be great in proportion to the point of contact by which they should cohere. If the cohesion of the particles of sand increased, the spreading quality would be diminished.

Many other differences might be pointed out; but supposing every thing else favourable to the mechanical theory, yet still there would remain to be explained the operation of fire, which is so essential to fluidity. This would lead us too far, as it would render it necessary for us to investigate the nature of that resistance by which the figure of bodies is preserved in their hardness. By fire hard bodies are made soft; but it is not properly that portion of loose fire which augments the volume of bodies that renders them fluid: their fluidity is occasioned by a *certain quantity of fire, which then disappears, with regard to any other sensible or perceptible effect.*

SECT. II. *Of the Gravity of the Particles of Fluids, and its Effects on the Fluids themselves.*

ALTHOUGH no one finds any difficulty in allowing that water and other fluids are really ponderous, and do actually gravitate when considered as a whole body, being convinced by their own senses, that a vessel weighs less when empty, than when filled with any fluid, and weighs heavier the more it contains; yet, in the early times of philosophy, there were those that believed fluids did not gravitate *in proprio loco*, as they termed it; that is, when immersed in the same, or a different fluid. A simple experiment will shew that they were mistaken, and that fluids lose nothing of their weight *in proprio loco*. Take a hollow glass ball, such as is represented in pl. 18, fig. 5, furnished with a brass stop-cock, and made so heavy as to sink in water. Exhaust it of its air, and then shut the cock. Exhausting the air from it, gives room to a quantity of water equal in bulk to the exhausted air. Suspend it now from the end of the balance, so that the bottle and the stop-cock may be under the surface of the water in the jar, and then counterpoise it by a weight in the opposite scale. If we now open the cock, that the water may run into the bottle, the water will rush in, and the ball will preponderate, and bear down the beam on which it hangs; clearly proving, *that the parts of water retain their gravity in water*, so as to press and bear down upon the parts beneath them, otherwise the phial would not become hea-

vier upon the admission of the water; and it will appear that the ball over-balances the counterpoise, as much as the weight of the quantity of water in the ball.

To facilitate the explanation of hydrostatic phenomena, it has been usual for the writers on this subject to consider the fluid in a vessel as cut into several horizontal planes, or imaginary surfaces, and to consist of a vast number of small, equal, lubricous, spherical globules. Thus, fig. 2, pl. 17, A B C D may represent a vessel consisting of such globules, a b, c d, e f, imaginary horizontal surfaces. Besides this imaginary horizontal division of a fluid, they often consider it as divided into perpendicular columns, from the top to the bottom of the fluid, as at fig. 3.

Though fluids are subject to the laws of gravity as well as solids, yet their fluidity occasions some peculiarities necessary to be noticed. The parts of a solid are so connected together as to form but one and the same whole; their effort is as it were concentrated in a single point, called the centre of gravity. This is not the case with fluids; the particles here are all independent of each other, are extremely moveable, yielding to the least effort that tends to separate the one from the other.

The parts of a fluid gravitate independently of each other, and this is a natural consequence of their fluidity, or their not adhering together; whereas the particles of a solid cohere together, and gravitate as one mass. It is clear, from this principle, that if a hole be made in a vessel full of water, the power necessary to prevent the fluid from running out, must be able to overcome the column of the fluid pressing on the hole, and that the weight to be overcome is the same, whether there is only this column of the fluid acting on the part stopping the hole, or whether the vessel be full.

This will be rendered clearer by an experiment, made with the cylindrical glass vessel A B C D, fig. 1, pl. 17, which has a hole at bottom. A cylindrical tube of brass passes through, and is fitted to this hole; a small piston, or plug, is fitted to this tube; and, being well greased, slides easily up and down; a long wire is fixed to this piston, to be hooked on to one arm of the balance E F. On the upper part of this short tube may be occasionally fitted a glass tube, G H, which is exactly of the same diameter as the brass tube, and of the same height with the large vessel.

Having fitted the glass tube in its place, and poured in water up to the mark, put weights into the scale at the opposite arm of the balance, till the piston just begins to rise; then take away the glass tube, and fill the large vessel with water to the same height, and it will be evident that the same weight as before overcomes the pressure. Now as the same weight overcomes the pressure, whether a column of water be only the size of the piston, or whether the vessel be full of water, it is clear that particles of water exercise their gravity independent of each other; but if the mass of water contained in the outer vessel was changed into ice, to raise the piston we must use a weight equal to the weight of the whole column of ice.

The surface of a fluid which is contained in an open vessel, and free from all external impediments, will be level, or parallel to the horizon. No part of a fluid can stand higher than the rest; for, if any part be raised, it must descend by the force of gravity, and, in so doing, will spread and diffuse itself till it is on a level with the other parts; for, having gravity, and yielding easily to every impression, they obey the force of gravity, and slip down till they come to a level.

As the gravity of the particles reduces the upper surface to a level, so likewise it occasions a pressure on the lower part, greater or less in proportion to their depths below the surface, each part containing a pressure equal to the weight of all those that lie above it; consequently, the particles which are at equal depths below the surface are equally pressed. In other words,

as the upper surface of the fluid is parallel to the horizon, and as the lower parts sustain the upper, and are pressed by them, this pressure will be in proportion to the incumbent matter, that is, *to the height of the fluid above the particle that is pressed*: but as the upper surface of the fluid is parallel to the horizon, *all the points of any surface that you may conceive within the fluid, parallel to the horizon, are equally pressed*. Should this equality of pressure be at any time destroyed, and *there be a less pressure on one part of the surface than on the other parts*, the fluid yielding to any impression, *this part will be moved, that is, will ascend till the pressure becomes equal*.

We may confirm this by a simple experiment with a glass tube. Stopping one end with your finger, immerse the other in water. The water will rise in the tube; but the tube being full of air, while you keep your finger upon the orifice, the rise is but small; but if you take away your finger, that the air which is compressed may escape, the water will rise up into the tube, and not be at rest till it attains the same height with the external water.

Solids, we know, make no effort but in the direction of gravity, or perpendicularly downwards; *but fluids exert a force of pressure equal to their gravity, in all directions, and in all equality*. This follows from the nature of a fluid, for its particles yield to any impression, and are easily moved; therefore no drop will remain in its place, if, whilst it be pressed by a superincumbent fluid, it be not equally pressed on all sides; because, being a fluid itself, it will yield to every impression, and begin to move, unless it be acted upon by equal forces, in all possible directions. But it cannot move, because the surrounding drops resist on all sides its motion with the same force that it endeavours to move, and consequently the drop must remain at rest; and what is thus proved of one drop, holds equally true of all; consequently *all the parts of a fluid, at equal depths below the surface, are pressed equally in all directions*.

Let us take the several glass tubes, A, B, C, D, fig. 4, pl. 17, which are open at both ends; immerse them in water to the same depth, their upper orifice being stopped by the finger. Upon taking away the finger, the water will rise to the same height in all the tubes, though it enters the lower end in very different directions: in A the pressure is directed upwards, in B downwards, in C sideways, and in D obliquely, but the pressure is equal in each. If we pour a greater quantity of water into the vessel, it will rise equally in the tubes; *so that fluids press in all manner of directions, and that with a force proportionable to their heights*.

The same experiment is perhaps rendered still clearer by pouring some mercury into tubes. The tubes for this purpose are smaller than those to be used in the former experiment: some of them are straight, and others bent at various angles. Though the tubes are open at both ends, one of the extremities should be closed till after the immersion, to prevent the mercury from falling out. On immersing the lower end of these tubes in water, the mercury will ascend toward the upper end of the tubes. It is to be remarked, concerning this experiment, that whatever be the angles at which the tubes are bent, and however they are inclined to the horizon, if before immersion the mercury in all the tubes be on a level, it will continue so after immersion, provided all the tubes are immersed to the same depth. Consequently, when it has been proved that the pressures of a fluid are as the surface pressed, and their depths from the surface of the incumbent fluid, it will follow, that the pressure of a fluid is not only propagated in all directions, but that the quantities of the pressure at the same depths, and on a given surface, are equal in all directions.

From a cursory view of the subject, some may consider it as

a kind of mechanical paradox, that the pressure of a fluid upward, or in a direction contrary to that of gravity, should be nothing more than a consequence of gravity itself; but it is very easy to shew, from mechanical principles, that a force acting in a given direction may communicate pressure through a number of intermediate bodies, so that the last body shall be impelled in any direction whatever, even in that which is directly contrary to the original impulse; and this is the case in respect of the particles which compose fluids.

From the foregoing experiments it very clearly appears, that the perpendicular pressure of any fluid column is, from some unknown connection of the parts, diffused laterally in every direction; and at the same depth, the pressures estimated in any direction are equal to each other. What has been proved of water, obtains in all other substances that are fluid, and under the influence of gravity.

SECT. III. *Of the Action of Fluids against the Bottoms, Sides, and Tops of the Vessels in which they are contained.*

It is evident that the bottom and sides of a vessel containing a fluid (and the top also, when the fluid is raised above it in a tube) are pressed by the parts of the fluids which immediately touch them; and as action and re-action are equal, these parts all sustain an equal degree of pressure.

As the pressure of fluids is equal every way, the bottoms and sides of the vessels are pressed as much as the neighbouring parts of the fluid; but it has been shewn that this action increases in proportion to the height of the fluid, and is every way equal at the same depth. This pressure depends on the height, not the quantity of the fluid; consequently, when the height of the fluid, and the area or surface pressed, remain the same, the action upon this surface will always be equal, however the figure of the vessel be changed. In other words, the pressure which the bottom of the vessel sustains from the fluid contained in it, whatever be the shape of the vessel, is equal to the weight of a pillar of the fluid, whose base is equal to the area of the bottom, and whose height is the same with the perpendicular height of the fluid.

That this is the case, in vessels that are equally wide from top to bottom, is obvious, because the bottom of such a vessel does actually sustain such a column of fluid, a column in this case equal to the whole weight of the fluid. Here the whole weight of the fluid contained in the vessel, and no other force besides, presses upon the bottom, and is consequently proportional to the quantity of matter contained in the vessel, which quantity is as the surface of the bottom, and the perpendicular height above it. But that the case should be the same in irregular vessels, is not so easy to conceive; for instance, that in a vessel which from a large bottom grows narrower as it rises, the bottom should bear the same pressure when the vessel is filled, as it would were the vessel equally wide throughout from bottom to top, seems strange, yet is what necessarily follows from the nature of fluidity.

Before we proceed to illustrate this proposition by experiment, it may not be improper to explain it by diagrams; considering it, 1. when the vessel is narrower at the top than the bottom; 2. when it is wider at the top than the bottom.

1. Then, if the vessel $M N F T$, fig. 6, pl. 17, is smaller at the top than at the bottom, the pressure upon the bottom, $E T$, is as great as the pressure upon the bottom of a cylindrical vessel, $A B C D$, fig. 7, of equal base and height, when they are both filled with water, or any other fluid, notwithstanding there will be considerably more water in the cylinder than the cone. Make $F G$, $Q R$, in the cylinder, fig. 7, equal to $O R$, the base of the column $M N O R$ of the cone, fig. 6. Now as these columns of water are equal, it is evident that $O R$ in the cylinder and $O R$ in the cone sustain an equal weight, and

consequently an equal pressure. It is also evident, from what has been explained at the beginning of this article, that every part equal to $O R$, at the bottom of the cylinder, is pressed just as much as $O R$. But it is requisite for us to prove, that every part at the bottom of the cone is equal to $O R$ at the bottom of the cylinder; for instance, the part $F I$ is pressed just as much as $O R$ is. It has been shewn that all equal parts of a fluid, at equal depths from the surfaces, are pressed equally; but the drops contiguous to $F I$ and $O R$ are at equal depths from the surfaces: therefore these drops, and consequently the parts $F I$ and $O R$, are equally pressed. Now as every part equal to $O R$, in the bottom both of the cone and cylinder, is pressed as much as $O R$, and since one bottom is equal to the other, it follows, that the whole pressure upon $F T$ is equal to the whole pressure upon $C D$.

But although it appears that the proposition is true, some persons have a difficulty in discovering the reason why it is true; for it certainly does not seem likely, at first view, that $F I$, with no more water over it than fills the space $F E I$, should be pressed as much as $O R$, which sustains the whole column $M N O R$. But it must be remembered, that the water $F E I$ presses upwards against $F E$, as well as downwards against $F I$; and if a hole was made at $F E$, and a tube soldered therein, the water, by the pressure upwards, would be sustained in the tube at the same height that it stands in the vessel; therefore this pressure is equal to the weight of as much water as would fill the tube $C A F E$.

Now the same pressure which would support the water in such a tube acts upon $F E$; but the re-action of $F E$ downwards is equal to the action upwards against it: that is, $E F$ keeps the water down with a force equal to that with which it endeavours to rise, equal to the difference of weight between $F E I$ and $M N O R$: and as $F I$ sustains both the weight of the water $F E I$, and the action or force with which the water is kept from rising, but $O R$ sustains only the weight of water $M N O R$, the pressure upon $F I$ will be equal to the pressure upon $O R$, and the same may be proved of any other column. Therefore the bottom of the cone is as much pressed by the weight of water which fills the cone, and this re-action together, as the same bottom would be pressed by the weight of as much water as would fill up the whole cylindrical space $C B F T$; that is, the pressure upon the bottom of a conical vessel, is equal to the pressure upon the bottom of a cylindrical one of the same base and height.

The same mode of reasoning may be applied to the vessel $D B L P$, fig. 8, which consists of two cylindrical parts $N M L P$, a great cylinder at the bottom, and $D B I V$, a lesser one at the bottom. For the pressure upon $L P$, when the vessel is full of water, will be as great as if the vessel was as wide at top as it is at bottom; that is, as great as it would be upon the same bottom $L P$, supposing the vessel was an uniform cylinder, whose base was $L P$, and height $L F$. $L A$, and $O R$, two equal drops at the same depth, are pressed equally; and $O R$ having as much water to sustain, is as much pressed as if the vessel was an uniform cylinder. Therefore $L A$, or $C P$, or any other equal part at the bottom, and consequently the whole bottom, is as much pressed in one case as it would be in the other. Indeed $L A$ or $C P$ have less water to sustain than $O R$; but the column $N T L A$ presses upwards against $N T$ with a force equal to the difference between this column and $D B O R$, or to the weight of as much water as would fill the space $F E N T$; for if a hole was made at $N T$, and a tube, $F E N T$, soldered into it, the pressure against the bottom of the tube would support water in it to the height $N T$, the same height it stands at in the tube $D B I V$. Now as the re-action of $N T$ downwards is equal to the action upwards against it, that is, the force with which $N T$ keeps the water below it,

down against L A, is equal to the force with which this water presses against N T. L A is therefore pressed down not only with the weight of the water N T L A, but likewise by the re-action of N T, which is equal to the weight of as much water as would fill F E N T, and make N T L A equal D B R O; from which it follows, that the weight and re-action together on L A, are equal to the weight on D B R O, by which O R is pressed; and the same may be proved of every other equal portion of the whole bottom and cover; and therefore, by the weight and re-action, L P is as much pressed as if it was the bottom of a cylindrical vessel F H L P, having the same dimensions at the top as at the bottom, and filled with water to the height L F. But to proceed with our subject.

Though the pressure upon F T, fig. 6, is equal to the pressure upon C D, when both vessels are filled with water to the same perpendicular height; yet *if they were filled with ice, or any other solid substance,* instead of water, C D would be more pressed than F T. For C D, whether the vessel be filled with ice or water, sustains the whole weight of the body which rests upon it, and no more; but F T, which, besides the weight M N F T, sustains the re-action of the sides M N F T, when the vessel is filled with water, has *only* the weight to sustain when it is filled with ice; for ice, or any other solid body, does not press upwards. This is a property, which, as it only arises from the nature of a fluid, belongs to fluids only; F T will therefore be only pressed by the weight of the ice, and consequently will be less pressed than C D, in proportion as the cone is less than the cylinder, when their bases and heights are equal. For the same reason L P, fig. 8, if it were full of ice, would be as much less pressed than when it is full of water, as the quantity of matter contained in the compound vessel N M L P is less than the quantity of matter contained in a cylindrical vessel, whose base is L P, and height L F.

The *second case* of the proposition is when the vessel A B O R, fig. 9, is wider at top than bottom. For here also the pressure of any fluid upon the bottom, O R, of it, is the same as in a cylindrical vessel, S T O R, of an equal base, and filled with the same sort of fluid to the same height. For the bottom O R, in either case, sustains just the same quantity of fluid, and consequently the same quantity of matter. If it is the bottom of a cylinder, then it sustains no more than the column S T O R, because the vessel holds no more. If it be the bottom of an inverted cone, as A B O R, then it sustains only the same column; for though the vessel holds more than this, yet all the rest of the fluid is supported by the sides A O, B R, and therefore does not press on the bottom.

Thus we see, that whether a vessel be narrower or wider at the top than at the bottom, the pressure upon the bottom is the same as in a cylindrical vessel of the same base and height; for when it is narrower at the top than at the bottom, though it holds less water than the cylindrical one would, yet the pressure is not less, because the re-action of the sides supplies the defect; and when it is wider at the top than at the bottom, though it holds more water than the cylindrical one would hold, yet the pressure is not greater, because the sides support the excess.

Let us now confirm by experiment, what we have thus endeavoured to render plain without it. The apparatus, fig. 10, is designed for this purpose. It is sometimes called the apparatus of *Paschal*, sometimes the apparatus for illustrating the *hydrostatic paradox*. It consists of three vessels, fig. 11, fig. 12, and A B C D, fig. 10, each of which are of the same size at bottom, and of the same height, and may be screwed alternately on the brass barrel E F, fig. 10, in which a piston slides up and down with ease. One of the vessels, fig. 12, is cylindrical; the other, A B C D, fig. 10, is an inverted cone, wider at top than bottom; the third, fig. 11, is a tube screwed to a plate, which makes the bottom the same size as

that of the other two; it has a funnel at top to prevent the water, in making the experiment, from being spilt.

First screw the cylindrical vessel to the barrel, pushing down the piston as low as it will go, then hook the wire of the piston to the rings from the short ends of the steelyards G H, I K. Now pour water in the cylinder up to the mark in the inside, and find what weights, suspended from the longer arms of the steelyard, will raise the piston; then take the cylindrical vessel from the barrel. Substitute the vessel A B C D, fig. 10, which is like an inverted cone, in place of the former; fill it with water to the mark, as before, and hook on the wire of the piston to the steelyards; and though the quantity of water is now many times greater than what was in the cylinder, yet the same counterpoise will raise the piston. Take off the conical vessel, and screw on the tubular one; and though this holds a much smaller quantity than either of the former, still it requires the same counterpoise. The friction of the piston being the same in every case, makes no alteration in the experiment.

In order to shew that the *lateral pressure* is equal to the perpendicular pressure upon a larger scale, and in a manner which relates more to the preceding experiment, we have delineated an apparatus, fig. 5, with different tubes, that communicate with each other. The middle one is a large glass tube or cylinder, A B; the lower end is firmly cemented into a strong brass hoop; to the sides of this hoop are soldered the brass tubes G, H, into each of which a glass tube is cemented. One of these, E F, is parallel to the large glass vessel A B; but the other, C D, is inclined thereto. The inclined tube is sometimes furnished with a joint, that the inclination may be varied as may be necessary.

If we pour water into the tube E F, this will run through G, into the larger vessel A B, and rise therein; and if we continue pouring water until it comes to any given height, as I K, and then leave off, the surface of the water in the small tubes E F, C D, will be found at the same height; the perpendicular altitude is the same in all the three tubes, however small the one may be in proportion to the other. This experiment clearly proves, that the small column of water balances and supports the large column; which it could not do if the lateral pressures at bottom were not equal to each other. Whatever be the inclination of the tube C D, still the perpendicular altitude will be the same as that of the other tubes, though to that end the column of water must be much longer than those in the upright tubes. Hence it is evident, that a small quantity of a fluid may, under certain circumstances, counterbalance any quantity of the same fluid. Hence also it is evident, *that in tubes that have a communication, whether they be equal or unequal, short or oblique, the fluid always rises to the same height.* Consequently water cannot be conveyed by means of a pipe that is laid from a reservoir to any place that is higher than the reservoir itself.

The ancients, it has been said, were ignorant of this principle, and knew not the use of pipes for conveying water up hills: but this assertion is not true; they did know the use of pipes, but chose to employ aqueducts in their stead, for reasons we cannot now with certainty account for.

Our next experiment proves, with great clearness, the hydrostatic paradox, that very great weights may be balanced by a very small weight of water, without its acting to any mechanical advantage: but, more particularly, it also proves, that its pressure upwards is equal to its pressure downwards, and all this even to those who have no previous knowledge of hydrostatical principles. The apparatus, fig. 1, pl. 18, consists of two large thick boards, C D, E F, connected together by leather, like a pair of bellows; hence it is usually called the *hydrostatic bellows*. A long brass pipe is fixed to the bottom board; so that water being poured in at the top, will pass

between the two boards. We will suppose the boards of the apparatus oval; and that the longest diameter is eighteen inches, the shorter one sixteen. Having poured water enough into the bellows to keep the boards asunder, and put six half hundred weights on the top of the boards, we next pour water into the tube, to the height of three feet, and find it will push up all the weights. Thus the water in the pipe, which weighs but a quarter of a pound, sustains three hundred pounds weight. If we take off the weights, and try, by pressing upon the upper board, to force the water out at the upper tube; our strength will be scarce sufficient for the purpose. Thus we see clearly how great a pressure upwards is exerted by the water.

Another instrument has been invented, for proving that the pressure of fluids is in proportion to their perpendicular heights, without any regard to their quantity.

A B C D, fig. 16, pl. 17, is a box, at one end of which, as at *a*, is a groove from top to bottom, for receiving the upright glass tube I, which is bent to a right angle at the lower end as at fig. 17; and to that end is tied the end of a large bladder K, fig. 17, which lies in the bottom of the box. Over this bladder is laid the moveable board M, fig. 18, in which is fixed an upright wire. Leaden weights N N, fig. 16, to the amount of sixteen pounds, with holes in the middle, are put upon the wire, over the board, and press upon it with all their force. The bar *p* is then put on, to secure the tube from falling, and keep it upright; and then the piece E F G is to be put on, to keep the weights in a horizontal position, there being a round hole at *e*. Within the box are four upright pins, to prevent the board at first from pressing on the bladder. Pour water into the tube at top; this will run into the bladder: and after the bladder has been filled up to the board, continue pouring water into the tube, and the upward pressure of the fluid will raise the board with all the weight upon it, even though the bore of the tube should be so small that less than an ounce of water would fill it.

Upon this principle mathematicians assert, that the same quantity of water, however small, may produce a force equal to any assignable one, by increasing the height and base upon which it presses. Dr. Goldsmith mentions having seen a strong hog's-head split by this means. A strong, though small tube of tin, twenty feet high, was inserted in the bung-hole; water was poured in this to fill the hog's-head, and continued till it rose within about a foot of the top of the tube; the hog's-head then burst, and the water was scattered about with incredible violence.

As the bottom of a vessel bears a pressure proportional to the height of the liquor, so likewise do those parts of the sides which are contiguous to the bottom, because the pressure of fluids is equal every way; and as the pressure which the lower parts of a fluid sustain from the weight of those above them exerts itself equally every way, and is likewise proportional to the height of the incumbent fluid, the sides of a vessel must every where sustain a pressure proportional to their distance from the upper surface of the liquor. Whence it follows, that in a vessel full of liquor, the sides bear the greatest stress in those parts next the bottom; and that the stress upon the sides decreases with the increase of the distance from the bottom, and in the same proportion; so that in vessels of considerable height, the lower parts ought to be much stronger than the upper, to be able to withstand the greater degree of pressure to which they are exposed.

SECT. IV. Of the Action of Fluids on Bodies immersed in them.

THE ancient philosopher *Archimedes*, in his two books *De inventis* *humido*, is the first we know of who made enquiries concerning the sinking and floating of bodies in fluids; their relative gravities, their levities, their situations, and positions.

He was also probably the first that ever attempted to determine in what proportion bodies differ from one another as to their specific gravities, and this he effected in order to discover the cheat of the workmen, who had debased king Hiero's crown; and though the means he employed were certainly much inferior to what would now be used, yet was he so pleased with his discovery, that not being able to contain his joy, like a madman leaping from the bath naked as he was, he is said to have run about the streets of Syracuse, crying out *Eureka* wherever he came. Before we proceed to explain this interesting subject, some terms which have only been as yet loosely explained must be defined.

1. *The density of a body is the quantity of matter which it contains under a given bulk.* The density of a body is therefore measured by the proportion which its quantity of matter bears to its bulk; for, the more numerous the particles of matter are in the same portion of space, the greater is the density of the body, and the fewer the particles the less the density.

2. *The specific gravity of a body is the weight of it when the bulk is given; or, the specific gravity of a body is its weight compared with another body of the same magnitude.* It is called the *specific gravity*, because it is the comparative weight of different species or sorts of bodies. Thus, if the specific gravity of gold is said to be to that of water as 19 to 1, the meaning is, that, bulk for bulk, or under equal dimensions, the weight of gold is to that of water as 19 to 1; or that a cubic inch of gold will weigh 19 times as much as a cubic inch of water.

3. *The specific gravity of bodies is as their density,* for the specific gravity is the weight of a given bulk, and the weight of bodies is as their quantities of matter; therefore the specific gravity of a body is as the quantity of matter contained in a given bulk, that is, as its density.

4. *The specific gravity of bodies is inversely as their bulk when their weights are equal.* The specific gravity of bodies is, we have already seen, as their density, and the density of bodies is inversely as their bulk when the weights are equal. Thus, if the specific gravity of gold be to that of silver as 19 to 11, and a cylinder of gold 11 inches high weigh a pound, a cylinder of silver having an equal base and weighing a pound must be 19 inches high; for since the specific gravities are 19 to 11, the bulks, that is, the heights must be as those gravities inverted, or as 11 to 19. If the specific gravity of mercury be to that of water as 14 to 1, and a cylinder of mercury of a certain weight is 30 inches high, then a cylinder of water of equal base must be 420 times as high; so that the height of the cylinder of water will be 14 times 30 or 420 inches, or 35 feet.

The *magnitude* of a body is expressed by a number denoting its relation to some criterion generally used, and similar to itself, as a cubical inch, foot, &c. The *absolute weight* of a body is relative, being expressed by a number denoting its relation to some arbitrary or conventional standard, as 1 pound, 1 ounce, of which it is a multiple or aliquot part; and in the same sort of matter, supposed to be homogeneous, it depends upon and varies as the magnitude.

The specific weight or gravity of the same species of matter, whether its magnitude be great or small, as of *A*, *2 A*, or *3 A*, is the same, being according to the definition of the weight of a given bulk. The object therefore of specific gravities is to distinguish different species of matter from each other, in one of their most obvious qualities, weight of matter contained in a given space.

The weight of any portion of matter is easily ascertained, but it is not always easy to measure the space occupied by a body or its *magnitude*, and in some instances it cannot be effected without artificial methods. It is found expedient to em-

ploy as a criterion some pure and homogeneous substance, as distilled water, whose specific gravity or weight of a given bulk is nearly the same at all times; and by comparing this with other substances, the ratio of their specific gravity may be discovered; and denoting the specific gravity of water by any number taken at pleasure, the numbers expressing the specific gravities of other bodies are hence obtained.

It follows, from what has been already demonstrated in the foregoing part of this treatise, *that when a solid is immersed in a fluid, it is pressed by that fluid on all sides, and that pressure increases in proportion to the height of the fluid above the solid*: but we may also prove it directly by experiment. Thus, tie a leather bag to the end of a glass tube, and fill it with mercury, immerse the bag in water, but so that the upper or open end of the tube may be always above the surface of the water; the pressure of the water against the bag will raise the mercury in the tube, and the ascent of the mercury will be in proportion to the height of the water above the bag.

When a solid is immersed in a fluid to a great depth, the pressure against the upper part differs very little from the pressure against the under part, whence bodies very *deeply* immersed are as it were *equally pressed on all sides*; but a pressure which is equal on all sides may be sustained by soft bodies without any change of figure, and by very brittle bodies without their breaking. Take a piece of soft wax of an irregular figure, and an egg, and inclose them in a bladder full of water; place it in a square box, and put on a moveable cover, which will bear on the bladder; there may be placed on this cover a weight of 100 or even 150 pounds, without breaking the egg, or any ways altering the figure of the wax.

It has been already shewn, that fluids press upon bodies to which they are contiguous every way, and on all sides, but the pressure upon each part is not the same; the *altitude* of the fluid is every where the measure of its force, and the several parts of the same body being at different depths, must needs be differently affected: we have therefore to consider which of these impressions will prevail.

Now it is evident that the *lateral* pressures do all balance each other, being equal, as arising from equal altitudes of the fluid, and opposite in their directions; so that from these the body is no ways determined to any motion. But a body immersed in a fluid is pressed more *upwards* than it is downwards; for those parts of the fluid which are contiguous to the under surface have a greater altitude, and therefore a greater force than those that are contiguous to the upper surface; the body must therefore be more violently elevated by the former than depressed by the other, and would therefore ascend by the excess of force, were it devoid of gravity. For when a solid body is immersed in a fluid, it presses down, and endeavours to descend by the force of its gravity; but it cannot descend without moving as much of the liquid out of its place as is equal to it in bulk: it is therefore resisted, pressed upwards by a force equal to the weight of as much of the fluid as is equal in magnitude to the bulk of the body, being the difference in weight of two columns of the fluid, whereof one reaches to the upper, the other to the under surface of the body.

Let us endeavour to illustrate this by a diagram. When any hard body, as a piece of lead, is immersed in water, the lower part of it ($m n$) fig. 13, pl. 17, must be continually pressed upwards just as much as the water itself in the same place as the lead is pressed upwards. Now the force with which the water ($m n$) is pressed upwards, is exactly equal to the force with which it would be pressed downwards if the lead was out of the way; for every part of a fluid is pressed as much upwards as it is downwards. The force with which ($m n$) would be pressed downwards if the lead was out of the way, would be equal to the weight of the incumbent column, or of as

much water as would fill the whole space $E H m n$; therefore the force with which $m n$ is pressed upwards, and consequently the force with which the piece of lead is pressed upwards, is equal to the weight of as much water as would fill the whole space $E H m n$, or the whole space $H P n o$, if this space be taken equal to $E H m n$.

Let us next consider the force with which this piece of lead is pressed downwards: this force is just equal to the weight of as much water as is above it, that is, it is equal to the weight of the column $E H r s$.

The difference therefore of the two pressures will be the difference in weight between the two columns $E H m n$, $E H r s$; for the weight of the former is equal to the pressure upwards, and the weight of the latter is equal to the pressure downwards: consequently the pressure upwards will be as much greater than the pressure downwards, as the weight of the water $E H m n$ is greater than the weight of water $E H r s$. But the difference between these two weights is just as much as would fill the space $r s m n$, which the body fills; for just so much water added to $E H r s$, would make it equal $E H m n$: consequently *the body is pressed more upwards than it is downwards by a force equal to the weight of as much water as would fill the space taken up by the body*. In other words, the body is acted upon by two forces in contrary directions, but the force with which the fluid acts upon it to make it ascend exceeds the force by which it presses downwards; and this excess is equal to the weight of as much of the fluid, whatever it is, as would fill the space taken up by the body.

The case will be the same whatever be the figure of the body immersed; for suppose it to be a cone $T S L V$, fig. 15, pl. 17, then as every equal part of a fluid at the same depth is pressed equally in all directions, if $V I$ be equal to $L V$, it follows, that these two parts of a thin sheet of fluid $F E$ will be pressed upwards by equal forces; but $V I$ is pressed as much upwards as downwards, therefore $L V$ is pressed as much upwards as $V I$ downwards.

Now the force that presses $V I$ downwards is the weight of the fluid $H P V I$ that is above it; consequently $L V$, where the bottom of the body is placed, is supported by a force equal to the weight of the column $H P V I$, and this column is equal to $M H L V$. Therefore the body is pressed upwards with a force that is equal to a weight of as much of the fluid as would fill the whole space $M H L V$.

The same body is in the mean time pressed downwards by the weight of all that fluid that is above any part of it, that is, by the weight $L T S V H M$, and not merely by the column $O N T S$, which reaches from the surface to the top of the body. From hence it follows, that the difference between the centre column $M H L V$, or such a column as this would be if the body was out of the way, and the column $L T S V H M$, is the difference between the pressure upwards and the pressure downwards. But this difference is plainly equal to as much of the fluid as would fill the space the body takes up; the force therefore by which the fluid acts upon the body to make it ascend, exceeds the force by which it presses downwards, and this excess is equal to the weight of as much of the fluid as would fill the space taken up by the body.

But as all bodies by the force of gravity tend downwards, it is clear from what has been said, that it depends upon the absolute weight of the immersed body whether it shall ascend or descend. 1. If the weight of the body exceed that of an equal bulk of the fluid, the excess of force will tend downwards. 2. If the weight of the body be less than an equal bulk of the fluid, the upward pressure will prevail, and it will ascend. 3. If both be precisely equal, the body will remain at rest in any part of the fluid.

First, then, *a body immersed in a fluid will sink if it be specific-*

cally heavier than that fluid; for it endeavours to descend by its own weight, and is supported by a force equal to the weight of an equal bulk of fluid, or of as much fluid as will fill the space taken up by the body. If therefore the body be specifically heavier than the fluid, i. e. bulk for bulk heavier than the fluid, its weight will be greater than the pressure upwards of the fluid which is to support it; and, consequently, this pressure will not so support as to keep it from sinking.

If we throw a stone into the water, it sinks, for it is specifically heavier than the water; that is, where the bulks are equal, the weight of the stone is greater than the weight of water; therefore the force with which it endeavours to descend is greater than the excess of pressure upwards, which is all there is to support it; which being too weak to sustain it, the stone sinks to the bottom.

A body that is immersed in a fluid will rise to the surface, and swim upon it, if it be specifically lighter than the fluid. A piece of cork, when it is immersed in water, is pressed by the water both upwards and downwards; but the pressure upwards exceeds the pressure downwards, and this excess is equal to the weight of as much water as is of the same bulk with the piece of cork; therefore, as far as the action of the water is concerned, the cork ought to rise to the top; and the cork itself being also specifically lighter than water, the force with which it endeavours to sink is less than the force which buoys it up; it must therefore on this account rise till it comes to the surface. Hence the reason is plain, why fir, oak, and elm, that are specifically lighter than water, will swim in it; while ebony and guaiacum, that are specifically heavier, will sink.

There is generally a part of any body that floats on the water below the surface, and this part is equal in bulk to as much of the fluid as would weigh what the body weighs. Let p, t, e, i , fig. 14, pl. 18, be a piece of cork, then s, n, e, i , the part below the surface $A B$ of the water, will be equal in bulk to as much water as would weigh what p, t, e, i , the whole cork weighs. The force with which the water at e, i , is pressed upwards, is exactly equal to the force with which it would be pressed downwards if the cork p, t, e, i , was out of the way, because every part of a fluid is pressed equally in all directions.

But the force with which e, i , would be pressed downwards if the cork was away, is equivalent to the weight of as much water as would fill the space taken up by the part of the cork below the water; and consequently the force with which e, i , the bottom of the cork, is pressed upwards, is equivalent to the weight of as much water as would fill up the space s, n, e, i , or the part of the cork below the surface. If therefore the part which is below the surface has the same bulk as a quantity of water that would weigh what the whole cork weighs, then the pressure upwards will be equal to the weight of the cork, and keep it from sinking.

A body that has the same specific gravity with the fluid into which it is immersed, will rest in any part of the fluid wherever it happens to be placed. For the body endeavours to descend by its own weight, and is prevented from descending by a force equal to the weight of an equal bulk of fluid; but when the body and the fluid are of the same specific gravity, equal masses of each are of the same weight, and consequently the force with which the body endeavours to descend, and the force which opposes the descent, are equal to each other; and as they act in contrary directions, the body will rest between them, so as neither to sink by its own weight, nor to ascend by the pressure of the fluid upwards.

It is manifest from these positions, that if by any contrivance the specific gravity of a solid can be varied so as to be one while greater, another less, and then equal to the specific gravity of the fluid wherein it is immersed, the body will sink, or rise or remain suspended, according to the variations of its

specific gravity. And this is the case in the experiment with those little glass images that some philosophers exhibit, which are made to ascend or descend, or remain suspended at pleasure.

The images being set to float on the water, the top of the vessel must be covered with a bladder closely bound about the neck of the vessel, to the end that the air which lies on the surface of the water may not force its way out when it is condensed by the hand. The images themselves are nearly of the same specific gravity with the water, but rather a little lighter, and consequently float near the surface: the images being hollow are full of air, which, by means of small holes in their heels, communicates with the air without. When the air which lies beneath the bladder is pressed by the hand, it presses on the surface of the water; and as the pressure is propagated through all the water, those portions which are contiguous to the heels of the images are thereby forced into the holes; by which means the air within is condensed, and at the same time the weight of the images is increased by the weight of the influent water; and when so much water is forced in as to render the specific gravity of the images greater than that of the water, the images descend to the bottom, where they remain as long as the pressure above continues; but when that is taken off by the removal of the hand, the condensed air in the images dilates and expands itself, and in so doing drives out the water, upon which account the images become specifically lighter than water, and of course ascend. As the pressure on the bladder is greater or less, so must the quantity of water be which is forced into the images; and therefore whenever it happens, that during the ascent or descent of an image, such a pressure is made as suffices to force in just as much water as is requisite to reduce the image to the same specific gravity with the water, the image stops, and remains suspended; upon increasing the pressure it descends, and ascends if it be lessened. Some of the images begin to descend sooner or rise later than others, either because they are specifically heavier, or because the cavities in their legs are greater in some images in proportion to their magnitudes, than they are in others. This is but an experiment of mere amusement; many and more important uses are the result of our being able to determine the specific gravities of bodies: to this, therefore, we shall now proceed.

All bodies, when immersed in a fluid, lose the weight of an equal bulk of that fluid; in other words, every body immersed in a fluid loses a part of its gravity equal to the weight of the fluid, which would fill the space taken up by the body. A piece of lead, or of any other substance, when it is immersed in water, is not so heavy as when it is out of water; for the water presses it more upwards than downwards, and the excess of the pressure upwards will support part of the weight. But this excess was shewn to be equivalent to the weight of as much water as has the same bulk with the lead; and consequently since the body immersed must lose as much of its weight as the fluid can support, the lead will lose the weight of an equal bulk of water.

Thus a cubic foot of lead r, s, m, n , hanging by the string $L I$, fig. 13, pl. 17, will weigh less in the water than it does out of it, because the water by its pressure upward against the lead will support a cubic foot of water, or one thousand avoirdupois ounces, for so much a cubic foot of water weighs, and consequently so much of its weight the lead must lose. Again, a body endeavours to descend by its whole weight; when it is immersed in a fluid, it is supported by a force equal to the weight of the same bulk of that fluid; and since these two forces act in contrary directions, the weight which the body retains in the fluid will be the difference between them, or it loses the weight of an equal bulk of the fluid.

The following experiment will render the position self-evident. The apparatus for it consists of a beam, a small hollow

cylindric bucket A B, and another cylinder C D, which precisely fits the capacity of the bucket A B, fig. 2, pl. 18, (only a portion of one arm E F of the beam is represented in this figure). First, suspend the bucket by one end of the beam. At the bottom of the bucket is fixed a strong thread of silk with a loop on the lower end; to this loop the close cylinder is suspended. It is necessary to counterpoise these by a weight at the other end of the beam. Then set a jar of water under the cylinder, and gently lower the beam, and it will become lighter and lighter upon the beam as the cylinder descends. When it is quite immersed, the equipoise is destroyed by the descent of the weight of the other arm. To shew how much weight is lost by the cylinder, add the weight of a quantity of as much water as is equal in bulk to the cylinder; that is, fill the bucket, which you know is exactly the same size; and by doing it gradually, you will observe the equipoise restored by degrees till the bucket is full, and then the beam becomes truly horizontal as at first, the loss of weight being restored by the equal cylinder of water in the bucket.

It is evident from what has been said, nor can it but be seen clearly, whence the loss of weight proceeds. It is no otherwise lost than as it is sustained by the action of a contrary force; and it becomes therefore obvious, why the weight of a bucket of water is not perceived while it is in the water, not because that weight is destroyed, but because it is supported; not because fluids do not gravitate when they are in fluids of the same sort, but because there is a pressure in a contrary direction which is exactly equal to their gravity.

Since the weight which a body loses when it is immersed in a fluid is always the weight of as much of that fluid as is equal in bulk to itself, it follows, that the weight lost by the body cannot at all depend either on the depth of the fluid itself, or the depth to which it is immersed therein. An anchor loses no more of its weight when it is at the bottom than when it is just below the surface, for in either case it loses the weight of as much water as is equal in bulk to itself. It is not more easy to swim in deep than in shallow water, provided the water is not so shallow as to prevent one from striking freely; for whatever is the depth of the water, a man loses the weight of as much water as is equal in bulk to his own body; for which reason, shallow water will buoy him up with as great force as deep water. Indeed it is easier to swim in the sea than in a river, because salt water is specifically heavier than fresh; and as a man loses the weight of as much salt water as is equal in bulk to his body, and in the river loses only the weight of an equal bulk of fresh water, the weight lost here being greater, salt water will buoy him up with the greatest force.

There are very few, if any animals, that are specifically heavier than common water. The substances indeed of both animals and vegetables are specifically heavier; the floating of either is therefore to be attributed to the cells or receptacles interspersed within them, which are filled with air, oil, &c. substances lighter than water; so that, taken together, they form a mass specifically lighter than a comparative bulk of common water.

We should also observe on this subject, that the bulk of the body is increased by distending the chest in inspiration. This has been proved by an experiment on a fat man of an ordinary size, by finding what weight he could support so as to have the top of the head just above water. When his chest was full of air; he was found to rise with fourteen pounds of lead without striking out in the least, and two ounces more would have kept him under; but when his breast was not thus distended, he could only bring up eleven pounds.

All equal solids, though of different specific gravity, when they are immersed into the same fluid, lose an equal weight. The weight which gold, or silver, or lead, or stones, or any other

body loses in water, does not at all depend upon the sort or figure of a body, but upon its bulk or size. The stone loses the weight of an equal bulk of water, so does the lead; when, therefore, they are of the same size, they each of them lose the weight of the same quantity of water, that is, they lose an equal weight: but if two bodies of the same sort differ in size, they will lose different weights in proportion to their size.

In order to prove that the loss of weight is not affected by the absolute weight of the body, but depends on its size, it is only necessary to alter the weight of the cylinder, by adding to or diminishing the number of shot contained in it, and then repeat the experiment with it and the bucket as before, and the event will be the same. In the same manner too it may be shewn, that all bodies, however different their specific gravity may be, if their magnitudes be equal, do suffer an equal loss of weight in the same fluid. Thus a cylinder of block-tin, equal in dimensions to the brass cylinder, but specifically lighter, being immersed in water, will lose the same weight.

Bodies of the same weight, but of different specific gravities, lose unequal parts of their weights when they are immersed in the same fluid. Thus suppose a piece of gold in one scale to weigh just as much in air as a piece of copper in the other scale. Now hang each by a horse-hair on the hooks of the balance, and let them down into the glass vessels; and as soon as they are immersed in the water, the equilibrium will be destroyed, and the gold will outweigh the copper; for, as they are of equal weight, their bulks are as their specific gravities; that is, the gold will be as much less than the copper as the specific gravity of the gold is greater than that of copper: the gold, therefore, because it is the smaller of the two bodies, will lose less of its weight in water than the copper does, and will consequently outweigh the copper.

On the other hand, if the gold and the copper are made of the same weight, when they are under water, then by drawing them out of the water the copper will become the heavier; for when they were under the water, each of them lost as much of their weight as the water could sustain, that is, each of them lost a weight in proportion to its bulk: but the copper being the bigger of the two, lost the greater weight; and as the weight which they lost in water is recovered upon their being drawn up in the air, the copper recovers more weight than gold, and will therefore outweigh the gold.

The weight lost by a solid immersed in a fluid is communicated to the fluid. Though a solid loses part of its weight when immersed in a fluid, we are not to suppose that the weight so lost by the solid is actually destroyed, but that it is imparted to the fluid, the fluid constantly gaining what the solid loses; for if we put the vessel with the water wherein the cylinders were immersed into a scale, and counterpoise it, it will appear upon the immersion of the cylinder that it will preponderate with exactly the same weight that the cylinder loses.

Before we proceed to the methods of discovering the specific weight of bodies, it will be necessary to note two curious facts, to shew how lead or gold may be made to swim upon water, or how a light body like wood may be made to remain sunk at the bottom of a vessel of water.

A body that is specifically heavier than a fluid, may be supported in it by the pressure upwards, if the pressure downwards is taken away. As bodies specifically heavier sink, because the force wherewith they press downwards exceeds the pressure from beneath which opposes their descent, and the force wherewith they descend is equal to the difference of those pressures; if by any contrivance those two forces can be reduced to an equality, then the bodies will not descend, but remain in the fluid. To shew this, let a circular brass plate be exactly fitted so as to cover the lower aperture of a cylindrical tube. Keep it close to the tube by means of a string, and then immerse the tube perpendi-

cularly in water till the plate of brass is plunged therein somewhat more than eight times its own thickness. When at this depth, the piece of brass is supported by the pressure of the water, and does not sink although you let go the string. The brass endeavours to descend by its own weight, it is pressed upward by a weight equal to that of a cylindrical column of water, having the same base with the brass plate, and being eight times thicker; and because brass is eight times specifically heavier than water, the weight of a cylindrical column of water which presses upward, and the weight of the brass by which it endeavours to descend, will be equal, and consequently the brass will be just supported in equilibrio.

Again, *a body that is specifically lighter than the fluid in which it is immersed, will not rise if the pressure upward is prevented.* To prove this, let there be a bit of cork so fitted to the bottom of a cylindrical vessel, (fig. 10, pl. 19,) that the surfaces shall be every where in contact: now, if you pour mercury into the vessel, you will find that the cork will not ascend till it be separated from the bottom of the vessel. *a* represents the cork, and *b* the mercury. The effect of a fluid's pressure in a direction contrary to that of gravity is here evinced by a very decisive experiment; as long as the fluid is prevented from communicating with the under surface, the cork continues attached to the bottom of the vessel partly by its own weight, and partly by the pressure of the mercury on its upper surface.

From what has been said we necessarily discover the rationale of *sinking* and *swimming*. We saw that when a body was bulk for bulk heavier than the fluid, by being immersed it loses only the weight of an equal bulk of the fluid, and consequently the *residual* or remaining gravity of the solid must carry it down to the bottom, or make it *sink*. On the other hand, if the solid has less weight in the same bulk than the fluid, then it cannot by its weight displace or raise upwards its whole bulk of the fluid, but only so much of it as is equal to its own weight; and from this deficiency in weight it will be only partly immersed, and will therefore *swim* upon the upper part of the fluid.

Man, of all the animals, whenever thrown into the water is the most helpless. The brute creation receive the art of swimming from nature, while man can only acquire it by practice; the one escapes without danger, the other sinks to the bottom. Some have asserted, that this arises from the different sensibilities each have of the danger; the brute, unterrified at his situation, struggles, while his very fears sink the lord of the creation. But much better reasons may be assigned for this impotence of man in water, when compared to other animals; and one is, that he has actually more specific gravity, or contains more matter within the same surface than any other animal. The trunk of the body in other animals is large, and their extremities proportionably small; in man it is the reverse, his extremities are very large in proportion to his trunk. The specific weight of the extremities is proportionably greater than that of the trunk in all animals, and therefore man must have the greatest weight in water, since his extremities are the largest.

Besides this, other animals to swim have only to walk (as it were) forwards upon the water; the motion they give their limbs in swimming is exactly the same they use upon land; but it is different with man, when making use of those limbs to help him forwards upon water, which he employs to a very different purpose upon land.

SECT. V. *On the Methods of estimating the Specific Gravity of Bodies.*

FROM the principles laid down in the preceding sections, it

will be easy to shew in what manner the specific gravities of different bodies, whether solid or fluid, may be estimated. The specific gravity of a body is the weight of that body, under a known and determinate magnitude; as a cubic inch, a foot, &c. To acquire this knowledge, the body is to be weighed *hydrostatically*; that is, 1. in air; 2. in water. We know that a body immersed in water displaces a volume of water exactly equal to its own, and that it loses a portion of its weight exactly equal to the volume displaced; we therefore obtain by this mode, 1. the weight of the body; 2. the weight of a volume of water perfectly equal in bulk to that of the body. These two weights, compared together, give the relation between the specific gravity of water, which we suppose to be known, and that of the given body, by making the following proportion, in which 1000 * represents the specific gravity of water. The weight of the volume of water displaced by the body, is to the weight of this body, as 1000 is to a fourth term representing the specific gravity of this body: for the specific gravities are as the weights of equal bulks; therefore the specific gravity of the fluid is to that of the body, as the weight lost in the fluid is to the whole weight.

Now, let us suppose a piece of gold to weigh 38 grains in air, and only 36 grains when weighed in water; it has therefore lost two grains. Reasoning therefore from what has been already proved, we say the gold has lost the weight of as much water as is equal in bulk to itself. But the gold itself weighs 38 grains; consequently, bulk for bulk, the weight of water is to that of gold, or the specific gravity of the fluid to that of the solid, as 2 to 38; that is, as the weight of the fluid is to the whole weight. Thus the whole art of comparing the specific gravity of bodies, consists in finding out what the body weighs in air, and how much of that weight is lost in water; and then dividing the first weight by the difference between the first and second weight, and the quotient of this division shews how many times the body is heavier than water.

The definition of *specific gravity* implies comparison. Some kind of body must be fixed upon, whose gravity must be made a standard for the gravity of other bodies of equal bulk to be compared with. This standard body should have two properties; first, it must be easy to be had or come at upon all occasions; and secondly, it should be of as fixed and unalterable a nature as possible, that there may be no variation in its gravity in equal bulks, in different times or places. Now as the best way of discovering the specific gravities of bodies is by immersion, the body must be of the fluid kind; and, among fluids, *water* is that which possesses in the highest degree the requisites for a standard. Distilled water is the least objectionable, next to this pure rain-water; but common water, for many purposes, will answer very well.

The specific gravity or weight of a given bulk of distilled water is nearly at all times the same; and by comparing this with other substances, the ratio of their specific gravities may be discovered; and denoting the specific gravity of water, by any number taken at pleasure, the numbers expressing the specific gravities of other bodies are hence given.

As the weight of one cubical foot of pure distilled water is equal to 1000 ounces avoirdupois, if its specific gravity be denoted by 1, or .000, the weight of one cubic foot, or other measure, of other substances, is hence found, and tables of the specific gravities of bodies are formed. One ounce avoirdupois is equal to 437.5 grains, and an ounce troy to 480 grains; consequently, one avoirdupois pound is to one troy pound, as 437×16 to 480×12 , or as 1750 to 1440. A cubic foot of

* In hydrostatic calculation, water, as the standard from which all the respective gravities are taken, is reckoned as unity, or 1, 10, 100, 1000, &c. as the case requires.

water is equal to 1000 ounces avoirdupois, or 62.5 lb. avoirdupois; whence we find it to be equal 75.95 lb. troy. A cubic inch of water is equal 253.18 grains, or .57869 parts of an avoirdupois ounce; and 253.18 grains, or 5274 parts of one troy ounce.

SECT. VI. *Of the Use of the Hydrostatic Balance, in determining the Quality of Gold, &c.*

BEING able to determine the specific gravities of bodies, we are thence enabled, by weighing metals in water, to discover their adulterations or mixtures, with greater exactness than by any other method whatsoever. By this means the counterfeit coin, which may be offered as gold, will be easily distinguished, and known to be a baser metal.

The principal and distinguishing qualities of pure gold are, the simplicity, minuteness, and close cohesion of its parts; whereby a greater number of those parts is contained in less space than any other body with which we are acquainted. As all bodies weigh in proportion to their quantity of gravitating matter, under the same bulk, the specific weight of gold must be superior to that of other metals. It follows from hence, that if gold be adulterated with any other metal, its *specific gravity*, or comparative weight, must be *less* in proportion to the quantity of *alloy*. The weight therefore of gold is a sure criterion of its quality.

In order to determine the precise quantity of alloy compounded with gold, gold must be weighed with some other mass as a *standard*, and their relative gravities be computed. It has been already shewn, that water is the most convenient standard. Weigh a piece of gold first in air, weigh it then in water, subtract its weight in water from the weight in air, and the difference shews the *loss* it has sustained by being weighed in a denser medium. Divide the *weight in air* by the *loss in water*; the quotient shews the specific gravity, or how many times gold is heavier than water. On the contrary, the specific gravity of *sterling gold* being known, if the *weight in air* of any piece of gold coin be divided by the *specific gravity* of sterling gold, the quotient shews what ought to be its *loss* in water; and if it be found to lose more, the gold is bad, or has too great a quantity of alloy.

Gold is about eighteen times as heavy as common water; the specific gravity of sterling gold being to the weight of water 17.793 to 1. If therefore a guinea weighs in air 129 grains, when weighed in water it must lose 7.25, or $7\frac{1}{2}$ grains of its weight; because as 7.250 is to 129, so is 1 to 17.793; so that a quantity of water equal in bulk to a sterling guinea weighs $7\frac{1}{4}$ grains.

SECT. VII. *Of the Hydrostatic Balance.*

THE beam of the hydrostatic balance is in general made from eight to ten inches long, and with the perfections necessary to a good balance-beam. It either rests upon a stand or fulcrum, as at fig. 3. pl. 18. or is pendent, as at fig. 4. To this beam are adjusted a pair of scale-pans, which may be taken off at pleasure. There is also another smaller pan, of equal weight with one of the others, furnished with shorter strings, so as to admit a vessel of water to be placed under it. When the balance is used for hydrostatic purposes, this pan is to be suspended at one end of the beam, and one of the common scale-pans at the other end.

The glass *bucket* is to hold any solid body to be weighed in water, and is to be suspended by the horse-hair to the hook at the bottom of the small scale. There is a weight to be placed in the opposite scale, in order to balance the bucket exactly in water. The brass *tongs* are for the same purpose, and to hold such substances as cannot conveniently be put into the bucket.

The small brass *nipper* is intended for weighing of gold coin; which may be more accurately weighed by this than in the *bucket*, which is principally designed for such things as cannot well be placed in the nipper or tongs: the beam will turn much easier with either of these than with the other. A scale-beam, loaded at each end with a considerable weight, is insensible of the addition of a small one: besides, the resisting medium of water, through which the whole surface of the bucket and its contents must pass, lessens the vibration of the beam, and renders the operation both tedious and uncertain. The glass solid is made use of to determine the specific gravity of fluids.

Each of these appendages has a respective weight, for a *balance in water*, which are distinguished by different marks. These weights are intended to balance them *exactly*; but their correctness may be injured by different circumstances, for water varies considerably in its density, according to the temperature of the air; in hot weather it is lighter, in cold it is heavier; in the former case the balance may appear rather too light, and in very cold weather rather too heavy. Whenever this happens, we restore the equilibrium by a small weight, dropped into the scale that requires it, before any hydrostatic experiments can be performed with accuracy. From hence it is natural to conclude, that the specific gravity of the same substances will be different at different times: this variation is however so small, particularly in the weight of gold, as not to be regarded in common experiments. For easier computation, it is best to use tenths of grains for the subdivisions in these experiments.

SECT. VIII. *To find the Specific Gravity of Solids.*

In order to find the specific gravity of solids, weigh the substances first accurately in air, setting down with a pen the weight in grains and decimal parts: then hang on the small water-scale to one end of the beam; place under it the glass vessel, pouring water in till it be filled to within three quarters of an inch from the brim. Let the body to be weighed be then placed in the nippers, tongs, or bucket, as is most convenient; and, immersing it in the water, let it be suspended by the horse-hair to the hook at the bottom of the water-scale. In this proceeding, we must take care that the same weights that balanced the body in air be in the opposite scale, and likewise the proper *balance water-weights*, and that no air-bubble adhere to any part of the substance in the water, which will render it apparently lighter. The *opposite* scale to that which contains the substance will now greatly preponderate; weights should therefore be put into the water-scale till the equilibrium be restored.

The pen will now finish the operation. Divide the *weight in air* by the *loss in water*; that is, divide the number of grains in the large scale by those in the small one, and the quotient will shew the specific gravity, or how many times heavier the substance that was weighed is than water. If the weight in the small scale be *subtracted* from that in the other, it will shew the *relative gravity* of the weighed substance, or the weight with which it will be evenly balanced in water.

SECT. IX. *Method of finding the Specific Gravity of Fluids.*

SINCE, by the term *specific gravity* of bodies, nothing more is meant than the difference, or comparative weight of those bodies to that of common water, we might easily find the specific gravity of any kind of *fluid*, by weighing a quantity of it against an equal quantity of water; but as a solid body, when immersed in a fluid, loses as much of its weight as a bulk of the fluid equal to the body weighs, a more convenient and accurate method is the immersion of a *solid* of some determinate weight in the fluid whose specific gravity we desire to know. Adapted to this purpose is the conical piece of *solid glass*, belonging to

the hydrostatic balance; whose weight both in air and water being known, shews immediately the weight of the fluid into which it is plunged; the solid being borne up by the fluid in a proportion equal to its respective gravity.

Thus, suppose the glass solid to weigh in air 1464 grains, and that, when it is suspended from the water-scale and immersed in water, it loses of its weight 445 grains; this would be the weight of a bulk of water equal to the solid. The balance-weight for the solid must be made just equal to what it weighs in water, *i. e.* 1019 grains.

Whatever fluid is to be weighed, let it be put into the glass recipient; suspend the solid to the hook of the water-scale, and let it hang freely in the liquor, putting the balance-weight in the opposite scale. If the fluid be heavier than water, the solid will rise in it; if lighter, it will sink to the bottom of the recipient. In either case small weights are to be put into the lighter scale, till the balance be made even.

1. When the fluid is *lighter* than water, the weight *gained* by the glass solid is to be *subtracted* from the weight of a bulk of water equal to the solid [445], and the remainder is the weight of an equal bulk of the fluid, or its specific gravity to water.

Example 1. When such a glass solid as the above was immersed in *brandy*, it balanced 38.2 grains more than in water. This, taken from 445.0, leaves 406.8; therefore the specific weight of the brandy was to water as 406.8 to 445. To reduce it to its proper terms, multiply the difference [38.2] by 1000, (the denominator of water) and divide the product by 445. As 445 : 38.2 :: 1000 : 86; subtract 86 from 1000, there remain .914, the specific gravity of the brandy. From hence it appears, that the brandy weighed 86 parts in 1000, or about $\frac{1}{12}$ th less than water.

Example 2. In *rum* the solid balanced 40.3 grains more than in water; as 445 : 40.3 :: 1000 : 91—91 from 1000, remain .909. The specific gravity of the rum to water was therefore .909, or about $\frac{1}{11}$ th.

Example 3. When the solid was immersed in highly rectified *spirit of wine*, it balanced 73.6 more than in water; therefore 445 : 73.6 :: 1000 : 165—165 from 1000, remain .835, or $\frac{1}{6}$ th.

It appears from these examples, that the *hydrostatic balance* is a certain and correct instrument for determining the *strength of spirits*, perhaps more so than the most accurate *hydrometer* that has yet been made for that purpose. It is of considerable consequence to distillers and dealers in spirituous liquors, to know the precise point of strength which is termed *proof*: though this indeed is rather arbitrary than any fixed standard; but the degree of strength which, I am informed, is now called *merchantable proof*, fixeth the specific gravity of the spirit to water at .930. Now 930 taken from 1000 leaves 70; therefore 1000 : 70 :: 445 : 31.15. So that in *proof spirit*, a glass solid of the weight above mentioned must balance 31.15, or about $3\frac{1}{4}$ grains more than in water.

It may easily be found in what proportion the spirit is *above* or *below* proof, by observing what quantity of *water* or *alcohol* is necessary to be mixed with it, in order to bring it to the above standard; and it might be immediately known, by comparing the weight of the spirit with that of water, if the specific gravity of both, when compounded, remained in the same ratio as when separate; but as it is found that, when water is mixed with spirit, the specific gravity of the compound is *greater* than that of the water and the spirit before they are compounded, the calculation must therefore turn out incorrect. For instance, a quantity of the *rum* before mentioned, equal in bulk to the glass solid, weighed very nearly 405 grains; an equal bulk of water 445 grains: suppose then, that in order to reduce the

rum to *proof*, one *fifth part* of water was to be mixed with it;

Water	-	1	=	445
Rum	-	4	=	1620
		5		2065
				413

Mean weight = 413

By this it appears, that a quantity of the compound, equal in bulk to the glass solid, should weigh 413 grains, and consequently that the solid, when immersed in it, should balance 32 grains more than in water; in which case it would still be somewhat above proof. But upon trial, it will be found to balance not much more than $29\frac{1}{2}$, and that there must be but little more than *one-seventh* part of water mixed with the rum to reduce it to the given standard.

Immediately after water is mixed with spirit, the compound appears *lighter*; but in a few hours afterwards, when the particles of each are more intimately united, its bulk diminishes, and consequently the specific gravity increases.

From a few experiments of this kind, the theory will appear sufficiently plain; and a table might easily be formed for shewing by inspection what quantity of water is necessary to be put to any given quantity of spirit to render it true proof.

2. When fluids are specifically *heavier* than water, the glass solid, as before observed, will *rise* in such fluid (the water balance-weight being in the opposite scale), and appear to be lighter: small weights are therefore to be put in the water-scale, till the equilibrium be restored; and the *loss* which the solid sustains, by being weighed in the heavy fluid, is to be *added* to the weight of a bulk of water equal to the solid: the sum shews the specific gravity of the fluid to water.

Example 4. Suppose it was required to find the specific gravity of *sea-water*, or how much heavier it is than rain-water. Let the solid be suspended as usual to the water-scale, and immersed in the sea-water, putting the balance-weight in the opposite scale. It will require 11.6 grains to bring it to an even balance. As 445 : 11.6 :: 1000 : 26. The specific gravity is therefore 1026; which shews that sea-water is 26 parts in 1000, or $\frac{1}{38}$ th heavier than rain-water; or that there must be 1026 measures of rain-water to weigh as much as 1000 measures of sea-water. The method is the same for every other fluid specifically heavier than water.

The specific gravity of *salt* and *water*, in equal quantities, (in measure) is 1205; or about one-fifth heavier than common water is found to be.

SECT. X. Of measuring the Specific Gravity of a Fluid by the Hydrometer.

If there are several fluids to be compared, and a given body which is specifically lighter than any of them is made to float upon their surface, the parts of the body that sink below the surface in these different fluids will be inversely as their specific gravities.—A piece of cork will sink deeper in spirits of wine than in water; and the part of it which sinks below the surface of the spirits will be to the part which sinks below the surface of the water as the specific gravity of the spirits is to that of the water when they are inverted, that is, as the specific gravity of the water is to that of the spirits. The part which sinks below the surface in the spirits, is the bulk of as much spirits as is equal in weight to the whole cork; and the part which sinks below the surface of the water, is the bulk of as much water as is equal in weight to the same cork. These parts are therefore to each other as the bulks of equal weights of spirits and water; but these bulks, and consequently the parts of the cork that sink below the surface, are inversely as the specific gravities of spirits and water.

Hence we can discover the specific gravity of different solids, by plunging them in the same fluid; so we can discover the specific gravity of different fluids, by plunging the same solid body into them; for, in proportion as the fluid is light, so much will it diminish the weight of the body weighed in it. Thus, we know that spirit of wine has less specific gravity than water, because a solid that will swim in water will sink in spirits of wine. The stronger any fluid is, the greater will be its resistance to any solid immersed; spirit of nitre has greater specific gravity than water; and a solid that will sink in water will swim in spirit of wine. The method of comparing fluids with each other by means of the hydrometer or aerometer depends on this principle. See the article HYDROMETER.

The *hydrometer* is indeed one of the most useful philosophical instruments; for, though the hydrostatic balance be the most general instrument for finding the specific gravities of all sorts of substances, yet the hydrometer is better to discover with ease and expedition those of fluids. It consists of four parts: 1. A ball of metal, ivory, or glass. 2. A tail and weight to poise the instrument, that a certain part of the instrument may be always downmost in the liquor. 3. A long stem arising from the opposite and upper part of the instrument. 4. A shoulder on the upper part of this instrument, for occasionally placing of weights to cause the instrument to sink so far that the surface of the fluid may always cut the stem at a particular point. When this instrument is swimming in the fluid, the part of the fluid displaced by it will be equal in bulk to the part of the instrument under water, and equal in weight to the whole instrument.

Let us suppose the weight of the whole to be 4000 grains. It is evident we can by this instrument compare together the different bulks of 4000 grains of various fluids: for instance, if the weight at bottom be such as shall cause the hydrometer to sink in rain water till its surface come to the middle point of the stem; and if after this it be immersed in common spring water, and the surface thereof is one tenth of an inch below the middle point, it is evident that the same weight of each water differs in bulk only by the magnitude of one-tenth of an inch in the stem.

Now, suppose for ease in calculation the stem were ten inches long, and weighed 100 grains, then every tenth of an inch would be one grain weight; and since the stem is of brass, and brass is about eight times heavier than water, the same bulk of water will be equal to one-eighth of a grain, and consequently to one-eighth of $\frac{1}{80}$ th part of the whole, that is, a $\frac{1}{640}$ th part of the whole bulk.

Hydrometers of various kinds have been constructed for the purpose of ascertaining the strength of spirits; but as Government, to avoid disputes respecting the duties, have passed an act to constitute *Clark's* hydrometer (for a short time) the only legal one, it will be unnecessary to describe the various constructions that have been made. Mr. Ramsden, in an excellent paper on this subject, has shewn, that to answer these valuable purposes, four points must be well ascertained. 1. A method of proportioning and expressing in measures the quantities of spirits in compounds, and of determining their specific gravities. 2. A means of ascertaining the increase or diminution in the bulk of a given compound arising from different degrees of temperature. 3. The application of the experiments under the two preceding heads to the construction of an hydrometer, which shall give the specific gravity of any compound in thousandth parts of that of distilled water; and at the same time the quantity of spirits of a given strength in the compound in hundredth parts of the volume. 4. A method to determine the proportion of spirits to water in the compound, now called *proof*, which the commissioners of the customs have stated to weigh seven pounds twelve ounces per gallon, at the temperature of 55 degrees; for which purpose it is necessary to have an exact gallon measure.

See Ramsden's Account of Experiments to determine the specific Gravities of Fluids. De Luc on Pyrometry, Aerometry, &c. Philos. Transf.

Hence it should seem, that the determining the specific gravities of fluids, in order thereby to obtain accurately the strength of spirituous liquors, is a very complicated problem. Mr. De Luc has shewn, that when an hydrometer is employed, there are three physical effects, the degrees of which are not proportionate to their apparent causes, and which are united in one effect, namely, the different sinking of the hydrometer. 1. It will not always sink in liquors of different densities proportionally to these densities, on account of the changes of its own bulk by heat, and the possible irregularities of its branch. 2. It will not sink in proportion to the changes of temperature of the fluid, because the changes of density in the latter do not follow the same law as the changes of temperature. 3. It will not sink exactly in the inverse ratio of the quantities of phlegm, because the specific gravity of the fluid does not follow the proportion of these quantities. It has an increasing progression; and here the intermediate cause of this disproportion, which is evident, may give you an idea of what takes place in nature, and hinders physical effects from appearing proportional to their causes.

The spirit and the phlegm penetrate each other, that is to say, 'the bulk of the mixture is somewhat less than the sum of the two bulks before the mixture;' and thus the specific gravity, which is the weight under a certain bulk, increases but little in the mixture comparatively with the mean specific gravity of the component parts. In order therefore to have equal degrees in the hydrometer, without sensible error in the spirituousity that it is intended to measure, it is necessary to fix these degrees by the comparison of effects observed within the limits of the common observations.

SECT. XI. *Of a Phenomenon not to be accounted for on the general Doctrine of Specific Gravity.*

BODIES of the *greatest known* specific gravity, when divided into very minute parts by the menstrua in which they are dissolved, will remain suspended therein for any length of time: thus, *aqua regia*, or even *ether*, holds suspended the parts of that most ponderous of all metals, gold. Some mathematicians endeavour to account for this part of the phenomenon; but there is another difficulty, which will not bend to theory. It does not follow from any established principles, how a body divided into parts, however minute, can possibly *ascend* in a fluid specifically lighter than itself; whereas it is well known, that in some solutions, when the solid to be dissolved is placed at the bottom of a vessel into which the dissolving fluid is poured, the parts of the solid during the solution, *without any motion* whatever being communicated to the vessel, will be diffused throughout the substance of the dissolving fluid, appearing to *overcome the natural tendency of bodies towards the centre of the earth*, and to have some new power of ascent impressed upon its particles. See Atwood's Treatise on Rectilinear Motion, pages 155, 162, &c.

SECT. XII. *Different Methods of ascertaining the Specific Gravity of Fluids.*

IN the following way the specific gravities of water and any other fluid may be compared together. Weigh very accurately an ounce or other weight of distilled water in a cylindrical glass phial, and mark precisely the space occupied by it; then pour in any other fluid till it fill exactly the same space with the water, and weighing it you will know the weights of equal magnitudes of the water and the other fluid, and their specific gravities.

The *magnitude* of a body, however irregular, may be found by immersing it in a cylindrical vessel of water, and marking

how far the fluid rises; for the space contained between the surfaces of the water before and after the immersion of the body, is equal to its magnitude; and this, together with its weight, being known, its specific gravity is also known.

The capacity of any irregular vessel may be known by filling it with water; for the water being weighed, its magnitude or the number of cubical inches contained in it will be found. Let the vessel be filled with water, and let the weight of the water be A ounces; then make the following proportion: As 52.46 to A, so is 1 to the capacity of the vessel expressed in cubic inches; this will be facilitated by the following table:

oz.	cubic inches.
1	1.8959
2	3.7918
3	5.6877
4	7.5835
5	9.4794
6	11.3753
7	13.2712
18	15.1671
19	17.0630

To exemplify the use of this table, suppose the water contained in a receiver of an air-pump or other vessel to weigh 235.18 oz. then referring to the table,

oz.	cubic inches:
200	= 379.18
30	= 56.88
5	= 9.48
.1	= .19
.08	= .15

445.88 the number of cubic

inches contained in the vessel.

If avoirdupois ounces are used in weighing the water, the numbers may be taken from the above table; but the resulting number must be multiplied into 91145, to give the true number of cubic inches contained in the vessel.

SECT. XIII. Table of Specific Gravities.

Refined gold	19.640	Selenites	2.252
English guinea	18.888	Sal gemmæ	2.143
Mercury	14.019	Brick	2.000
Lead	11.344	Nitre	1.900
Refined silver	11.091	Alabaster	1.875
Bismuth	9.700	Dry ivory	1.825
Copper from Japan	9.000	Brimstone	1.800
Copper from Sweden	8.843	Dantzick vitriol	1.715
Hammered brass	8.349	Alum	1.714
Cast brass	8.100	Borax	1.714
Turbith mineral	8.235	Human calculus	1.700
Cinnabar, factitious	8.200	Oil of vitriol	1.700
Cinnabar, natural	7.300	Oil of tartar	1.550
Elastic steel	7.820	Bezoar	1.500
Soft steel	7.738	Honey	1.450
Iron	7.645	Gum arabic	1.375
Pure tin	7.471	Spirit of nitre	1.315
Glass of antimony	5.280	Aqua fortis	1.300
A pseudo topaz	4.270	Pitch	1.150
A diamond	3.400	Spirit of salt	1.130
Crystal glass	3.150	Human blood	1.126
Island crystal	2.720	Spirit of urine	1.120
Rock crystal	2.650	Human blood	1.054
Common glass	2.620	Amber	1.040
Fine marble	2.704	Serum of human blood	1.030
Stone of a mean gravity	2.500	Milk	1.030

Urine	1.030	Spirit of turpentine	0.874
Dry box-wood	1.030	Rect. spirit of wine	0.865
Sea-water	1.030	Dry ash	0.800
Common-water	1.000	Dry maple	0.755
Camphire	0.996	Dry elm	0.600
Bees wax	0.955	Dry fir	0.550
Linsced oil	0.932	Cork	0.240
Dry oak	0.925	Air	0.005
Oil, olive	0.913		

This table exhibits the specific weights of the various substances contained in it, discovered by some of the methods already described; and the absolute weight of a cubic foot of each body is ascertained in avoirdupois ounces by multiplying the number opposite to it into 1000; as, for example, S. g. of water: S. g. of mercury :: 1 : 14.019 :: 1000 oz. : wt. of a cubical foot of mercury, which is therefore equal to 1000 x 14.109 avoirdupois ounces. There are some uncertainties in this subject; for substances of the same kind, though denominated by the same name, may not be precisely similar, and some small errors may perhaps be inevitable in physical experiments; but they will be inconsiderable if the scales be nicely adjusted, and the experiments cautiously conducted, so that the body weighed do not touch the bottom or sides of the vessel, nor rise above the surface of the fluid, nor bubbles of air adhere to its surface. There is another cause of uncertainty; for most substances are dilated by heat and contracted by cold, and the dimensions of the same body, and consequently its specific gravity, are different according to the different temperatures of the ambient air; and the altitude of the thermometer ought to be considered in constructing a table of specific gravities. The different expansion of bodies in summer and winter, and consequently their different specific gravities, appear from the experiments of Homberg, and Eifenschmedites in his "Disquisition nova de Ponderibus, &c." from the latter of whom the following table, exhibiting the weight of a cubical inch, Paris measure, of different substances, is taken.

A cubic inch, Paris Measure.	In summer.			In winter.		
	oz.	dr.	gr.	oz.	dr.	gr.
Of mercury	7	1	66	7	2	14
Oil of vitriol	7	59		7	71	
Spirit of vitriol	5	33		5	38	
Spirit of nitre	6	24		6	44	
Spirit of salt	5	49		5	55	
Aqua fortis	6	23		6	35	
Vinegar	5	15		5	21	
Distilled vinegar	5	11		5	15	
Burgundy wine	4	67		4	75	
Spirit of wine	4	32		4	42	
Pale ale	5	1		5	9	
Brown ale	5	2		5	7	
Cow's milk	5	20		5	25	
Goat's milk	5	24		5	28	
Urine	5	14		5	19	
Spirit of urine	5	45		5	53	
Spirit of tartar	7	27		7	43	
Oil of olives	4	53				frozen
Oil of turpentine	4	39		4	46	
Sea water	6	12		6	18	
River water	5	10		5	13	
Spring water	5	11		5	14	
Distilled water	5	8		5	11	

It appears from this table, that the expansions of different fluids are different in the same changes of the temperature of

the air; and it appears from observation, that substances not fluid are also in similar circumstances differently dilated; but the weight of given magnitudes, both of fluid and firm bodies, being diminished by heat, and increased by cold, the variation

of their specific gravities is less than if the dimensions of one of them only had been variable.

Having brought this part of our subject to a conclusion, we shall now proceed to speak of Hydraulics.

PART II. H Y D R A U L I C S.

SECT. I. *Of the Motion of Fluids.*

IN the foregoing pages we have shewn that by *hydrostatics* we are taught to determine the weight or pressure of fluids upon solids, or upon each other, in vessels where the water is not suffered to escape, but remains at rest. *Hydraulics* has for its object the *motion of fluids*: and upon the principles of this science many machines are constructed: several engines used in the mechanic arts, and various kinds of mills, pumps, and fountains, are the result of hydraulics judiciously applied.

Could we know with certainty the mass, the figure, and the number of particles of a fluid in motion, the laws of its motion might be determined by the resolution of a mathematical problem, namely, by finding the motion of a system of small free bodies acting one on the other in obedience to some exterior force, as that of gravity. We are, however, very far from being in possession of the data requisite for the solution of this problem: even if we were in possession of them, it is doubtful whether we should be much farther advanced, as it would be difficult to deduce any satisfactory results from the intricate calculations in which the question would be involved. Some great mathematicians have endeavoured to deduce the laws of motion in fluids from the equilibrium of their particles, but unfortunately they are so complicated as to be of no practical use.

Accurate physical principles are always necessary before any utility can be drawn from mathematical abilities. Men may enter deeply into abstract speculations, and rise from assumed data to the most sublime efforts of the human mind; but if no physical existences correspond with those data, no advantage can arise to the general state of knowledge from exercises of this kind, and they can only be considered as mere amusements of the understanding. It will be therefore necessary for those who wish to investigate this subject, to endeavour to establish their physical principles on experimental facts, and accurate observation. For what we have to observe on this subject, we are chiefly indebted to the Abbé Bossut.

SECT. II. *Of the Spouting of Fluids through small Orifices.*

WHEN water is ejected from a small hole in the bottom of a vessel, 1. The water descends nearly in a vertical direction, and the surface deviates very little from a horizontal plane; but at about three or four inches from the bottom the particles turn from the vertical direction, and come from all parts with a motion more or less oblique towards the aperture. The same thing takes place when the water escapes from a small hole in the side of the vessel. The tendency of the particles towards the orifice is a necessary consequence of their perfect mobility; for they are hereby naturally directed towards that part where they meet with the least resistance, which part is the aperture. 2. At a small distance from the bottom of the vessel the water forms itself into a kind of funnel, whose point or

summit corresponds with the centre of the hole. When the water runs out of a hole in the side of the vessel, it forms only a kind of half funnel, beginning when the surface nearly touches the upper edge of the hole. It is probable that the funnel begins to be formed as soon as the water begins to run out; but it does not become very sensible, except when the surface is at a small distance from the bottom*. The funnel commences at a greater height from the bottom of the vessel, in proportion as the bottom is larger; the size thereof is, however, varied by a number of circumstances.

The *velocity* of the water spouting from a small hole in the bottom of the vessel, is equal to that which a heavy body would acquire in falling vertically from a height equal to that of the surface of the fluid above the aperture. The same law takes place when the hole is in the side of the vessel; for the pressure of the fluid is equal (at the same depth) in all directions, and will consequently produce the same velocity. The fluid in issuing out of the hole gives a velocity sufficient to make it rise vertically to a height equal to that of the surface of the fluid above the aperture; in the same manner as a body falling from a certain height acquires a velocity sufficient to make it ascend to the height from which it fell.

From the theory of falling bodies, it is plain, that if the fluid continued to move uniformly with the velocity it had acquired at coming out of the hole, it would move through a space equal to double the height of the fluid above the aperture, while a heavy body was descending through the same space. The height being the same, the velocity of the fluid at the aperture will be always the same, and this though the fluid varies in density; for though with a denser fluid the pressure is greater, the mass escaping is also greater, and the velocities are equal when the moving forces are proportioned to the masses they put in motion.

The *quantities* of a fluid proceeding in the same time through different apertures, each acted upon by a constant height or load (supposing of course that the vessels are kept equally full during the whole experiment), are to each other as the *product of the areas of the apertures by the square root of the heights*. For example, it has been proved by experiment, that a circular aperture of 1 inch diameter, in a thin vessel, gives in one minute of time, the water being four feet high, 5436 cubic inches of water. To know what will be furnished in the same time by an aperture two inches in diameter, the altitude of the water nine feet (French measure), use the following proportion (observing that the aperture of two inches is four times as large as that of one, because the areas of circles are as the squares of the diameters): As $1 \times \sqrt{4}$ is to $4 \times \sqrt{9}$, so is 5436 to x : or, as 2 is to 12, so is 5436 to 32616 cubic inches of water, the quantity that will be furnished by an aperture of two inches diameter from a reservoir whose surface is always kept at nine feet from the aperture.

* The writers on this subject (says Mr. George Adams) seem to have neglected a revolving motion in the water, but which on making further experiments they will find worthy their attention. "If at the bottom of a vessel of water an aperture be made for the fluid to escape, it will revolve about the aperture, and at some distance from it, and escape with this revolving motion; the water rushes from all sides in concentrating streams to supply the continual waste."

If you fill with water a prismatic vessel, and let the water run out by an aperture in the bottom, observing the time employed by the water in running out; and then fill the vessel again, keeping the surface of the water at the same height; you will find in this last case, that in the same interval of time that the vessel was emptying itself in the first instance, nearly double the quantity of water has been expended in the second.

In practice the water often issues from lateral openings, which, although but small in comparison with the size of the reservoirs, cannot be considered as having all their points at an equal distance from the surface of the fluid. In these cases, the usual method of determining the quantity of water flowing through the aperture depends on the following principles: Imagine the whole to be stopped by a plate, and this plate to be pierced with a great number of holes through which the water escapes; now, considering each of these holes as a single insulated aperture, the velocity for each will be according to the correspondent height of the fluid. If the number of these holes be infinitely augmented, or, what comes to the same thing, if the plate be taken away, the velocity of each point of the given aperture will be as the height corresponding thereto; and in determining the quantity of effluent water, regard must be had to this inequality of velocity.

It should not however be concealed, that this mode of reasoning is not very conclusive; for though it may be just as far as relates to the number of insulated holes, it does not appear clearly that the water will flow exactly in the same manner when the threads thereof are united, as when they proceed from small separate apertures: as the results of theory, however, upon this plan do not differ much from experiments, it may be useful to preserve it till some better method is discovered.

The quantity of water flowing through holes in a given time is not so great as might have been naturally expected, because the water does not flow in a compact parallel stream, but *contracts* in diameter on coming out of the aperture, and this contraction extends to a distance nearly equal to half the diameter of the aperture. The diameter of the *contracted stream* is to the diameter of the aperture as 3 to 4, or as $3\frac{1}{2}$ to 4, or as 19 to 24, so that its area to that of the aperture is as 10 to 16: it is nearly the same thing when the water flows from lateral apertures.

This contracted stream is a proof that within the vessel the lateral particles are directed towards the hole, with different degrees of obliquity, which obliquity may be decomposed into two forces, one parallel to the plane of the hole, which contracts the fluid; the other perpendicular to the same plane, which occasions the efflux. This contraction takes place also when water passes through tubes, and the contraction is at the entrance of the water into the tube, not at its going out, where it preserves its cylindrical form. This contraction diminishes sensibly the quantity of water that should be furnished by the tubes. To ascertain these facts, M. Bossut made a great number of experiments, the results of which we shall here set forth. The apertures for the efflux of the water were all pierced perpendicularly in plates about $\frac{1}{2}$ a line thick, and the time of each experiment is reduced to 1 minute.

The water was kept constantly at eleven feet eight inches ten lines from the centre of each aperture.	Number of cubic inches furnished in one minute.
---	---

Exp.	
1. With an horizontal circular aperture, 6 lines diameter	2311
2. With a circular horizontal aperture, 1 inch diameter	9281

The water was kept constantly at eleven feet eight inches ten lines from the centre of each aperture.	Number of cubic inches furnished in one minute.
---	---

Exp.	
3. With a circular horizontal aperture, 2 inches diameter	37203
4. With a rectangular horizontal aperture, 1 inch by 3 lines	2933
5. With a square horizontal aperture, the side 1 inch	11817
6. By a square horizontal aperture, the sides 2 inches	47361
<i>Constant Height 9 Feet.</i>	
7. Lateral circular aperture, 6 lines diameter	2018
8. Lateral circular aperture, 1 inch diameter	8135
<i>Constant Height 4 Feet.</i>	
9. Lateral circular aperture, 6 lines diameter	1353
10. Lateral circular aperture, 1 inch diameter	5436
<i>Constant Height 7 Lines.</i>	
11. By a lateral and circular orifice, 1 inch diameter	628

From the preceding Experiments we make the following deductions:

1. 'The quantities of fluid discharged in equal times from different sized apertures, the altitude of the fluids being the same, are nearly to each other as the areas of the apertures.' Thus in the second and third experiments the areas of the apertures are as one to four, and the water discharged 9281 cubic inches; 37203 is nearly in the same ratio.

2. 'The quantities of water discharged, in equal times, by the same aperture, with different altitudes of the reservoir, are nearly as the square roots of the corresponding altitude of the water in the reservoir above the centre of the aperture.' Compare together the eighth and tenth experiments, in which the respective altitudes of the reservoir were of 9 and 4 feet, of which the square roots are 3 and 2, and we find the water discharged by the first was 8135 cubic inches, the second 5436 cubic inches; nearly in the proportion of 3 to 2.

3. 'That in general, the quantities of water discharged in the same time, by different apertures and under unequal altitudes of the reservoirs, are to each other in a compound ratio of the areas of the apertures and the square roots of the altitudes.'

4. 'That on account of the friction, the smallest apertures discharge less water than those that are larger and of a similar figure, the water in the respective reservoirs being at the same height.'

5. 'That of several apertures whose areas are equal, that which has the smallest circumference will discharge more water than the others, the water in the reservoirs being at the same altitude,' and this because there is less friction. Hence circular apertures are most advantageous, as they have less rubbing surface under the same area.

It is easy to perceive, that the quantities of water expended in the foregoing experiments are not nearly so much as they ought to be, considering the size of the apertures and the altitude of the reservoirs. The quantity discharged is diminished considerably by the friction, and by the contraction of the stream; and

probably on account also of the circular motion of the fluid: for the velocity which depends on the altitude of the reservoir is not sensibly altered. The difference in the discharge of water, supposing, 1. that the area of the stream is the same with that of the aperture; 2. that this stream is contracted, is as 16 to 10: in other words, by supposing the area of the orifice to be diminished in the proportion of 16 to 10, you may determine with sufficient exactness the efflux of fluids from vessels where the surfaces are maintained at the same height.

SECT. III. *Of the Discharge of Fluids through additional Tubes.*

If the water, instead of flowing through an aperture pierced in a thin substance, passes through the end of a vertical tube of the same diameter as the aperture, there is a much greater discharge of water, because the contracted stream is greater in the first instance than in the second. In the following experiments the constant height of the water in the reservoir above the upper aperture of the tube was 11 feet 8 inches 10 lines, the diameter of the tube 1 inch.

Different lengths of the tube expressed in lines.		Number of cubic inc. of water discharged in 1 minute.
Exp. 1	48 } The stream filling the tube	
2	24 }	12188
3	18 }	12168
4	18 } The water not filling the tube	9282

It appears on comparing the three first experiments, that the longer the vertical tube is, the greater is the discharge of the water, because the contraction of the stream is less; it is, however, always somewhat contracted, even when it appears to fill the tube.

By comparing the quantities of water discharged in the third and fourth experiments, we find the two discharges 12168, 9282, are to each other nearly in the proportion of 13 to 10; but we have seen, that the water discharged through a thin aperture without any contraction in the stream, would be to the same aperture with a contracted stream as 16 to 10. From hence we may conclude, that the altitude in the reservoir and the apertures being the same, the discharge through a thin aperture without any contraction in the stream, the discharge through an additional tube, and the discharge through a similar aperture with a contracted stream, are to each other nearly as the numbers 16, 13, 10; these proportions are sufficiently exact for practice. Hence it is plain that an additional tube only destroys in part the contraction of the stream, which contraction is greatest when the water passes through a thin aperture from a large reservoir.

If the additional tube, instead of being vertical, or placed at the bottom of the reservoir, was horizontal or placed in the side, it would furnish the same quantity of water, provided it was of the same length, and that the exterior aperture was at the same distance from the surface of the water in the reservoir.

If the additional tube instead of being cylindrical was conical, having its largest base nearest the reservoir, it would discharge a greater quantity of water. The most advantageous form that can be given, in order to obtain the greatest quantity of water in a given time by a given aperture, is that which the stream assumes in coming out of the aperture; i. e. the tube must be of the form of a truncated cone, whose smallest base should be of the same diameter as the aperture; the area of the small base

should be to that of the larger base as 10 to 16; and the distance from one base to the other should be the semidiameter of the largest base; and the efflux of water will be as abundant as it would be through a thin aperture equal to the smallest base, and where the stream was not contracted. This form may be applied where it is necessary to obtain a certain quantity of water from a river, an aqueduct, &c. by a canal or lateral tube.

On comparing the efflux of water through additional tubes of different diameters, and with different altitudes of the water in the reservoirs, the following results were obtained; the additional tubes were two inches long, and were vertical and placed at the bottom of the reservoir.

Constant altitude of the water above the tubes.	Diameter of the tubes expressed in lines.	Number of cub. in. in 1 min.
3 feet 10 inches	6 } Water filling the tube	1689
	10 }	4703
	6 } The water not following the sides	1293
	10 }	3598
2 feet	6 } The water filling the tube	1222
	10 }	3402
	6 } The water not filling the tube	935
	10 }	2603

It results from these experiments, 1. That the discharge by different additional tubes, with the same altitude of the reservoir, are nearly in proportion to the area of the apertures, or to the squares of the diameters. 2. That the discharge of water by additional tubes of the same diameter, with different altitudes of water in the reservoir, are nearly proportional to the square root of the altitude of the reservoir. 3. That in general the discharge of water in the same time, through different additional tubes, with different altitudes of water in the same reservoir, are to each other nearly as the product of the square of the diameters of the tubes by the square root of the altitude of the reservoirs.' So that, additional tubes, transmitting water, follow (amongst themselves) the same laws as through the thin orifice. The following table was formed from the foregoing experiments.

Constant altitude of the water in the reserv. above the aperture expressed in feet.	Water discharged in one minute through an hole 1 inch diam. the stream not contracted. in cub. inc.	Water discharged in 1 minute through an additional tube of 1 inch diam. 2 inc. long, in cub. inc.	Water discharged during 1 minute through a hole 1 inch diam. with a contracted stream, in cub. inches.

SECT. IV. *Of Fountains or Jets d'Eau.*

THE subject which we shall now proceed to consider, is the nature of *Fountains*. There are few things that give more pleasure to the eye than a diversity in the play of water from a fountain: but these machines give still greater pleasure in sultry climates, where they contribute to cool the air, as well as to enliven the prospect.

Whatever be the direction of the jet, the discharge of water is always the same; provided that the ajutage, and the altitude of the reservoir above the ajutage, be the same. This is a necessary consequence of the equal pressure of fluids in all directions. Water, spouting from a small ajutage, has sufficient velocity to carry it to the same height as the water in the reservoir; but it never attains entirely this height, being prevented by various concurring causes. 1. The friction in the tubes between the reservoir and the ajutage. 2. The friction against the circumference of the aperture. 3. The resistance of the air to the weight of the water at the top of the spout; for this, having lost its motion, rests on the part below, and by its weight obstructs the motion of the column. The resistance from this cause is so great, that the jet is frequently destroyed, the rising water being by fits and starts pressed down to the very orifice from which it spouts; but this inconvenience is remedied, if you give the jet a little inclination; for then the particles which have lost their motion upwards do not fall back as before, but fall off from the rest, and thus do not incumber the rising fluid; hence such jets as are a little inclined will rise higher than those that are vertical.

When the ajutage is inclined to the horizon, the projectile force and the gravity of the water cause the stream to describe a parabola, whose amplitude is greater in proportion to the height of the reservoir. When the ajutage is in an horizontal direction, the jet describes a semi-parabola.

Jets of water rise higher in proportion as the aperture of the ajutage is large; because, 1. Of two jets proceeding from the same reservoir with equal velocities, the largest undergoes less friction: 2. It has more mass, and consequently more force to overcome obstacles. But though a large jet will rise higher than a small one, it does not discharge more water; for the discharge is as the product of the aperture by the velocity at the moment of efflux; and this velocity is the same in each, friction not being considered.

In order to make large jets rise higher than small ones, the conduit-pipe must be large enough to furnish a sufficient quantity of water; for experience has shewn, that if these are narrow, small jets will rise higher than those that are larger. The diameter of the conduit-pipe should therefore bear a certain proportion to that of the ajutage, in order to make a jet rise to the greatest possible height. If we compare two different jets, and are desirous that each should attain its greatest altitude, the squares of the diameters of the conduit-pipes must be to each other in the compound ratio of the squares of the diameters of the ajutages, and the square root of the altitude of the reservoir. Thus, if we know by experience the diameter that ought to be given to a conduit-pipe, to furnish water for the discharge of a given ajutage, with a reservoir of a given altitude, we may determine the diameter of another tube, to feed a given ajutage with a reservoir of a given altitude.

Experience has shewn, that, for an ajutage six lines diameter, with a reservoir of fifty-two feet, the conduit-pipe should be about thirty-nine lines; for an ajutage six lines diameter, and a reservoir sixteen feet, the conduit-pipe twenty-eight lines and an half. There is no inconvenience in giving a conduit-pipe a greater diameter than is required by the above rule, but there would be a considerable one in giving it a smaller diameter.

From the comparison of several experiments made on jets

d'eau, it appears that the difference between the altitudes of vertical jets, and the altitudes of the reservoirs, is to each other as the squares of the jet's altitude. If we know, therefore, by experiment, how far any jet falls short of the altitude of its reservoir, you may find by the rule of three, how much any other jet falls short of its reservoir. If we wish to know the altitude of the reservoir, we have only to add to the altitude of the jet the quantity found by the proportion. It is to be observed, that conduit-pipes should never be fixed at right-angles to each other.

The following table will facilitate the application of the foregoing principles. In the two first columns are the altitudes of the jets, and the corresponding altitudes of the reservoir. The third column contains (in Paris pints, thirty-six of which make a cubic foot) the discharge during one minute, through an ajutage six lines diameter, relatively to the altitudes of the second column. Knowing the discharge with an ajutage of six lines by the rule of three, we discover the discharge by any other ajutage with a reservoir of the same height; since it has been proved, that the discharges are as the area of the ajutage, or as the squares of the diameters of these ajutages. In the fourth column appear the diameters for the conduit-pipes of an ajutage six lines diameter, relatively to the altitudes of the second column.

Altitude of the jet in feet.	Altitude of the reservoir in feet and inches.	Discharge in minute by an ajutage of 6 lines diam. in Paris pints.	Diam. of the conduit pipes relative to the 2d and 3d cols.
	Feet. In.	Pints.	Lines.
5	5 1	32	21

100	133 4	163	49

The application of these principles has supplied an infinite variety of amusing contrivances. We shall here produce one instance in what is called the *Circulating Fountain*. See plate 20.

In this fountain, the air being compressed by the concealed fall of water, makes a jet, which, after some continuance, is considered by the ignorant as a perpetual motion; because they imagine that the same water which fell from the jet rises again. The boxes CE and DYX being close, we see only the basin ABW, with a hole at W, into which the water spouting at B falls; but that water does not come up again; for it runs down through the pipe WX into the box DYX, from whence it drives out the air through the ascending pipe YZ, into the cavity of the box CE, where, pressing upon the water that is in it, it forces it out through the spouting pipe OB, as long as there is any water in CE; so that this whole play is only whilst the

Water contained in CE, having spouted out, falls down through the pipe WX into the cavity DYX. The force of the jet is proportionable to the height of the pipe WX, or of the boxes CE and DY above one another: the height of the water, measured from the basin ABW to the surface of the water in the lower box DYX, is always equal to the height measured from the top of the jet to the surface of the water in the middle cavity at CE. Now, since the surface CE is always falling, and the water in DY always rising, the height of the jet must continually decrease, till it is shorter by the height of the depth of the cavity CE, which is emptying, added to the depth of the cavity DY, which is always filling; and when the jet is fallen so low, it immediately ceases. The air is represented by the points in this figure. To prepare this fountain for playing, which should be done unobserved, pour in water at W, till the cavity DXY is filled; then invert the fountain, and the water will run from the cavity DXY into the cavity CE, which may be known to be full when the water runs out at B held down. Set the fountain up again, and, in order to make it play, pour in about a pint of water into the basin ABW; and as soon as it has filled the pipe WX, it will begin to play, and continue as long as there is any water in CE. You may then pour back the water left in the basin ABW, into any vessel, and invert the fountain, which, being set upright again, will be made to play, by putting back the water poured out into ABW; and so on as often as you please.

SECT. V. *Of Pumps.*

WHAT has been said concerning conduit-pipes, the efflux of water from different apertures, &c. naturally leads us to consider the nature and action of pumps. Their general principles will be explained under the articles PNEUMATICS and PUMP. We shall here notice the different kinds, and remark some varieties in their construction.

Among the most valuable mechanical inventions of this sort is what is called the *chain-pump*. This is generally made from twelve to twenty-four feet in length; consists of two collateral square barrels, and a chain of pistons of the same form, fixed at proper distances thereon. The chain is moved round a coarse kind of wheel-work, fixed at one end of the machine. The teeth of this are so contrived as to receive one half of the flat pistons, and let them fold in, and they take hold of the links as they rise. A whole row of the pistons (which go free of the sides of the barrel by near a quarter of an inch) are always lifting when the pump is at work; and as this machine is generally worked with briskness, they bring up a full bore of water in the pump. It is wrought either by one or two handles, according to the labour required.

The chain-pump is so contrived, that, by the continual folding in of the pistons, stones, dirt, and whatever may happen to come in the way, may also be cleared: it is therefore used to drain ponds, sewers, and remove foul water, in which no other pump could be employed.

A section of this machine, as fixed in a frigate of war, is exhibited in plate 20, where A is the keel, V the floor-timber, X the kelson, a, a, a the several links of the chain, b b the valves, C the upper wheels, D the lower wheels, c c the cavities upon the surface of the wheels to receive the valves, as they pass round thereon, d d the bolts fixed across the surface of the wheels, to fall in the interval between every two links, to prevent the chain from sliding back.

SECT. VI. *Of Pumps which act by the Pressure of the Atmosphere.*

PUMPS of this description are pneumatic as well as hydraulic engines, and are usually divided into two kinds: 1. the common, or *sucking pump*; 2. the *forcing pump*. The nature of

these, their action and operation, are best explained by glass models; in which the motion of the pistons and the play of the valves may be distinctly seen.

Common Pump, (fig. 1, pl. 19).—By pouring water into a tub or trough, we may represent the well from which water is to be raised. There are two valves in this pump: one (b) at the upper end of the small tube; the other (a) on the moveable piston.

When the pump is not worked, their weight makes them lie close upon the holes over which they are placed. We raise or depress the piston, by means of the piston-rod, which is connected with the pump-handle. The piston being placed at the bottom of the barrel, before we begin to work, we should raise the piston from the bottom to the top of the barrel; which makes room for the air in the pump, below the piston, to expand itself. The air in the pipe being thus dilated, presses less on the surface of the water within the pipe, than the atmosphere does without on that in the trough; and consequently the water rises in the tube till the pressures are equal; that is, till the air within is just as dense as that without; and it will there remain at rest between the two equal pressures. The valve at the bottom, which rose a little to let some of the rarefied air into the barrel, falls down again, and closes the hole at the top of the pipe.

We now depress the piston; and as the air in the barrel cannot get back again through the valve b, at the top of the pipe, it will raise the valve in the piston, and so make its way through the upper part of the barrel into the open air. Upon raising the piston again, the air between it and the water in the lower pipe will again be left at liberty to fill a larger space; and so its spring being again weakened, the pressure of the atmosphere will force more water into the pipe; and when the piston is at the top of the barrel, the lower valve falls, and stops the hole at the top of the pipe, as before. The same effect is produced by every stroke, till at last the water in the pipe reaches the bottom of the barrel. Now, upon depressing the piston, as the water cannot be forced back again through the lower valve, it will raise the upper valve as the piston descends, and will be lifted up by the piston when raised again.

The whole space below the piston being now full of water, as the water cannot escape by the lower valve, it will, on depressing the piston, raise the valve, in order to let the piston down. When this is quite at the bottom, the valve will fall by its own weight, and stop the hole in the piston. When the piston is next raised, all the water above it will be lifted up, and run out of the spout; and thus, by alternately raising and depressing the piston still more water will be raised; which, getting above the pipe into the wide part at top, will supply the spout, and make it run with a continual stream. Thus, every time the piston is elevated, the lower valve *rises*, and the upper valve falls; but every time we *depress* the piston, the lower valve *falls*, and the upper one *rises*.

Now, as it is the pressure of the air of the atmosphere which causes the water to rise, and follow the piston, as it is drawn up; and as a column of water, of thirty-three feet high, is of equal weight with as thick a column of air, from the earth to the very top of the atmosphere; therefore the perpendicular height of the piston from the surface of the water in the well must always be less than thirty-three feet, otherwise the water will never rise above the piston. But when the height is less, the pressure of the atmosphere will be greater than the weight of the water in the pump, and will therefore raise it above the piston; and when the water has once got above the piston, it may be thereby lifted to any height, if the rod be made long enough, and a sufficient degree of strength be employed to raise it with the weight of water above the piston.

The force required to work a pump is as the altitude of the water to be raised, and as the square of the diameter in that part where the piston works. Hence, if two pumps be of equal

height, and one of them be twice the bore of the other, the largest will raise four times as much water as the narrowest, and will therefore require to be worked with four times as much strength.

The wideness or narrowness of the pump, in any other part besides that where the piston works, does not render the pump either more or less difficult to work, except what difference may arise from the friction of the water in the bore, which is always greater in a narrow bore than a wide one.

The pump rod is generally raised by means of a lever, whose longer arm, where the power is applied, is generally five or six times the length of the shorter arm; by which means it gives five or six times as much advantage to the power.

Mr. Ferguson gives the following table for finding the dimensions of a pump that shall work with a given force, and draw water from a given depth, the handle being supposed to increase the power five times. It is also supposed that one man can work a pump four inches diameter, and thirty feet high, and discharge $27\frac{1}{2}$ gallons of water in a minute; the measure being that called English wine-measure.

Height of the pumps above the surface of the well.	Diameter of the bore where the piston works.	Water discharged in a minute.
Feet.	Inches.	Galls. Pts.
10	6.93	81 6
15	5.66	54 4
20	4.90	40 7
25	4.38	32 6
30	4.00	27 2
35	3.70	23 3
40	3.46	20 3
45	3.27	18 1
50	3.10	16 3
55	2.95	14 7
60	2.84	13 5
65	2.72	12 4
70	2.62	11 5
75	2.53	10 7
80	2.45	10 2
85	2.38	9 5
90	2.31	9 1
95	2.25	8 5
100	2.19	8 1

To find the diameter of a pump that shall raise water with the same ease as a man can work a pump thirty feet high, with a four inch bore, look for the height in the first column, and over against it, in the second, is shewn the diameter or width of the pump, and in the third we find the quantity of water which a man of ordinary strength can discharge in a minute.

The Forcing Pump.—This machine is so called, because it not only raises the water into the barrel, like the foregoing, but it afterwards forces it up into a reservoir, in a lofty situation. The operation and nature of this pump will be evident by attending to the working of the model, fig. 2. The pipe and barrel are the same as in the other pump, but the piston, G, is solid, having no valve, so that no water can get above it. At the bottom of the barrel B a pipe M M is fixed, and at right-angles to this pipe a cistern or air-vessel, K K; at the bottom of the air-vessel there is a valve, b; from the top a small pipe, O H I, is inserted so as nearly to reach the bottom of the air-vessel, and at the same time be air-tight at top.

In working this kind of pump, the pipe valve, a, rises when we draw the piston up; but falls down, and stops the hole, the moment the piston is at its greatest height. Now as the water which has been raised above this valve cannot get back again into the pipe, but has a free passage by the pipe M M, that opens into the air-vessel, it is forced into this vessel by depressing the piston, and retained therein by its valve b; which shuts the moment the piston begins to be raised, because the pressure of the water against the under side exists no longer.

The water being thus forced into the air-vessel by repeated strokes of the piston, we suppose to have now got above the lower end, I, of the pipe, and that it begins to condense the air in the air-vessel; for the air has no way to get out of this vessel, but through the tube O H I of the pipe, and is prevented from escaping this way when the mouth of this tube is covered with water. It is also gradually more and more condensed as the water rises in this vessel; till at last it presses so strongly upon the water as to force it up through the pipe O H I; from whence it spouts at F in a jet to a great height, and is supplied by alternately raising and depressing of the piston. The higher the surface of the water is raised in the air-vessel, the smaller is the space into which the air is condensed; and consequently its spring will be stronger, and the pressure greater upon the water, which will be thereby driven with greater force through the pipe; and as the spring of the air continues to act even while the piston is rising, the stream will be uniform as long as the piston is worked.

The valve of the pipe opens to let the water follow the piston in rising. Whilst this valve is open, that of the air-vessel is closed, to prevent the water, which is forced into the air-vessel, from running back by its pipe into the air-vessel.

The effect of this kind of pump is not limited to raising water to any particular altitude; since the air's condensation may be raised to any degree. If the air's condensation is double to that of the atmosphere, its elastic force will raise the water to about the height of thirty four feet. If the condensation be increased three-fold, the altitude to which water may be raised by it will be about twice the former height, or sixty-eight feet; the altitude of the raised water being increased thirty-four feet for each addition of unity to the number which expresses the air's condensation.

The engines used for *extinguishing fire* are upon this construction; consisting of two barrels, by which water is alternately driven into a close air-vessel. The forcing the water therein condenses the air, which compresses the water so strongly, that it rushes out with great impetuosity and force through a pipe that comes down into it, and makes a continued uniform stream by the condensation of air upon its surface. See Sect. vii.

De la Hire's Pump.—This invention is calculated to raise water as fast by the descent as the ascent of the piston. As before, the trough in which the two pipes are placed represents the well: one of the pipes, B, fig. 3. is fitted to the lower end of the barrel, in which the piston works; the top of the other pipe, C, is so connected with a smaller one, as to communicate with the upper part of the barrel. There is a valve on the top of the pipes B, C, and also on the two pipes E F, which proceed from the pump-barrel into the air-vessel P. The piston is solid, or without any valve or opening.

As the piston rises, the air, pressing on the surface of the water in the trough, forces it up the pipe B, at the bottom of the barrel, and fills it with water up to the piston. The valves e and s lie close and air-tight at the top of their respective pipes E and F. When the piston stops at its greatest height, the valve at the bottom of the barrel closes, and prevents the water from being forced back. Hence, as the piston is depressed, it forces all the water in the barrel up through the lower crooked pipe F, and through its valve into the air-vessel. The piston rod

moves through what is called a collar of leather, which makes it air-tight.

During the descent of the piston, the valve upon the upper crooked pipe falls down, and the pressure of the air on the water in the trough raises the water through this pipe, C, and the valve at the top of it, which is opened upwards by the power of the ascending water; and this water runs into the barrel of the pump, and fills all the space therein above the piston. As soon as the piston is as low as it can go, the valve at the end of the upper pipe, D, falls down and closes it, so that no water can be forced back through it. As the piston is raised, all this water is forced through the upper pipe E, and, after opening its valve e, into the air-vessel P.

Thus, as the piston descends, it forces all the water below it up the pipe F; and, as it rises, it forces all the water above it up the pipe E; so that there is as much water forced up into the air-vessel by the ascent as by the descent of the piston. The air is compressed in the air-vessel as in the preceding case; and the water, being equally forced in, rushes out with a constant and very nearly equal stream. It is evident, from what has been already observed, that the top of the pipe that opens into the upper part of the barrel should never exceed thirty-two feet.

New Hand Pump.—This valuable machine was invented by Mr. Walter Taylor of Southampton, and is now used by the navy. Every friend of mankind must rejoice, that the accidents to which ships that spring a leak at sea were liable from the imperfections of the chain pump, are happily removed by this ingenious contrivance. It seems rather surprising that the common pump, whose effects are so well known, should have remained for centuries inadequate to the purposes of the navy. The mechanism adapted by Mr. Taylor is so important, and, in various particulars, so different from what is in general applied to the common pump, that it may with great propriety be considered as a new invention altogether.

These pumps have been in general use in the navy for five or six years, and they have answered every expectation he first formed, though he has made many improvements on them during that period. In the plate are three figures, which will afford a general idea of these pumps; they were copied by Mr. George Adams's directions from drawings which were kindly communicated to him for that purpose by Mr. Taylor. Fig. 4. pl. 19. is a section of one of these pumps, of a simple construction. The piston is represented as descending in a chamber properly adapted to it. At a and b we have a view of Mr. Taylor's pendulum valves; which, from their form, disengage themselves from chips, gravel, sand, &c. The piston is also so contrived, that no chips, gravel, or sand, can get between the leather and lower part of the piston; to both which defects the former constructions were liable. Fig. 7. is a separate view of the pendulum valve.

A pump, working with one piston-rod, is shewn at fig. 3. and at fig. 5. is a pump working with two piston-rods; the one rising as the other falls: in fig. 4. and 5. the rods are supposed to be worked by levers. By a judicious application of ropes, to be carried on either deck, (see fig. 6.) Mr. Taylor is enabled, where men are plenty, as in a man of war, to raise any quantity of water. The drawing is taken from a pump with a seven-inch bore, and heaves one ton per minute twenty-four feet high, with ten men, five only working at a time. One is now constructing by Mr. Taylor to heave five tons per minute twenty-four feet high. The pumps are also so constructed that a copper pump may be taken out of the wooden case, in order, when necessity requires, to make two pumps for separate work.

Hessian Pump.—ABC, DE, fig. 7 and 8. pl. 18, are two tin vessels, soldered together, but communicating with each other by a hole at the bottom. The larger vessel is furnished with a rim, to receive the water thrown up by the circulating tubes,

and convey it into the vessel DE. m, n, o, p, represent four tubes of metal, or glass, open at both ends, but bent at top, and fixed in an angular position to the axis KL. When in their place, the extremity L of the axis rests upon a point at the bottom of the large vessel, while the upper part is steadied, and kept in a vertical position, by passing through a hole in a bar going over the large vessel ABC.

To shew the operation of this pump, fill the vessels about two thirds with water, and then make the tubes circulate rapidly by turning the handle S, and the rotatory centrifugal motion will raise the water, and discharge it into the small vessel DE, by the pipe h.

Vera's Pump.—This is an engine to raise water by means of hair ropes. A and B, fig. 8. pl. 19. are three hair ropes passing over the pulleys b and d, each of which has three grooves. The lower pulley b, is immersed in the water, and is kept therein by a weight suspended from it. These pulleys are turned round with great rapidity by means of two multiplying wheels, one of which is seen at G. By turning the pulleys, the cords revolve also with great rapidity, and the ascending sides carry up a considerable quantity of water, which they discharge with violence into the reservoir H, from whence it is conveyed into any convenient place by the pipe KL. The ropes should not be more than an inch asunder.

At Winds, there are two of these machines. The depth of the well where one of them is fixed is ninety-five feet, and the quantity of water raised by the utmost efforts of a man is about nine gallons per minute.

In the beginning of the motion, the column adhering to the rope is always less than when it has been worked for some time, and continues to increase till the surrounding air partakes of its motion.

SECT. VII. Of Fire Engines.

ENGINES for extinguishing Fire are, in their external figure, their operation, and their uses, too generally known to need a very minute description. They consist either of forcing or lifting-pumps; and being made to raise water with great velocity, their execution in great measure depends upon the length of their levers, and the force wherewith they are wrought.

Before the present improvements took place in these inventions, the attempts to extinguish fires were made with the common squirting fire engine; which consists of the frame of a lifting-pump, wrought by levers acting always together. During the stroke, the quantity of water raised by the piston in these engines spouts with force through a pipe made capable of any degree of elevation by means of a yielding leather neck, or by a ball and socket, capable of turning every way, screwed on the top of the pump. Between the strokes on this machine the stream is discontinued. The engine is supplied by water poured in with buckets above; the dirt and filth whereof are kept from choking the pump-work by the help of a strainer.

A considerable improvement afterwards was made in these machines in order to keep them discharging a continual stream. In doing which it is not to be understood that they really throw out more water than do the squirting ones of the same size and dimensions; but that the velocity of the water, and of course the friction of all the parts, being less violent, the stream is more even and manageable, and may be directed hither or thither with greater ease and certainty than if it come forth only by fits and starts. The machine, thus improved, is therefore generally better adapted to the purpose intended than the former, especially in the beginning of the conflagration.

In the engine we now speak of, the stream is made continual from the spring of air confined in a strong metal vessel fixed between two forcing-pumps, wrought with a common double lever moving on a centre. The pistons both suck and force alternately, and have their respective valves in proper situations.

The water to supply this engine, if there be no opportunity of putting the end of a sucking pipe, occasionally to be screwed on, into a moat or canal, which would spare much hurry and labour in case of fire, is poured into the body of the machine; and being strained through a wire grate, is, by the pressure of the atmosphere, raised through the valves into the barrels, when either of their foreers ascend; whence again it is powerfully pushed forth, when they descend, into the air-vessel through the valves by turns: by the force whereof the common air between the water and the top of the air-vessel becomes from time to time forcibly crowded into less room, and much compressed; and the air being a body naturally endowed with a strong and lively spring, and always endeavouring to dilate itself every way alike in such circumstances, bears strongly both against the sides of the vessel wherein it is confined, and the surface of the water thus injected; and so makes a constant regular stream to rise through the metal pipe, which may be led about into rooms and entries, as the case may require.

Should the air contained in this vessel be compressed into half the space it took up in its natural state, the spring thereof will be much about doubled; and as before it equalled and was able to sustain the pressure of a single atmosphere, it having now a double force, by the power of that spring alone will throw water into air, of the common degree of density, about thirty feet high. And should this compression be still augmented, and the quantity of air which at first filled the whole vessel be reduced into one-third of that space, its spring will be then able to resist, and consequently to raise the weight of a treble atmosphere; in which case, it will throw up a jet of water sixty feet high. And should so much water again be forced into the vessel as to fill three parts of the capacity, it will be able to throw it up about ninety-feet high: and wherever the service shall require a still greater rise of water, more water must be forced into this vessel; and the air therein being thus driven by main force into a still narrower compass, at each explosion, the gradual restitution thereof to its first dimensions is what regularly carries on the stream between the strokes, and renders it continual during the operation of the machine.

But the improvements made on fire-engines have been so considerable, as to render either of the former little worthy of notice. To describe each, however, would require an unreasonable extension of this section; and for this reason, though all may have their degrees of merit, we shall confine ourselves to the description of the engine invented by Rowntree and Co. in Black-Friars Road, London, which is certainly the best on many accounts.

Fig. 1, in plate 20, presents an end view of the working part of this engine, supposing the engine cut down the middle. A is a metal cylinder. B a piston or plunger acting in a circular direction by means of the levers CC, fixed upon the ends of its axis. DD, the lower valve boxes on the outside the cylinder, with each a valve EE. These boxes are large, and so constructed as to prevent the metal cylinder being clogged up with gravel, sand, or other dirt, which frequently is the cause of other engines being useless after working a short time. These boxes have each a clack door on the outside, which screws off for the convenience of taking out the gravel, sand, or other dirt which may have collected there; by which means the engine is always kept in a working state.

These clack-doors are shewn at A, fig. 2. E the upper box with its valves FF. G the air-vessel. H the discharge pipe, and I the pipe that conveys the water to the engine, commonly called the suction pipe.

Fig. 3 represents a side view of the working parts. A the metal cylinder. B the piston and axle. F the upper valve box. HH the discharge pipes covered with caps KK, which screw off when the engine is played, and the leather pipes and branches are screwed on. G the air-vessel. II the suction

pipe. L, L, L, L, springs fixed to the side of the wood cistern.

Fig. 4 is a perpendicular view, where AA represents the cylinder. B the piston and axle. D, D the valve boxes. C, C, C, C, C, C, C, C, the levers fixed on the piston-axle, and connected by the bars PP. OO bearings for the axle of the piston.

At fig. 2 the engine is shown in profile with its handle, &c. ready for working. M a wooden cistern. L, L, L, L, four springs firmly fixed to the sides of the cistern, on which the levers C, C, C, C, C, C, C, C, strike. In working, these springs help to return the stroke, so that the arms of the men employed are effectually relieved from that heavy shock attendant on the use of all other engines. P the bars which connect the levers C, C, C, &c. and at a small distance from which the wooden handles N, N are fixed. K, K the caps on the discharging pipes, which are to be taken off to fix the leather-pipe or branches on, when the engine is to be put in action.

This engine has been proved, to the satisfaction of the best judges, to be, in point of simplicity and execution, the most complete machine for extinguishing fires ever yet invented; and has accordingly been adopted, in preference to all others, by the principal fire-offices in London.

SECT. VIII. *Improvements of the Common Pump.*

IN the year 1766 it was announced in the public papers, that at Seville in Spain, a simple sucking pump had been constructed, which raised water sixty feet; and they concluded from thence, that those were strangely deceived who had asserted that the pressure of the atmosphere would not support a higher column than thirty-two feet. On examination it was found, that an ignorant tin-man at Seville had made a common sucking pipe with its lower valve sixty feet from the surface of the water; but finding he could raise no water by it, either through impatience or passion, with a stroke of a hatchet he made a small opening about ten feet above the surface of the water, and which forced a small quantity of water above the lower valve; the reason of which we shall explain by a diagram. See fig. 1. plate 19.

Suppose PF the sucking tube, d the surface of the water, from d to F sixty feet; and that after a certain number of strokes of the piston, the water was raised thirty-two feet in the tube, or to c; and that then a small hole was made at ten feet from the surface of the water. The air which enters this pressing equally every way, makes the water which is below b fall down into the well; while the pressure upwards forces the water up thirty-two feet through the valve into the body of the pump. But this is not all, for it would have carried it to a much greater height; for the air near the earth is above eight hundred times rarer, or less dense, than water; and supposing the density of a column thereof to be uniform (which is not the case), ten feet of water taken away would be equivalent to a column of eight thousand feet of air; so that the remaining twenty-two feet would be in equilibrium with the air, after being raised eight thousand feet. To have a second portion of water, the hole b must be stopped up, and the piston worked till the water rises to c, and then re-open the hole. In the first place we see, that this pretended discovery is so far from invalidating the principle of the pressure of the air, that it is a direct consequence thereof; secondly, that even to make it answer at all, it is necessary that the pipe be very small, or the column of water would be broken to pieces, the air would pass through, and very little would rise.

But a real improvement of the common pump has been made by Mr. Todd of Hull. This invention in some particulars bears a resemblance to the ordinary one, but he has contrived to double its powers by the following means:

Having prepared the piston cylinder, which may be twelve feet high, he cuts from the bottom thereof about three feet;

at the end of the great cylinder he places an atmospheric valve, and to the top of the small cylinder a serving valve. In the bottom of the small cylinder, which contains the serving valve, is inserted an oblong elliptical curved tube, of equal calibre with the principal cylinder, and the other end is again inserted in the top of the great cylinder. This tube is divided in the same manner as the first cylinder, with atmospheric and serving valves, exactly parallel with the valves of the first cylinder. The pump, thus having double valves, produces double effects, which effects may be still farther increased by extending the dimensions.

The cylinder is screwed for service on a male tube-screw, which projects from the side of a reservoir or water cistern, and is worked by hand.

The piston-plunger is worked by a toothed segment-wheel, similar to the principle of the one used in working the chain-pumps of ships belonging to the royal navy (see pl. 20.); and the wheel receives motion from a hand-winch, which is considerably accelerated by a fly-wheel of variable dimensions, at the opposite end.

This pump, in addition to its increased powers, possesses another very great and prominent advantage. By screwing to it the long leather tube and fire-pipe of the common engine, it is in a few minutes converted into an effective fire-engine. Hence, whoever possesses one may be said to have a convenient domestic apparatus against fire. Three men can work it; one to turn the winch, another to direct the fire-pipe, and a third to supply the water.

SECT. IX. *Of the Motion of Water in Conduit Pipes.*

In conducting water from one place to another, the conduit-pipes must be longer in proportion as the places to which it is to be conveyed are more distant from each other. In the additional tubes heretofore spoken of, we took no notice of *friction*, as in the cases then under consideration it was scarcely sensible. In long tubes, however, it is different; for the friction of these lessens considerably the velocity of the water.

On this part of our subject, all that is necessary is to relate the result of the various experiments that have been made. In those of M. Bossut, the tubes were straight; one of them was sixteen lines inside diameter, the other two inches; and the tubes were successively lengthened from thirty to an hundred and eighty feet. The constant altitude of the water in the reservoir, above the axis of each tube, was in some cases one foot, in other cases two feet. This is a branch of hydrostatics, in which theory is necessarily imperfect, and the only means of arriving at truth must be from experiment.

Constant altitude of the water in the reservoir above the axis of the tube, expressed in it.	Distance to which the water was conveyed, expressed in it.	No. of cubic inches of water discharged by the tube of 16 lines diameter in a minute.	No. of cubic inches of water discharged by the tube of two inches diameter in a minute.
1	30	2778	7680
1	60	1957	5564
1	90	1587	4534
1	120	1351	3944
1	150	1178	3486
1	180	1052	3119
2	30	4066	11219
2	60	2888	8190
2	90	2352	6812
2	120	2011	5885
2	150	1762	5252
2	180	1583	4710

By comparing this with the table in page 563, it appears that the discharges of water there are much greater than the corresponding ones in the present table, and that the discharge is lessened as the tube is lengthened, because there is a greater surface for friction. We may also notice that the diminution in the discharge is not in proportion to the length of the tube; for the first thirty feet diminishes the discharge much more than the second thirty feet, and the third length of thirty feet diminishes still less in the discharge, and so on.

From these experiments it appears, that great accuracy is not necessary in practice; and perhaps we may adopt for a general rule, 'that the discharges made in equal times by an horizontal tube, with the same altitude of reservoir, but at different distances from the first aperture of the tubes, are to each other nearly in the inverse ratio of the square roots of the distances.' The discharge is more in proportion from the larger tube than from the smaller one; because there is less rubbing surface in proportion in the larger tube.

If the tubes are curved, instead of being straight, the discharge will be somewhat diminished. This diminution in the discharge appears to arise from the impact of the water against the angular parts of the tube, whereby its velocity is diminished. This diminution will therefore vary with the degree of curvature.

When the plane of the curvature of the tube is in a vertical direction, there will be portions of the tube where the air will fix itself, so as to lessen the velocity, or even stop the course of the water. Let ABCDE, fig. 9. pl. 18. be a tube, whose upper end A is joined to the reservoir that furnishes the water, G the end by which the fountain is supplied. When the communication at A is opened, the tube is filled with air; the water will fill the tube AB, drive out the air, and rise to C. Here experience has shewn, that the water runs down the lower part of the curvature, and fills up the neck D, leaving behind it the column of air CD; which will remain there, notwithstanding the pressure of the column of air AB. The water continuing to flow, runs down the lower part of EF, and fills the neck F, leaving the second column of air at EE; so that the water will be only raised to I, and will not run out at G.

SECT. X. *Of the Syphon.*

A SYPHON is an instrument used to decant fluids, or convey them from one place, over an obstacle that is higher than their surface, to another that is lower. Its form is exceeding simple, being nothing more than a crooked tube, one extremity of which descends lower than the other. Its effects are accounted for from the gravitation of fluids of different weights, one upon another.

If one leg of a syphon be immersed in a vessel of water, and the other leg hang out of it, in such manner that the lower end be below the surface of the water; on opening both the orifices at the same instant, the water will be found to flow out at the lower orifice, till its surface has sunk down to the orifice of the leg in the water.

Now, on examining this experiment, you will find, that the columns of air pressing on the two equal orifices differ from each other in length only by the *perpendicular distance between the surface of the water, and the horizontal plane of the lower orifice of the syphon*; which space, compared with the whole height of the atmosphere, is too inconsiderable to be taken into the account; and we may therefore conclude, that the action of the atmosphere on both the orifices is *equal*.

Now, as we supposed the tubes full of water when the holes are first opened, these *equal* pressures of the atmosphere will be counteracted by the weight of two *different* columns of water; one in the shorter, the other in the longer leg of the syphon. The difference of the force of these counteracting pressures is equal to the weight of a column of water whose base is equal to

the diameter of the tube, and whose height is equal to the perpendicular height of the surface of the water from the orifice of the longer leg. Now equal pressures of the atmosphere will be counteracted by unequal forces of gravitating waters, which will make the opposite pressures of the vertex unequal: and as the superior weight of the longer column carries it downwards, there is less pressure on that side of the vertex; the water will be pressed forwards, and continue to flow till the water be fallen to the bottom of the immersed leg, or (if it be the longer leg) as low as the end of the flowing one; for the descent of the water in the longer leg, by its own gravity, would leave a vacuum in the tube, if not immediately succeeded by other water. This descent gives the atmosphere, which urges the water up the syphon, the same power to act as if it were not at all opposed at the issuing orifice.

For the same reason that the atmosphere urges the water in the vessel *after* that which descends, it would fill the whole syphon, provided it were void of air; and by sucking the air out of the smaller kind of these instruments with the mouth, through a pipe placed for that purpose by the side of the issuing leg, they are easily set a-running. In larger syphons, for the draining of pits, quarries, &c. the evacuation is effected by a pump placed in like manner at the issuing end.

The Distiller's Syphon.—This is usually about an inch in diameter, and three feet in length, with a cock fixed into the issuing end. To use it, the cock is shut, and the contrary end is put into the bung-hole, till the liquor reach within about five or six inches of the bend. Then, on opening the cock pretty quickly, the contents flow out of the syphon in the usual manner. By the immersion of the drawing leg, the liquor is prevented by the pent-up air from rising as high within the syphon as it is on the outside. On opening the cock, the ambient fluid obtains power to raise that within the tube to its own level; but, by a law already explained, the contained liquor, before it rises as high as that of the other, will have acquired a velocity nearly sufficient to carry it as much above that surface as it was before below it. Hence the fluid shoots over the bend; and there falling into a tube with a contracted orifice, the syphon is soon filled, and of course continues to flow. See pl. 17.

Gravesande's Syphon.—This is a syphon for raising water into a cistern by means of the expenditure of other water through the outer leg, and may be applied to many cases where water, &c. is to be raised ten or twenty feet, and where you have at the same time water sufficient to supply the lower reservoir. This syphon has been lately much improved by a very ingenious gentleman. See Gravesande's Elements of Philosophy, vol. i. p. 235.

Several entertaining deceptions have been practised by means of the Syphon. One of the most usual is that of *Tantalus's Cup*, a view of which we have given in pl. 17, but the explanation of which is not necessary here, as its operation will be evident at the first view. It is usual to conceal the syphon in the figure of a man, representing Tantalus; and when the cup is filled with water as high as his mouth, that is, a little above the curve of the syphon, the latter beginning to act at length discharges the whole contents of the cup. Similar deceptions have been practised by concealing the syphon in the handle of a drinking vessel.

We shall conclude this part of our subject with some account of a *Clepsydra* invented by Mr. C. Hamilton, and depending on the action of syphons. See in pl. 20 a view of this machine, to which the following explanation is applicable.

An open canal *ee*, supplied with a constant and equal stream by the syphon *d*, has at each end, *f, f*, open pipes of exactly equal bores, which deliver the water that runs along the canal *e*, alternately into the vessel, *g 1, g 2*, in such a quantity as to raise the water from the mouth of the tantalus *t* exactly in an hour. The canal *ee* is equally poised by the two pipes *f 1, f 2*, upon

a centre *r*; the ends of the canal *e* are raised alternately, as the cups *zz* are depressed, to which they are connected by lines running over the pulleys *l, l*. The cups *zz* are fixed at each end of the balance *mm*, which moves up and down upon its centre *v*: *n 1, n 2*, are the edges of two wheels or pulleys, moving different ways alternately, and fitted to the cylinder *o* by oblique teeth both in the cavity of the wheel and upon the cylinder, which, when the wheel *n* moves one way, that is, in the direction of the minute hand, meet the teeth of the cylinder and carry the cylinder with it; and when *n* moves the contrary way, slip over those of the cylinder, the teeth not meeting, but receding from each other. One or other of these wheels *nn* continually moves *o* in the same direction, with an equable and uninterrupted motion. A fine chain goes twice round each wheel, having at one end a weight *x*, always out of water, which equiperates with *y* at the other end, when kept floating on the surface of the water in the vessel *g*, which *y* must always be; the two cups *z, z*, one at each end of the balance, keep it in equilibrio, till one of them is forced down by the weight and impulse of the water, which it receives from the tantalus *tti*: each of these cups *z, z*, has likewise a tantalus of its own *bb*, which empties it after the water has done running from *g*, and leaves the two cups again in equilibrio: *q* is a drain to carry off the water. The dial-plate, &c. needs no description. The motion of the *clepsydra* is effected thus: As the end of the canal *ee*, fixed to the pipe *f 1*, is, in the figure, the lowest, all the water supplied by the syphon runs through the pipe *f 1*, into the vessel *g 1*, till it runs over the top of the tantalus *t*; when it immediately runs out at *i* into the cup *z*, at the end of the balance *m*, and forces it down; the balance moving on its centre *v*. When one side of *m* is brought down, the string which connects it to *f 1*, running over the pulley *l*, raises the end *f 1* of the canal *e*, which turns upon its centre *r*, higher than *f 2*; consequently, all the water which runs through the syphon *d* passes through *f 2* into *g 2* till the same operation is performed in that vessel, and so on alternately. As the height the water rises in *g* in an hour, viz. from *s* to *t*, is equal to the circumference of *n*, the float *y* rising through that height along with the water, lets the weight *x* act upon the pulley *n*, which carries with it the cylinder *o*; and this, making a revolution, causes the index *k* to describe an hour on the dial-plate. This revolution is performed by the pulley *n 1*; the next is performed by *n 2*, whilst *n 1* goes back as the water in *g 1* runs out through the tantalus; for *y* must follow the water, as its weight increases out of it. The axis *o* always keeps moving the same way; the index *p* describes the minutes; each tantalus must be wider than the syphon, that the vessels *g g* may be emptied as low as *s*, before the water returns to them. See drawings of this instrument in different positions, with a description in the Philosophical Transactions.

SECT. XI. Of the Vibratory Motion of Water in a Syphon.

It is a known fact in Mechanics, that the vibrations of a pendulum are isochrone, or of the same duration, though the arches it describes are unequal. It is also acknowledged, that in their duration, the vibrations of two unequal pendulums are to each other as the square root of their respective lengths. The motion of water vibrating in a syphon follows the same laws.

To illustrate this, let us suppose *l, o o m*, to be a syphon consisting of three parts, or legs; two, *ln, mo*, vertical, and one, *no*, horizontal; and that it be of an equal diameter throughout its whole extent. Let us further suppose, that the fluid, while at rest, occupies the space *anod*, the two surfaces, *ab, cd*, will be level. Now if by any means the fluid be forced to descend to *gb* in the leg *no*, it will rise to *ef* in the leg *ln*; and as soon as this cause ceases to act, the fluid is left alone to the action of its gravity. The excess in length of the column *ez*

over the column ba , will force the fluid to descend even below the level of the other, on account of the acceleration it acquires in descending, which will raise the fluid in the other leg; and it will thus continue rising and falling alternately, forming oscillations similar to those of a pendulum; and the duration of each vibration will be precisely the same as the vibration of a pendulum whose length is half the length of the column pqr of the fluid.

As the oscillations of water follow the same laws as those of a pendulum, if the length of the column of water is increased or diminished, the duration of the oscillations will be also augmented and diminished, and will be in a subduplicate ratio of this length.

SECT. XII. *Of the Oscillatory Motion of Waves.*

THE great *Newton*, in his *Principia*, compares the undulatory motion of waves to the vibratory one of water in a syphon. Let $ABCDEF$, fig. 10, pl. 18, represent a stagnant water, whose surface is elevated and depressed by successive waves. Let A, C, E , be the convex, and B, D, F , the concave part of the waves. As waves are formed by the successive ascent and descent of the water, so that those parts which were the highest become the lowest alternately and successively; and as the moving force which makes the lowest parts rise, and the highest sink, is the weight of the elevated water, this ascent and descent may be considered as analogous to the vibratory motion of water in a syphon, and observes the same laws.

If, therefore, we have a pendulum, whose length is equal to half the transversal distance between the most convex point A , and the most concave point B , that is, equal to the half of Ab ; the highest part will become the lowest during the vibration of such a pendulum, and in another vibration they will become the highest, going through its whole space while the pendulum performs two vibrations. And as a pendulum whose length is quadruple the preceding one, that is, which is equal to the width AC of the waves, would perform but one vibration while the other performed two, we conclude that the waves perform their vibrations in the same time as a pendulum whose length is equal to the breadth of the waves.

From hence it follows, that a wave, whose breadth is 3 feet $8\frac{1}{8}$ lines broad, by advancing its whole breadth in one second, would in a minute describe 183 feet 6 inches 10 lines; and in an hour, 11014 feet 2 inches. If the breadth was quadruple, it would describe the breadth in double the time; consequently the broader they are, the greater space they describe in a given time.

In this view of the subject, we have assumed that the waves rose and fell in straight lines; but this is not exactly true, and consequently the deductions can only be considered as approximations towards the truth.

SECT. XIII. *Of the Resistance of Fluids.*

ONE of the most important problems in hydrostatics, is to determine the resistance that a body in motion meets from a fluid at rest; and to know the effort necessary to keep a body at rest in a fluid in motion. Water and air are two of the great inanimate agents in nature, and they are those which man renders most easily subservient to his purposes. Necessity first pointed out the use of these agents, and engaged him to investigate their properties. In this respect, however, much of his labour has been spent in vain; particularly that which has been employed in the resolution of the above-mentioned problems. These have hitherto evaded every research, though they have engaged the attention, and exercised the talents, of the greatest mathematicians in Europe. It has been shewn, by many instances, that the philosophy of the *ancients* was neither so unreasonable, nor so limited, as it has often been represented. It does not, how-

ever, appear, that they were well versed in the science that is termed *mixed mathematics*, or mathematical philosophy; a science which consists in the application of calculation to the phenomena of nature. Among the branches of this science which they have the least studied, we may reckon that of the resistance of fluids; for we must confess, that they had obtained some knowledge thereof, as it was necessary for the construction of their ships, the principles of building which they had carried further than the moderns.

Modern mathematicians have imagined themselves able to discover the motions, and penetrate into the elements of bodies, by the aid of geometry and calculation. By the assistance of these alone they conceived it was possible to investigate the nature of fluids, discover the working of the parts, and the action of those innumerable particles which go to constitute a fluid; particles which, at the same time, are, as it were, united and separated, dependent and independent one of the other. Notwithstanding, however, the aid of geometry, and the fluxionary process, they have made little or no progress in the knowledge of the resistance of fluids. The desire of using calculation has determined their principles; whereas their first business should have been to have examined these principles by experiment and observation, instead of bending and twisting experiments to make them subservient to the powers of calculation.

Sir Isaac Newton, to whom philosophy and geometry are so much indebted, was the first who undertook to determine, on mechanical principles, the resistance a body meets with when moving in a fluid medium. Unfortunately for science his labours were not successful. His first theory consists of ingenious researches, that may awaken curiosity, but which are not applicable to nature; his second, though more conformable to the nature of fluids, is too complicated, and subjected to too many difficulties, to be reduced to practice.

Since his time, many able geometricians have endeavoured to render this theory more perfect; among these we are to reckon Bernouilli, D'Alembert, and Euler, who have made upon this subject the most profound researches, but which are too complicated for practice. New experiments were afterwards made by these gentlemen, which were so far from according with the theory, that they contradicted some of its most important rules. M. Bossut and Borda endeavoured in vain to solve these difficulties, and remove these contradictions.

In the year 1775 Messrs. D'Alembert, Condorcet, and Bossut, instituted, by order of government, a set of experiments on the impact of fluids, which they have published in a work on that subject: after a number of experiments, they were obliged to confess, that the generally received theory was found to be essentially defective. The importance of this subject is so great, that there is little room to doubt, that the society lately established for promoting the branches of science relative to naval affairs, will find means to extricate this part from its present opprobrious state. But though the theory delivered by Sir I. Newton is confessedly imperfect, as another and more perfect one has not been established, it will be necessary in this place to give a short account of its principles.

A body cannot move forward in water or any other fluid, without removing the parts of the fluid which lie before it out of the way; but as these particles possess that general property of matter which is called their inertia, this resistance will be made by the most perfect as well as the most imperfect fluid, by air as well as by liquid honey. For, if a body move in a fluid, it must give motion to a certain quantity of that fluid, and the reaction of that quantity will destroy part of the motion of that body. But by displacing the fluid, and communicating motion, it loses an equal quantity of its own motion, from whence we obtain some idea of the resistance of the fluid: much here will, however, depend on the form, magnitude, &c. of the moving body,

and the velocity of its motion; for a greater body will displace a greater quantity of the fluid than a smaller one, every thing else being the same; and the greater the velocity wherewith a body moves in a fluid, the more motion will be communicated thereto, and consequently lost to the body.

There is another cause of resistance which arises from the tenacity of the parts of a fluid; for, as a body cannot move forward in a fluid till the parts that lie before it are removed out of the way, the adhesion or tenacity must necessarily resist its motion. There is a third cause of resistance, that is, the friction of the body against the particles of a fluid; but this, from the nature of fluids, is deemed to be very inconsiderable. The resistance will also depend on the fluid's density, every thing else being the same; for it is manifest, that it will require more force to displace a given quantity of mercury than the same quantity of water, and a quantity of water than an equal quantity of air.

But the principal resistance which fluids give to bodies in motion is supposed to arise from the inertia of their parts, and this depends on the *velocity of the moving body*, and that for two reasons. In the first place, the quantity of fluid moved out of its place, in any determinate space of time, must be greater in proportion as the body moves with greater velocity through the fluid. And, in the next place, the velocity with which each particle of the fluid is moved, will also be proportional to the velocity of the body; for it communicates a greater or less quantity of motion to each particle in proportion to the velocity of its motion, and will therefore be resisted on this account also in the proportion of the velocity. Since the resistance which any body makes against being put in motion, is proportional both to the quantity of matter moved, and the velocity it is moved with; but as the resistance of a fluid is as the velocity of the body moving therein, it will be doubly increased, 1. Because the number of particles moved is as the velocity of the moving body. 2. Because the resistance arising from a given number of particles is also as the velocity of the moving body. Therefore the resistance is considered as being in a duplicate proportion of the velocity of a moving body, or as the square thereof.

A cylinder moving in a fluid, in the direction of its axis, is resisted by a force equal to the weight of a column of a fluid, the base of which is the base of the cylinder, and altitude equal to the space through which a body must fall freely from rest to acquire the velocity of the cylinder's motion. A sphere moving in a fluid is opposed by a resistance, which is to the force which resists a cylinder moving in the direction of its axis with the same velocity, in the proportion of 1 to 2.

Two suppositions are generally taken for granted, in proving the propositions on the resistance of fluids: 1. That the fluid in which the body moves is so compressed, that its pressure on every part of the moving bodies shall be the same as when they are at rest. 2. That the hinder part of the solids contribute nothing to the resistance, which will be the same as if the anterior part only were exposed to the fluid. This last supposition is not admissible, for the hinder part of most solids contributes to lessen the resistance by the power it receives from the returning curves of the fluid.

The theory of resistances opposed to bodies moving in perfect fluids, could not even be demonstrated by Sir I. Newton but under certain conditions and restrictions. 1. The particles of fluid wherein the bodies move are supposed to be perfectly non-elastic. 2. The fluid is imagined to be infinitely compressed. The second condition is allowed not to obtain in any fluid whatsoever, and it is doubted whether the first is strictly applicable even to the most perfect known fluids.

It is certain that the resistance of fluids depends on the cohesion, tenacity, and friction, as well as the inertia of the matter moved; but the illustrious author of the theory here slightly touched upon considered the geometrical estimation of these

circumstances as of no use in physical inquiries. He therefore chiefly noticed the properties of retardation, which bodies suffer when moving through fluids, the cohesion and friction among whose parts were in a physical sense evanescent.

The doctrine of hydrostatics and hydraulics, like every other part of philosophy, serves to shew the weakness and imperfection of human knowledge, and how ignorant we are even of those subjects in which we are deeply interested, and with which we are continually engaged. It also shews us how long human ingenuity may be exercised, without improving the science on which it is exercised. In every other part of natural science new discoveries are made, and new phenomena are brought to view, which enlarge the boundaries of knowledge, though they convince us of greater objects and numerous phenomena that remain concealed from our observation; but in hydrostatics and hydraulics, little that is new has been discovered, and a general shade of ignorance seems to be cast over the whole science.

SECT. XIV. *Of a New Principle in Hydraulics.*

IN Vol. VI. of the Repository, there is given a specification of the Patent granted to Mr. JOHN RICHMOND, of London, for his discovery of the application of a principle in Hydraulics, suitable to an Hydraulic Machine which he invented for raising water, from all depths, out of mines, pits, or wells, and for other purposes.

He says, "The machine or engine is to consist of three working pumps, tubes, or barrels, of any size and diameter that may be found most convenient for use, and suitable to the purpose and situation of the place where they may be wanted. These are to be joined together as pumps usually are, or in any manner found most convenient to keep them firm and tight in an upright position. But the upper and lower pumps, tubes, or barrels, are to be of equal bores, and the middle one is to be of a diameter that shall contain a larger quantity of water, in any given length of pipe, than what either of the other two can contain, even to double the quantity, or more, and is to be open at top, so as to admit of a free passage for air, notwithstanding its junction with the upper pump, tube, or barrel, by means of a hollow trumpet-tube hereinafter mentioned; but it is to be close at the bottom, where it joins the lower pump, tube, or barrel, excepting a hole to be left for the pump-rod to pass through. By this means, the hydrostatic paradox is introduced to act upon the bottom part of a hollow tube, which is to be worked within the upper and middle pump, tube, or barrel, and to be of a length sufficient to make the full stroke of the engine, of whatsoever length it may be; with its lower end of a diameter sufficient to fill the bore of the middle pump, tube, or barrel, and its upper end to fill the bore of the upper pump, tube, or barrel, in the form of a trumpet, or any such-like form, in order to admit the motion up and down to the full extent of the engine's stroke, and to receive the pressure of the water underneath on its expanded bottom; which may be opened and shut with a valve, or not, as may be found most beneficial. From the middle pump, or tube, to the lower one, a communication is to be made by a hole, as before mentioned, through which the pump-rod is to pass, connected with the aforesaid movable tube, and to be fixed to a movable bucket and valve, which is to be worked in the lower pump, tube, or barrel; the lower end of which pump, tube, or barrel, is to be immersed in the water, and to have a fixed box, and a valve, in the like manner as other pumps have, for the purpose of lifting water. The pump-rod, which is to be carried through the upper pump, tube, or barrel, to the top of the pit or well, or to the ends of the pumps, tubes, or barrels, for the purpose of working the machine, either by fire, water, wind, horse, man's labour, or other motive force, is to be connected with the movable tube before mentioned, so as to lift it up and down, to make a stroke

of the machine. To the three pumps, tubes, or barrels, before mentioned, is to be added a lateral pump, tube, or barrel, of the same bore as the upper and lower pumps, tubes, or barrels, and to communicate with them by a junction at each end. One end is to open into the lower pump, tube, or barrel, just above the stroke of the bucket which draws the water from below, and the other end is to open into the upper pump, tube, or barrel, just above the stroke of the moveable tube before mentioned; by which means the water drawn at every stroke of the machine, from the lower pump, tube, or barrel, through the lateral pump, tube, or barrel, is carried into the pumps, tubes, or barrels, that may be added above, to discharge the water to any height. But, in order to procure the counterbalance of water which is the object of this invention, or of weights equal thereto, to act with the advantage of the hydrostatic paradox, or by any means to assist the lift of the pump by a counterbalance of the water contained therein, there must be a horizontal tube of communication between the said middle pump, tube, or barrel, and another upright pump, tube, or barrel, of the same

dimensions and bore as the middle pump, tube, or barrel, before mentioned; and such upright pump, tube, or barrel, is also to be connected with other pipes, &c. in like manner as before described, when the machinery is to be worked by double pumps, which in deep mines may be the most effectual manner of working; but, if by single pumps, weights must be added on the surface of the water in the upright pump, tube, or barrel, joined as before mentioned, till they shall balance the whole column of the water, in like manner as if pumps, tubes, or barrels, were carried to a level of the other pumps, tubes, or barrels, to form the machinery of working with double pumps. In constructing the double pumps, there may be a horizontal tube of communication between the two upper pumps, tubes, or barrels, a little above the highest ascent of the movable middle tube in each pump."

We shall take leave of our subject by apprising the reader, that such hydraulic and hydrostatic inventions as are not noticed here will be described under their several articles.

H Y G

HYDROTHORAX, a collection of water in the breast. See MEDICINE.

HYDRUNTUM, in ancient geography, a noble and commodious port of Calabria, from which there was a shorter passage to Apollonia (Pliny). Famous for its antiquity, and for the fidelity and bravery of its inhabitants. Now Otranto, a city of Naples, at the entrance of the gulph of Venice. E. lon. 19. 15. N. lat. 40. 12.

HYEMANTES, in the primitive church, offenders who had been guilty of such enormities, that they were not allowed to enter the porch of the churches with the other penitents, but were obliged to stand without, exposed to all the inclemency of the weather.

HYGEIA, in mythology. See HEALTH.

HYGIEINE, Ἑγίεινη, formed of ὑγιής, "sound, healthy," that branch of medicine which considers health, and discovers proper means and remedies, with their use, in the preservation of that state. The objects of this branch of medicine are, the non-naturals. See DIET, EXERCISE, &c. The term Hygieine, more largely taken, is divided into three parts; prophylactice, which foresees and prevents diseases; syneritice, employed in preserving health; and analeptice, whose office is to cure diseases, and restore health.

HYGINUS (CAIUS JULIUS), a grammarian, the freedman of Augustus, and the friend of Ovid, was born in Spain, or, according to others, in Alexandria. He wrote many books which are mentioned by ancient authors; all of which are lost, except some fables, and a work entitled *Astronomicum Poeticum*; and even these are come down to us very imperfect. The best edition of these remains is that of Munker, published with some other pieces of antiquity in 2 vols. 8vo. 1681, under the title of *Mythographi Latini*.

HYGROMETER, or HYGROSCOPE, or NOTIOMETER, an instrument for measuring the degrees of moisture in the air. There are various kinds of Hygrometers; for whatever body either swells by moisture, or shrinks by dryness, is capable of being formed into an Hygrometer. Such are woods of most kinds, particularly deal, ash, poplar, &c. Such also is catgut, the beard of a wild oat, and twisted cord, &c. The best and most usual contrivances for this purpose are as follow:

1. Stretch a common cord, or a fiddle-string, ABD (pl. 12, fig. 1.) along a wall, passing it over a pulley B; fixing it at one end A, and to the other end hanging a weight E, carrying a

style or index F. Against the same wall fit a plate of metal HI, graduated, or divided into any number of equal parts; and the Hygrometer is complete.

For it is matter of constant observation, that moisture sensibly shortens cords and strings; and that, as the moisture evaporates, they return to their former length again. The like may be said of a fiddle-string: and from hence it happens that such strings are apt to break in damp weather, if they are not slackened by the screws of the violin. Hence it follows, that the weight E will ascend when the air is more moist, and descend again when it becomes drier. By which means the index F will be carried up and down, and, by pointing to the several divisions on the scale, will shew the degrees of moisture or dryness.

2. Or, for a more sensible and accurate Hygrometer; strain a whipcord, or catgut, over several pulleys B, C, D, E, F, fig. 2. and proceed as before for the rest of the construction. Nor does it matter whether the several parts of the cord be parallel to the horizon, as expressed in the annexed figure, or perpendicular to the same, or in any other position; the advantage of this over the former method being merely the having a greater length of cord in the same compass; for the longer the cord, the greater is the contraction and dilatation, and consequently the degrees of variation of the index over the scale, for any given change of moisture in the air.

3. Or you may fasten a twisted cord, or fiddle string, AB, fig. 3, by one end at A, sustaining a weight at B, carrying an index C round a circular scale DE described on a horizontal board or table. For a cord or catgut twists itself as it moistens, and untwists again as it dries. Hence, upon an increase or decrease of the humidity of the air, the index will shew the quantity of twisting or untwisting, and consequently the increase or decrease of moisture or dryness.

4. Those Dutch toys, called weather houses, where a small image of a man, and one of a woman, are fixed upon the ends of an index, are constructed upon this principle. For the index, being sustained by a cord or twisted catgut, turns backwards and forwards, bringing out the man in wet weather, and the woman in dry.

5. Fasten one end of a cord, or catgut, AB, fig. 4, to a hook at A; and to the other end a ball D of about one pound weight; upon which draw two concentric circles, and divide them into any number of equal parts, for a scale; then fit a style or index EC into a proper support at E, so as the extremity C may al-

most touch the divisions of the ball.—Here the cord twisting or untwisting, as in the former case, will indicate the change of moisture, by the successive application of the divisions of the circular scale, as the ball turns round, to the index C.

6. Or an Hygrometer may be made of the thin boards of ash or fir, by their swelling or contracting. But this, and all the other kinds of this instrument, above described, become in time sensibly less and less accurate; till at last they lose their effect entirely, and suffer no alteration from the weather. But the following sort is much more durable, serving for many years with tolerable accuracy. To the extremity of the balance, fig. 5, fix at E a sponge, or other body, that easily imbibes moisture. To prepare the sponge, it may be proper first to wash it in water very clean; and, when dry again, in water or vinegar in which there has been dissolved sal ammoniac, or salt of tartar; after which let it dry again.—Now, if the air become moist, the sponge will imbibe it and grow heavier, and consequently will preponderate, and turn the index towards C; on the contrary, when the air becomes drier, the sponge becomes lighter, and the index turns towards A; thus shewing the state of the air.

7. In the last-mentioned Hygrometer, Mr. Gould, in the *Philos. Transf.* instead of a sponge, recommends oil of vitriol, which grows sensibly lighter or heavier from the degrees of moisture in the air; so that being saturated in the moistest weather, if afterwards retains or loses its acquired weight, as the air proves more or less moist. The alteration in this liquor is so great, that in the space of 57 days it has been known to change its weight from 3 drachms to 9; and has shifted a tongue or index of a balance 30 degrees. So that in this way a pair of scales may afford a very nice Hygrometer. The same author suggests, that oil of sulphur or campanam, or oil of tartar per deliquium, or the liquor of fixed nitre, might be used instead of the oil of vitriol.

This balance may be contrived in two ways; by either having the pin in the middle of the beam, with a slender tongue a foot and a half long, pointing to the divisions on an arched plate, as represented in the last figure above. Or the scale with the liquor may be hung to the point of the beam near the pin, and the other extremity made so long, as to describe a large arch on a board placed for the purpose; as in 6.

8. Mr. Arderon has proposed some improvement in the Sponge Hygrometer. He directs the sponge A (fig. 7.) to be so cut, as to contain as large a superficies as possible, and to hang by a fine thread of silk upon the beam of a balance B, and exactly balanced on the other side by another thread of silk at D, strung with the smallest lead shot, at equal distances, so adjusted as to cause an index E to point at G, the middle of a graduated arch FGH, when the air is in a middle state between the greatest moisture and the greatest dryness. Under this silk so strung with shot, is placed a little table or shelf I, for that part of the silk or shot to rest upon which is not suspended. When the moisture imbibed by the sponge increases its weight, it will raise the index, with part of the shot, from the table, and vice versa when the air is dry. *Philos. Transf.* vol. 44, p. 96.

9. From a series of Hygroscopical observations, made with an apparatus of deal wood, described in the *Philos. Transf.* number 480, Mr. Coniers concludes, 1st, that the wood shrinks most in summer, and swells most in winter, but is most liable to change in the spring and fall. 2d, That this motion happens chiefly in the day time, there being scarce any variation in the night. 3d, That there is a motion even in dry weather, the wood swelling in the morning, and shrinking in the afternoon. 4th, That the wood, by night as well as by day, usually shrinks when the wind is in the north, north-east, and east, both in summer and winter. 5th, That by constant observation of the motion and rest of the wood, with the help of a thermometer, the direction of the wind may be told nearly without a weather-

cock. He adds, that even the time of the year may be known by it; for in spring it moves more and quicker than in winter; in summer it is more shrunk than in spring; and has less motion in autumn than in summer. See an account of a method of constructing these and other Hygrometers, in *Phil. Transf. Abr.* vol. 2, p. 30, &c. and plate 1 annexed. See also *Philos. Transf.* vol. 11, p. 647 and 715; vol. 15, p. 1032; vol. 43, p. 6; vol. 44, p. 95, 169 and 184; vol. 54, p. 257; vol. 61, p. 198; vol. 63, p. 404, &c.

10. The Doctors Hales and Desaguliers both contrived another form of Sponge Hygrometer, on this principle. They made an horizontal axis, having a small part of its length cylindrical, and the remainder tapering conically with a spiral thread cut in it, after the manner of the fuzee of a watch. See fig. 8. The sponge is suspended by a fine silk thread to the cylindrical part of the axis, upon which it winds. This is balanced by a small weight W, suspended also by a thread, which winds upon the spiral fuzee. Then when the sponge grows heavier, in moist weather, it descends and turns the axis, and so draws up the weight; which coming to a thicker part of the axis it becomes a balance to the sponge, and its motion is shewn by an attached scale. And vice versa when the air becomes drier.—Salt of tartar, or any other salt, or pot-ashes, may be put into the scale of a balance, and used instead of the sponge. *Desag. Exper. Philos.* vol. 2, p. 300.

11. Mr. Ferguson made an Hygrometer of a thin deal pannel; and to enlarge the scale, and so render its variations more sensible, he employed a wheel and axle, making one cord pass over the axle, which turned a wheel ten times as large, over which passed a line with a weight at the end of it, whose motion was therefore ten times as much as that of the deal pannel. The board should be changed in 3 or 4 years. See *Philos. Transf.* vol. 54, art. 47.

12. Mr. Smeaton gave also an ingenious and elaborate construction of an Hygrometer; which may be seen in the *Philos. Transf.* vol. 61, art. 24.

13. Mr. De Luc's contrivance for an Hygrometer is very ingenious, and on this principle. Finding that even ivory swells with moisture, and contracts with dryness, he made a small and very thin hollow cylinder of ivory, open only at the upper end, into which is fitted the under or open end of a very fine long glass tube, like that of a thermometer. Into these is introduced some quicksilver, filling the ivory cylinder, and a small part of the length up the glass tube. The consequence is this: When moisture swells the ivory cylinder, its bore or capacity grows larger, and consequently the mercury sinks in the fine glass tube; and vice versa, when the air is drier, the ivory contracts, and forces the mercury higher up the tube of glass. It is evident that an instrument thus constructed is in fact also a thermometer, and must necessarily be affected by the vicissitudes of heat and cold, as well as by those of dryness and moisture; or that it must act as a thermometer as well as an Hygrometer. The ingenious contrivances in the structure and mounting of this instrument may be seen in the *Philos. Transf.* vol. 63, art. 38; where it may be seen how the above imperfection is corrected by some simple and ingenious expedients, employed in the original construction and subsequent use of the instrument; in consequence of which, the variations in the temperature of the air, though they produce their full effects on the instrument, as a thermometer, do not interfere with or embarrass its indications as an Hygrometer.

14. In the *Philos. Transf.* for 1791, Mr. De Luc has given a second paper on Hygrometry. This has been chiefly occasioned by a Memoir of M. De Saussure on the same subject, entitled *Essais sur l'Hygrometrie*, in 4to, 1783. In this work M. De Saussure describes a new Hygrometer of his construction, on the following principle. It is a known fact that a hair will stretch when it is moistened, and contract when dried: and M. De Saussure

found, by repeated experiments, that the difference between the greatest extension and contraction, when the hair is properly prepared, and has a weight of about 3 grains suspended by it, is nearly one 40th of its whole length, or one inch in 40. This circumstance suggested the idea of a new Hygrometer. To render these small variations of the length of the hair perceptible, an apparatus was contrived, in which one of the extremities of the hair is fixed, and the other, bearing the counterpoise abovementioned, surrounds the circumference of a cylinder, which turns upon an axis to which a hand is adapted, marking upon a dial in large divisions the almost insensible motion of this axis. About 12 inches high is recommended as the most convenient and useful: and to render them portable, a contrivance is added, by which the hand and the counterpoise can be occasionally fixed.

But M. De Luc, in his *Idées sur la Meteorologie*, vol. 1, anno 1786, shews that hairs, and all the other animal or vegetable hygroscopic substances, taken lengthwise, or in the direction of their fibres, undergo contrary changes from different variations of humidity; that when immersed in water, they lengthen at first, and afterwards shorten; that when they are near the greatest degree of humidity, if the moisture be increased, they shorten themselves; if it be diminished, they lengthen themselves first before they contract again. These irregularities, which render them incapable of being true measures of humidity, he shews to be the necessary consequence of their organic reticular structure. De Saussure takes his point of extreme moisture from the vapours of water under a glass bell, keeping the sides of the bell continually moistened; and affirms, that the humidity is, there, constantly the same in all temperatures; the vapours even of boiling water having no other effect than those of cold. De Luc, on the contrary, shews that the differences in humidity under the bell are very great, though De Saussure's Hygrometer was not capable of discovering them; and that the real undecomposed vapour of boiling water has the directly opposite effect to that of cold, the effect of extreme dryness; and on this point he mentions an interesting fact, communicated to him by Mr. Watt, viz. that wood cannot be employed in the steam engine, for any of those parts where the vapour of the boiling water is confined, because it dries so as to crack as if exposed to the fire.

To these charges of M. De Luc, a reply is made by M. De Saussure, in his *Defence of the Hair Hygrometer*, in 1788; where he attributes the general disagreement between the two instruments, to irregularities of M. De Luc's; and assigns some aberrations of his own Hygrometer, which could not have proceeded from the above cause, but to its having been out of order; &c.

This has drawn from M. De Luc a second paper on Hygrometry, published in the *Philos. Trans.* for 1791, p. 1, and 389. This author here resumes the four fundamental principles which he had sketched out in the former paper, viz. 1st, That fire is a sure, and the only sure means of obtaining extreme dryness. 2d, That water, in its liquid state, is a sure, and the only sure means of determining the point of extreme moisture. 3d, There is no reason, a priori, to expect, from any hygroscopic substance, that the measurable effects, produced in it by moisture, are proportional to the intensities of that cause. — But, 4th, perhaps the comparative changes of the dimensions of a substance, and of the weight of the same or other substances, by the same variations of moisture, may lead to some discovery in that respect. On these heads M. De Luc expatiates at large in this paper, shewing the imperfections of M. De Saussure's principles of Hygrometry, and particularly as to a hair, or any such substance when extended lengthwise, being properly used as an Hygrometer. On the other hand, he shews that the expansion of substances across the fibres, or grain, renders them, in that respect, by far the most proper for this purpose. He chooses such as can be made very thin, as ivory or deal shavings, but over

all he finds whalebone to be far the best of any. But, for all the reasonings of these ingenious philosophers on this interesting subject, and complete information, see the publications above quoted, as also the *Monthly Review*, vol. 51, p. 224; vol. 71, p. 213; vol. 76, p. 316; vol. 78, p. 236; and vol. 6, of the new series for the year 1791, p. 133.

We shall conclude this article with the following description of M. De Saussure's original Hygrometer. In the plate there is a representation of the whole instrument, with the hair and other appendages complete. The lower extremity of the hair *a b* is held by the chaps of the screw pincers *b*. These pincers are represented more distinctly at B: by a screw at its end, it fastens into the nut of the bottom plate C. This nut of the plate turns independently of the piece that supports it, and serves to raise or depress the pincers B at pleasure.

The upper extremity *a* of the hair is held by the under chaps of the double pincers *a*, represented aside at A. These pincers fasten the hair below, and above fasten a very fine narrow slip of silver, carefully annealed, which rolls round the arbor or cylinder *d*, a separate figure of which is shown at DF. This arbor, which carries the needle or index *e e*, or E in the separate figure, is cut in the shape of a screw; and the intervals of the threads of this screw have their bases flat, and are cut squarely so as to receive the slip of silver that is fastened to the pincers *a*, and joined in this manner with the hair. M. De Saussure observes, that hair alone fixed immediately to the arbor would not do; for it curled upon it, and acquired a stiffness that the counterpoise was not able to surmount. The arbor was cut in a screw form, in order that the slip of silver in winding upon it should not increase the diameter of the arbor, and never take a situation too oblique and variable. The slip is fixed to the arbor by a small pin F. The other extremity of the arbor D is shaped like a pulley, flat at the bottom so as to receive a fine supple silken string, to which is suspended the counterpoise *g* in the large figure, and G in the side one. This counterpoise is applied to distend the hair; and acts in a contrary direction to that of the hair, and the moveable pincers to which the hair is fixed. If then the hair should be loaded with the weight of four grains, the counterpoise must weigh four grains more than the pincers. The arbor at one end passes through the centre of the dial, and turns therein, in a very fine hole, on a pivot made very cylindrical and well polished: at the other end is also a similar pivot, which turns in a hole made in the end of the arm *b* of the cock *b i*, H. I. This cock is fixed behind the dial by means of the screw I.

The dial *k e e k*, divided into 360 degrees, is supported by two arms *ll*; these are soldered to two tubes, which inclose the cylindrical columns *m m m m*. The setting screws *n n* move upon these tubes, and serve thereby to fix the dial and arbor to any height required. The two columns which support the dial are firmly fastened to the case of the hygrometer, which rests upon the four screws *o o o o*; by the assistance of these screws, the instrument is adjusted, and placed in a vertical situation.

The square column *p p*, which rests upon the base of the hygrometer, carries a box *q*, to which is fixed a kind of port-crayon *r*, the aperture of which is equal to the diameter of the counterpoise *g*. When the hygrometer is to be moved from one place to another; to prevent a derangement of the instrument from the oscillations of the counterpoise, the box *q*, and the port-crayon *r*, must be raised up so as the counterpoise may fall into and be fixed in it, by tightening the screw *s*, and the box and counterpoise together by the screw *t*. When the hygrometer is intended for use, the counterpoise must be disengaged by lowering the box, as may be conceived from the figure.

Lastly, at the top of the instrument is a curved piece of metal *x, y, z*, which is fastened to the three columns just described, and keeps them together. It has a square hole at *y*, which serves to hang up the hygrometer by when required.

The variations of which this hygrometer is capable, are (all things besides equal) as much greater as the arbor round which the slip of silver winds is than a smaller diameter, and as the instrument is capable of receiving a longer hair. M. Sauffure has had hygrometers made with hairs 14 inches long, but he finds one foot sufficient. The arbor is three-fourths of a line in diameter at the base between the threads of the screw or the part on which the slip winds. The variations, when a hair properly prepared is applied to it, are more than an entire circumference, the index describing about 400 degrees in moving from extreme dryness to extreme humidity. M. Sauffure mentions an inconvenience attending this hygrometer, *viz.* its not returning to the same point when moved from one place to another; because the weight of three grains that keeps the silver slip extended, cannot play so exactly as to act always with the same precision against the arbor round which it winds. But this weight cannot be sensibly increased without still greater inconveniences: he therefore observes, that this hygrometer is well calculated for a fixed situation in an observatory, and for various hygrometrical experiments; since, instead of the hair, there may be substituted any other substance of which a trial may be wanted; and it may be kept extended by a counterpoise more or less heavy as they may require: but the instrument will not admit of being moved, nor serve even for experiments which may subject it to agitation.

To obviate this objection, M. Sauffure has contrived another apparatus more portable and convenient, and which, if not so extensive in its variations, is in fact very firm, and not in the least liable to be deranged by carriage and agitation.

This hygrometer he calls the *portable hygrometer*, in distinction from the preceding, which he calls the *great hygrometer*, or the *hygrometer with the arbor*. Both these instruments are accurately made by Mr. W. Jones, in Holborn.

HYGROSCOPE. The same with HYGROMETER.

HYLA, in ancient geography, a river of Mysia Minor, famous for Hylas the favourite boy of Hercules, who was carried down the stream and drowned. It is said to run by Prusa; whence it seems to be the same with the *Rhyndacus*, which runs north-west into the Propontis.

HYLAS, in fabulous history, son of Theodamus, was ravished by the nymphs of a fountain as he was taking out some water for Hercules, by whom he was beloved.

HYLOZOISTS, formed of *ύλη matter*, and *ζωη life*, the name of a sect of atheists among the ancient Greek philosophers, who held matter to be animated; maintaining that matter had some natural perception, without animal sensation, or reflection in itself considered; but that this imperfect life occasioned that organization whence sensation and reflection afterwards arose. Of these, some held only one life, which they called a PLASTIC nature, presiding regularly and invariably over the whole corporeal universe, which they represented as a kind of large plant or vegetable: these were called the cosmoplastic and stoical atheists, because the Stoics held such a nature, though many of them supposed it to be the instrument of the Deity. Others thought that every particle of matter was endued with life, and made the mundane system to depend upon a certain mixture of chance and plastic or orderly nature united together. These were called the Stratonici, from Strato Lampfacenus, a disciple of Theophrastus, called also Phisicus, (Cicero, De Nat. Deor. lib. 1. cap. 13.) who was first a celebrated Peripatetic, and afterwards formed this new system of atheism for himself. Besides these two forms of atheism, some of the ancient philosophers were Hylopathians, or ANAXIMANDRIANS, deriving all things from dead and stupid matter, in the way of qualities and forms, generable and corruptible; and others again adopted the ATOMICAL or Democritical system, who ascribe the production of the universe to atoms and figures. This subject is treated in *Cudworth's Intellectual System*, book i. chap. 3.

HYMEN, or HYMENÆUS, a fabulous divinity, the son of Bacchus and Venus Urania, was supposed by the ancients to preside over marriages; and accordingly was invoked in epithalamiums, and other matrimonial ceremonies, under the formula, *Hymen, or Hymenæe!* The poets generally crown this deity with a chaplet of roses; and represent him, as it were, dissolved and enervated with pleasures; dressed in a yellow robe, and shoes of the same colour; with a torch in his hand.—Catullus, in one of his epigrams, addresses him thus:

*Cinge tempora floribus
Suavolentis amara.*

It was for this reason that the new-married couple bore garlands of flowers on the wedding-day: which custom also obtained among the Hebrews, and even among Christians during the first ages of the church, as appears from Tertullian *De corona militari*, where he says, *Coronant & nuptæ sponfos.*—S. Chrysostom likewise mentions these crowns of flowers; and to this day the Greeks call marriage *επιγαμία*, in respect of this crown or garland.

HYMEN, *Ἦμην*, in anatomy, a thin membrane or skin, sometimes circular, of different breadths, more or less smooth, and sometimes semilunar, formed by the union of the internal membrane of the vagina with that on the inside of the *alæ*, resembling a piece of fine white leather somewhat corrugated. This membrane stretches below the nymphæ, leaving in some subjects a very small opening, in others a larger, and in all rendering the external orifice narrower than the rest of the cavity, and to be broke when they are deflowered; an effusion of blood following the breach.

This membranous circle may be ruptured by imprudent digital contact, and other accidents. The hymen is justly looked upon as the test of virginity; and when broke, or withdrawn, shows that the person is not in a state of innocence. This notion is very ancient. Among the Hebrews, it was the custom for the parents to have the blood shed on this occasion as a token of the virginity of their daughter, and to send the sheets next day to the husband's relations. And the like is said to be still practised in Portugal and some other countries.

And yet so various are the natural or accidental appearances of this part, that authors were not till of late years agreed as to the existence of such a membrane. De Graaf himself, the most accurate inquirer into the structure of these organs, confesses that all he could find was, a different degree of straitness or wideness, and different corrugations, which were greater or less according to the respective ages; the aperture being still the less, and the rugosities the greater, as the subject was younger and more untouched. Modern anatomists, however, have put the natural existence of this part beyond all question. In infants, indeed, it is a fine thin membrane, not very conspicuous, because of the natural straitness of the passage itself, which does not admit of any great expansion in so little room; and this might have led De Graaf into the mistake of its being no more than a corrugation.

Mr. Cowper relates the case of a married woman, twenty years of age, whose hymen was found altogether impervious, so as to detain the menses, and to be driven out by the pressure thereof beyond the labia of the pudendum, not unlike a prolapsus of the uterus. On dividing it, a prodigious quantity of grumous blood came forth. It seems the husband, being denied a passage that way, had found another through the meatus urinaris; which was found very open, and its sides extruded like the anus of a cock.

Upon a rupture of the hymen, after the consummation of marriage, and especially after delivery, its parts shrinking up form those little ragged fleshy fragments called *caruncule myrtiformes*.

HYMENÆA, the BASTARD LOCUST TREE; a genus of the monogynia order, belonging to the decandria class of plants; and in the natural method ranking under the 33d order, *Lomentaceæ*.

Fig. 1.

Fig. 5.

Fig. 6.

Fig. 7.

Fig. 8.

Hydrometer.

HYSTRIX.

Hystrix eritata.

Hystrix coendu.

Hystrix dorsata.

The calyx is quinquepartite; there are five petals, nearly equal; the style is intorted; the legumen full of mealy pulp. There is but one species, the courbaril, which is a large tree growing naturally in the Spanish West Indies. The trunk is covered with a light ash-coloured bark, is often more than 60 feet high, and three in diameter. The branches are furnished with dark green leaves, which stand by pairs on one common foot-stalk, diverging from their base in manner of a pair of shears when opened. The flowers come out in loose spikes at the ends of the branches, and are yellow striped with purple. Each consists of five petals, placed in a double calyx, the outer leaf of which is divided into five parts, and the inner one is cut into five teeth at its brim. In the centre are ten declining stamina, longer than the petals, surrounding an oblong germen, which becomes a thick, fleshy, brown pod, four or five inches long and one broad, with a suture on both edges, and includes three or four purplish seeds, somewhat of the shape of Windsor beans, but smaller. The seeds are covered with a light brown sugary substance, which the Indians scrape off and eat with great avidity, and which is very pleasant and agreeable.—At the principal roots under ground, is found collected in large lumps a yellowish red transparent gum, which dissolved in rectified spirit of wine affords a most excellent varnish, and is the gum anime of the shops.

HYMENOPTERA, derived from *ὕμην* membrane, and *πτερον* wing, in the Linnæan system of natural history, is an order of insects having four membranaceous wings, and the tails of the females are furnished with stings, which in some are used for instilling poison, and in others for merely piercing the bark and leaves of trees, and the bodies of other animals, in which they deposit their eggs.

HYMETTUS, in ancient geography, a mountain of Attica near Athens, famous for its marble quarries, and for its excellent honey. *Hymettius* is the epithet. Pliny says that the orator Crassus was the first who had marble columns from this place.

HYMN, a song or ode in honour of God; or a poem, proper to be sung, composed in honour of some deity. The word is Greek, *ὕμνος* *hymn*, formed of the verb *ὕδω* *celebro*, "I celebrate." Isidore, on this word, remarks, that *hymn* is properly a song of joy, full of the praises of God: by which, according to him, it is distinguished from *threnia*, which is a mourning song, full of lamentation. St. Hilary, bishop of Poitiers, is said to have been the first that composed hymns to be sung in churches, and was followed by St. Ambrose. Most of those in the Roman Breviary were composed by Prudentius. They have been translated into French verse by Messieurs de Port Royal. In the Greek Liturgy there are four kinds of hymns; but the word is not taken in the sense of a praise offered in verse, but simply of a laud or praise. The angelic hymn, or *Gloria in excelsis*, makes the first kind; the *trifagion*, the second; the *cherubic hymn*, the third; and the hymn of *victory and triumph*, called *ἐπιμικτός*, the last. The hymns or odes of the ancients generally consisted of three sorts of stanzas; one of which, called *strophè*, was sung by the band as they walked from east to west; another, called *antistrophè*, was performed as they returned from west to east; the third part, or *epode*, was sung before the altar. The Jewish hymns were accompanied with trumpets, drums, and cymbals, to assist the voices of the Levites and people.

HYOBANCHE, in botany, a genus of the angiospermia order, belonging to the didynamia class of plants. The calyx is heptaphyllous; the corolla ringent, with no under lip. The capsule bilocular, and polyspermous.

HYOIDES, in anatomy, a bone placed at the root of the tongue. See **ANATOMY**, page 213.

HYOSCYAMUS, **HENBANE**; a genus of the monogynia

order, belonging to the pentandria class of plants; and in the natural method ranking under the 28th order, *Lurideæ*. The corolla is funnel-shaped and obtuse; the stamina inclining to one side; the capsule covered and bilocular. There are several species, one of which, *viz.* the niger, or common henbane, is a native of Britain. It grows on road sides, and among rubbish. It is a biennial plant, with long fleshy roots which strike deep into the ground, sending out several large soft leaves, deeply slashed on their edges: the following spring the stalks come up, which are about two feet high, garnished with flowers standing on one side in a double row, sitting close to the stalks alternately. They are of a dark purplish colour, with a black bottom; and are succeeded by roundish capsules which open with a lid at the top, and have two cells filled with small irregular seeds. The seeds, leaves, and roots of this plant, as well as of all other species of this genus, are poisonous: and many well attested instances of the bad effects are recorded; madness, convulsions, and death, being the common consequence. In a smaller dose they occasion giddiness and stupor. It is said that the leaves scattered about a house will drive away mice. The juice of the plant evaporated to an extract is prescribed in some cases as a narcotic; in which respect undoubtedly it may be a powerful medicine if properly managed. The dose is from half a scruple to half a dram. The roots are used for anodyne necklaces. Goats are not fond of the plant; horses, cows, sheep, and swine, refuse it.

HYOSERIS, in botany; a genus of the polygamia æqualis order, belonging to the syngenesia class of plants; and in the natural method ranking under the 49th order, *Compositæ*. The receptacle is naked, the calyx nearly equal; the pappus hairy, or scarce perceptible.

HYO-THYROIDES, in anatomy, one of the muscles belonging to the os hyoides. See **ANATOMY**, *Table of the Muscles*.

HYPALLAGE, among grammarians, a species of hyperbaton, consisting in a mutual permutation of one case for another. Thus Virgil says, *Dare classibus austros, for dare classes austris*; and again, *Needum illis labra admovi, for needum illa labris admovi*.

HYPANTE, or **HYPERPANTE**, a name given by the Greeks to the feast of the presentation of Jesus in the temple. This word, which signifies *lowly* or *humble meeting*, was given to this feast from the meeting of old Simeon and Anna the prophets in the temple when Jesus was brought thither.

HYPATIA, a learned and beautiful lady of antiquity, the daughter of Theon a celebrated philosopher and mathematician, and president of the famous Alexandrian school, was born at Alexandria about the end of the fourth century. Her father, encouraged by her extraordinary genius, had her not only educated in all the ordinary qualifications of her sex, but instructed in the most abstruse sciences. She made such great progress in philosophy, geometry, astronomy, and the mathematics, that she passed for the most learned person of her time. At length she was thought worthy to succeed her father in that distinguished and important employment, the government of the school of Alexandria, and to teach out of that chair where Ammonius, Hierocles, and many other great men had taught before; and this at a time too when men of great learning abounded both at Alexandria and in many other parts of the Roman empire. Her fame was so extensive, and her worth so universally acknowledged, that we cannot wonder if she had a crowded auditory. "She explained to her hearers (says Socrates) the several sciences that go under the general name of philosophy; for which reason there was a confluence to her, from all parts, of those who made philosophy their delight and study." One cannot represent to himself without pleasure, the flower of all the youth of Europe, Asia, and Africa, sitting at the

feet of a very beautiful lady (for such we are assured Hypatia was), all greedily swallowing instruction from her mouth, and many of them, doubtless, love from her eyes; though we are not sure that she ever listened to any solicitations, since Suidas, who talks of her marriage with Isidorus, yet relates at the same time that she died a maid.

Her scholars were as eminent as they were numerous; one of whom was the celebrated Synesius, who was afterwards bishop of Ptolemais. This ancient Christian Platonist every where bears the strongest as well as the most grateful testimony to the virtue of his tutors; and never mentions her without the most profound respect, and sometimes in terms of affection coming little short of adoration. But it was not Synesius only, and the disciples of the Alexandrian school, who admired Hypatia for her virtue and learning: never was woman more caressed by the public, and yet never woman had a more unspotted character. She was held as an oracle for her wisdom, which made her consulted by the magistrates in all important cases; and this frequently drew her amongst the greatest concourse of men, without the least censure of her manners. In a word, when Nicephorus intended to pass the highest compliment on the princess Eudocia, he thought he could not do it better than by calling her another *Hypatia*.

While Hypatia thus reigned the brightest ornament of Alexandria, Orestes was governor of the same place for the emperor Theodosius, and Cyril was bishop or patriarch. Orestes, having had a liberal education, could not but admire Hypatia; and as a wife governor frequently consulted her. This, together with an aversion which Cyril had against Orestes, proved fatal to the lady. About 500 monks assembling, attacked the governor one day, and would have killed him, had he not been rescued by the townsmen; and the respect which Orestes had for Hypatia causing her to be traduced among the Christian multitude, they dragged her from her chair, tore her to pieces, and burned her limbs. Cyril is not clear from a suspicion of fomenting this tragedy. Cave indeed endeavours to remove the imputation of such an horrid action from the patriarch; and lays it upon the Alexandrian mob in general, whom he calls *levissimum hominum genus*, "a very trifling inconstant people." But though Cyril should be allowed neither to have been the perpetrator nor even the contriver of it, yet it is much to be suspected that he did not discountenance it in the manner he ought to have done: which suspicion must needs be greatly confirmed by reflecting, that he was so far from blaming the outrage committed by the monks upon Orestes, that he afterwards received the dead body of Ammonius, one of the most forward in that outrage, who had grievously wounded the governor, and who was justly punished with death. Upon this riotous ruffian Cyril made a panegyric in the church where he was laid, in which he extolled his courage and constancy, as one that had contended for the truth; and changing his name to *Thaumastias*, or the "Admirable," ordered him to be considered as a martyr. "However (continues Socrates), the wisest part of Christians did not approve the zeal which Cyril showed on this man's behalf, being convinced that Ammonius had justly suffered for his desperate attempt."

HYPECOUM, **WILD CUMMUN**; a genus of the digynia order, belonging to the tetrandria class of plants; and in the natural method ranking under the 24th order, *Corydalis*. The calyx is diphyllous; the petals four; the exterior two larger and trifid; the fruit a pod. There are four species, all of them low herbaceous plants with yellow flowers. The juice of these plants is of a yellow colour, resembling that of celandine, and is affirmed by some eminent physicians to be as narcotic as opium. From the nectarium of the blossom the bees collect great quantities of honey. All the species are easily propagated by seeds.

HYPER, a Greek preposition frequently used in composition, where it denotes excess, its literal signification being *above*, or *beyond*.

HYPERBATON, in grammar, a figurative construction inverting the natural and proper order of words and sentences. The several species of the hyperbaton are, the anastrophe, the hysteron-proteron, the hypallage, synchysis, tmesis, parenthesis, and the hyperbaton strictly so called. See *ANASTROPHE*, &c. **HYPERBATON**, strictly so called, is a long retention of the verb which completes the sentence, as in the following example from Virgil:

*Interea reges : ingenti mole Latinus
Quadrijugo vebitur curru, cui tempora circum
Aurati bis sex radii fulgentia cingunt,
Solis avi specimen : bigis it Turnus in albis,
Bina manu lato crispans bastilia ferro.
Hunc Pater Æneas, Romanæ stirpis origo,
Sidereo flagrans clypeo et cælestibus armis ;
Et juxta Ascanius, magnæ spes alera Romæ ;
Procedunt castris.*

HYPERBOLA, a curve formed by cutting a cone in a direction parallel to its axis. See *CONIC Sections*.

HYPERBOLE, in rhetoric, a figure, whereby the truth and reality of things are excessively either enlarged or diminished. Lord Kaims observes, that an object uncommon with respect to size, either very great of its kind or very little, strikes us with surprise; and this emotion forces upon the mind a momentary conviction, that the object is greater or less than it is in reality: the same effect precisely attends figurative grandeur or littleness; and hence the hyperbole, which expresses this momentary conviction. A writer, taking advantage of this natural delusion, enriches his description greatly by the hyperbole: and the reader, even in his coolest moments, relishes this figure, being sensible that it is the operation of nature upon a warm fancy.

It cannot have escaped observation, that a writer is generally more successful in magnifying by a hyperbole than in diminishing. The reason is, that a minute object contracts the mind, and fetters its powers of imagination; but that the mind dilated and inflamed with a grand object moulds objects for its gratification with great facility. Longinus, with respect to a diminishing hyperbole, cites the following ludicrous thought from a comic poet: "He was owner of a bit of ground not larger than a Lacedemonian letter." But, for the reason now given, the hyperbole has by far the greater force in magnifying objects; of which take the following examples:

For all the land which thou see'st, to thee will I give it, and to thy seed for ever. And I will make thy seed as the dust of the earth: so that if a man can number the dust of the earth, then shall thy seed also be numbered.

Gen. xiii. 15, 16.

*Illa vel intactæ segetis per summa volaret
Gramina : nec teneras cursu læsisset aristas.*

Æneid. vii. 308.

— — — — — atque imo barathri ter gurgite vastos
Sorbet in abruptum fluctus, rursusque sub auras
Erigit alternos, et sidera verberat undâ.

Æneid. iii. 421.

— — — — — horrificis juxta tonat Ætna ruinis,
Intèrdumque atram prorumpit ad æthera nubem,
Turbine fumantem piceo et candente favilla :
Attollitque globos flammatarum, et sidera lambit.

Æneid. iii. 571.

Speaking of Polyphemus,

————— Ipse arduus, altaque pulsat
Sidera. *Æneid.* iii. 619.

————— When he speaks,
The air, a charter'd libertine, is still.
Henry V. act 1. sc. 1.

Now shield with shield, with helmet helmet clos'd,
To armour armour, lance to lance oppos'd,
Host against host with shadowy squadrons drew,
The sounding darts in iron tempests flew,
Victors and vanquish'd join promiscuous cries,
And shrilling shouts and dying groans arise;
With streaming blood the slipp'ry fields are dy'd,
And slaughter'd heroes swell the dreadful tide.
Iliad iv. 508.

Quintilian is sensible that this figure is natural: "For (says he), not contented with truth, we naturally incline to augment or diminish beyond it; and for that reason the hyperbole is familiar even among the vulgar and illiterate:" and he adds, very justly, "That the hyperbole is then proper, when the object of itself exceeds the common measure." From these premises one would not expect the following inference, the only reason he can find for justifying this figure of speech, "Conceditur enim amplius dicere, quia dici quantum est non potest: meliusque ultra quam citra stat oratio." (We are indulged to say more than enough, because we cannot say enough; and it is better to be above than under.) In the name of wonder, why this slight and childish reasoning, when immediately before he had observed, that the hyperbole is founded on human nature? We could not resist this personal stroke of criticism; intended not against our author, for no human creature is exempt from error; but against the blind veneration that is paid to the ancient classic writers, without distinguishing their blemishes from their beauties.

HYPERBOREAN, in the ancient geography. The ancients denominated those people and places *Hyperborean* which were to the northward of the Scythians. They had but very little acquaintance with these Hyperborean regions; and all they tell us of them is very precarious, much of it false. Diodorus Siculus says, the Hyperboreans were thus called by reason they dwelt beyond the wind Boreas; *ὑπερ* signifying "above, or beyond," and *Βορεας*, *Boreas*, the "north wind." This etymology is very natural and plausible; notwithstanding all that Rudbeck has said against it, who would have the word to be Gothic, and to signify *nobility*. Herodotus doubts whether or no there were any such nations as the Hyperborean. Strabo, who professes that he believes there are, does not take *hyperborean* to signify *beyond Boreas* or the north, as Herodotus understood it: the preposition *ὑπερ*, in this case, he supposes only to help to form a superlative; so that *hyperborean*, on his principle, means no more than *most northern*: by which it appears the ancients scarce knew themselves what the name meant. Most of our modern geographers, as Hoffman, Cellarius, &c. have placed the Hyperboreans in the northern parts of the European continent, among the Siberians and Samoieds: according to them, the Hyperboreans of the ancients were those in general who lived farthest to the north. The Hyperboreans of our days are those Russians who inhabit between the Volga and the White Sea. According to Chuvier, the name *Celtes* was synonymous with that of Hyperboreans.

HYPERCATALECTIC, in the Greek and Latin poetry, is applied to a verse that has one or two syllables too much, or beyond the regular and just measure; as, *Muse sorores sunt Minerva*: Allo, *Muse sorores Palladis ingent*.

HYPERCRITIC, an over-rigid censor, or critic: one who will let nothing pass, but animadvert severely on the slightest fault. The word is compounded of *ὑπερ* *super*, "over, above, beyond;" and *κριτικος*, of *κριτης* *judge*, of *κρινω* *judico*, "I judge."

HYPERDULIA, in the Romish theology, is the worship rendered to the holy virgin. The word is Greek, *ὑπερδουλεια*, composed of *ὑπερ* *above*, and *δουλια* *worship, service*. The worship offered to saints is called *dulia*; and that to the mother of God, *hyperdulia*, as being superior to the former.

HYPERIA, in ancient geography, the seat of the Phæacians near the Cyclops (Homer): some commentators take it to be Camarina in Sicily; but, according to others, it is supposed to be an adjoining island, which they take to be Melita, lying in sight of Sicily. And this seems to be confirmed by Apollonius Rhodius. Whence the Phæacians afterwards removed to Corcyra, called *Scheria*, *Phæacia*, and *Maoris*; having been expelled by the Phœnicians, who settled in Melita for commerce, and for commodious harbours, before the war of Troy. (Diodorus Siculus.)

HYPERICUM, **ST. JOHN'S WORT**; a genus of the polyandria order, belonging to the polyadelphia class of plants; and in the natural method ranking under the 20th order, *Rotaceæ*. The calyx is quinquepartite; the petals five; the filaments many, and coalited at the base into five pencils; the seed-vessel is a pencil. Of this genus there are 29 species, most of them hardy deciduous shrubs, and under-shrubby plants, adorned with oblong and oval simple foliage, and pentapetalous yellow flowers in clusters. The most remarkable are, 1. The *hircinum*, or stinking St. John's wort. This rises three or four feet high, with several shrubby two-edged stalks from the root, branching by pairs opposite at every joint; oblong, oval, close-fitting opposite leaves; and at the ends of all the young shoots, clusters of yellow flowers. Of this there are three varieties; one with strong stalks, six or eight feet high, broad leaves and large flowers; the other with strong stalks, broad leaves and without any disagreeable odour; the third hath variegated leaves. All these varieties are shrubby; and flower in June and July in such numerous clusters, that the shrubs appear covered with them; and produce abundance of seed in autumn. 2. The *canariensis* hath shrubby stalks, dividing and branching six or seven feet high; oblong, close-fitting leaves by pairs: and, at the ends of the branches, clusters of yellow flowers appearing in June and July. 3. The *ascyron*, or dwarf American St. John's-wort, hath spreading roots, sending up numerous slender square stalks, a foot long; oval, spear-shaped, close-fitting, smooth leaves by pairs opposite; and, at the end of the stalks, large yellow flowers. 4. The *androsæmum*, commonly called *tutsan*, or *park-leaves*, hath an upright under-shrubby stalk, two feet high, branching by pairs opposite; and at the ends of the stalks, clusters of small yellow flowers appearing in July and August, and succeeded by roundish berry-like black capsules. This grows naturally in many parts of Britain. 5. The *balcanicum*, or water-leaved St. John's wort, is a native of Majorca; and hath a shrubby stalk, branching two feet high, with reddish scarified branches, small oval leaves warted underneath, and large yellow flowers appearing great part of the year. 6. The *monogynum*, or one-styled *China hypericum*, hath a shrubby purple stalk, about two feet high; oblong, smooth, stiff, close-fitting leaves, of a shining green above, and white underneath; clusters of small yellow flowers, with coloured cups, and only one style, flowering the greatest part of the year.

The *tutsan* long held a place in the medicinal catalogues; but its uses are very little thought of at present. The leaves given in substance are said to destroy worms. By distillation they yield an essential oil. The flowers tinge spirits and oils of a fine purple colour. Cows, goats and sheep eat the plant;

horses and swine refuse it. The dried plant boiled in water with alum dyes yarn of a yellow colour; and the Swedes give a fine purple tinge to their spirits with the flowers.

HYPERIDES, an orator of Greece, was the disciple of Plato and Isocrates, and governed the republic of Athens. He defended with great zeal and courage the liberties of Greece; but was put to death by Antipater's order, 322 B. C. He composed many orations, of which only one now remains. He was one of the ten celebrated Greek orators.

HYPERMNESTRA, in fabulous history, one of the 50 daughters of Danaus king of Argos. She alone refused to obey the cruel order Danaus had given to all his daughters, to murder their husbands the first night of their marriage; and therefore saved the life of Lynceus, after she had made him promise not to violate her virginity. Danaus, enraged at her disobedience, confined her closely in prison, whence Lynceus delivered her some time after.

HYPERSARCOSIS, in medicine and surgery, an excess of flesh, or rather a fleshy excrescence, such as those generally rising upon the lips of wounds, &c.

HYPHEN, an accent or character in grammar, implying that two words are to be joined, or connected into one compound word, and marked thus -; as *pre-established, five-leaved, &c.* Hyphens also serve to connect the syllables of such words as are divided by the end of the line.

HYPNOTIC, in the materia medica, such medicines as any way produce sleep, whether called *narcotics, hypnotics, opiates, or soporifics.*

HYPNOTICUS SERPENS, the *Sleep-snake*, in zoology, the name of an East-Indian species of serpent, called by the Ceylonese *nint'polong*, a word importing the same sense. It is of a deep blackish brown, variegated with spots of white, and is a very fatal kind in its poison; its bite always bringing on a sleep which ends in death.

HYPNUM, **FEATHER-MOSS**, in botany; a genus of the natural order of musci, belonging to the cryptogamia class of plants. The anthera is operculated, or covered with a lid; the calyptra smooth; the filament lateral, and rising out of a perichætium, or tuft of leaflets different from the other leaves of the plant. There are 46 species, all of them natives of Great Britain; none of them, however, have any remarkable property, except the proliferum and parietinum. The first is of a very singular structure, one shoot growing out from the centre of another; the veil is yellow and shining; the lid with a kind of long bill; the leaves not shining; sometimes of a yellowish, and sometimes of a deep green. This moss covers the surface of the earth in the thickest shades, through which the sun never shines, and where no other plant can grow. The second hath shoots nearly flat and winged, undivided for a considerable length, and the leaves shining; but the old shoots do not branch into new ones as in the preceding species. It grows in woods and shady places; and, as well as the former, is used for filling up the chinks in wooden houses.

HYPO, a Greek particle, retained in the composition of divers words borrowed from that language: literally denoting *under, beneath.* In this sense it stands opposed to *ὑπερ supra*, "above."

HYPOBOLE, or **SUBJECTION**, from *ὑπο*, and *βαλλω I cast*, in rhetoric, a figure; so called, when several things are mentioned, that seem to make for the contrary side, and each of them refuted in order. This figure, when complete, consists of three parts; a proposition, an enumeration of particulars with their answer, and a conclusion. Thus Cicero, upon his return from banishment, vindicates his conduct in withdrawing so quietly, and not opposing the faction that ejected him. See **ORATORY.**

HYPOCATHARSIS, compounded of *ὑπο under*, and

καθαρσιν I purge, in medicine, a too faint or feeble purgation.

HYPOCAUSTUM, among the Greeks and Romans, a subterraneous place, where was a furnace to heat the baths. The word is Greek, formed of the preposition *ὑπο under*, and the verb *καίω to burn*. Another sort of hypocaustum was a kind of kiln to heat their winter parlours. The remains of a Roman hypocaustum, or sweating-room, were discovered under ground at Lincoln in 1739. We have an account of these remains in the Philosophical Transactions, No. 461, § 29. Among the moderns, the hypocaustum is that place where the fire is kept which warms a stove or hot-house.

HYPOCHÆRIS, **HAWK'S-EYE**, in botany; a genus of the polygamia æqualis order, belonging to the Syngnetica class of plants; and in the natural method ranking under the 49th order, *Compositæ*. The receptacle is paleaceous; the calyx a little imbricated; the pappus glutinous. There are four species; none of which have any remarkable property, except the maculata, or spotted hawk's-eye. It is a native of Britain, and grows on high grounds. The leaves are oblong, egg-shaped, and toothed; the stem almost naked, generally with a single branch; the blossoms yellow, opening at six in the morning, and closing at four in the afternoon. The leaves are boiled and eaten like cabbage. Horses are fond of this plant when green, but not when dry. Cows, goats, and swine eat it; sheep are not fond of it.

HYPOCHONDRIA, in anatomy, a space on each side the epigastric region, or upper part of the abdomen. See **ANATOMY**, page 185.

HYPOCHONDRIAC PASSION, a disease in men, similar to the hysteric affection in women. See **MEDICINE.**

HYPOCISTIS, in the materia medica, an inspissated juice obtained from the sessile acarum, much resembling the true Egyptian acacia. They gather the fruit while unripe, and express the juice, which they evaporate over a very gentle fire, to the consistence of an extract, and then form into cakes, and expose them to the sun to dry. It is an astringent of considerable power; is good against diarrhoeas and hæmorrhages of all kinds; and may be used in repellent gargarisms in the manner of the true acacia; but it is very rarely met with genuine in our shops, the German acacia being usually sold under its name.

HYPOCRISY, *ὑποκρισις*, in ethics, denotes dissimulation with regard to the moral or religious character. In other words, it signifies one who feigns to be what he is not; and is generally applied to those who assume the appearances of virtue or religion, without having any thing in reality of either.

HYPOGÆUM, *ὑπογαιον*, formed of *ὑπο under*, and *γαια earth*, in the ancient architecture, is a name common to all the parts of a building that are under ground; as the cellar, butteries, and the like places. The term *hypogæum* was used by the Greeks and Romans for subterraneous tombs in which they buried their dead.

HYPOGÆUM, *ὑποσαιον*, in astrology, is a name given to the celestial houses which are below the horizon; and especially the *imium cæli*, or bottom of heaven.

HYPOGASTRIC, an appellation given to the internal branch of the iliac artery.

HYPOGASTRIUM, in anatomy, the middle part of the lower region of the belly.

HYPOGLOSSI, **EXTERNI**, or **MAJORES**, in anatomy, the ninth pair of nerves, called also *linguales & gustatorii.*

HYPOGLOTTIS, or **HYPOGLOSSIS**, compounded of *ὑπο under*, and *γλωττα tongue*, in anatomy, is a name given to two glands of the tongue. There are four large glands of the tongue; two of them called *hypoglottides*, situated under it, near the venæ ranales; one on each side of the tongue. They serve to filtrate

a kind of ferous matter of the nature of saliva, which they discharge into the mouth by little ducts near the gums.

HYPOGLORITIS, or *Hypoglossitis*, in medicine, denotes an inflammation or ulceration under the tongue; called also *ranula*.

St. HYPOLITE, a small town of France, in the department of Gard and late province of Languedoc. A canal crosses the town, which turns several mills, and supplies many fountains with water. An insult offered by the inhabitants to a priest, who was carrying the viaticum, occasioned the revocation of the edict of Nantes. This town has a good fort, and is situated on the Vidourle, near its source, 12 miles S. W. of Alais. E. lon. o. 4. N. lat. 43. 55.

HYPOPYON, in surgery, a collection of purulent matter under the corner of the eye.

HYPOSCENIUM, in antiquity, a partition under the pulpit or logeum of the Greek theatre, appointed for the music.

HYPOSTASIS, a Greek term, literally signifying *substance*, or *subsistence*; used in theology for *person*. The word is Greek, *ὑποστασις*; compounded of *ὑπο* *sub*, "under," and *ἵστημι* *sto*, *existo*, "I stand, I exist;" q. d. *sub sistentia*. Thus we hold, that there is but one nature or essence in God, but three *hypostases* or persons. The term *hypostasis* is of a very ancient standing in the church. St. Cyril repeats it several times, as also the phrase *union according to hypostasis*. The first time it occurs is in a letter from that father to Nestorius, where he uses it instead of *πρόσωπον*, the word we commonly render *person*, which did not seem expressive enough. "The philosophers (says St. Cyril) have allowed three *hypostases*: they have extended the Divinity to three *hypostases*: they have even sometimes used the word *trinity*: and nothing was wanting but to have admitted the consubstantiality of the three *hypostases*, to show the unity of the divine nature, exclusive of all triplicity in respect of distinction of nature, and not to hold it necessary to conceive any respective inferiority of *hypostases*."

This term occasioned great dissensions in the ancient church; first among the Greeks, and afterwards also among the Latins. In the council of Nice, *hypostasis* was defined to denote the same with *essence* or *substance*; so that it was heresy to say that Jesus Christ was of a different *hypostasis* from the Father; but custom altered its meaning. In the necessity they were under of expressing themselves strongly against the Sabellians, the Greeks made choice of the word *hypostasis*, and the Latins of *persona*; which change proved the occasion of endless disagreement. The phrase *τρεις ὑποστασεις*, used by the Greeks, scandalized the Latins, whose usual way of rendering *ὑποστασις* in their language was by *substantia*. The barrenness of the Latin tongue in theological phrases allowed them but one word for the two Greek ones, *βσια* and *ὑποστασις*; and thus disabled them from distinguishing *essence* from *hypostasis*. For which reason they chose rather to use the term *tres personæ*, and *tres hypostases*.—An end was put to logomachias, in a synod held at Alexandria about the year 362, at which St. Athanasius assisted; from which time the Latins made no great scruple of saying *tres hypostases*, nor the Greeks of *three persons*.

HYPOTHECA, in the civil law, an obligation, whereby the effects of a debtor are made over to his creditor, to secure his debt. The word comes from the Greek *ὑποθηκη*, a *thing subjected to some obligation*; of the verb *ὑποτιθεμαι*, *supponor*, "I am subjected;" of *ὑπο* *under*, and *τιθημι* *pono*, "I put."

As the hypotheca is an engagement procured on purpose for the security of the creditor, various means have been made use of to secure to him the benefit of the convention. The use of the pawn or pledge is the most ancient, which is almost the same thing with the hypotheca; all the difference consisting in this, that the pledge is put into the creditor's hands; whereas, in a simple hypotheca, the thing remained in the possession of the debtor. It was found more easy and commodious to engage an

estate by a civil covenant than by an actual delivery: accordingly the expedient was first practised among the Greeks; and from them the Romans borrowed both the name and the thing: only the Greeks, the better to prevent frauds, used to fix some visible mark on the thing, that the public might know it was hypothecate or mortgaged by the proprietor; but the Romans, looking on such advertisements as injurious to the debtor, forbade the use of them.

The Roman lawyers distinguished four kinds of hypothecas: the conventional, which was with the will and consent of both parties; the legal, which was appointed by law, and for that reason called *tacit*; the prætor's pledge, when by the flight or non-appearing of the debtor the creditor was put in possession of his effects; and the judiciary, when the creditor was put in possession by virtue of a sentence of the court. The *conventional* hypotheca is subdivided into general and special. The hypotheca is general, when all the debtor's effects, both present and future, are engaged to the creditor. It is special, when limited to one or more particular things. For the *tacit* hypotheca, the civilians reckon no less than twenty-six different species thereof.

HYPOTHENUSE, in geometry, the longest side of a right-angled triangle, or that which subtends the right angle.

HYPOTHESIS (formed of *ὑπο* "under," and *θεσις* *positio*, of *τιθημι* *pono*, "I put"), is a proposition or principle which we suppose, or take for granted, in order to draw conclusions for the proof of a point in question. In disputation, they frequently make false hypotheses, in order to draw their antagonists into absurdities; and even in geometry truths are often deducible from such false hypotheses. Every conditional or hypothetical proposition may be distinguished into hypothesis and thesis: the first rehearses the conditions under which any thing is affirmed or denied; and the latter is the thing itself affirmed or denied. Thus, in the proposition, A triangle is half of a parallelogram, if the bases and altitudes of the two be equal; the latter part is the hypothesis, "if the bases," &c. and the former the thesis, "a triangle is half a parallelogram." In strict logic, we are never to pass from the hypothesis to the thesis; that is, the principle supposed must be proved to be true, before we require the consequence to be allowed.

HYPOTHESIS, in physics, &c. denotes a kind of system laid down from our own imagination, whereby to account for some phenomenon or appearance of nature. Thus, we have hypotheses to account for the tides, for gravity, for magnetism, for the deluge, &c. The real and scientific causes of natural things generally lie very deep: observation and experiment, the proper means of arriving at them, are in most cases extremely slow; and the human mind is very impatient: hence we are frequently driven to feign or invent something that may seem like the cause, and which is calculated to answer the several phenomena, so that it may possibly be the true cause.

Philosophers are divided as to the use of such fictions or hypotheses, which are much less current now than they were formerly. The latest and best writers are for excluding hypotheses, and standing wholly on observation and experiment. Whatever is not deduced from phenomena, says Sir Isaac Newton, is an hypothesis; and hypotheses, whether metaphysical, or physical, or mechanical, or of occult qualities, have no place in experimental philosophy.

The Cartesians take upon them to suppose what affections in the primary particles of matter they please; just what figures, what magnitudes, what motions, and what situations, they find for their purpose. They also feign certain unseen, unknown fluids, and endue them with the most arbitrary properties; give them a subtilty which enables them to pervade the pores of all bodies, and make them agitated with the most unaccountable motions. But is not this to set aside the real constitution of

things, and to substitute dreams in their place? Truth is scarce attainable even by the surest observations; and will fanciful conjectures ever come at it? They who found their speculations on hypotheses, even though they argue from them regularly, according to the strictest laws of mechanics, may be said to compose an elegant and artful fable; but it is still only a fable.

HYPOTHESIS is more particularly applied in astronomy to the several systems of the heavens; or the different ways in which different astronomers have supposed the heavenly bodies to be ranged, moved, &c.

The principal hypotheses are the Ptolemaic, Copernican, and Tychonic. The Copernican is now become so current, and is so well warranted by observation, that the retainers thereto hold it injurious to call it an *hypothesis*. See ASTRONOMY.

HYPOTYPOSIS, or *Imagery*, ὑποτύποισις, formed of the verb ὑποτίπω *per figuram demonstrare, I show, represent, or make any thing be seen*; of ὑπό *under*, and τύπος *type, image, resemblance*, in Rhetoric, a figure whereby a thing is described or painted in such strong and bright colours, that it does not seem to be read, or heard, but actually seen, or presented before the eyes. Such is that elegant one of Cicero, wherein he paints the barbarity of Verres: *Ipse inflammatus scelere & furore in forum venit. Ardebant oculi; toto ex ore crudelitas emanabat. Expectabant omnes quo tandem progressurus, aut quidnam acturus esset; cum repente hominem corripit, atque in foro medio nudari ac deligari, & virgas expedire jubet. Clamabat ille miser se civem esse Romanum, &c.* Such is also the picture which he has drawn of Catiline, consisting of an unaccountable mixture of contrary qualities. Pro Cœl. c. 5. The *hypotyposis* is frequently used by the poets, and particularly Virgil, who abounds in paintings. This figure is peculiarly suited for drawing characters, and often affords the finest ornaments in poetry and history, as well as oratory. It is also adapted to move and interest different passions, according to the nature of the subject, and the artful management of the speaker.

HYPOXIS, in botany; a genus of the monogynia order, belonging to the hexandria class of plants; and in the natural method ranking under the 10th order, *Coronariæ*. The corolla is divided into six parts, and persilting, superior; the capsule narrowing at the base; the calyx a bivalved glume.

HYPHISTARII, formed from ὑψιστος "*highest*," a sect of heretics in the fourth century; thus called from the profession they made of worshipping the most high God. The doctrine of the Hyphesterians was an assemblage of Paganism, Judaism, and Christianity. They adored the most high God with the Christians: but they also revered fire and lamps with the Heathens; and observed the sabbath, and the distinction of clean and unclean things, with the Jews. The Hyphesterii bore a near resemblance to the Euchites, or Massalians.

HYRCANIA, in ancient geography, a country of the farther Asia, lying to the south-east of the *Mare Hyrcanum* or *Caspium*; with Media on the west, Parthia on the south, and Margiana on the east. Famous for its tigers (Virgil); for its vines, figs, and olives (Strabo).

HYRCANIA, in ancient geography, a town of Lydia, in the *campus Hyrcanus*, near Thyatira; so called from colonists brought from Hyrcania, a country lying to the south of the Caspian sea. The people called *Hyrcani Macedones*, because a mixed people (Pliny).—Another Hyrcania, the metropolis of the country called *Hyrcania*. Thought to be the Tape of Strabo, the Syrius of Polybius, the Zeudracarta of Arrian, and the Asaac of Isidorus Characenus. A third, a strong place of Judea, built by Hyrcanus.

HYSSOP. See HYSSOPUS.

Hedge HYSSOP. See GRATIOLA.

HYSSOPUS, HYSSOP; a genus of the gymnospermia order, belonging to the didynamia class of plants. There are three spe-

cies; but only one of them, viz. the *officinalis*, or common hyssop, is cultivated for use. This hath under-shrubby, low, bushy stalks, growing a foot and an half high; small, spear-shaped, close-fitting, opposite leaves, with several smaller ones rising from the same joint; and all the stalks and branches terminated by erect whorled spikes of flowers, of different colours in the varieties. They are very hardy plants; and may be propagated either by slips or cuttings, or by seeds. The leaves have an aromatic smell, and a warm pungent taste. Besides possessing the general virtues of aromatics, they have been supposed useful in humoural asthma, coughs, and other disorders of the lungs; and are said to promote expectoration.

Hyssop was generally made use of in purifications amongst the Jews by way of a sprinkler. Sometimes they added a little wool to it of a scarlet colour; for example, they dipped a bunch of hyssop, some branches of cedar, and red wool, in water mingled with the blood of a bird, in the purification of lepers. Hyssop, it is probable, grew to a considerable height in Judæa, since the Gospel informs us that the soldiers filled a sponge with vinegar, put it upon a reed (or long stem) of hyssop, and presented it to our Saviour upon the cross.

HYSTERIC AFFECTION, or *Passion*, formed of ὑστέρα "*womb*;" a disease in women, called also vulgarly *fits of the mother*. It is a spasmodic affection of the nervous system, proceeding often from uterine affections, but chiefly from mental causes. See MEDICINE.

HYSTERON PROTERON, in grammar and rhetoric, a species of the hyperbaton, wherein the proper order of construction is so inverted, that the part of any sentence which should naturally come first is placed last: as in this of Terence, *Valet et vivit*, for *vivit et valet*; and in the following of Virgil, *Morianur, & in media arma ruamus*, for *In media arma ruamus, & morianur*.

HYSTRIX, in zoology, a genus of quadrupeds belonging to the order of glires, the characters of which are these: They have two fore teeth, obliquely divided both in the upper and under jaw, besides eight grinders; and the body is covered with quills or prickles. See pl. 12. There are four species, viz.

1. The *crislata*, or crested porcupine, has four toes on the fore-feet, five toes on the hind-feet, a crested head, a short tail, and the upper lip is divided like that of a hare. The length of the body is about two feet, and the height about two feet and an half. The porcupine is covered with prickles, some of them nine or ten inches long, and about $\frac{1}{4}$ th of an inch thick. Like the hedge-hog, he rolls himself up in a globular form, in which position he is proof against the attacks of the most rapacious animals. The prickles are exceedingly sharp, and each of them has five large black and as many white rings, which succeed one another alternately from the root to the point. These quills the animal can erect or let down at pleasure; when irritated, he beats the ground with his hind-feet, erects his quills, shakes his tail, and makes a considerable rattling noise with his quills.—Most authors have asserted that the porcupine, when irritated, darts his quills to a considerable distance against the enemy, and that he will kill very large animals by this means. But M. Buffon and some other late naturalists assure us, that the animal possesses no such power. M. Buffon frequently irritated the porcupine, but never saw any thing like this darting of his quills. He says indeed, that when the creature was much agitated with passion, some of the quills which adhered but slightly to the skin would fall off, particularly from the tail; and this circumstance, he imagines, has given rise to the mistake. The porcupine, though originally a native of Africa and the Indies, can live and multiply in the more temperate climates of Spain and Italy. Pliny, and every other natural historian since the days of Aristotle, tells us, that the porcupine, like the bear, conceals itself during the winter, and that it brings forth its young in 80 days.

But these circumstances remain to this day uncertain. It is remarkable, that although this animal be very common in Italy, no person has ever given us a tolerable history of it. We only know in general, that the porcupine, in a domestic state, is not a fierce or ill-natured animal; that with his fore-teeth, which are strong and sharp, he can cut through a strong board; that he eats bread, fruits, roots, &c.; that he does considerable damage when he gets into a garden; that he grows fat, like most animals, about the end of summer; and that his flesh is not bad food.

2. The *prehensilis*, or *Brazilian porcupine*, has four toes on the fore-feet, five on the hind-feet, and a long tail. It is considerably less than the former species; being only 17 inches long from the point of the muzzle to the origin of the tail, which is nine inches long; the legs and feet are covered with long brownish hair; the rest of the body is covered with quills interspersed with long hairs: the quills are about five inches long, and about $\frac{1}{4}$ th of an inch in diameter. He feeds upon birds and small animals. He sleeps in the day like the hedge-hog, and searches for his food in the night. He climbs trees, and supports himself by twirling his tail round the branches. He is generally found in the high grounds of America from Brasil to Louisiana, and the southern parts of Canada. His flesh is esteemed very good eating.

A variety of this species is the *Hoitzlacuatzin*, or Mexican porcupine (*Le Coendou* de Buffon). It is of a dusky colour, with very long bristles intermixed with the down: the spines three inches long, slender, and varied with white and yellow; scarcely apparent except on the tail, which is, according to Hernandez, thicker and shorter than that of the preceding species. He adds, that the tail from the middle to the end is free from spines; and that it grows to the bulk of a middle-sized dog.

M. de Buffon says, its length is 16 or 17 inches from the nose to the tail; the tail 9 French measure, but taken from a mutilated skin. It inhabits the mountains of Mexico, where it lives on the summer fruits, and may be easily made tame. The Indians pulverise the quills, and say they are very efficacious in gravelly cases; and applied whole to the forehead, will relieve the most violent headach. They adhere till filled with blood, and then drop off.

3. The *dorsata*, or Canada porcupine (*Purson* de Buffon); has four toes on the fore-feet, five on the hind-feet; and has quills only on the back, which are short, and almost hid among the long hair. He is about two feet long. This species inhabits North America as high as Hudson's Bay, and makes its nest under the roots of great trees. It will also climb among the boughs, which the Indians cut down when one is in them, and kill the animal by striking it over the nose. They are very plentiful near Hudson's Bay; and many of the trading Indians depend on them for food, esteeming them both wholesome and pleasant. These animals feed on wild fruits and bark of trees, especially juniper; eat snow in winter, and drink water in summer; but avoid going into it. When they cannot avoid their pursuer, they will sidle towards him, in order to touch him with their quills, which seem but weak weapons of offence; for, on stroking the hair, they will come out of the skin, sticking to the hand. The Indians stick them in their noses and ears, to make holes for the placing their ear-rings and other finery: they also trim the edges of their deer-skin habits with fringes made of the quills, or cover with them their bark-boxes.

4. The *macroura*, has five toes both on the hind and fore-feet; his tail is very long, and the prickles are elevated. He inhabits the isles of the Indian Archipelago, and lives in the forests.

HYTHE. See HITHE.

I.

I

J A B

I, or *i*, the ninth letter and third vowel of the alphabet, is pronounced by throwing the breath suddenly against the palate, as it comes out of the larynx, with a small hollowing of the tongue, and nearly the same opening of the lips in talk as in pronouncing *a* or *e*. Its sound varies: in some words it is long, as *bigb*, *mind*, &c.; in others short, as *bid*, *bid*, *fin*, &c.; in others, again, it is pronounced like *y*, in *collier*, *onion*, &c.; and in a few, it sounds like *ee*, as in *machine*, *magazine*, &c. No English word ends in *i*, *e* being either added to it, or else the *i* turned into *y*.

But besides the vowel, there is the *jod* consonant; which, because of its different pronunciation, has likewise a different form, thus *J, j*. In English, it has the soft sound of *g*; nor is used but when *g* soft is required before vowels where *g* is usually hard: thus we say, *jack*, *jet*, *join*, &c. instead of *gack*, *get*, *join*, &c. which would be contrary to the genius of the English language.

I, used as a numeral, signifies *one*, and stands for so many units as it is repeated times: thus **I**, one; **II**, two; **III**, three, &c.; and when put before a higher numeral, it subtracts itself, as **IV**, four; **IX**, nine, &c. But when set after it, so many are added to the higher numeral as there are **I**'s added: thus **VI** is 5 + 1, or six; **VII**, 5 + 2, or seven; **VIII**, 5 + 3, or eight. The ancient Romans likewise used **l̄** for 500, **cl̄** for 1000, **l̄cc̄** for 5000, **cc̄l̄cc̄** for 10,000, **l̄cc̄cc̄** for 50,000, and **ccc̄l̄cc̄cc̄** for 100,000. Farther than this, as Pliny observes, they did not go in their notation; but, when necessary, repeat-

ed the last number, as **ccc̄cl̄cc̄cc̄**, **ccc̄cl̄cc̄cc̄**, for 200,000; **ccc̄cl̄cc̄cc̄**, **ccc̄cl̄cc̄cc̄**, **ccc̄cl̄cc̄cc̄**, for 300,000; and so on.

The ancients sometimes changed *i* into *u*; as *decumus* for *decimus*; *maxumus* for *maximus*, &c.

According to Plato, the vowel *i* is proper to express delicate, but humble things, as in this verse in Virgil which abounds in *i*'s, and is generally admired: *Accipiunt inimicum imbrem, rimisque fatiscunt*.

I, used as an abbreviature, is often substituted for the whole word **JESUS**, of which it is the first letter.

JABOK, a brook on the other side of the Jordan, the spring whereof is in the mountains of Gilead. It falls into Jordan pretty near the sea of Tiberias, to the south of this sea. Near this brook the patriarch Jacob wrestled with the angel (Gen. xxxii. 22). The Jabbok separated the land of the Ammonites from the Gaulonites, and the territories of Og king of Bashan.

JABESH, or **JABESH-GILEAD**, was the name of a city, in the half tribe of Manassah, beyond Jordan. The scripture calls it generally Jabesh Gilead, because it lay in Gilead, at the foot of the mountains which go by this name. Eusebius places it six miles from Pella, towards Gerasa; and consequently it must be eastward of the sea of Tiberias.

JABIRU. See MYCTERIA.

JABLONSKI (**DANIEL ERNEST**), a learned Polish Protestant divine, born at Dantzick in 1660. He became successively minister of Magdeburg, Lissa, Koningberg, and Berlin; and was at length ecclesiastical counsellor, and president of the academy

of sciences at the latter. He took great pains to effect an union between the Lutherans and Calvinists; and wrote some works which are esteemed, particularly *Meditations on the Origin of the Scriptures*, &c. He died in 1741.

JABLONSKI (Theodore), counsellor of the court of Prussia, and secretary of the royal academy of sciences at Berlin, was also a man of distinguished merit. He loved the sciences, and did them honour, without that ambition which is generally seen in men of learning: it was owing to this modesty that the greatest part of his works were published without his name. He published, in 1711, a French and German Dictionary; a Course of Morality, in 1713; a Dictionary of Arts and Sciences, in 1721; and translated *Tacitus de Moribus Germanorum* into High Dutch, in 1724.

JABLUNKA, a town of Silesia, in the territory of Teschen, 30 miles S. E. of Troppaw. E. lon. 18. 10. N. lat. 49. 41.

JABNE, in ancient geography, a town of Palestine, near Joppa; called *Jannia* or *Jannial*, by the Greeks and Romans. In Joshua xv. it seems to be called *Jabneel*; but in 2 Chron. xxvi. *Jabne*. It was taken from the Philistines by Uzziab, who demolished its fortifications. Its port, called *Jannitarum portus*, lay between Joppa and Azotus.

JACAMAR, in ornithology. See ALCEDO.

JACCA, an ancient town of Spain, in Arragon, with a bishop's see, and a fort, seated on a river of the same name, among the mountains of Jacca, which are a part of the Pyrenees, 22 miles N. of Huefca, and 50 N. by E. of Saragossa. W. lon. 0. 9. N. lat. 42. 36.

JACI-DE-AGUILA, a sea-port of Sicily, on the eastern coast, between Catania and Tavormina. E. lon. 15. 26. N. lat. 37. 27.

JACK, in mechanics, an instrument in common use for raising heavy timber, or very great weights of any kind. See pl. 22. fig. 1. But as the wheel-work of this engine is enclosed in the strong piece of timber C B, the inside of it is represented in fig. 2, where the rack A B must be supposed at least four times as long in proportion to the wheel Q, as the figure represents it; and the teeth, which will be then four times more in number, to be contained about three in an inch. Then if the handle HP be seven inches long, five turns of it, i. e. 5 times 22 inches, or 110 inches, will be the velocity of the power, whilst the weight raised by the claw A, or depressed by the claw B, moves one inch: for, as the pinion of the handle has but four leaves, and the wheel Q twenty teeth, there must be five revolutions of the handle to turn the wheel once round, whose three-leaved pinion R will, in that revolution, just move the rack three teeth, or one inch. This might have been also known without seeing, or even knowing the number of the teeth of the wheel and pinions, by measuring a revolution of the handle in fig. 1, and comparing the space gone through by it with the space gone through by the end A or B. This machine is sometimes open behind from the bottom almost up to the wheel Q, to let the lower claw, which in that case is turned up as at B, draw up any weight. When the weight is drawn or pushed sufficiently high, it is kept from going back by hanging the end of the hook S, fixed to a staple, over the curved part of the handle at b.

JACK, a well-known engine used for turning a spit: the weight is the power applied; the friction of the parts, and the weight with which the spit is charged, are the force to be overcome; and a steady uniform motion is maintained by means of the FLY.

Smoke-JACK, an engine used for the same purpose with the common jack, and so called from its being moved by means of the smoke or rarefied air, ascending the chimney, and striking against the tail of the horizontal wheel AB, pl. 22, which, being inclined to the horizon, is moved about the axis of the wheel,

together with the pinion C, which carries the wheels D and E; and E carries the chain F, which turns the spit. The wheel AB should be placed in the narrow part of the chimney, where the motion of the smoke is swiftest, and then the greatest part of it must strike upon the sails. The force of this machine depends on the draught of the chimney, and the vehemence of the fire.

In the Repertory of Arts, vol. vi. we find the following specification of Mr. Braithwaite's patent for certain improvements in the construction of smoke-jacks.

Fig. 1. pl. 22. represents a perspective view of a vertical flyer of a smoke or air jack, supposed to be fixed in a chimney, the axis of which should be placed parallel to the horizon; and although it will do if the axis is not exactly parallel with the horizon, yet the nearer it is horizontal the better. The axis of the flyer may pass through the breast of the chimney, on the extremity of which (being left square) a chain suspended will turn a spit, with sufficient power to roast a moderate-sized joint of meat; but, as greater force will sometimes be required, it will be expedient to fix on the axis a pinion or worm, to which may be applied a cog or tooth wheel, of any convenient size, which will be turned by the pinion or worm, when the flyer is put into motion by the pressure of the air or smoke on the fans or floats, arising from the draught occasioned by the fire. On the cog or tooth wheel, or a metal or wooden wheel on the same axis, a chain or chains suspended will turn a spit or spits for roasting. If the chain be suspended from the axis of the flyer, two collars ought to be fixed upon the axis, to confine the chain to its proper place.

B represents a plate of iron, or other metal, which should be fixed to one side of the chimney, either above or below the flyer or wheel, but it will have the greater effect when fixed below: its use is as a conductor of the air or smoke to the fans or floats of the flyer in a particular direction, as may be seen in the drawing; and it should be so placed as to guard and cover about three fifths of the flyer, so as to conduct the air or smoke beyond the centre of the flyer or wheel, that it may act with all its force on the fans or floats of the flyer not guarded by the plate B. Without this plate, the air or smoke would act on both sides of the flyer with nearly an equal power, and consequently would prevent the flyer from moving at all. The effect of the plate may be produced by erecting an abutment of brick, stone, or other materials; in which case, however, a cavity ought to be made in the breast of the chimney, covered by a movable plate, sufficiently large to admit the flyer, which will require to be taken down when the chimney is swept. The size of the flyer or wheel must be increased or diminished, according to the size of the chimney it is to be fixed in; and the number of fans or floats must be more or less, according as the diameter is increased or diminished.

Fig. 2. is a sectional view of one side of a flyer, drawn to a scale supposed to be two feet six inches in diameter, which will be found large enough for common use; it has twelve floats or fans, marked from No. 1 to 12, but the number may be more or less, as shall be found most convenient. They may be supported from the centre by twelve arms, or by an arm at each end of the flyers, or by rings, or in a water-wheel, or by any other mode which the maker may prefer. The angle which the fans or floats are set to, from a straight line drawn through the axis of the flyer, in this drawing, (namely, about fifty degrees,) is probably the best; though they might be fixed in a right line from the centre, and the flyer or wheel move, but not with so much power as when set in the manner of the drawing. B B represents the conducting-plate, which should be fixed to one side of the chimney, and closed to the back and breast, so as to prevent the air from passing through any other channel except over the end of the plate.

Fig. 3. represents the section of the flyer or wheel, shewing

Jack for raising heavy Weights.

Itzecuintepotzotli.

Jatropha Elastica.

Jatropha Manihot.

two fans or floats. A and B are plates of iron, copper, or other proper materials; the length of the fans or floats here represented is fourteen inches, and the breadth about six inches; the extreme diameter of the fans or floats, from out to out, two feet six inches. CC are arms which the fans or floats are made fast to, which may be fixed in a collar of iron, or other metal, turned with a hole for the axis D; which axis is also turned to fit the hole; and, when the flyer is put in its proper place in the chimney, the screw E, being turned, fastens the flyer or wheel on the axis; and, by loosening the screw, and removing the axis, the flyer may be taken down when the chimney requires sweeping. Or the arms may be fixed into the axis; and also the axis may be supported in many other ways, according to the direction of the workman; particularly by fixing the arms at the extremity of the axis, and supporting the axis within the breast of the chimney, so as to obviate the necessity of carrying it to the back of the chimney. No oil in this case will be requisite within the chimney, which has hitherto been found an inconvenience attending the common smoke jack.

JACK, in the sea language, a sort of flag or colours, displayed from a mast erected on the outer end of a ship's bowsprit. In the British navy the jack is nothing more than a small union flag, composed of the intersection of the red and white crosses; but in merchant ships this union is bordered with a red field.

JACK is used also for a horse or wooden frame to saw timber upon; for an implement to pull off a pair of boots; for a great leathern pitcher to carry drink in; for a small bowl that serves as a mark at the exercise of bowling; and for a young pike.

JACK-Flag, in a ship, that hoisted up at the spritsail top-mast head.

JACK Daw, the English name of a species of corvus. See **CORVUS**. This bird is very mischievous to the farmer and gardener; and is of such a thievish disposition, that he will carry away much more than he can make use of. There is a method of destroying them by a kind of springe much used in England; and is so proper, that it ought to be made universal.—A stake of about five feet long is to be driven firmly into the ground, and made so fast that it cannot move, and so sharp in the point that the bird cannot fettle upon it. Within a foot of the top there must be a hole bored through it, of three quarters of an inch diameter; through this hole is to be put a stick of about eight inches long; then a horse-hair springe or noose is to be made fast to a thin hazel wand, and this brought up to the place where the short stick is placed, and carried with it through the hole, the remainder being left open under that stick. The other end of the hazel rod is to be put through a hole in the stake near the ground, and fastened there. The stake is to be planted among the jackdaw's food, and he will naturally be led to fettle on it; but finding the point too sharp, he will descend to the little cross stick. This will sink with his weight, and the springe will receive his leg, and hold him fast.

JACKALL, in zoology. See **CANIS**.

JACKSON (THOMAS), an eminent English divine, was born at Witton in the bishopric of Durham in 1579, of a good family. He commenced doctor of divinity at Oxford in 1612; and at last was made chaplain in ordinary, prebendary of Winchester, and dean of Peterborough. He was a very great scholar, and died in 1640. His publication on the Creed is a learned and valuable piece; which, with his other works, was published in 1673.

JACOB, the son of Isaac and Rebekah, was born in the year of the world 2168; before Jesus Christ 1830. The history of this patriarch is given at large in the book of Genesis. He died in Egypt in the 147th year of his age. Joseph directed that the body should be embalmed, after the manner of the Egyptians; and there was a general mourning for him throughout Egypt for seventy days. After this, Joseph and his brethren, accompa-

nied with the principal men of Egypt, carried him, with the king of Egypt's permission, to the burying-place of his fathers near Hebron, where his wife Leah had been interred. When they were come into the land of Canaan, they mourned for him again for seven days; upon which occasion the place where they staid was called *Abelmisraim*, or the mourning of the Egyptians.

JACOB (Ben Hajim), a rabbi famous for the collection of the *Maforah* in 1525; together with the text of the Bible, the Chaldaic paraphrase, and Rabbinical commentaries.

JACOB (Ben Naphthali), a famous rabbi of the 5th century: he was one of the principal *massorets*, and bred at the school of Tiberias in Palestine with *Ben Afer*, another principal *massoret*. The invention of points in Hebrew to serve for vowels, and of accents to facilitate the reading of that language, are ascribed to these two rabbis; and said to be done in an assembly of the Jews held at Tiberias, A. D. 476.

JACOB (Giles), an eminent law-writer, born at Romsey in the county of Southampton, in 1686. He was bred under a considerable attorney; and is principally known for his *Law Dictionary* in one vol. folio, which has been often printed; a new and improved edition having been given by counsellors Ruffhead and Morgan. Mr. Jacob also wrote two dramatic pieces; and a *Poetical Register*, containing the lives and characters of English dramatic poets. The time of his death is not known.

JACOBÆUS (OLIGER), a celebrated professor of physic and philosophy at Copenhagen, was born in 1651 at Arhusen in the peninsula of Jutland, where his father was bishop. Christian V. intrusted him with the management of his grand cabinet of curiosities; and Frederic IV. in 1698 made him counsellor of his court of justice. He wrote many medical works, and some excellent poems.

JACOBINE MONKS, the same with **DOMINICANS**.

JACOBITES, a term of reproach bestowed on the persons who, vindicating the doctrines of passive obedience and non-resistance with respect to the arbitrary proceedings of princes, disavowed the revolution in 1688, and asserted the supposed rights and adhered to the interests of the abdicated King James and his family.

JACOBITES, in church history, a sect of Christians in Syria and Mesopotamia; so called, either from Jacob a Syrian who lived in the reign of the emperor Mauritius, or from one Jacob a monk who flourished in the year 550. The Jacobites are of two sects, some following the rites of the Latin church, and others continuing separated from the church of Rome. There is also a division among the latter, who have two rival patriarchs. As to their belief, they hold but one nature in Jesus Christ; with respect to purgatory and prayers for the dead, they are of the same opinion with the Greeks and other eastern Christians: they consecrate unleavened bread at the eucharist, and are against confession, believing that it is not of divine institution.

JACOBUS, a gold coin, worth 25 shillings; so called from King James I. of England, in whose reign it was struck. We usually distinguish two kinds of *Jacobus*, the *old* and the *new*; the former valued at 25 shillings, weighing six pennyweights ten grains; the latter called also *Carolus*, valued at 23 shillings, in weight five pennyweights twenty grains.

JACQUINIA, in botany; a genus of the monogynia order, belonging to the hexandria class of plants; and in the natural method ranking with those of which the order is doubtful. The corolla is decemfid; the stamina inserted into the receptacle; the berry monospermous.

JACULATOR, or **SHOOTING-FISH**. See **CHLÆTODON**.

JADDESSES is the name of an inferior order of priests in Ceylon, who have the care of the chapels appropriated to the genii, who form a third order of gods among these idolaters. These priests are applied to by the people in a time of disease or

calamity, who offer a cock on their behalf to appease the anger of the demons.

JADE-STONE, **LAPIS NEPHRITICUS**, or *Jaspachates*, a genus of siliceous earths. It gives fire with steel, and is semitransparent like flint. It does not harden in the fire, but melts in the focus of a burning glass into a transparent green glass with some bubbles. A kind brought from the river of the Amazons in America, and called *circusifon stone*, melts more easily in the focus into a brown opaque glass, far less hard than the stone itself. The jade-stone is unctuous to the touch; whence Mr. Kirwan seems to suspect, that it contains a portion of argillaceous earth, or rather magnesia. The specific gravity is from 2.970 to 3.389; the texture granular, with a greasy look, but exceedingly hard, being superior in this respect even to quartz itself. It is infusible in the fire, nor can it be dissolved in acids without a particular management; though M. Saussure seems to have extracted iron from it. Sometimes it is met with of a whitish milky colour from China; but mostly of a deep or pale green from America. The common lapis nephriticus is of a grey, yellowish, or olive colour. It has its name from a supposition of its being capable of giving ease in nephritic pains, by being applied externally to the loins. It may be distinguished from all other stones by its hardness, semipellucidity, and specific gravity.

JAEN, a handsome town of Spain, in Andalusia, with a bishop's see, and a strong castle. It is seated in a country producing excellent fruits, and very fine silk, at the foot of a mountain, 15 miles S. W. of Baeza, and 115 E. of Seville. W. lon. 3. 22. N. lat. 37. 38.

JAFFA, an ancient town of Asia, in Palestine, formerly called Joppa. It is entirely fallen from its ancient grandeur, and is 50 miles N. W. of Jerusalem. E. lon. 35. 0. N. lat. 32. 16.

JAFFATEEN ISLANDS, the name of four islands in the Red Sea, visited by Mr. Bruce in his late travels. They are joined together by shoals or sunk rocks; are crooked or bent like half a bow; and are dangerous for ships in the night-time, because there seems to be a passage between them, to which while the pilots are paying attention, they neglect two small sunk rocks which lie almost in the middle of the entrance in deep water.

JAFNAPATAN, a sea-port town, seated at the north-east end of the island of Ceylon in the East Indies. The Dutch took it from the Portuguese in 1658, and have continued in the possession of it since that time. They export from thence great quantities of tobacco, and some elephants, which are accounted the most docile of any in the world. E. lon. 80. 25. N. lat. 9. 30.

JAGARNAUT, a famous pagoda, in the peninsula of Hindoostan, and province of Orissa. It lies on the bay of Bengal, close to the shore, and a few miles to the E. of lake Chilka. It is a shapeless mass of building, and no otherwise remarkable than as one of the first objects of Hindoo veneration, and an excellent sea-mark. It has no claim to great antiquity. It is 311 miles S. W. of Calcutta. E. lon. 85. 40. N. lat. 19. 35.

JAGERNDORF, a town and castle of Silesia, capital of a province of the same name, seated on the river Oppa, 65 miles S. by E. of Breslaw. E. lon. 17. 24. N. lat. 50. 4.

JAGGERNAUT, a black pyramidal stone worshipped by the Gentoos, who pretend that it fell from heaven or was miraculously presented on the place where their temple stands. There are many other idols of this figure in India; which, however, are all but accounted copies from the Jaggernaut. According to the best information Mr. Grose could obtain, this stone is meant to represent the power presiding over universal generation, which they attribute to the general heat and influence of the sun acting in subordination to it. Domestic idols of the form of the Jaggernaut, and distinguished by the same name, are made by the Gentoos. These are niched up in a kind of triumphal car,

decorated with gilding and tinsel; which for some days they keep in the best apartment in their house. During this time their devotion consists in exhibiting the most obscene postures and acting all manner of lasciviousness, in sight as it were of the idol, and as the most acceptable mode of worship to that deity it represents; after which they carry it in its gilded car in procession to the Ganges, and throw in all together as an acknowledgment to that river of its congenial fertilization with that of the sun. Formerly this machine was decorated with jewels and other expensive ornaments; but the Indians are now become less extravagant, as they found that the Moors and Christians, watching the places where they threw in their idols, dived for them for the sake of the jewels with which they were adorned.

Our author conjectures, that this pyramidal form of the Gentoos idol was originally taken from that of flame, which always inclines to point upwards. From this Indian deity he supposes the shape of the Paphian Venus to have been derived, for which Tacitus could not account. This image had nothing of the human form in it, but rose orbicularly from a broad basis, and in the nature of a race goal tapering to a narrow convex a-top; which is exactly the figure of the idol in India, consecrated to such an office as that heathen deity was supposed to preside over, and to which, on the borders of the Ganges especially, the Gentoos virgins are brought to undergo a kind of superficial defloration before they are presented to their husbands.

JAGHIRE OF THE CARNATIC, a tract of land, in the peninsula of Hindoostan, subject to the English E. India Company. It extends along the bay of Bengal, from Madras to lake Pullycate on the N. to Alemparvé on the S. and to Conjeveram on the W. being 108 miles along the shore, and 47 inland in the widest part. The term Jaghire means, generally, a grant of land from a sovereign to a subject, revokable at pleasure, but generally a life-rent. But the Jaghire of the Carnatic, major Rennell thinks, is understood to be held in perpetuity. It contains 2440 square miles, and its revenue is about 150,000l. per annum.

JAGO (RICHARD), an ingenious poet, was vicar of Snitterfield in Warwickshire, and rector of Kimcote in Leicestershire. He was the intimate friend and correspondent of Mr. Shenstone, contemporary with him at Oxford, and, it is believed, his schoolfellow; was of University College; took the degree of M. A. July 9, 1739; was author of several poems in the 4th and 5th volumes of Doddsley's Poems; published a sermon, in 1755, on the Causes of Impenitence considered, preached May 4, 1755, at Harbury in Warwickshire, where he was vicar, on occasion of a conversation said to have passed between one of the inhabitants and an apparition in the church-yard there; wrote "Edge-hill," a poem, for which he obtained a large subscription in 1767; and was also author of "Labour and Genius," 1768, 4to; of "The Blackbirds," a beautiful elegy in the Adventurer; and of many other ingenious performances. He died May 28, 1781.

ST. JAGO, a large river of South America, which rises in the audience of Quito and Peru. It is navigable; and falls into the South Sea, after having watered a fertile country abounding in cotton-trees, and inhabited by wild Americans.

ST. JAGO, the largest, most populous and fertile of the Cape Verd islands, on the coast of Africa, and the residence of the Portuguese viceroy. It lies about 13 miles eastward from the island of Mayo, and abounds with high barren mountains; but the air, in the rainy season, is very unwholesome to strangers. Its produce is sugar, cotton, wine, and some excellent fruits. The animals are black cattle, horses, asses, deer, goats, hogs, civet-cats, and some very pretty green monkeys with black faces.

ST. JAGO, a handsome and considerable town of South America, the capital of Chili, with a good harbour, a bishop's see,

and a royal audience. It is seated in a large and beautiful plain, abounding with all the necessaries of life, at the foot of the Cordilleras, on the river Mapocho, which runs across it from east to west. Here are several canals and a dyke, by means of which they water the gardens and cool the streets.—It is very much subject to earthquakes. W. lon. 69. 35. S. lat. 33. 40.

ST. JAGO *de Cuba*, a town in North America, situated on the southern coast of the island of Cuba, in the bottom of a bay with a good harbour, and on a river of the same name. W. lon. 76. 44. N. lat. 20. 0.

JAGO *de los Caballeros*, a town of America, and one of the principal of the island of Hispaniola. It is seated on the river Yague, in a fertile soil, but bad air. W. lon. 70. 5. N. lat. 19. 40.

ST. JAGO *del Entero*, a town of South America, one of the most considerable of Tucuman, and the usual residence of the inquisitor of the province. It is seated on a large river, in a flat country, where there is game, tigers, guanacos, commonly called *camel sheep*, &c.

JAGO *de la Vega*, otherwise called *Spanish Town*, is the capital of the island of Jamaica, in the West Indies; and stands in 18. 1. north latitude, and 76. 45. west longitude. It is about a mile in length, and little more than a quarter of a mile in breadth; and contains between 500 and 600 houses, with about 4000 inhabitants of all colours and denominations. This town is situated in a delightful plain, on the banks of the Rio Cobre, 13 miles from Kingston, and 10 from Port Royal. It is the residence of the commander in chief: and here the supreme court of judicature is held, four times in the year, viz. on the last Tuesdays of February, May, August, and November, and sits three weeks.—St. Jago de la Vega is the county-town of Middlesex, and belongs to the parish of St. Catharine; in which parish there are 11 sugar-plantations, 108 pens, and other settlements, and about 10,000 slaves.

JAGODNA, a town of Turkey in Europe, in Servia, seated on the river Morava, 70 miles S. E. of Belgrade.

JAGUAR, or JAQUAR, a name given to the Brazilian Ounce, a species of FELIS. See FELIS.

JAGUEER, in East India affairs, any pension from the Grand Mogul, or king of Delhi; generally such as are assigned for military services.

JAGUEERDAR, the holder or possessor of a jagueer. It comes from three Persian words, *ja* "a place;" *gueristun* "to take;" and *dystun* "to hold;" *quasi* "a place-holder or pensioner." In the times of the Mogul empire, all the great officers of the court, called *amrabs*, were allowed jagueers, either in lands of which they collected the revenues, or assignments upon the revenues for specified sums, payable by the lord lieutenant of a province: which sums were for their maintenance, and the support of such troops as they were necessitated to bring into the field when demanded by the emperor, as the condition of their jagueers, which were always revokable at pleasure.

JAICZA, a town of Turkey in Europe, in the province of Bosnia, 50 miles N. E. of Bosna Serago, with a strong citadel, and seated on the river Plena.

JAIL-FEVER, a very dangerous fever of the contagious kind, arising from the putrescent disposition of the blood and juices. See MED. CINE.

JALAP, in botany and the materia medica, the root of a species of convolvulus or bind-weed. See CONVOLVULUS. This root is brought to us in thin transverse slices from Xalapa, a province of New Spain. Such pieces should be chosen as are most compact, hard, weighty, dark-coloured, and abound most with black circular striæ. Slices of bryony root are said to be sometimes mixed with those of jalap: these may be easily distinguished by their whiter colour and less compact texture. This root has no smell, and very little taste upon the tongue; but when

swallowed, it affects the throat with a sense of heat, and occasions a plentiful discharge of saliva. Jalap in substance, taken in a dose of about half a dram (less or more, according to the circumstances of the patient), proves an effectual, and in general a safe purgative, though it sometimes occasions nausea and gripes, like other strong cathartics. An extract made by water purges almost universally, but weakly; and at the same time has a considerable effect by urine. The root remaining after this process gripes violently, because the pure resinous part only is left. On the like principle, the pure resin prepared with spirit of wine occasions most violent gripings, and other distressing symptoms. Triturated with sugar, or with almonds into the form of an emulsion, or dissolved in spirit, and mixed with syrups, it purges plentifully in a small dose, without occasioning much disorder: the part of the jalap remaining after the separation of the resin yields to water an extract, which has no effect as a cathartic, but operates powerfully by urine. Nothing more effectually corrects the operation of jalap when given in powder than joining it with cream of tartar.

JALEMUS, in antiquity, a kind of mournful song, used upon occasion of death, or any other affecting accident. Hence the Greek proverbs had their original, *ιαλεμυ οικροτερος*, or *ψυκροτερος*, i. e. *more sad or colder than a jalemus*, *εις της ιαλεμυς εργαπτος*, *worthy to be ranked among jalemuses*.

JAMA, a strong fort of Ingria, in the Russian government of St. Petersburg, seated on a river of the same name, 13 miles N. E. of Narva.

JAMADAR, an officer of horse or foot, in Hindostan. Also the head or superintendant of the Peons in the Sewaury, or train of any great man.

JAMAGOROD, a strong town of Ingria, in the Russian government of St. Petersburg, seated on the Jama, 12 miles N. E. of Narva. E. lon. 28. 3. N. lat. 59. 25.

JAMAICA, an island of the W. Indies, discovered by Christopher Columbus in 1494. It is situated in the Atlantic Ocean, about 4000 miles S. W. of England. It has the island of Hispaniola, at the distance of 30 leagues, to the east; Cuba, at about the same distance, to the north; the gulf of Honduras to the west; and Carthagena, on the great continent of S. America, to the S. distant 145 leagues. It is about 150 miles in length, and 40 in breadth. It is of an oval figure, and grows narrow from the middle, till it terminates in two points at the extremities of the island. It contains upwards of 4,000,000 of acres, and is divided by a ridge of hills which run nearly from E. to W. from sea to sea. Here abundance of fine rivers take their rise, and flow from both sides in gentle streams, refreshing the valleys as they glide along, and furnishing the inhabitants with sweet and cool water. They are well stored with fish of various kinds, not known in Europe, but exceedingly good. However, they have eels and crawfish in great plenty, not unlike ours. None of these rivers are navigable, even for barges: but some of them are so large, that the sugars are carried upon them in canoes from the remote plantations to the sea side. They are so numerous, that it is impossible to describe them all, and some of them run under ground for a considerable space, particularly the Rio-Cobre and the Rio-Pedra. The mountains, and indeed the greatest part of the island, are covered with woods, which never lose their verdure, but look green at all times of the year; for here is an eternal spring. There are a thousand different kinds of trees adorning the brow of every hill, irregularly mixing their different branches, appearing in gay confusion, and forming groves and cool retreats. Among these are the *lignum vitæ*, the cedar, and the mahogany-trees. In the valleys are sugar-canes, and such a variety of fruit-trees as to make the country look like a paradise. But to balance this, there are dreadful alligators in the rivers; guanoes and galliwatps in the fens and marshes; and snakes and noxious animals in the moun-

tains. The longest day is about 13 hours; and about nine in the morning it is so intolerably hot, that it would be difficult to live, if the sea breezes did not arise to cool the air. Sometimes the nights are pretty cool, and there are great dews, which are looked upon as unwholesome, especially to new comers. There are two springs, or seasons for planting grain, and the year is distinguished into two seasons, which are the wet and dry; but the rains are not so frequent as they were formerly, which is supposed to be owing to the cutting down of the woods. The months of July, August, and September, are called the hurricane months, because then they are the most frequent; and there is lightning almost every night. There is not above a third part of the island inhabited, for the plantations are all by the sea-side. Here and there are savannas, or large plains, where the original natives used to plant their Indian corn, and which the Spaniards made use of for breeding their cattle; but these are now quite bare and barren. The gentlemen's houses are generally built low, being only one story, on account of the hurricanes and earthquakes; and the negroes' huts are made of reeds, and will hold only two or three persons. The common drink is Madeira wine, or rum punch. The common bread, or that which serves for it, is plantains, yams, and cassava-roots. The yams are like potatoes, only coarser, and of a much larger size. But in February 1793, by the benevolent directions of his Majesty, a great number of the bread fruit trees were brought here from Otaheite, by the Providence frigate, captain Bligh, in order to be introduced into the different plantations. Hogs are plentiful, and their mutton and lamb pretty good; but the servants generally feed upon Irish salt-beef, and the negroes have herrings and salt fish. The common dress of the men is linen drawers and waistcoats, thread stockings, and handkerchiefs tied round the head; but upon public occasions the gentlemen wear wigs, silk coats, and waistcoats, trimmed with silver. The ladies are richly dressed, and the servant-maids wear linen gowns. The current coin is all Spanish money, for that of the English is kept as a curiosity. The general produce of this island is sugar, rum, ginger, cotton, indigo, pimento, chocolate, several kinds of woods and medicinal drugs. They have some tobacco, which is but indifferent, and used only by the Negroes, who can scarce live without it. They have no sorts of European grain; but they have Indian corn, Guinea corn, and peas of various kinds (but none like ours), with variety of roots. Fruits are in great plenty, such as Seville and China oranges, common and sweet lemons, shaddocks, citrons, pomegranates, mammees, sweet sops, papaws, pine-apples, star-apples, prickly pears, alicada pears, melons, pumpions, guavas, and many other sorts. The common distempers are, fevers, fluxes, and the dry gripes. There are four negroes to a white man; and of the former there are about 100,000, besides a mixed breed between the blacks, whites, and mulattoes. This island was taken by the English in 1655. The principal town is Kingston; but St. Jago de la Vega, or Spanish Town, is the seat of government. The centre of this island is in W. lon. 76. 45. N. lat. 18. 2.

JAMANA, a town of Asia, in Arabia Felix, capital of a principality that lies between Hagias, Oman, and Arabia Deserta, seated on the river Aftan, 150 miles W. of Elcatif.

JAMBI, or JAMBIS, a sea-port and small kingdom of Asia, on the eastern coast of the island of Sumatra. It is a trading place. The Dutch have a fort here, and export pepper hence, with the best sort of canes. It is 160 miles N. of Bencoolen. E. lon. 102. 35. N. lat. 0. 59.

JAMBIA VICUS. See YAMBRO.

IAMBIC, in ancient poetry, a sort of verse, so called from its consisting either wholly, or in great part, of iammbuses. See IAMBUS. Ruddiman makes two kinds of iambic, viz. dimeter and trimeter; the former containing four feet, and the latter six.

And as to the variety of their feet, they consist wholly of iammbuses, as in the two following verses of Horace:

1	2	3	4	5	6
Dim.	Inar	sit æ	fluo	sius	
Trim.	Suis	& i	p/a Ro	ma vi	ribus
					ruit.

Or, a dactylus, spondeus, anapestus, and sometimes tribrachys, obtain in the odd places; and the tribrachys also in the even places, excepting the last. Examples of all which may be seen in Horace; as,

Dimeter.					
1	2	3	4	5	6
Canidi	a tra	Etavit	dapes		
Vide	re prope	rantes	domum		

Trimeter.					
Quò quò	scele	si rui	tis aut	cur dex'	teris.
Prius	quæ cæ	lum si	det in	ferius	mari.
Aliti	bus at	que cani	bus homi	cid' He	Etorem.
Pavidum	que lepo	r'ant ad	venam laqueo	gruem.	

JAMBLICUS, the name of two celebrated Platonic philosophers, one of whom was of Colchis, and the other of Apamea in Syria. The first, whom Julian equals to Plato, was the disciple of Anaxagoras and Porphyry, and died under the reign of the emperor Constantine.—The second also enjoyed great reputation. Julian wrote several letters to him, and it is said he was poisoned under the reign of Valens. It is not known to which of the two we ought to attribute the works we have in Greek under the name of *Jamblicus*, viz. 1. The history of the life of Pythagoras, and the sect of the Pythagoreans. 2. An exhortation to the study of philosophy. 3. A piece against Porphyry's letter on the mysteries of the Egyptians.

JAMBOLIFERA, in botany; a genus of the monogynia order, belonging to the octandria class of plants; and in the natural method ranking with those of which the order is doubtful. The calyx is quadridented; the corolla tetrapetalous, and funnel-shaped; the filaments a little plane; the stigma simple.

IAMBUS, in the Greek and Latin prosody, a poetical foot; consisting of a short syllable followed by a long one; as in

Ἐὐ λέγω, Δεί, μέας.

Syllaba longa brevi subiecta vocatur iambus, as Horace expresses it; who also calls the iambus a swift, rapid foot, *pes cilius*.

The word, according to some, took its rise from Iambus, the son of Pan and Echo, who invented this foot; or, perhaps, who only used sharp-biting expressions to Ceres, when afflicted for the death of Proserpine. Others rather derive it from the Greek *ios*, *venenum*, "poison;" or from *ιαμειζω maledico*, "I rail or revile;" because the verses composed of iammbuses were at first only used in satire.

ST. JAMES of the Sword, (*San Jago del Espada*) a military order in Spain, instituted in 1170 under the reign of Ferdinand II. king of Leon and Galicia. Its end was to put a stop to the incursions of the Moors; these knights obliging themselves by a vow to secure the roads. An union was proposed and agreed to in 1170 between these and the canons of St. Eloy; and the order was confirmed by the pope in 1175. The highest dignity in that order is that of grand master, which has been united to the crown of Spain. The knights are obliged to make proof of their descent from families that have been noble for four generations on both sides; they must also make it appear, that their said ancestors have neither been Jews, Saracens, nor heretics; nor even to have been called in question by the Inquisition. The novices are obliged to serve six months in the galleys, and to live a month in a monastery. Heretofore they were truly religious, and took a vow of celibacy; but Alexander III. gave them a permission to marry. They now make no vows but of poverty, obedience, and conjugal fidelity; to which, since the year 1652, they have added that of defending the immacu-

late conception of the holy Virgin. Their habit is a white cloak, with a red cross on the breast. This is esteemed the most considerable of all the military orders in Spain: the king carefully preserves the office of grand-master in his own family, on account of the rich revenues and offices whereof it gives him the disposal. The number of knights is much greater now than formerly, all the grandees choosing rather to be received into this than into the order of the golden fleece; inasmuch as this puts them in a fair way of attaining to commands, and gives them many considerable privileges in all the provinces of Spain, but especially in Catalonia.

JAMES (Thomas), a learned English critic and divine, born about the year 1571. He recommended himself to the office of keeper of the public library at Oxford, by the arduous undertaking of publishing a catalogue of the MSS in each college library at both universities. He was elected to this office in 1602, and held it 18 years, when he resigned it to prosecute his studies with more freedom. In the convocation held with the parliament at Oxford in 1625, of which he was a member, he moved to have proper commissioners appointed to collate the MSS of the Fathers in all the libraries in England, with the Popish editions, in order to detect the forgeries in the latter; but this proposal not meeting with the desired encouragement, he engaged in the laborious task himself, which he continued until his death in 1629. He left behind him a great number of learned works.

JAMES (Richard), nephew of the former, entered into orders in 1615: but being a man of humour, of three sermons preached before the university, one concerning the observation of Lent was without a text, according to the most ancient manner; another against the text; and the third beside it. About the year 1619, he travelled through Wales, Scotland, Shetland, into Greenland and Russia, of which he wrote observations. He assisted Selden in compiling his *Marmora Arundeliana*; and was very serviceable to Sir Robert Cotton; and his son Sir Thomas, in disposing and settling their noble library. He died in 1638; and has an extraordinary character given him by Wood for learning and abilities.

JAMES (Dr. Robert), an English physician of great eminence, and particularly distinguished by the preparation of a most excellent fever-powder, was born at Kinverston in Staffordshire, A. D. 1703: his father a major in the army, his mother a sister of Sir Robert Clarke. He was of St. John's college in Oxford, where he took the degree of A. B. and afterwards practised physic at Sheffield, Lichfield, and Birmingham successively. Then he removed to London, and became a licentiate in the college of physicians; but in what years we cannot say. At London he applied himself to writing as well as practising physic; and published a Medicinal Dictionary in 3 vols. folio, and many lesser works.

JAMES'S Powder, a medicine prepared by Dr. James, of which the basis has been long known to chemists, though the particular receipt for making it lay long concealed, till made public by Dr. Monro in his *Medical and Pharmaceutical Chemistry*. The following (Dr. Monro informs us) is a copy of the receipt, extracted from the Records of Chancery; the inventor, when he took out a patent for selling his powder, having sworn, in the most solemn manner, that it was the true and genuine receipt for preparing it:

'Take antimony, calcine it with a continued protracted heat, in a flat, unglazed earthen vessel, adding to it from time to time a sufficient quantity of any animal oil and salt, well dephlegmated; then boil it in melted nitre for a considerable time, and separate the powder from the nitre, by dissolving it in water.'

"This extract Dr. Monro accompanies with the following observations. "When the Doctor first administered his powder,

he used to join one grain of the following mercurial preparation to thirty grains of his antimonial powder; but in the latter part of his life he often declared that he had long laid aside the addition of the mercurial. His mercurial, which he called a pill, appears by the records of chancery to have been made in the following manner: 'Purify quicksilver, by distilling it nine times from an amalgam, made with martial regulus of antimony, and a proportional quantity of sal ammoniac; dissolve this purified quicksilver in spirit of nitre, evaporate to dryness, calcine the powder till it becomes of a gold colour; burn spirits of wine upon it, and keep it for use.' Dr. James, at the end of the receipt given into chancery, says, 'The dose of these medicines is uncertain; but in general thirty grains of the antimonial and one grain of the mercurial is a moderate dose. Signed and sworn to by Robert James.'

There is the greatest reason to believe, however, that the medicine sold subsequent to the recording of this receipt in chancery, was not made conformably to it. From an analysis made by Dr. Higgins, the London college have introduced into their new Pharmacopœia, an imitation of Dr. James's powder under the title of *pulvis antimonialis*.

"It has been called Dr. James's Fever Powder (continues Dr. Monro), and many have believed it to be a certain remedy for fevers, and that Dr. James had cured most of the patients whom he attended, and who recovered, by the use of this powder. But the bark, and not the antimonial powder, was the remedy which Dr. James almost always trusted to for the cure of fevers: he gave his powders only to clear the stomach and bowels; and after he had effected that, he poured in the bark as freely as the patient could swallow it. The Doctor believed all fevers to be more or less of the intermitting kind; and that if there was a possibility of curing a fever, the bark was the remedy to effectuate the cure; for if the fever did not yield to that, he was sure that it would yield to no other remedy whatever, as he has more than once declared to me when I have attended patients in fevers along with him."

JAMES-Island, an island of Africa, 30 miles up the river Gambia, in the middle of the river, and three miles from its nearest shore. On this island, which is about a mile in circumference, the English have a fort and a considerable factory. W. long. 16. 0. N. lat. 13. 15.

JAMES-Island, an island of N. America, opposite Charleston in S. Carolina. It contains about 50 families.

JAMES-River, a fine river of Virginia, in N. America, which enters the bay of Chesapeake, near James-Town.

ST. JAMES, an hospital and burying-ground not far from Basil in Switzerland, and near the small river Birs. It is celebrated for a desperate combat fought by about 3000 Swifs against an army of 30,000 French, commanded by the dauphin, afterward Lewis XI. in which only 32 of the former remained alive, desperately wounded, on the field of battle. Sixteen that escaped from the field were branded with infamy, for not having sacrificed their lives in defence of their country. The conqueror himself, who was compelled to retire with his army into Alsace, declared that such another victory would ruin it.

JAMES-Town, a town of N. America, once the capital of Virginia, seated in a peninsula on the N. side of James River. W. lon. 76. 29. N. lat. 37. 3.

JAMES-Town, a borough of Ireland, in the county of Leitrim, five miles N. W. of Carrick on Shannon, and 73 N. W. of Dublin. W. lon. 8. 15. N. lat. 53. 44.

St. JAMES'S Day, a festival of the Christian church, observed on the 25th of July, in honour of St. James the greater, son of Zebedee.

Epistle of St. JAMES, a canonical book of the New Testament, being the first of the catholic or general epistles; which are so called, as not being written to one, but to several Chris-

tian churches. This general epistle is addressed partly to the believing and partly to the infidel Jews; and is designed to correct the errors, soften the ungoverned zeal, and reform the indecent behaviour of the latter; and to comfort the former under the great hardships they then did, or shortly were to suffer, for the sake of Christianity.

JAMESONE (GEORGE), an excellent painter, justly termed the *Vandyck of Scotland*, was the son of Andrew Jamesone, an architect; and was born at Aberdeen, 1586. He studied under Rubens, at Antwerp; and, after his return, applied with indefatigable industry to portraits in oil, though he sometimes practised in miniature, and also in history and landscapes. His largest portraits were somewhat less than life. His earliest works are chiefly on board, afterwards on a fine linnen cloth, smoothly primed with a proper tone to help the harmony of his shadows. His excellence is said to consist in delicacy and softness, with a clear and beautiful colouring; his shades not charged, but helped by varnish, with little appearance of the pencil. When king Charles I. visited Scotland in 1633, the magistrates of Edinburgh, knowing his majesty's taste, employed this artist to make drawings of the Scottish monarchs; with which the king was so pleased, that, inquiring for the painter, he sat to him, and rewarded him with a diamond-ring from his own finger. It is observable, that Jamesone always drew himself with his hat on, either in imitation of his master Rubens, or on having been indulged in that liberty by the king when he sat to him. Many of Jamesone's works are in both the colleges of Aberdeen; and the Sybils there he is said to have drawn from living beauties in that city. His best works are from the year 1630 to his death, which happened at Edinburgh in 1644.

JAMETS, a town of France, in the department of Meuse, and late province of Barrois, 12 miles S. of Stenay.

JAMYN (AMANDIS), a celebrated French poet in the 16th century. He is esteemed the rival of Ronsard, who was his cotemporary and friend. He was secretary and chamber-reader in ordinary to Charles IX. and died about 1585. He wrote, 1. Poetical works, 2 vols. 2. Philosophical discourses to Paphis and Rodanthe, with seven academical discourses. 3. A translation of the Iliad of Homer, begun by Hugh Sabel, and finished by Jamyn; with a translation into French verse of the three first books of the Odyssey.

JANE of FLANDERS, a remarkable lady, who seems to have possessed in her own person all the excellent qualities of both sexes, was the wife of John de Mountfort, a competitor for the dukedom of Brittany upon the death of John III. This duke, dying without issue, left his dominions to his niece Jane, married to Charles de Blois nephew to the king of France; but John de Mountfort, brother to the late duke, though by a second marriage, claimed the duchy, and was received as successor by the people of Nantes. The greatest part of the nobility swore fealty to Charles de Blois, thinking him best supported. This dispute occasioned a civil war; in the course of which John was taken prisoner and sent to Paris. This misfortune would have entirely ruined his party, had not his interest been supported by the extraordinary abilities of his wife Jane of Flanders. Bold, daring, and intrepid, she fought like a warrior in the field; shrewd, sensible, and sagacious, she spoke like a politician in the council; and, endowed with the most amiable manners and winning address, she was able to move the minds of her subjects by the force of her eloquence, and mould them exactly according to her pleasure. She happened to be at Rennes when she received the news of her husband's captivity; but that disaster, instead of depressing her spirits, served only to rouse her native courage and fortitude. She forthwith assembled the citizens; and, holding in her arms her infant son, recommended him to their care and protection in the most pathetic terms, as

the male heir of their ancient dukes, who had always governed them with lenity and indulgence, and to whom they had ever professed the most zealous attachment. She declared herself willing to run all hazards with them in so just a cause; pointed out the resources that still remained in the alliance of England; earnestly beseeching them to make one vigorous effort against an usurper, who being forced upon them by the intrigues of France, would, as a mark of his gratitude, sacrifice the liberties of Brittany to his protector. The people, moved by the affecting appearance, and animated by the noble conduct of the princess, vowed to live and die with her in defending the rights of her family; and their example was followed by almost all the Bretons. The countess went from place to place, encouraging the garrisons of the several fortresses, and providing them with every thing necessary for their subsistence: after which she shut herself up with her son in Hennebon, where she resolved to wait for the succours which the king of England (Edward III.) had promised to send to her assistance. Charles de Blois, accompanied by the Dukes of Burgundy and Bourbon, and many other noblemen, took the field with a numerous army, and, having reduced Rennes, laid siege to Hennebon, which was defended by the countess in person. This heroine repulsed the assailants in all their attacks with the most undaunted courage; and observing one day that their whole army had left the camp to join in a general storm, she rushed forth at a postern gate, with three hundred horse, set fire to their tents and baggage, killed their sutlers and servants, and raised such a terror and consternation through all their quarters, that the enemy gave over their assault, and, getting betwixt her and the walls, endeavoured to cut off her retreat to the city. Thus intercepted, she put the spurs to her horse, and, without halting, galloped directly to Brest, which lay at the distance of two-and-twenty miles from the scene of action. There being supplied with a body of five hundred horse, she immediately returned, and, fighting her way through one part of the French camp, was received into Hennebon amidst the acclamations of the people. Soon after this the English succours appeared, and obliged the enemy to raise the siege.

JANEIRO, called also RIO JANEIRO, a province of Brazil in South America, seated between the tropic of Capricorn and 22° of S. lat. It is bounded on the north by the province of Spirito Sancto, on the east and south by the Atlantic Ocean, and on the west by the mountains which separate it from Guiana in Spanish America. This is the most valuable province which the Portuguese are masters of; for they import from thence yearly great quantities of gold and precious stones, which they find in the mountains to a prodigious value.

JANICULUM, or JANICULARIS, a hill of ancient Rome, added by Ancus Martius; the burial-place of Numa, and of Statius Cæcilius the poet: to the east and south, having the Tiber; to the west, the fields; to the north, a part of the Vatican. So called, either from an ancient city, (Virgil); or because it was a *janua*, or gate, from which to issue out and make incursions on the Tuscans, (Verrius Flaccus.) Now called *Mons Aureus*, corruptly *Momorius*, from its sparkling sands. From this hill, on account of its height, is the most extensive prospect of Rome; but it is less inhabited, because of its gross air; neither is it reckoned among the seven hills. Hither the people retired, and were hence afterwards recalled by Q. Hortensius the dictator. (Pliny.)

JANIZARIES, an order of infantry in the Turkish armies; reputed the grand seignior's foot-guards. Vossius derives the word from *genizers*, which in the Turkish language signifies *novi homines* or *milites*. D'Herbelot tells us, that *jenitcheri* signifies a *new band*, or *troop*; and that the name was first given by Amurath I. called the *Conqueror*, who choosing out one fifth part of the Christian prisoners whom he had taken from

the Greeks, and instructing them in the discipline of war and the doctrines of their religion, sent them to Hagi Bektafche (a person whose pretended piety rendered him extremely revered among the Turks), to the end that he might confer his blessing on them, and at the same time give them some mark to distinguish them from the rest of the troops.—Bektafche, after blessing them in his manner, cut off one of the sleeves of the fur-gown which he had on, and put it on the head of the leader of this new militia; from which time, viz. the year of Christ 1361, they have still retained the name *jenitcheri*, and the fur-cap.

As, in the Turkish army, the European troops are distinguished from those of Asia; the janizaries are also distinguished into *janizaries of Constantinople*, and of *Damascus*. Their pay is from two aspers to twelve *per diem*; for when they have a child, or do any signal piece of service, their pay is augmented. Their dress consists of a dolymen, or long gown with short sleeves, which is given them annually by the grand seignior on the first day of Ramazan. They wear no turban; but, in lieu of that, a kind of cap which they call *zarcola*, and a long hood of the same stuff hanging on their shoulders. On solemn days they are adorned with feathers, which are stuck in a little case on the fore part of the bonnet.—Their arms, in Europe, in time of war, are a fabre, a carabine or musket, and a cartouch-box hanging on the left side. At Constantinople, in time of peace, they wear only a long staff in their hand. In Asia, where powder and fire-arms are more uncommon, they wear a bow and arrows, with a poignard, which they call *baniare*.—Though the janizaries are not prohibited marriage, yet they rarely marry, nor then but with the consent of their officers; as imagining a married man to make a worse soldier than a bachelor.—It was Osman, or Ottoman, or, as others will have it, Amurath, who first instituted the order of janizaries. They were at first called *jaja*, that is, footmen, to distinguish them from the other Turks, the troops whereof consisted mostly of cavalry. The number of janizaries is generally above 40,000; divided into 162 companies or chambers called *odas*, in which they live together at Constantinople as in a convent. They are of a superior rank to all other soldiers, and are also more arrogant and factious, and it is by them that the public tranquillity is mostly disturbed. The government may therefore be said to be in the hands of the janizaries. They have, however, some good qualities: they are employed to escort travellers, and especially ambassadors and persons of high rank, on the road; in which case, they behave with the utmost zeal and fidelity.

JANIZARIES, at Rome, are officers or pensioners of the pope, called also *participantes*, on account of certain rights or duties which they enjoy in the annates, bulls, or expeditions, and the Roman chancery.—Most authors are mistaken in the nature of their office: the truth is, they are officers of the third bench or college of the Roman chancery. The first bench consists of writers, the second of abbreviators, and the third of *janizaries*; who are a kind of correctors and revisers of the pope's bulls.

JANNA, a territory of Turkey in Europe, in Macedonia, bounded on the S. by Livadia, on the W. by Albania, and on the E. by the Archipelago. It is the Thessalia of the ancients, and Larissa is the capital.

JANNA, a town of Turkey in Europe, in the province of Janna. It is inhabited by rich Greek merchants, and is 62 miles W. of Larissa. E. lon. 21. 36. N. lat. 39. 44.

JANOWITZ, a town of Bohemia, in the circle of Kaushim, famous for a battle, in 1645, between the Swedes and the Imperialists, when the latter were defeated. It is 48 miles S. E. of Prague. E. lon. 15. 38. N. lat. 49. 45.

JANSEN (CORNELIUS), bishop of Ypres, one of the most learned divines of the 17th century, and principal of the sect called from his name *Jansenists*. He was born in Holland of

Catholic parents, and studied at Louvain. Being sent to transact some business of consequence relating to the university, into Spain, the Catholic king, viewing with a jealous eye the intriguing policy of France, engaged him to write a book to expose the French to the Pope as no good Catholics, since they made no scruple of forming alliances with Protestant states. Jansen performed this task in his *Mars Gallicus*; and was rewarded with a mitre, being promoted to the see of Ypres in 1635. He had, among other writings, before this, maintained a controversy against the Protestants upon the points of grace and predestination; but his *Augustinus* was the principal labour of his life, on which he spent above 20 years. See the next article.

JANSENISTS, in church-history, a sect of the Roman Catholics in France, who followed the opinions of Jansenius bishop of Ypres, and doctor of divinity of the universities of Louvain and Douay, in relation to grace and predestination. In the year 1640 the two universities just mentioned, and particularly father Molina and father Leonard Celsus, thought fit to condemn the opinions of the Jesuits on grace and free-will. This having set the controversy on foot, Jansenius opposed to the doctrine of the Jesuits the sentiments of St. Augustine; and wrote a treatise on grace, which he entitled *Augustinus*. This treatise was attacked by the Jesuits, who accused Jansenius of maintaining dangerous and heretical opinions; and afterwards, in 1642, obtained of pope Urban VIII. a formal condemnation of the treatise written by Jansenius: when the partisans of Jansenius gave out that this bull was spurious, and composed by a person entirely devoted to the Jesuits. After the death of Urban VIII. the affair of Jansenism began to be more warmly controverted, and gave birth to an infinite number of polemical writings concerning grace. And what occasioned some mirth, was the titles which each party gave to their writings; one writer published *The torch of St. Augustine*, another found *Snuffers for St. Augustine's torch*, and father Veron formed *A gag for the Jansenists*, &c. In the year 1650, 68 bishops of France subscribed a letter to pope Innocent X. to obtain an inquiry into and condemnation of the five following propositions, extracted from Jansenius's *Augustinus*: 1. Some of God's commandments are impossible to be observed by the righteous, even though they endeavour with all their power to accomplish them. 2. In the state of corrupted nature, we are incapable of resisting inward grace. 3. Merit and demerit, in a state of corrupted nature, does not depend on a liberty which excludes necessity, but on a liberty which excludes constraint. 4. The Semipelagians admitted the necessity of an inward preventing grace for the performance of each particular act, even for the beginning of faith; but they were heretics in maintaining that this grace was of such a nature, that the will of man was able either to resist or obey it. It is Semipelagianism to say, that Jesus Christ died, or shed his blood, for all mankind in general.

In the year 1652 the pope appointed a congregation for examining into the dispute in relation to grace. In this congregation Jansenius was condemned; and the bull of condemnation, published in May 1653, filled all the pulpits in Paris with violent outcries and alarms against the heresy of the Jansenists. In the year 1656 pope Alexander VII. issued out another bull, in which he condemned the five propositions of Jansenius. However, the Jansenists affirm, that these propositions are not to be found in this book; but that some of his enemies, having caused them to be printed on a sheet, inserted them in the book, and thereby deceived the pope. At last Clement XI. put an end to the dispute by his constitution of July 17, 1705; in which, after having recited the constitutions of his predecessors in relation to this affair, he declares, "That in order to pay a proper obedience to the papal constitutions concerning the present question, it is necessary to receive them

with a respectful silence." The clergy of Paris, the same year, approved and accepted this bull, and none dared to oppose it. This is the famous bull *Unigenitus*, so called from its beginning with the words *Unigenitus Dei Filius*, &c. which occasioned so much confusion in France.

JANSSENS (ABRAHAM), history-painter, was born at Antwerp in 1569. He was cotemporary with Rubens, and also his competitor, and in many of the finest parts of the art was accounted not inferior to that celebrated master. It is reported, that having wasted his time and his substance by a life of dissipation and pleasure, and falling into necessitous circumstances, which he imputed more to ill fortune than to his own neglect of his business, he grew envious at the grandeur in which Rubens appeared, and impatient at his merit and success; and with peevish insolence challenged him to paint a picture with him only for fame, which he was willing to submit to impartial judges. But Rubens rejected the proposal, answering with modesty, that he freely submitted to him, and the world would certainly do justice to them both. Sandrart, who had seen several of his works, assures us, that he not only gave a fine roundness and relief to his figures, but also such a warmth and clearness to the carnations, that they had all the look of real flesh: and his colouring was as durable as it was beautiful, retaining its original lustre for a number of years. His most capital performance is said to be a resurrection of Lazarus, which is in the cabinet of the Elector Palatine, and is an object of admiration to all who behold it.

JANSSENS (VICTOR HONORIUS), history-painter, was born at Brussels in 1664, and was a disciple of one Volders, under whose direction he continued for seven years; in which time he gave many proofs of a genius far superior to those who were instructed in the same school. He afterwards went to Rome, where he attended particularly to the works of Raphael; he designed after the antiques, and sketched the beautiful scenes around that city; and in a short time his paintings rose in esteem, and the principal nobility of Rome were desirous to employ him. He associated with Tempesta, the celebrated landscape painter, for several years, and painted the figures in the works of that great master as long as they resided together.

Janssens composed historical subjects, both in a small and a large size; but he found the demand for his small pictures so considerable, that he was induced to paint most frequently in that size. During 11 years he continued at Rome, which barely sufficed for his finishing those pictures for which he was engaged; nor could he have been even then at his liberty, had he not limited himself to a number, and determined not to undertake more.—Returning to Brussels, his performances were as much admired there as they had before been in Italy; but having married, and gradually become the father of 11 children, he was compelled to change his manner of painting in small, and to undertake only those of the large kind, as being more lucrative, more expeditious, and also more agreeable to his genius and inclination. He adorned most of the churches and palaces of his own country with his compositions.—The invention of this artist was fruitful; he designed correctly, his colouring is natural and pleasing, his pencil free, and the airs of his heads have beauty and elegance. As to the difference between his large and small paintings, it is observed, that in correctness and taste they had an equal degree of merit; but the colouring of the former appears more raw and cold than the colouring of the latter; and it is agreed that, for small historical pictures, he was preferable to all the painters of his time.

JANSSEN (CORNELIUS) called *Johnson*, an eminent painter of portraits, was born at Amsterdam (though in the Chronological Tables, and in Sandrart, it is improperly asserted that he was born in London), and he resided in England for several years; where he was engaged in the service of king James I. and

Painted several excellent portraits of that monarch, as also of his children and of the principal nobility of his court. He had not the freedom of hand, nor the grace of Vandyck; but in other respects he was accounted his equal, and in the finishing his pictures superior. His paintings are easily distinguished by their smooth, clear, and delicate tints, and by that character of truth and nature with which they are strongly marked. He generally painted on board; and, for the most part, his draperies are black; probably because the opposition of that tint made his flesh colours appear more beautifully bright, especially in his female figures. It is said that he used a quantity of ultra-marine in the black colours, as well as in his carnations; which may be one great cause of their preserving their original lustre even to this day. Frequently he painted in a small size in oil, and often copied his own works in that manner: His fame began to be somewhat obscured, on the arrival of Vandyck in England; and the civil war breaking out some time after, induced him to return to his own country, where his paintings were in the highest esteem. He died in 1683.

ST. JANUARIUS, the patron saint of Naples, where his head is occasionally carried in procession, in order to stay the eruption of Vesuvius. The liquefaction of his blood is a famous miracle at Naples. The saint suffered martyrdom about the end of the third century. When he was beheaded, a pious lady of Naples caught about an ounce of his blood, which has been carefully preserved in a bottle ever since, without having lost a single grain of its weight. This, of itself, were it equally demonstrable, might be considered as a greater miracle than the circumstance on which the Neapolitans lay the whole stress, *viz.* that the blood, which has congealed, and acquired a solid form by age, is no sooner brought near the head of the saint, than, as a mark of veneration, it immediately liquefies. This experiment is made three different times every year, and is considered by the Neapolitans as a miracle of the first magnitude. The substance in the bottle, which is exhibited for the blood of the saint, is a sort of red size somewhat solid, but which melts with a small degree of heat. When it is first brought out of the cold chapel, it is in its natural solid state; but when brought before the saint by the priest, and rubbed between his warm hands, and breathed upon for some time, it melts; and this is the whole mystery.

The head and blood of the saint are kept in a kind of press with folding doors of silver, in the chapel of St. Januarius belonging to the cathedral church. The real head is probably not so fresh, and well preserved, as the blood. On that account it is not exposed to the eyes of the public; but is inclosed in a large silver bust, gilt and enriched with jewels of high value. This being what appears to the people, their idea of the saint's features and complexion is taken entirely from the bust.—The blood is kept in a small repository by itself.

JANUARY, the name of the first month of the year, according to the computation now used in the west. The word is derived from the Latin *Januarius*, a name given it by the Romans, from Janus, one of their divinities, to whom they attributed two faces, because on the one side the first day of January looked towards the new year, and on the other towards the old one. The word *Januarius* may also be derived from *janua* "gate;" in regard this month, being the first, is, as it were, the gate of the year.

January and February were introduced into the year by Numa Poinpilius; Romulus's year beginning in the month of March.—The kalends, or first day of this month, was under the protection of Juno, and in a peculiar manner consecrated to Janus by an offering of a cake made of new meal and new salt, with new frankincense and new wine. On the first day of January, a beginning was made of every intended work, the consuls elect

took possession of their office, who, with the flamens, offered sacrifices and prayers for the prosperity of the empire. On this day all animosities were suspended, and friends gave and received new-year's gifts, called *Strenæ*. On this day too the Romans above all things took care to be merry and divert themselves, and oftentimes such a scene of drunkenness was exhibited that they might with propriety enough have distinguished it by the name of *All-fools day*. The Christians heretofore fasted on the first day of January, by way of opposition to the superstitions and debaucheries of the heathens.

JANUS, in heathen worship, the first king of Italy, who, it is said, received Saturn into his dominions after his being driven from Arcadia by Jupiter. He tempered the manners of his subjects, and taught them civility; and from him they learned to improve the vine, to sow corn, and to make bread. After his death he was adored as a god. This deity was thought to preside over all new undertakings. Hence, in all sacrifices, the first libations of wine and wheat were offered to Janus, all prayers prefaced with a short address to him; and the first month of the year was dedicated to, and named from him. See JANUARY. Janus was represented with two faces, either to denote his prudence, or that he views at once the past and approaching years; he had a sceptre in his right hand, and a key in his left, to signify his extensive authority and his invention of locks. Though this is properly a Roman deity, the abbé La Pluche represents it as derived from the Egyptians, who made known the rising of the dog star, which opened their solar year, with an image with a key in its hand and two faces, one old and the other young, to typify the old and new year.

Temple of JANUS, in ancient history, a square building at Rome (as some say) of entire brass, erected by Romulus, and so large as to contain a statue of Janus five feet high, with brazen gates on each side, which were always kept open in time of war, and shut in time of peace. But the Romans were so much engaged in war, that this temple was shut only twice from the foundation of Rome till the reign of Augustus, and six times afterwards. It was first shut during the long reign of Numa, who instituted this ceremony. 2. In the year of the city 519, after the end of the first Punic war. 3. By Augustus, after the battle of Actium, in the year of Rome 725. 4. On Augustus's return from the war which he had against the Cantabrians in Spain, in the year of Rome 729. 5. Under the same emperor, in 744, about five years before the birth of Christ, when there was a general peace throughout the whole Roman empire, which lasted 12 years. 6. Under Nero, 811. 7. Under Vespasian, 824. 8. Under Constantius, when, upon Magnentius's death, he was left sole possessor of the empire, 1105. Some dispute the authority on which it is said to have been shut by Constantius, and say that the last time of its being shut was under Gordian, about the year of Rome 994. Virgil gives us a noble description of this custom, *Æn.* lib. iii. ver. 607, &c. The origin of this custom is not certainly known.

JANUS was also the name of a street in Rome, inhabited for the most part by bankers and usurers. It was so called from two statues of Janus which were erected there, one at the top, the other at the bottom of the street. The top of the street was therefore called *Janus Summus*, the bottom *Janus Imus*, and the middle *Janus Medius*. Hence Horace, lib. i. Epist. i.

*Hec Janus summus ab imo
Perdocet—*

and Sat. 3. lib. 2.

*—Postquam omnis res mea Janum
Ad medium fracta est.*

JAPAN, a large country in the most eastern part of Asia, with the title of an empire. It is composed of several islands, the principal of which is called Nippon. It was discovered in

1542, by the Portuguese, who were cast on shore by a tempest. The whole empire is divided into seven principal countries, which are subdivided into 70 provinces. It is the richest country in the world for gold, and the air and water are very good. It produces a great deal of rice, which they reap in September; millet, wheat, and barley, which they get in in May. Cedars are common, and so large that they are proper for the masts of ships and columns for temples. They have a large quantity of porcelain, silk, and skins; as also red pearls, which are not in less esteem than the white. In short, Japan is accounted one of the best countries in Asia. The inhabitants are naturally ingenious, and have a happy memory; but their manners are diametrically opposite to those of the Europeans. Our common drinks are cold, and theirs are all hot; we uncover the head out of respect, and they the feet; we are fond of white teeth, and they of black; we get on horseback on the left side, and they on the right; and they have a language so peculiar that it is understood by no other nation. The sciences are highly esteemed among them, and they have several schools at different places. Those they study most, are, arithmetic, rhetoric, poetry, history, and astronomy. Some of their schools at Meaco have each 3 or 4000 scholars. They treat the women with great severity, and punish adultery with death; yet a man may take as many wives as he pleases. The Japanese are naturally good soldiers, and skilful at shooting with a bow: however, as they inhabit nothing but islands, they are seldom at war with their neighbours. They formerly carried on a trade with the neighbouring countries, but now all communication with others is forbidden, especially with Christians; for they do not look upon the Dutch to be such. Their emperor is called Dairo; and in the minority of one of them, in 1150, when they had civil wars, one of the competitors for the crown assumed the ecclesiastical government, retaining the same title; while the other, who ruled in civil affairs, was called Cuba; and things have remained on the same footing to this day. The Dairo is the chief emperor, and confers the dignity upon the other, as if he were his vassal. He resides at Meaco, and has no lands: but he has a right of selling titles and dignities; and the idolatrous priests make great contributions. He wears a black habit, and a cap upon his head. His feet must never touch the ground, nor must he ever be exposed to the rays of the sun. He never cuts his hair, nor his beard, nor his nails; and all his victuals must be dressed in new vessels. When he goes abroad, he is carried by 14 men in a litter surrounded with curtains, so that he may see and not be seen. He has generally twelve wives (each of whom has a palace), with singing and dancing women for his diversion. He has also an unlimited number of concubines. His palace is adorned with 365 idols. The religion of the whole country is paganism; but there are two different sects. There were once a great number of Christians in different parts of the empire; but in 1638 they underwent great persecutions, insomuch that they were all extirpated. The cause of this was the opposition of the priests; the haughty behaviour of the Portuguese, they not allowing several wives; and the persuasions of the Dutch, who told them that their emperor would become a slave to the pope. The emperor of Japan is a sovereign monarch, and all the petty kings are his vassals. His army generally consists of 100,000 foot, and 20,000 horse, exclusive of those maintained by his vassals. His ordinary revenue is immense. The palace of the emperor is at Jeddo in the island of Nippon, and it is the capital of the whole. The only Europeans that trade with Japan are the Dutch; and whenever their ships arrive, they take away their guns, sails, and helms, and carry them on shore till they are ready to return back. In the absence of the ships, the factors are shut up in a small peninsula, and are not suffered so much as to have a lighted candle in their houses in the night-time. The merchandize which the Dutch carry to Japan are

spices, sugar, silks, linen and woollen cloth, elephant's teeth, and haberdashery wares; for which they receive gold, silver, cabinets, and other japanned and lackered wares. The Japanese have neither tables, beds, nor chairs; but they sit and lie on carpets and mats, in the manner of the Turks.

JAPAN Earth. See MIMOSA and TERRA Japonica.

JAPANNING, the art of varnishing and drawing figures on wood, in the same manner as is done by the natives of Japan in the East Indies. The substances which admit of being japanned are almost every kind that are dry and rigid, or not too flexible; as wood, metals, leather, and paper prepared.

Wood and metals do not require any other preparation, but to have their surface perfectly even and clean: but leather should be securely strained either on frames or on boards; as its bending or forming folds would otherwise crack and force off the coats of varnish; and paper should be treated in the same manner, and have a previous strong coat of some kind of size; but it is rarely made the subject of japanning till it is converted into *papier maché*, or wrought by other means into such form that its original state, particularly with respect to flexibility, is lost.

One principal variation from the method formerly used in japanning is, the using or omitting any priming or undercoat on the work to be japanned. In the older practice, such priming was always used; and is at present retained in the French manner of japanning coaches, and snuff-boxes of the *papier maché*, but in the Birmingham manufacture here it has been always rejected. The advantage of using such priming or undercoat is, that it makes a saving in the quantity of varnish used; because the matter of which the priming is composed fills up the inequalities of the body to be varnished, and makes it easy, by means of rubbing and water-polishing, to gain an even surface for the varnish: and this was therefore such a convenience in the case of wood, as the giving a hardness and firmness to the ground was also in the case of leather, that it became an established method; and is therefore retained, even in the instance of the *papier maché*, by the French, who applied the received method of japanning to that kind of work on its introduction. There is nevertheless this inconvenience always attending the use of an undercoat of size, that the japan coats of varnish and colour will be constantly liable to be cracked and peeled off by any violence, and will not endure near so long as the bodies japanned in the same manner, but without any such priming; as may be easily observed on comparing the wear of the Paris and Birmingham snuff-boxes; which latter, when good of their kind, never peel or crack, or suffer any damage, unless by great violence, and such a continued rubbing as wastes away the substance of the varnish; while the Japan coats of the Parisian crack and fly off in flakes, whenever any knock or fall, particularly near the edges, exposes them to be injured. But the Birmingham manufacturers, who originally practised the japanning only on metals, to which the reason above given for the use of priming did not extend, and who took up this art of themselves as an invention, of course omitted at first the use of any such undercoat; and not finding it more necessary in the instance of *papier maché*, than on metals, continue still to reject it. On this account the boxes of their manufacture are, with regard to the wear, greatly better than the French.

The laying on the colours in gum-water, instead of varnish, is also another variation from the method of japanning formerly practised; but the much greater strength of the work, where they are laid on in varnish or oil, has occasioned this way to be exploded with the greatest reason in all regular manufactures: however, they who may practise japanning on cabinets, or other such pieces as are not exposed to much wear and violence, for their amusement only, and consequently may not find it worth their while to encumber themselves with the preparations

necessary for the other methods, may paint with water colours on an undercoat laid on the wood or other substance of which the piece to be japanned is formed; and then finish with the proper coats of varnish, according to the methods below taught; and if the colours are tempered with the strongest isinglass size and honey, instead of gum water, and laid on very flat and even, the work will not be much inferior in appearance to that done by the other method, and will last as long as the old japan.

Of JAPAN Grounds.—The proper grounds are either such as are formed of the varnish and colour, where the whole is to remain of one simple colour; or by the varnish either coloured or without colour, on which some painting or other decoration is afterwards to be laid. It is necessary, however, before we proceed to speak of the particular grounds, to shew the manner of laying on the priming or undercoat, where any such is used.

This priming is of the same nature with that called *clar-coating*, or vulgarly *clear-coaling*, practised erroneously by the house-painters; and consists only in laying on and drying in the most even manner, a composition of size and whiting, or sometimes lime instead of the latter. The common size has been generally used for this purpose; but where the work is of a nicer kind, it is better to employ the glover's or the parchment size; and if a third of isinglass be added, it will be still better, and, if not laid on too thick, much less liable to peel and crack. The work should be prepared for this priming, by being well smoothed with the fish-skin or glass-shaver; and being made thoroughly clean, should be brushed over once or twice with hot size, diluted with two thirds of water, if it be of the common strength. The priming should then be laid on with a brush as even as possible; and should be formed of a size whose consistence is betwixt the common kind of glue, mixed with as much whiting as will give it a sufficient body of colour to hide the surface of whatever it is laid upon, but not more.

If the surface be very clean on which the priming is used, two coats of it laid on in this manner will be sufficient: but if, on trial with a fine wet rag, it will not receive a proper water polish on account of any inequalities not sufficiently filled up and covered, two or more coats must be given it; and whether a greater or less number be used, the work should be smoothed, after the last coat but one is dry, by rubbing it with the Dutch rushes. When the last coat is dry, the water polish should be given, by passing over every part of it with a fine rag, gently moistened, till the whole appear perfectly plain and even. The priming will then be completed, and the work ready to receive the painting or coloured varnish; the rest of the proceedings being the same in this case as where no priming is used.

When wood or leather is to be japanned, and no priming is used, the best preparation is to lay two or three coats of coarse varnish composed in the following manner: "Take of rectified spirit of wine one pint, and of coarse seed-lac and resin each two ounces. Dissolve the seed-lac and resin in the spirit; and then strain off the varnish." This varnish, as well as all others formed of spirit of wine, must be laid on in a warm place; and, if it can be conveniently managed, the piece of work to be varnished should be made warm likewise; and for the same reason all dampness should be avoided; for either cold or moisture chills this kind of varnish, and prevents its taking proper hold of the substance on which it is laid.

When the work is so prepared, or by the priming with the composition of size and whiting above described, the proper japan ground must be laid on, which is much the best formed of shell-lac varnish and the colour desired, if white be not in question, which demands a peculiar treatment, or great brightness be not required, when also other means must be pursued.

The colours used with the shell-lac varnish may be any pigments whatever, which give the tint of the ground desired: and

they may be mixed together to form browns or any compound colours.

As metals never require to be undercoated with whiting, they may be treated in the same manner as wood or leather, when the undercoat is omitted, except in the instances particularly spoken of below.

White JAPAN Grounds.—The forming a ground perfectly white, and of the first degree of hardness, remains hitherto a desideratum, or matter sought for, in the art of Japanning, as there are no substances, which form a very hard varnish, but what have too much colour not to deprave the whiteness when laid on of a due thickness over the work.

The nearest approach, however, to a perfect white varnish, already known, is made by the following composition :

“ Take flake white, or white lead, washed over and ground up with a sixth of its weight of starch, and then dried ; and temper it properly for spreading with the mastich varnish prepared as under the article VARNISH.

“ Lay these on the body to be japanned, prepared either with or without the undercoat of whiting, in the manner as above ordered ; and then varnish it over with five or six coats of the following varnish :

“ Provide any quantity of the best seed-lac ; and pick out of it all the clearest and whitest grains, reserving the more coloured and fouler parts for the coarse varnishes, such as that used for priming or preparing wood or leather. Take of this picked seed-lac two ounces, and of gum-animi three ounces ; and dissolve them, being previously reduced to a gross powder, in about a quart of spirit of wine, and strain off the clear varnish.”

The seed-lac will yet give a slight tinge to this composition, but cannot be omitted where the varnish is wanted to be hard ; though, when a softer will answer the end, the proportion may be diminished, and a little crude turpentine added to the gum-animi, to take off the brittleness.

A very good varnish, free entirely from all brittleness, may be formed by dissolving as much gum-animi as the oil will take in old nut or poppy oil ; which must be made to boil gently when the gum is put into it. The ground of white colour itself may be laid on in this varnish, and then a coat or two of it may be put over the ground ; but it must be well diluted with oil of turpentine when it is used. This, though free from brittleness, is nevertheless liable to suffer by being indented or bruised by any slight strokes ; and it will not well bear any polish, but may be brought to a very smooth surface without, if it be judiciously managed in the laying it on. It is likewise somewhat tedious in drying, and will require some time where several coats are laid on ; as the last ought not to contain much oil of turpentine.

Blue JAPAN Grounds.—Blue japan grounds may be formed of bright Prussian blue, or of verditer glazed over by Prussian blue, or of smalt. The colour may be best mixed with shell-lac varnish, and brought to a polishing state by five or six coats of varnish of seed-lac ; but the varnish, nevertheless, will somewhat injure the colour by giving to a true blue a cast of green, and fouling in some degree a warm blue by the yellow it contains : where, therefore, a bright blue is required, and a less degree of hardness can be dispensed with, the method before directed in the case of white grounds must be pursued.

Red JAPAN Grounds.—For a scarlet japan ground, vermilion may be used : but the vermilion has a glaring effect, that renders it much less beautiful than the crimson produced by glazing it over with carmine or fine lake ; or even with rose-pink, which has a very good effect used for this purpose. For a very bright crimson, nevertheless, instead of glazing with carmine, the Indian lake should be used, dissolved in the spirit of which the varnish is compounded, which it readily admits of when

good : and, in this case, instead of glazing with the shell-lac varnish, the upper or polishing coats need only be used ; as they will equally receive and convey the tinge of the Indian lake, which may be actually dissolved by spirit of wine : and this will be found a much cheaper method than the using carmine. If, nevertheless, the highest degree of brightness be required, the white varnishes must be used.

Yellow JAPAN Grounds.—For bright yellow grounds, the king's yellow or the turpeth mineral should be employed, either alone, or mixed with fine Dutch pink : and the effect may be still more heightened by dissolving powdered turmeric root in the spirit of wine, of which the upper or polishing coat is made ; which spirit of wine must be strained from off the dregs before the seed-lac be added to it to form the varnish.

The seed-lac varnish is not equally injurious here, and with greens, as in the case of other colours ; because, being only tinged with a reddish yellow, it is little more than an addition to the force of the colours.

Yellow grounds may likewise be formed of the Dutch pink only ; which, when good, will not be wanting in brightness, though extremely cheap.

Green JAPAN Grounds.—Green grounds may be produced by mixing the king's yellow and bright Prussian blue, or rather the turpeth mineral and Prussian blue ; and a cheap but fouler kind by verdegris, with a little of the above-mentioned yellows, or Dutch pink. But where a very bright green is wanted, the crystals of verdegris, called *distilled verdegris*, should be employed ; and to heighten the effect they should be laid on a ground of leaf-gold, which renders the colour extremely brilliant and pleasing.

They may, any of them, be used successfully with good seed-lac varnish, for the reason before given ; but will be still brighter with white varnish.

Orange-coloured JAPAN Grounds.—Orange-coloured japan grounds may be formed by mixing vermilion or red lead with king's yellow or Dutch pink ; or the orange lac, which will make a brighter orange ground than can be produced by any mixture.

Purple JAPAN Grounds.—Purple japan grounds may be produced by the mixture of lake and Prussian blue ; or a fouler kind, by vermilion and Prussian blue. They may be treated as the rest with respect to the varnish.

Black JAPAN Grounds to be produced without Heat.—Black grounds may be formed by either ivory-black or lamp-black : but the former is preferable where it is perfectly good.

These may be always laid on with shell-lac varnish ; and have their upper or polishing coats of common seed-lac varnish, as the tinge or foulness of the varnish can be here no injury.

Common Black JAPAN Grounds on Iron or Copper, produced by means of Heat.—For forming the common black japan grounds by means of heat, the piece of work to be japanned must be painted over with drying oil ; and when it is of a moderate dryness, must be put into a stove of such degree of heat as will change the oil to black, without burning it so as to destroy or weaken its tenacity. The stove should not be too hot when the work is put into it, nor the heat increased too fast ; either of which errors would make it blister : but the slower the heat is augmented, and the longer it is continued, provided it be restrained within the due degree, the harder will be the coat of japan. This kind of varnish requires no polish, having received, when properly managed, a sufficient one from the heat.

The fine Tortoise-shell JAPAN Ground produced by means of Heat.—The best kind of tortoise-shell ground produced by heat is not less valuable for its great hardness, and enduring to be made hotter than boiling water without damage, than for its beautiful appearance. It is to be made by means of a var-

nish prepared in the following manner:—"Take of good linseed-oil one gallon, and of umbre half a pound: boil them together till the oil become very brown and thick: strain it then through a coarse cloth, and set it again to boil; in which state it must be continued till it acquire a pitchy consistence; when it will be fit for use."

Having prepared thus the varnish, clean well the iron or copper plate or other piece which is to be japanned; and then lay vermilion tempered with shell-lac varnish, or with drying oil diluted with oil of turpentine, very thinly, on the places intended to imitate the more transparent parts of the tortoise-shell. When the vermilion is dry, brush over the whole with the black varnish, tempered to a due consistence with oil of turpentine; and when it is set and firm, put the work into a stove, where it may undergo a very strong heat, and must be continued a considerable time; if even three weeks, or a month, it will be the better.

This was given amongst other receipts by Kunckel; but appears to have been neglected till it was revived with great success in the Birmingham manufactures, where it was not only the ground of snuff-boxes, dressing-boxes, and other such lesser pieces, but of those beautiful tea-waiters which have been so justly esteemed and admired in several parts of Europe where they have been sent. This ground may be decorated with painting and gilding, in the same manner as any other varnished surface, which had best be done after the ground has been duly hardened by the hot stove; but it is well to give a second annealing with a more gentle heat, after it is finished.

Method of painting JAPAN Work.—Japan work ought properly to be painted with colours in varnish; though, in order for the greater dispatch, and, in some very nice works in small, for the freer use of the pencil, the colours are sometimes tempered in oil; which should previously have a fourth part of its weight of gum-animi dissolved in it; or, in default of that, of the gums sandarac or mastich. When the oil is thus used, it should be well diluted with spirit of turpentine, that the colours may be laid more evenly and thin; by which means, fewer of the polishing or upper coats of varnish become necessary.

In some instances, water-colours are laid on grounds of gold, in the manner of other paintings; and are best, when so used, in their proper appearance, without any varnish over them; and they are also sometimes so managed as to have the effect of embossed work. The colours employed in this way, for painting, are best prepared by means of isinglass size corrected with honey or sugar-candy. The body of which the embossed work is raised, need not, however, be tinged with the exterior colour, but may be best formed of very strong gum-water, thickened to a proper consistence by bole-armenian and whiting in equal parts; which being laid on the proper figure, and repaired when dry, may be then painted with the proper colours tempered in the isinglass size, or in the general manner with shell-lac varnish.

Manner of Varnishing JAPAN Work.—The last and finishing part of japanning lies in the laying on and polishing the outer coats of varnish; which are necessary, as well in the pieces that have only one simple ground of colour, as with those that are painted. This is in general best done with common seed-lac varnish, except in the instances and on those occasions where we have already shown other methods to be more expedient: and the same reasons which decide as to the fitness or impropriety of the varnishes, with respect to the colours of the ground, hold equally with regard to those of the painting; for where brightness is the most material point, and a tinge of yellow will injure it, seed-lac must give way to the whiter gums; but where hardness and a greater tenacity are most essential, it must be adhered to; and where both are so necessary that it is proper

one should give way to the other in a certain degree reciprocally, a mixed varnish must be adopted.

This mixed varnish, as we have already observed, should be made of the picked seed-lac. The common seed-lac varnish, which is the most useful preparation of the kind hitherto invented, may be thus made:—"Take of seed-lac three ounces, and put it into water to free it from the sticks and filth that are frequently intermixed with it; and which must be done by stirring it about, and then pouring off the water, and adding fresh quantities in order to repeat the operation, till it be freed from all impurities, as it very effectually may be by this means. Dry it then, and powder it grossly, and put it, with a pint of rectified spirit of wine, into a bottle of which it will not fill above two-thirds. Shake the mixture well together; and place the bottle in a gentle heat, till the seed appear to be dissolved; the shaking being in the mean time repeated as often as may be convenient: and then pour off all that can be obtained clear by this method, and strain the remainder through a coarse cloth. The varnish thus prepared must be kept for use in a bottle well stoped."

When the spirit of wine is very strong, it will dissolve a greater proportion of the seed-lac: but this will saturate the common, which is seldom of a strength sufficient for making varnishes in perfection. As the ch'ling, which is the most inconvenient accident attending those of this kind, is prevented, or produced more frequently, according to the strength of the spirit; we shall therefore take this opportunity of showing a method by which weaker rectified spirits may with great ease at any time be freed from the phlegm, and rendered of the first degree of strength.

"Take a pint of the common rectified spirit of wine, and put it into a bottle of which it will not fill above three parts. Add to it half an ounce of pearl-ashes, salt of tartar, or any other alkaline salt, heated red hot, and powdered as well as it can be without much loss of its heat. Shake the mixture frequently for the space of half an hour; before which time, a great part of the phlegm will be separated from the spirit, and will appear, together with the undissolved part of the salts, in the bottom of the bottle. Let the spirit then be poured off, or freed from the phlegm and salts, by means of a tritorium or separating funnel; and let half an ounce of the pearl-ashes, heated and powdered as before, be added to it, and the same treatment repeated. This may be done a third time, if the quantity of phlegm separated by the addition of the pearl-ashes appear considerable. An ounce of alum reduced to powder and made hot, but not burnt, must then be put into the spirit, and suffered to remain some hours; the bottle being frequently shaken: after which, the spirit, being poured off from it, will be fit for use."

The addition of the alum is necessary, to neutralize the remains of the alkaline salt or pearl-ashes; which would otherwise greatly deprave the spirit with respect to varnishes and laquer, where vegetable colours are concerned; and must consequently render another distillation necessary.

The manner of using the seed-lac or white varnishes is the same, except with regard to the substance used in polishing; which, where a pure white or great clearness of other colours is in question, should be itself white: whereas the browner sorts of polishing dust, as being cheaper, and doing their business with greater dispatch, may be used in other cases. The pieces of work to be varnished should be placed near a fire, or in a room where there is a stove, and made perfectly dry; and then the varnish may be rubbed over them by the proper brushes made for that purpose, beginning in the middle, and passing the brush to one end; and then with another stroke from the middle, passing it to the other. But no part should be crossed or twice passed over, in forming one coat, where it can possibly be

avoided. When one coat is dry, another must be laid over it; and this must be continued at least five or six times, or more, if on trial there be not sufficient thickness of varnish to bear the polish, without laying bare the painting or the ground colour underneath.

When a sufficient number of coats is thus laid on, the work is fit to be polished; which must be done, in common cases, by rubbing it with a rag dipped in Tripoli or pumice-stone, commonly called *rotten stone*, finely powdered: but towards the end of the rubbing, a little oil of any kind should be used along with the powder; and when the work appears sufficiently bright and glossy, it should be well rubbed with the oil alone, to clean it from the powder, and give it a still brighter lustre.

In the case of white grounds, instead of the Tripoli or pumice-stone, fine putty or whiting must be used; both which should be washed over to prevent the danger of damaging the work from any sand or other gritty matter that may happen to be commixed with them.

It is a great improvement of all kinds of japan work, to harden the varnish by means of heat; which, in every degree that it can be applied short of what would burn or calcine the matter, tends to give it a more firm and strong texture. Where metals form the body, therefore, a very hot stove may be used, and the pieces of work may be continued in it a considerable time; especially if the heat be gradually increased: but where wood is in question, heat must be sparingly used, as it would otherwise warp or shrink the body, so-as to injure the general figure.

JAPYDIA, in ancient geography, a western district of Illyricum, anciently threefold; the first *Japydia* extending from the springs of the Timavus to Istria; the second, from the river Arsia to the river Tedanius; and the third, called *Inalpina*, situated in mount Albius and the other Alps, which run out above Istria. *Japodes*, or *Japydes*, the people. Now constituting the south part of Carniola, and the west of Austrian Croatia.

JAPYDIA, CALABRIA, anciently so called by the Greeks. *Japyges*, the people.

JAPYGIUM, in ancient geography, a promontory of Calabria; called also *Salentinum*. Now *Capo di S. Maria di Leuca*.

JAQUELOT (ISAAC), a celebrated French Protestant divine, born in 1647 at Vassy in Champagne, where his father was minister. The revocation of the edict of Nantz obliging him to quit France, he took refuge first at Heidelberg, and then at the Hague, where he procured an appointment in the Walloon church. Here he continued till that capital was taken by the king of Prussia, who, hearing him preach, made him his French minister in ordinary at Berlin; to which city he removed in 1702. While he lived at Berlin, he entered into a warm controversy with M. Bayle on the doctrine advanced in his dictionary favouring manichæism, which continued until death imposed silence on both parties: and it was in this dispute that M. Jaquelot openly declared in favour of the Remonstrants. He wrote, among other works, 1. *Dissertations sur l'existence de Dieu*. 2. *Dissertations sur le Messie*. 3. *Lettres à Messieurs les Prelats de l'Eglise Gallicane*. He was employed in finishing an important work upon the divine authority of the holy scriptures, when he died suddenly in 1708, aged 61.

JAR, an earthen pot or pitcher, with a big belly and two handles. The word comes from the Spanish *jarra*, or *jarro*, which signify the same.

JAR is used for a sort of measure or fixed quantity of fluid or solid goods. The *jar* of oil is from 18 to 26 gallons; the *jar* of green ginger is about 100 pounds weight.

JARCHI (SOLOMON), otherwise *Raschi* and *Isoaki Solomon*, a famous rabbi, born at Troyes in Champagne, who flourished

in the 12th century. He was a perfect master of the talmud and gemara; and he filled the postils of the bible with so many talmudical reveries, as totally extinguished both the literal and moral sense of it. A great part of his commentaries are printed in Hebrew, and some have been translated into Latin by the Christians. They are all greatly esteemed by the Jews, who have bestowed on the author the title of *prince of commentators*.

JARDYN, or JARDIN, (KAREL DU), painter of conversations, landscapes, &c. was born at Amsterdam in 1640, and became a disciple of Nicholas Berchem. He travelled to Italy whilst he was yet a young man; and arriving at Rome, he gave himself up alternately to study and dissipation. Yet, amidst this irregularity of conduct, his proficiency in the art was surprising; and his paintings rose into such high repute, that they were exceedingly coveted at Rome, and bought up at great prices. With an intention to visit his native city he at last left Rome; but passing through Lyons, and meeting some agreeable companions, they prevailed on him to stay there for some time, and he found as much employment in that city as he could possibly undertake or execute. But the profits which arose from his paintings were not proportionable to his profusion; and in order to extricate himself from the encumbrances in which his extravagance had involved him, he was induced to marry his hostess, who was old and disagreeable, but very rich. Mortified and ashamed of that adventure, he returned as expeditiously as possible to Amsterdam, accompanied by his wife, and there for some time followed his profession with full as much success as he had met with in Italy or Lyons. He returned to Rome the second time; and after a year or two spent there in his usual extravagant manner, he settled at Venice. In that city his merit was well known before his arrival, which procured him a very honourable reception. He lived there highly caressed, and continually employed; but died at the age of 38. He was sumptuously interred, out of respect to his talents; and, although a Protestant, permitted to be laid in consecrated ground. This painter, in his colouring and touch, resembled his master Berchem; but he added to that manner a force which distinguishes the great masters of Italy; and it is observed, that most of his pictures seem to express the warmth of the sun, and the light of mid-day. His pictures are not much encumbered; a few figures, some animals, and a little landscape for the backgrounds, generally comprise the whole of his composition. However, some of his subjects are often more extensive, containing more objects, and a larger design. His works are as much sought after, as they are difficult to be met with.

JARGEAU, an ancient town of France, in the department of Loiret and late provinces of Orleanois, taken by the English in 1438, and retaken by Joan of Arc the next year. It is 10 miles S. E. of Orleans, and 70 S. W. of Paris.

JARGON, a kind of precious stone, of the nature of the diamond, but softer; found in Brasil according to M. de Bomare; but in Ceylon, according to M. Romé de l'Isle. Its specific gravity is nearly equal to that of the ponderous spar, being 4.416. Its crystals consist of two tetrahedral pyramids of equal sides, separated by a short prism; so that the jargon is properly of a dodecahedral form. According to some lapidaries, the jargon comes nearest to the sapphire in hardness; and as they have when cut and polished a great resemblance to the diamond, they are called by some *soft diamonds*; and one may be easily imposed upon in purchasing these for the true kind, when they are made up in any sort of jewellery work. On exposing this stone to a violent fire, M. d'Arcot found the surface a little vitrified where it stuck to the porcelain test in which it was set; whence it appears, that the jargon has not the least resemblance to the diamond, which is destructible by fire. See DIAMOND.

JARMUTH, JARMUTH, or *Jerimoth*, Josh. xv. a town

reckoned to the tribe of Judah, four miles from Eleutheropolis westward, (Jerom.) Thought to be the same with Ramoth and Remeth, Joshua xix. and Nehem. x. 2. (Reland.)

JARNAC, a town of France, in the department of Charente and late province of Angoumois. It is remarkable for a victory obtained by Henry III. (then duke of Anjou) over the Huguenots, in 1569, when their general, Lewis I. prince of Condé, was killed. It is seated on the river Charente, 20 miles W. of Angouleme, and 235 S. by W. of Paris. W. lon. c. 4. N. lat. 45. 43.

JAROMITZ, a town of Bohemia, seated on the river Elbe, 27 miles S. W. of Glatz, and 52 N. E. of Prague. E. lon. 15. 57. N. lat. 50. 22.

JAROSLOW, a handsome town of Austrian Poland, in the palatinate of Red Ruffia, with a strong citadel. It is remarkable for its great fair, its handsome buildings, and a battle gained by the Swedes in 1656, after which they took the town. It is seated on the river Saine, 55 miles W. of Lemburg, and 100 E. of Cracow. E. lon. 22. 43. N. lat. 50. 4.

JARROW, a village in the bishopric of Durham, situated near Shields, on the Tyne; where, in 1763, a stone was dug up in the church, importing that the foundation of that building was begun in 674, in the reign of Egfrid, king of Northumberland, by Ceolfrid its abbot.

JASENITZ, a town of Germany, in Prussian Pomerania and in the duchy of Stetin. It is seated at the mouth of the Oder, eight miles below Stetin.

JASHER (THE BOOK OF). This is a book which Joshua mentions, and refers to in the following passage: "And the sun stood still, and the moon stayed, until the people had avenged themselves upon their enemies: is not this written in the book of Jasher?" It is difficult to determine what this *book of Jasher*, or "the upright," is. St. Jerom and the Jews believed it to be Genesis, or some other book of the Pentateuch, wherein God foretold he would do wonderful things in favour of his people. Huetius supposes it was a book of morality, in which it was said that God would subvert the course of nature in favour of those who put their trust in him. Others pretend, it was public annals, or records, which were styled *justice* or *upright*, because they contained a faithful account of the history of the Israelites. Grotius believes, that this book was nothing else but a song, made to celebrate this miracle and this victory. This seems the more probable opinion, because the words cited by Joshua as taken from this work, "Sun, stand thou still upon Gibeon, and thou moon in the valley of Ajalon," are such poetical expressions as do not suit with historical memoirs; besides that in the 2d book of Samuel (i. 18.) mention is made of a book under the same title, on account of a song made on the death of Saul and Jonathan.

JASIONE, in botany; a genus of the monogamia order, belonging to the syngenesia class of plants; and in the natural method ranking under the 29th order, *Campanaceæ*. The common calyx is ten-leaved; and the corolla has five regular petals; the capsule beneath, two-celled.

JASMINE. See JASMINUM.

Arabian JASMINE. See NYCTANTHES.

JASMINUM, JASMINE, or *Jessamine-tree*, in botany; a genus of the monogynia order, belonging to the diandria class of plants; and in the natural method ranking under the 44th order, *Sepiariæ*. The corolla is quinquesid, the berry dicoccus; the seeds arillated, the antheræ within the tube.

The *species* are, 1. The *officinalis*, or common white jasmine, with shrubby long slender stalks and branches, rising upon support 15 or 20 feet high, with numerous white flowers from the joints and ends, of a very fragrant odour. There is a variety with white-striped, and another with yellow-striped leaves. 2. The *fruticans*, or shrubby yellow jasmine, hath

shrubby, angular, trailing stalks and branches, rising upon support eight or ten feet high; trifoliate and simple alternate leaves; with yellow flowers from the sides and ends of the branches, appearing in June; frequently producing berries of a black colour. This species is remarkable for sending up many suckers from its roots; often so plentifully as to overspread the ground, if not taken up annually. 3. The *humilis*, or dwarf yellow jasmine, hath shrubby firm stalks, and angular branches, of low, somewhat robust and bushy growth; broad, trifoliate, and pinnated leaves; and large yellow flowers in July, sometimes succeeded by berries. 4. The *grandiflorum*, or great-flowered Catalonian jasmine, hath a shrubby firm upright stem, branching out into a spreading head from about three to six or eight feet high, with large flowers of a blush red colour without, and white within, appearing from July to November. Of this there is a variety with semi-double flowers, having two series of petals. 5. The *azoricum*, or azorian white jasmine, hath shrubby, long slender stalks and branches, rising upon support 15 or 20 feet high, with pretty large flowers of a pure white colour; coming out in loose bunches from the ends of the branches, and appearing most part of the summer and autumn. 6. The *odoratissimum*, or most sweet-scented yellow Indian jasmine, hath a shrubby upright stalk branching erect, without support, six or eight feet high, with bright yellow flowers in bunches from the ends of the branches; flowering from July till October, and emitting a most fragrant odour.

The three first species are sufficiently hardy to thrive in this climate without any shelter. They may be easily propagated by layers and cuttings; and the striped varieties by grafting or budding on stocks of the common kind. The other three species, which are tender, may also be increased by layers, or seeds, or by grafting and budding them upon the common white and shrubby yellow jasmine. They require shelter in a green-house in winter, and therefore must always be kept in pots to move them out and in occasionally. The pots must be filled with light, rich earth, frequently watered in summer, and about once a week in winter, but always moderately during that season. Prune off all the decayed wood at any time when it appears, and shorten or retrench the rambling shoots as you see occasion, to preserve the heads somewhat regular; managing them in other respects as the common green house plants.

JASON, the Greek hero who undertook the Argonautic expedition, the history of which is obscured by fabulous traditions, flourished about 937 B. C.

JASPACHATES. See JADE-STONE.

JASPER, in natural history, a genus of stones belonging to the siliceous class. According to Cronstedt, all the opaque flints are called by this name whose texture resembles dry clay, and which cannot be any other way distinguished from flints, except that they are more easily melted; which perhaps may also proceed from a mixture of iron. The species are,

1. *Pure jasper*; which, Cronstedt informs us, cannot be decomposed by any means hitherto known; though Mr. Kirwan says that it contains 75 *per cent.* of silice; 20 of argil, and about five of calx of iron. The specific gravity is from 2680 to 2778. It is found of different colours; viz. green with red dots from Egypt, called also the *heliotrope*, or *blood-stone*; quite green from Bohemia; red from Italy, called there *diaspro rosso*, or yellow, called *melites* by the ancients; a name, according to Pliny, of the same import with *male coloris*. It is also found red with yellow spots and veins in Sicily, Spain, and near Constantinople, called by the Italians *diaspro florido*; or black from some places in Sweden, called by the Italians *paragone antico*.

2. *Jaspis martialis*, or sinople, containing iron. This is a dark red stone containing 18 or 20 *per cent.* of metal. Near Chemnitz, where it forms very considerable veins, as Brunnich

informs us, it has frequently specks of marcasite, cubic lead ores, and blend. It has likewise so much gold as to be worth working: there is likewise a striped sople of various colours. There are several varieties differing in the coarseness and fineness of their texture, as well as the shade of their colour; varying from a deep brown to a yellow. The last is attracted by the magnet after calcination.

Cronstedt observes that jasper, when fresh broken, so nearly resembles a bole of the same colour, that it can only be distinguished by its hardness. In the province of Dalarne in Sweden, it is found in a kind of hard sand stone; in other places it is found within such unctuous clefts as are usually met with in Cornish clay, red chalk, and other substances of that kind. There are likewise some jaspers that imbibe water; from whence, and other considerations, our author is of opinion that they have clay for their basis, notwithstanding their hardness. According to Magellan, it resists the blow-pipe *per se*, and is only partially soluble with the mineral alkali; separating into small particles with effervescence: with borax or microcosmic salt it melts without any effervescence. Bergman, in his *Sciagraphia*, informs us, that it is composed of siliceous earth united to a clay very full of iron. The mineral acids have no effect upon it in a short time, but corrode it by some months immersion. On treating a small piece of green jasper with vitriolic acid, some crystals of alum and green vitriol were obtained; which shows that iron and clay are ingredients in its composition. M. Daubenton mentions 15 varieties of this substance. 1. Green, from Bohemia, Silesia, Siberia, and the shores of the Caspian sea; which seems to be the *pavonium* of Aldrovandus. 2. The diaspro rosso, or red jasper; less common, and in smaller masses, than the green. 3. Yellow from Freyberg and Rohtliz; sometimes of a citron colour, and appearing as if composed of silky filaments; commonly called the *silk jasper*. 4. Brown from Dalecarlia in Finland and Sweden. 5. The violet from Siberia. 6. The black from Sweden, Saxony, and Finland. 7. The blueish-grey, a very rare species. 8. The milky white mentioned by Pliny, and found in Dalcarlia. 9. The variegated with green, red, and yellow clouds. 10. The blood stone, green with red specks, from Egypt, which was supposed to stop the blood. 11. The veined with various colours. Sometimes these veins have a distant resemblance to various letters, and then the jasper is named by the French *jaspe grammatique*. Some of these, found near Rochelle in France, on account of their curious variety in this respect are named *polygrammatiques*. 12. The jasper with various coloured zones. 13. That called *florido* by the Italians; which has various colours mixed promiscuously without any order. 14. When the jasper has many colours together, it is then (very improperly) called *universal*. 15. When it contains some particles of agate, it is then called *agatefused* jasper.

JASPONYX, in natural history, the purest horn-coloured onyx, with beautiful green zones, which are composed of the genuine matter of the finest jaspers. See the articles JASPER and ONYX.

JASQUE, a seaport of Persia, on the gulf of Ormus, and in the province of Tuberan. E. lon. 59. 15. N. lat. 26. 10.

JASSELLMERE, a town of Hindoostan Proper, in a small territory of the same name, subject to a petty rajah, in the province of Agimere. It is 680 miles N. of Bombay. E. lon. 73. 0. N. lat. 27. 34.

JASSY, a considerable city of Europe, the capital of Moldavia, and residence of the hospodar of that country, who is a vassal of the grand signior. In 1753 the whole city, with the palace of the hospodar, some papish convents, and a new Lutheran church, was destroyed by fire. It is seated on the river Pruth, and is a well-fortified place, defended by a castle. However, it has been several times taken in the wars between the Turks and

the Russians or Austrians; the last time by the latter in 1788, who restored it by the peace of Reichenbach in 1790. E. lon. 27. 35. N. lat. 47. 8.

JATROPHA, the CASSADA PLANT; a genus of the monadelphia order, belonging to the monœcia class of plants; and in the natural method ranking under the 38th order, *Tricocca*. There is no male calyx; the corolla is monopetalous, and funnel-shaped; there are ten stamina, one alternately longer than the other. There is no female calyx; the corolla is pentapetalous, and patent; there are three bifid styles; the capsule is trilocular, with one seed in each cell.

There are nine species, of which the most remarkable are, 1. The *curcas*, or English physic-nut, with leaves cordate and angular, is a knotty shrub growing about 10 or 12 feet high. The extremities of the branches are covered with leaves; and the flowers, which are of a green herbaceous kind, are set on in an umbel fashion round the extremities of the branches, but especially the main stalks. These are succeeded by as many nuts, whose outward tegument is green and husky, which being peeled off discovers the nut, whose shell is black, and easily cracked: this contains an almond-like kernel, divided into two parts, between which separation lie two milkwhite thin membranaceous leaves, easily separable from each other. These have not only a bare resemblance of perfect leaves, but have, in particular, every part, the stalk, the middle rib, and transverse ones, as visible as any leaf whatsoever. 2. The *gossypifolia*, cotton-leaved jatropha or belly-ach bush, the leaves of which are quinquepartite, with lobes ovate and entire, and glandular branchy bristles. The stem, which is covered with a light greyish bark, grows to about three or four feet high, soon dividing into several wide extended branches. These are neither decorated with leaves nor flowers till near the top, which is then surrounded by the former: their foot-stalks, as well as the young buds on the extremity of the branches, are guarded round with stiff hairy bristles, which are always tipped with glutinous liquid drops. From among these rise several small deep red pentapetalous flowers, the pistil of each being thick-set at the top with yellow farinaceous dust which blows off when ripe: these flowers are succeeded by hexagonal husky blackish berries, which when ripe open by the heat of the sun, emitting a great many small dark-coloured-seeds, which serve as food for ground doves. The leaves are few; but seldom or never drop off, nor are eaten by vermin of any kind. 3. The *multifida*, or French physic-nut, with leaves many-parted and polished, and stipules bristly and multiseid, grows to be ten feet high. The main stalk divides into very few branches, and is covered with a greyish white bark. The leaves stand upon six-inch foot-stalks, surrounding the main stalk, generally near the top in an irregular order. The flowers grow in bunches, umbel fashion, upon the extremities of each large stalk, very much resembling, at their first appearance, a bunch of red coral: these afterwards open into small five leaved purple flowers, and are succeeded by nuts, which resemble those of the first species. 4. The *manibet*, or bitter cassada, has palmated leaves; the lobes lanceolate, very entire, and polished. 5. The *janipha*, or sweet cassada, has palmated leaves, with lobes very entire; the intermediate leaves lobed with a sinus on both sides. 6. The *classica*, with ternate leaves, elliptic, very entire, hoary underneath, and longly petioled. See figures of the two last in plate 22. which renders a more particular description unnecessary.

The first species, a native of the West Indies, is planted round negro gardens. A decoction of the leaves of it, and of the second species (which grows wild), Dr. Wright informs us, is often used with advantage in spasmodic belly-ach attended with vomiting: it sits easier on the stomach than any thing else, and seldom fails to bring about a discharge by stool. The third species, a native of the same countries, is cultivated there as an

ornamental shrub. The seeds of all the three are drastic purgatives and emetics; and they yield, by decoction, an oil of the same uses and virtues as the oleum ricini. See RICINUS. The 4th and 5th species, the janipha and manihot, are natives of Africa and the West Indies, where they are cultivated as articles of food. It is difficult, Dr. Wright says, to distinguish the bitter from the sweet cassada by the roots: but it will be best to avoid those of the cassada that bears flowers, as it is the bitter, which is poisonous when raw.

The root of bitter cassada has no fibrous or woody filaments in the heart, and neither boils nor roasts soft. The sweet cassada has all the opposite qualities. The bitter, however, may be deprived of its noxious qualities (which reside in the juice) by heat. Cassada bread, therefore, is made of both the bitter and sweet, thus:—The roots are washed and scraped clean; then grated into a tub or trough: after this they are put into a hair bag, and strongly pressed with a view to squeeze out the juice, and the meal or farina is dried in a hot stone basin over the fire: it is then made into cakes. It also makes excellent puddings, equal to millet.—The scrapings of fresh bitter cassada are successfully applied to ill disposed ulcers.—Cassada roots yield a great quantity of starch, which the Brazilians export in little lumps under the name of *tapioca*. According to Father Labat, the small bits of manioc which have escaped the grater, and the clods which have not passed the sieve, are not useless. They are dried in the stove after the flour is roasted, and then pounded in a mortar to a fine white powder, with which they make soup. It is likewise used for making a kind of thick coarse cassada, which is roasted till almost burnt; of this, fermented with molasses and West-India potatoes, they prepare a much esteemed drink or beverage called *ouycou*. This liquor, the favourite drink of the natives, is sometimes made extremely strong, especially on any great occasion, as a feast: with this they get intoxicated, and, remembering their old quarrels, massacre and murder each other. Such of the inhabitants and workmen as have not wine, drink ouycou. It is of a red colour, strong, nourishing, refreshing, and easily inebriates the inhabitants, who soon accustom themselves to it as easily as beer.

The 6th species is the *Hevea Guianensis* of Aublet, (*Histoire des Plantes de la Guiane Françoise*, p. 87.) or tree which yields the elastic resin called *caoutchouc* or *India rubber*; for a particular account of which, see the article CAOUTCHOUC. The figure we have given is copied from Aublet's tab. 335, and not from the erroneous plate given in the *Acta Parisiana*.

JATS, THE, once a powerful Hindoo tribe, in Hindoostan Proper, to whom all that now remains is the small territory of Bhartpour, 45 miles W. of Agra.

JAVA, a large island of the East Indies. See BATAVIA.

JAVELIN, in antiquity, a sort of spear five feet and an half long; the shaft of which, was of wood, with a steel point. Every soldier in the Roman armies had seven of these, which were very light and slender.

JAVELLO (CHRYSOSTOME), a learned Italian Dominican of the 16th century, taught philosophy and theology at Bologna, and died about the year 1540. He wrote a work on philosophy, another on politics, and another on Christian œconomy, which are esteemed; with notes on Pomponatius, and other works, printed in 3 vols. folio.

JAWER, a city of Silesia, capital of a province of the same name, with a citadel, and a large square surrounded with piazzas. It is 12 miles south-east of Lignitz, 30 south-west of Breslau, and 87 east of Prague. E. lon. 16. 29. N. lat. 50. 56.

JAUNDICE, from the French *jaunisse* "yellowness," of *jaune* "yellow;" a disease consisting in a suffusion of the bile over the whole surface of the body. See MEDICINE.

JAWS. See MAXILLÆ.

Locked JAW, is a spasmodic contraction of the lower jaw,

commonly produced by some external injury affecting the tendons or ligaments. See MEDICINE.

JAY, in ornithology. See CORVUS.

JAY (Guy Michael le), a French gentleman, who distinguished himself by causing a polyglott bible to be printed at his own expense in 10 vols. folio: but he ruined himself by that impression, first because he would not suffer it to appear under the name of cardinal Richelieu, who, after the example of cardinal Ximenes, was ambitious of eternizing his name by this means; and next, because he made it too dear for the English market; on which Dr. Walton undertook his polyglott bible, which, being more commodious, reduced the price of M. le Jay's. After the death of his wife, M. le Jay took orders, was made dean of Vezelay in the Nivernois, and Louis XIV. gave him the post of counsellor of state.

JAZER, or JASER, in ancient geography, a Levitical city in the territory of the Amorrhites beyond Jordan, 10 miles to the west, or rather south-west, of Philadelphia, and 15 miles from Esbon; and therefore situated between Philadelphia and Heshbon, on the east border of the tribe of Gad, supposed to be the *Jazorem* of Josephus. In Jeremiah xlvi. mention is made of the sea of Jazer, that is a lake; taken either for an effusion or overflowing of the Arnon, or a lake through which it passes, or from which it takes its rise.

IBERIA (SPAIN), so called by the ancients from the river Iberus. *Iberes* the people, from the nominative *Iber*. Iberia was also the name of an inland country of Asia, having Colchis to the west, with a part of Pontus; to the north mount Caucasus; on the east Albania; and on the south Armenia Magna: Now the western part of Georgia. Iberia, according to Josephus, was first peopled by Tubal, the brother of Gomer and Magog. His opinion is confirmed by the Septuagint; for Meshech and Tubal are by these interpreters rendered *Moschi* and *Iberians*. We know little of the history of the country till the reign of Mithridates, when their king, named *Artocis*, siding with that prince against Lucullus, and afterwards against Pompey, was defeated by the latter with great slaughter; but afterwards obtained a peace, upon delivering up his sons as hostages. Little notice is taken of the succeeding kings by the ancient historians. They were probably tributary to the Romans till that empire was overturned, when this, with the other countries in Asia bordering on it, fell successively under the power of the Saracens and Turks.

IBERIS, SCIATICA CRESSES, or *Candy-tuft*; a genus of the siliquosa order, belonging to the tetradynamia class of plants; and in the natural method ranking under the 39th order, *Siliquosæ*. The corolla is irregular; the two exterior petals larger than the interior ones; the silicula polyspermous, emarginated. The species are, 1. The *umbellata*, or common candy-tuft, hath herbaceous, short, round, and very branchy stalks of tufty growth, from about six to eight or ten inches high; small spear-shaped leaves, the lower ones ferrated, the upper entire; and all the stalks and branches terminated by umbellate clusters of flowers of different colours in the varieties. 2. The *amara*, or bitter candy-tuft, hath stalks branching like the former, which rise from eight to ten or twelve inches high; small, spear-shaped, and slightly indented leaves; and all the branches terminated by racemose bunches of white flowers in June and July. 3. The *sempervirens*, commonly called *tree candy-tuft*, hath low undershrubby stalks, very branchy and bushy, rising to the height of 10 or 12 inches, with white flowers in umbels at the ends of the branches, appearing great part of the summer. 4. The *semperflorens*, or ever-flowering shrubby iberis, hath low undershrubby stalks very branchy, growing to the height of 18 inches, with white flowers in umbels at the ends of the branches, appearing at all times of the year. The two first kinds, being hardy annuals, may be sowed in any common soil in the month of March,

or from that time till midsummer, and will thus afford a succession of flowers from June to September, which are succeeded by great plenty of seeds. The other two are somewhat tender; and therefore must be planted in pots, in order to be sheltered from the winter-frosts. They are easily propagated by slips or cuttings.

IBEX, in zoology. See CAPRA.

IBIS, in ornithology. See TANTALUS.

IBORG, or IBERG, a town of Germany, in the circle of Westphalia, and bishopric of Osnaburgh, 10 miles S. W. of Osnaburgh, and 30 N. E. of Munster. E. lon. 8. 20. N. lat. 52. 14.

IBYCUS, a Greek lyric poet, of whose works there are only a few fragments remaining, flourished 550 B. C. It is said that he was assassinated by robbers; and that, when dying, he called upon some cranes he saw flying to bear witness. Some time after, one of the murderers seeing some cranes, said to his companions, "There are the witnesses of Ibycus's death:" which being reported to the magistrates, the assassins were put to the torture, and, having confessed the fact, were hanged. Thence arose the proverb *Ibyci Crues*.

ICE, a brittle transparent body, formed of some fluid frozen or fixed by cold. See the articles FREEZING and FROST. The specific gravity of ice to water is various, according to the nature and circumstances of the water, degree of cold, &c. Dr. Living (Phipps's Voyage towards the North Pole) found the densest ice he could meet with about a 14th part lighter than water. M. de Mairan found it, at different trials, 1-14th, 18th, or 19th, lighter than water; and when the water was previously purged of air, only a 22d part.

The refraction of ice has been supposed owing to the air-bubbles produced in it while freezing: these, being considerably large in proportion to the water frozen, render the ice so much specifically lighter. It is well known that a considerable quantity of air is lodged in the interstices of water, though it has there little or no elastic property, on account of the disunion of its particles; but upon these particles coming closer together, and uniting as the water freezes, light, expansive, and elastic air-bubbles are thus generated, and increase in bulk as the cold grows stronger, and by their elastic force burst to pieces any vessel in which the water is closely contained. But snow-water, or any water long boiled over the fire, affords an ice more solid, and with fewer bubbles. Pure water long kept in vacuo and frozen afterwards there, freezes much sooner, on being exposed to the same degree of cold, than water unpurged of its air and set in the open atmosphere. And the ice made of water thus divested of its air is much harder, more solid and transparent, and heavier than common ice.

But M. de Mairan, in a dissertation on Ice, attributes the increase of the bulk of the water under this form, chiefly to a different arrangement of its parts: the icy skin on water being composed of filaments which are found to be joined constantly and regularly at an angle of 60°, and which, by this disposition, occupy a greater volume than if they were parallel. Besides, after ice is formed, he found it continue to expand by cold; a piece of ice, which was at first only a 14th part specifically lighter than water, on being exposed some days to the frost, became a 12th part lighter; and thus he accounts for the burling of ice in ponds.

It appears from an experiment of Dr. Hooke, in 1663, that ice refracts the light less than water; whence he infers, that the lightness of ice, which causes it to swim in water, is not produced merely by the small bubbles which are visible in it, but that it arises from the uniform constitution or general texture of the whole mass: a fact which was afterward approved by M. de la Hire. See Hooke's Exper. by Derham, p. 26, Acad. Par. 1693, Mem. p. 25.

VOL. IV.

But a discovery the most curious and important of any of modern times, relative to the formation of ice, is that described by Count Rumford in his Essay "On the Manner in which Heat is propagated in Fluids."

After proving in a very satisfactory way, that the particles of fluids are incapable of imparting heat to each other, and that, when their temperature is undergoing any change, an intestine motion is kept up in them, by a successive alteration taking place in the specific gravity of their particles, he proceeds to show, that "all bodies are condensed by cold without limitation, *water only excepted*," and describes the wonderful effects produced in consequence of this particular law.

"Though in temperatures above blood-heat (says Count Rumford), the expansion of water with heat is very considerable, yet in the neighbourhood of the freezing point it is almost nothing. And what is still more remarkable, as it is an exception to one of the most general laws of Nature with which we are acquainted, when in cooling it comes within eight or nine degrees of Fahrenheit's scale of the freezing point, instead of going on to be farther condensed as it loses more of its heat, it *actually expands* as it grows colder, and continues to expand more and more as it is more cooled."

"If the whole amount of the condensation of any given quantity of boiling hot water, on being cooled to the point of freezing, be divided into any given number of equal parts, the condensations corresponding to equal changes of temperature will be very unequal in different temperatures."

"In cooling 22½ degrees of Fahrenheit's scale, (or one eighth part of the interval between the boiling and the freezing points), the condensation will be,

		Condensation.	
"In cooling 22½° viz. from 212°	to 189½°	- 18 parts.	
189½	— 167	- 16.2	
167	— 144½	- 13.8	
144½	— 122	- 11.5	
122	— 99½	- 9.3	
99½	— 77	- 7.1	
77	— 54½	- 3.9	
54½	— 32	- 0.2	

"Hence it appears that the condensation of water, or increase of its specific gravity in being cooled 22½ degrees of Fahrenheit's scale, is at least *ninety times greater* when the water is boiling-hot, than when it is at the mean temperature of the atmosphere in England (54½°), or within 22½ degrees of freezing—(for 18 is to 0.2 as 90 to 1).

"All liquids, it is true, in cooling, are more condensed by any given change of temperature when they are very hot, than when they are colder; but these differences are nothing compared to those we observe in water."

"The ratio of the condensation in cooling from 212° to 189½° to that in cooling from 54½° to 32° in each of the under-mentioned fluids, has been shown, by the Experiments of M. DE LUC, to be as follows:

Olive oil	-	as 1,758 to 1
Strong spirits of wine	-	as 1,200 to 1
A saturated solution of sea-salt in water	-	as 1,000 to 1

"The difference between the laws of the condensation of pure water, and of the same fluid when it holds in solution a portion of salt, is striking; but when we trace *the effects* which are produced in the world by that arrangement, we shall be lost in wonder and admiration."

After enlarging on this subject, he proceeds thus—"As nourishment and life are conveyed to all living creatures through the medium of water;—*liquid*,—*living* water;—to preserve life, it was absolutely necessary to preserve a great quantity of water in a fluid state, in winter as well as in summer."

"But in cold climates the temperature of the atmosphere, during many months in the year, is so much below the freezing point, that, had not measures been taken to prevent so fatal an accident, all the water must inevitably have been changed to ice, which would infallibly have caused the destruction of every living thing.

"Extraordinary measures were therefore necessary for preserving in a liquid state as much of the water existing in those climates as is indispensably necessary for the preservation of vegetable and animal life; and this could only be done by contriving matters so as to prevent this water from parting with its heat to the cold atmosphere.

"It has been shown,—I believe I may venture to say proved,—in the most satisfactory manner,—that liquids part with their heat ONLY in consequence of their internal motions;—and that the more rapid these motions are, the more rapid is the communication of the heat;—that these motions are produced by the change in the specific gravity of the liquid, occasioned by the change of temperature,—and of course that they are more rapid, as the specific gravity of the liquid is the more changed by any given change of temperature.

"But it has been shown that the change in the specific gravity of water is extremely small, which takes place in any given change of temperature, *below the mean temperature of the atmosphere*; and particularly when the temperature of the water is very near the freezing point; and hence it follows, that water must give off its heat very slowly when it is near freezing.

"But this is not all. There is a still more extraordinary, and in its consequences more wonderful, circumstance which remains to be noticed. When water is cooled to within eight or nine degrees of the freezing point, it not only ceases to be farther condensed, but is actually expanded by farther diminutions of its heat; and this expansion goes on as the heat is diminished, as long as the water can be kept fluid; and when it is changed to ice, it expands even still more, and the ice floats on the surface of the uncongealed part of the fluid."

Count Rumford next shews how very powerfully this wonderful contrivance tends to retard the cooling of water when it is exposed in a cold atmosphere.

"It is well known that there is no communication of heat between two bodies as long as they are both at the same temperature; and it is likewise known that the *tendency* of heat to pass from a hot body into one which is colder, with which it is in contact, is greater, as the difference is greater in the temperatures of the two bodies.

"Suppose now that a mass of very cold air reposes on the quiet surface of a large lake of fresh water, at the temperature of 55° of Fahrenheit's thermometer. The particles of water at the surface, on giving off a part of their heat to the cold air with which they are in contact, and in consequence of this loss of heat becoming specifically heavier than those hotter particles on which they repose, must of course descend. This descent of the particles which have been cooled necessarily forces other hotter particles to the surface, and these being cooled in their turns bend their course downwards; and the whole mass of water is put into motion, and continues in motion as long as the process of cooling goes on.

"As soon as the water in cooling has arrived at the temperature of about 40°, as at that temperature it ceases to be farther condensed, its internal motion ceases, and those of its particles which happen to be at its surface remain there; and after being cooled down to the freezing point, they give off their latent heat, and ice begins to be formed.

"As soon as the surface of the water is covered with ice, the communication of heat from the water to the atmosphere is rendered extremely slow and difficult; for ice being a *bad conductor of heat* forms a very warm covering to the water,—and

moreover it prevents the water from being agitated by the wind. Farther, as the temperature of the ice at its lower surface is always very nearly the same as that of the particles of liquid water with which it is in contact, (the warmer particles of this fluid, in consequence of their greater specific gravity, taking their places below,) the communication of heat between the water and the ice is necessarily very slow on that account.

"As soon as the upper surface of the ice is covered with snow, (which commonly happens soon after the ice is formed,) this is an additional and very powerful obstacle to prevent the escape of the heat out of the water; and though the most intense cold may reign in the atmosphere, the increase of the thickness of the ice will be very slow."

This subject is continued by Count Rumford in p. 293 of his Essay; but as the enquiry takes a direction not agreeable to the purport of this article, we must refer to the article *PROPAGATION of Heat*, where we purpose to give some account of the origin of this curious discovery.

Sir Robert Barker thus describes the process of making ice in the East Indies, in a country where he never saw any natural ice. On a large plain they dig three or four pits, each about 30 feet square, and 2 feet deep; the bottoms of which are covered, about 8 or 12 inches thick, with sugar-cane, or the stems of the large Indian corn, dried. On this bed are placed in rows a number of small shallow unglazed earthen pans, formed of a very porous earth, a quarter of an inch thick, and about an inch and a quarter deep; which, at the dusk of the evening, they fill with soft water that has been boiled. In the morning before sunrise the ice-makers attend at the pits, and collect what has been frozen in baskets, which they convey to the place of preservation. This is usually prepared in some high and dry situation, by sinking a pit 14 or 15 feet deep, which they line first with straw, and then with a coarse kind of blanketing. The ice is deposited in this pit, and beaten down with rammers, till at length its own accumulated cold again freezes it, and it forms one solid mass. The mouth of the pit is well secured from the exterior air with straw and blankets, and a thatched roof is thrown over the whole. *Philos. Transf. vol. 65, p. 252.*

Blink of the ICE, is a name given by the pilots to a bright appearance near the horizon, occasioned by the ice, and observed before the ice itself is seen. See *ICE ISLAND*.

ICE Boats, boats so constructed as to sail upon ice, and which are very common in Holland, particularly upon the river Maese and the lake Y. See plate 23. They go with incredible swiftness, sometimes so quick as to affect the breath, and are found very useful in conveying goods and passengers over lakes and great rivers in that country. Boats of different sizes are placed in a transverse form upon a 2½ or 3 inch deal board: at the extremity of each end are fixed irons, which turn up in the form of skaits: upon this plank the boat rests, and the two ends seem as out-riggers, to prevent oversetting; whence ropes are fastened that lead to the head of the mast in the nature of shrouds, and others passed through a block across the bowsprit: the rudder is made somewhat like a hatchet with the head placed downward, which being pressed down, cuts the ice, and serves all the purposes of a rudder in the water, by enabling the helmsman to steer, tack, &c.

ICE-Cream, a well known luxury, used in hot climates to cool the palate. It may be made after the following receipt: Take a sufficient quantity of cream, and when it is to be mixed with raspberry, or currant, or pine, a quarter part as much of the juice or jam as of the cream: after beating and straining the mixture through a cloth, put it with a little juice of lemon into the mould, which is a pewter vessel, and varying in size and shape at pleasure: cover the mould, and place it in a pail about two thirds full of ice, into which two handfuls of salt have been thrown: turn the mould by the hand-hold

with a quick motion to and fro, in the manner used for milling chocolate, for eight or ten minutes; then let it rest as long, and turn it again for the same time; and having left it to stand half an hour, it is fit to be turned out of the mould, and to be sent to table. Lemon-juice and sugar, and the juices of various kinds of fruits, are frozen without cream; and when cream is used, it should be well mixed.

ICE-Hills, a sort of structure or contrivance common upon the river Neva at Petersburg, and which afford a perpetual fund of amusement to the populace. They are constructed in the following manner: A scaffolding is raised upon the river about 30 feet in height, with a landing-place on the top, the ascent to which is by a ladder. From this summit a sloping plain of boards, about four yards broad and 30 long, descends to the superficies of the river: it is supported by strong poles gradually decreasing in height, and its sides are defended by a parapet of planks. Upon these boards are laid square masses of ice, about four inches thick, which being first smoothed with the axe, and laid close to each other, are then sprinkled with water: by these means they coalesce, and, adhering to the boards, immediately form an inclined plain of pure ice. From the bottom of this plain the snow is cleared away for the length of 200 yards and the breadth of four, upon the level bed of the river; and the sides of this course, as well as the sides and top of the scaffolding, are ornamented with firs and pines. Each person, being provided with a sledge, mounts the ladder; and having attained the summit, he seats himself upon his sledge at the upper extremity of the inclined plain, down which he suffers it to glide with considerable rapidity, poising it as he goes down; when the velocity acquired by the descent carries it above 100 yards upon the level ice of the river. At the end of this course, there is usually a similar ice-hill, nearly parallel to the former, which begins where the other ends; so that the person immediately mounts again, and in the same manner glides down the other inclined plain of ice. This diversion he repeats as often as he pleases. The boys also are continually employed in skating down these hills: they glide chiefly upon one skait, as they are able to poise themselves better upon one leg than upon two. These ice-hills exhibit a pleasing appearance upon the river, as well from the trees with which they are ornamented, as from the moving objects which at particular times of the day are descending without intermission.

ICE-House, a repository for ice during the summer months. The aspect of ice-houses should be towards the east or south-east, for the advantage of the morning sun to expel the damp air, as that is more pernicious than warmth; for which reason trees in the vicinity of an ice-house tend to its disadvantage. The best soil for an ice-house to be made in is chalk, as it conveys away the waste water without any artificial drain; next to that, loose stony earth or gravelly soil. Its situation should be on the side of a hill, for the advantage of entering the cell upon a level, as represented in plate 23.

To construct an ice-house, first choose a proper place at a convenient distance from the dwelling-house or houses it is to serve: dig a cavity (if for one family, of the dimensions specified in the design) of the figure of an inverted cone, sinking the bottom concave, to form a reservoir for the waste water till it can drain off; if the soil requires it, cut a drain to a considerable distance, or so far as will come out at the side of the hill, or into a well, to make it communicate with the springs; and in that drain form a sink or air trap, marked *l*, by sinking the drain so much lower in that place as it is high, and bring a partition from the top an inch or more into the water, which will consequently be in the trap; and will keep the well airtight. Work up a sufficient number of brick piers to receive

a cart-wheel, to be laid with its convex side upwards to receive the ice; lay hurdles and straw upon the wheel, which will let the melted ice drain through, and serve as a floor. The sides and dome of the cone are to be nine inches thick—the sides to be done in steened brickwork, *i. e.* without mortar, and wrought at right angles to the face of the work: the filling in behind should be with gravel, loose stones or brick-bats, that the water which drains through the sides may the more easily escape into the well. The doors of the ice-house should be made as close as possible, and bundles of straw placed always before the inner door to keep out the air.

The following is a description of the parts referred to in the plate:—*a* The line first dug out. *b* The brick circumference of the cell. *c* The diminution of the cell downwards. *d* The lesser diameter of the cell. *e* The cart wheel; or joists and hurdles. *f* The piers to receive the wheel or floor. *g* The principal receptacle for straw. *h* The inner passage, *i* the first entrance, *k* the outer door, passages having a separate door each. *l* An air-trap. *m* The well. *n* The profile of the piers. *o* The ice filled in. *p* The height of the cone. *q* The dome worked in two half brick arches. *r* The arched passage. *s* The doorways inserted in the walls. *t* The floor of the passage. *u* An aperture through which the ice may be put into the cell; this must be covered next the crown of the dome, and then filled in with earth. *x* The sloping door, against which the straw should be laid.

The ice when to be put in should be collected during the frost, broken into small pieces, and rammed down hard in strata of not more than a foot, in order to make it one complete body; the care in putting it in, and well ramming it, tends much to its preservation. In a season when ice is not to be had in sufficient quantities snow may be substituted.

Ice may be preserved in a dry place under ground, by covering it well with chaff, straw, or reeds. Great use is made of chaff in some parts of Italy to preserve ice: the ice-houses for this purpose need only be a deep hole dug in the ground on the side of a hill, from the bottom of which they can easily carry out a drain, to let out the water which is separated at any time from the ice, that it may not melt and spoil the rest. If the ground is tolerably dry, they do not line the sides with any thing, but leave them naked, and only make a covering of thatch over the top of the hole: this pit they fill either with pure snow, or else with ice taken from the purest and clearest water; because they do not use it as we do in England, to set the bottles in, but really mix it with the wine. They first cover the bottom of the hole with chaff, and then lay in the ice, not letting it any where touch the sides, but ramming in a large bed of chaff all the way between: they thus carry on the filling to the top, and then cover the surface with chaff; and in this manner it will keep as long as they please. When they take any of it out for use, they wrap the lump up in chaff, and it may then be carried to any distant place without waste or running.

ICE Island, a name given by sailors to a great quantity of ice collected into one huge solid mass, and floating about upon the seas near or within the Polar circles. Many of these fluctuating islands are met with on the coasts of Spitsbergen, to the great danger of the shipping employed in the Greenland fishery. In the midst of those tremendous masses navigators have been arrested and frozen to death. In this manner the brave Sir Hugh Willoughby perished with all his crew in 1553; and in the year 1773, Lord Mulgrave, after every effort which the most finished seaman could make to accomplish the end of his voyage, was caught in the ice, and was near experiencing the same unhappy fate. See the account at large in *Phipps's Voyage to the North Pole*. As there described, the scene, divested

of the horror from the eventful expectation of change, was the most beautiful and picturesque:—Two large ships becalmed in a vast basin, surrounded on all sides by islands of various forms: the weather clear; the sun gilding the circumambient ice, which was low, smooth, and even; covered with snow, excepting where the pools of water on part of the surface appeared crystalline with the young ice: the small space of sea they were confined in, perfectly smooth. After fruitless attempts to force a way through the fields of ice, their limits were perpetually contracted by its closing; till at length it beset each vessel till they became immoveably fixed. The smooth extent of surface was soon lost: the pressure of the pieces of ice, by the violence of the swell, caused them to pack; fragment rose upon fragment, till they were in many places higher than the main-yard. The movements of the ships were tremendous and involuntary, in conjunction with the surrounding ice, actuated by the currents. The water shoaled to 14 fathoms. The grounding of the ice or of the ships would have been equally fatal: the force of the ice might have crushed them to atoms, or have lifted them out of the water and overset them, or have left them suspended on the summits of the pieces of ice at a tremendous height, exposed to the fury of the winds, or to the risk of being dashed to pieces by the failure of their frozen dock. An attempt was made to cut a passage through the ice; after a perseverance worthy of Britons it proved fruitless. The commander, at all times master of himself, directed the boats to be made ready to be hauled over the ice, till they arrived at navigable water (a task alone of seven days), and in them to make their voyage to England. The boats were drawn progressively three whole days. At length a wind sprung up, the ice separated sufficiently to yield to the pressure of the full-sailed ships, which, after labouring against the resisting fields of ice, arrived on the 10th of August in the harbour of Smeeringberg, at the west end of Spitzbergen, between it and Hackluyt's Headland.

The forms assumed by the ice in this chilling climate are extremely pleasing to even the most incurious eye. The surface of that which is congealed from the sea-water (for we must allow it two origins) is flat and even, hard, opaque, resembling white sugar, and incapable of being slid on like the British ice. The greater pieces, or fields, are many leagues in length: the lesser are the meadows of the seals, on which those animals at times frolic by hundreds. The motion of the lesser pieces is as rapid as the currents: the greater, which are sometimes 200 leagues long, and 60 or 80 broad, move slow and majestically; often fix for a time, immovable by the power of the ocean, and then produce near the horizon that bright white appearance called the *blink*. The approximation of two great fields produces a most singular phenomenon; it forces the lesser (if the term can be applied to pieces of several acres square) out of the water, and adds them to their surface: a second and often a third succeeds; so that the whole forms an aggregate of a tremendous height. These float in the sea like so many rugged mountains, and are sometimes 500 or 600 yards thick; but the far greater part is concealed beneath the water. These are continually increased in height by the freezing of the spray of the sea, or of the meltings of the snow, which falls on them. Those which remain in this frozen climate receive continual growth; others are gradually wasted by the northern winds into southern latitudes, and melt by degrees by the heat of the sun, till they waste away, or disappear in the boundless element.

The collision of the great fields of ice, in high latitudes, is often attended with a noise that for a time takes away the sense of hearing any thing else; and the lesser with a grinding of unspeakable horror. The water which dashes against the

mountainous ice freezes into an infinite variety of forms; and gives the voyager ideal towns, streets, churches, steeples, and every shape which imagination can frame.

ICE-Plant. See *MISEMBRYANTHEMUM*.

ICEBERGS, are large bodies of ice filling the valleys between the high mountains in northern latitudes. Among the most remarkable are those of the east coast of Spitzbergen. They are seven in number, but at considerable distances from each other; each fills the valleys for tracts unknown, in a region totally inaccessible in the internal parts. The glaciers of Switzerland (see *GLACIERS*) seem contemptible to these; but present often a similar front into some lower valley. The last exhibits over the sea a front 300 feet high, emulating the emerald in colour: cataracts of melted snow precipitate down various parts, and black spiring mountains, streaked with white, bound the sides, and rise crag above crag, as far as eye can reach in the back ground. At times immense fragments break off, and tumble into the water with a most alarming dashing. In *Phipps's Voyage to the North Pole*, p. 70, we are told, a piece of this vivid green substance has fallen, and grounded in 24 fathoms water, and spired above the surface 50 feet. Similar icebergs are frequent in all the Arctic regions; and to their lapses is owing the solid mountainous ice which infests those seas.—Frost sports wonderfully with these icebergs, and gives them majestic as well as other most singular forms. Masses have been seen assuming the shape of a Gothic church, with arched windows and doors, and all the rich drapery of that style, composed of what an Arabian tale would scarcely dare to relate, of crystal of the richest sapphirine blue: tables with one or more feet; and often immense flat-roofed temples, like those of Luxor on the Nile, supported by round transparent columns of cœrulean hue, float by the astonished spectator. These icebergs are the creation of ages, and receive annually additional height by the falling of snows and of rain, which often instantly freezes, and more than repairs the loss occasioned by the influence of the melting sun.

ICELAND, a large island to the north of Europe, about 400 miles in length, and 150 in breadth. For two months together the sun never sets, and in the winter it never rises for the same space, at least not entirely. The middle of this island is mountainous, stony, and barren; but in some places there are excellent pastures, and the grass has a fine smell. The ice, which gets loose from the more northern country in May, brings with it a large quantity of wood, and several animals, such as foxes, wolves, and bears. Mount Hecla is the most noted mountain, and is a volcano, which sometimes throws out sulphureous torrents (see the article *HUER*). The inhabitants believe that some of the souls of the damned go to this mountain, and that others are confined to the ice near this island. Their houses are scattered about, at a distance from each other, and many of them are deep in the ground; but they are all miserable huts, covered with skins. Many of the inhabitants profess Christianity; but those that live at a distance are Pagans. They are mostly clothed with the skins of beasts. The Danes trade with the natives for hides, tallow, train-oil, whalebone, and sea horses' teeth, which are as good as ivory. Iceland, which was considered by the ancients as the Ultima Thule, or the extremity of the world, and by us as scarcely habitable, once abounded in learning and science, at a time when great part of Europe was involved in darkness. Their language was the old Gothic or Teutonic, the vernacular tongue of the Swedes, Danes, and Norwegians, before it branched into the several dialects since spoken by the natives of those three kingdoms. N. lat. from 64. to 67.

ICELAND-Agate, a kind of precious stone met with in the islands of Iceland and Ascension, employed by the jewellers as

an agate, though too soft for the purpose. It is supposed to be a volcanic product; being solid, black, and of a glassy texture. When held between the eye and the light, it is semi-transparent, and greenish like the glass bottles which contain much iron. In the islands which produce it, such large pieces are met with that they cannot be equalled in any glass-house.

ICELAND (or *Iceland*) *Crystal*. See CRYSTAL (*Iceland*).

ICENI, the ancient name of the people of Suffolk, Norfolk, Cambridgeshire, and Huntingdonshire, in England.

ICH-DIEN. See HERALDRY, p. 216.

ICHNEUMON, in zoology. See VIVERRA.

ICHNEUMON is also the name of a genus of flies of the hymenoptera order. The mouth is armed with jaws, without any tongue: the antennæ have above 30 joints; the abdomen is generally petiolated, joined to the body by a pedicle or stalk; the tail is armed with a sting, which is enclosed in a double-valved cylindrical sheath; the wings are lanceolated and plain. This genus is exceedingly numerous. In Gmelin's or the 13th edition of the *Systema Naturæ*, no fewer than 415 species are enumerated. They are divided into families, from the colour of their scutellum and antennæ, as follow: 1. Those with a whitish scutcheon, and antennæ annulated with a whitish band. 2. Those which have a white scutcheon and antennæ entirely black. 3. With a scutcheon of the same colour as the thorax; the antennæ encompassed with a fillet. 4. With a scutcheon of the same colour as the thorax; and antennæ black and setaceous. 5. With setaceous clay-coloured antennæ. 6. With small filiform antennæ, and the abdomen oval and slender.

One distinguishing and striking character of these species of flies is the almost continual agitation of their antennæ. The name of *Ichneumon* has been applied to them, from the service they do us by destroying caterpillars, plant-lice, and other insects; as the ichneumon or mangouste destroys the crocodiles. The variety to be found in the species of ichneumons is prodigious: among the smaller species there are males who perform their amorous preludes in the most passionate and gallant manner. The posterior part of the females is armed with a wimble, visible in some species, no ways discoverable in others; and that instrument, though so fine, is able to penetrate through mortar and plaster: the structure of it is more easily seen in the long wimble fly. The food of the family to be produced by this fly is the larva of wasps or mason-bees: for it no sooner espies one of those nests, but it fixes on it with its wimble, and bores through the mortar of which it is built. The wimble itself, of an admirable structure, consists of three pieces; two collateral ones, hollowed out into a gutter, serve as a sheath, and contain a compact, solid, dentated stem, along which runs a groove that conveys the egg from the animal, who supports the wimble with its hinder legs, lest it should break; and by a variety of movements, which it dexterously performs, it bores through the building, and deposits one or more eggs, according to the size of the ichneumon, though the largest drop but one or two. Some agglutinate their eggs upon caterpillars; others penetrate through the caterpillar's eggs, though very hard, and deposit their own in the inside. When the larva is hatched, its head is so situated, that it pierces the caterpillar and penetrates to its very entrails. These larvæ pump out the nutritious juices of the caterpillar, without attacking the vitals of the creature, who appears healthy, and even sometimes transforms itself to a chrysalis. It is not uncommon to see those caterpillars fixed upon trees, as if they were sitting upon their eggs; and it is afterwards discovered that the larvæ, which were within their bodies, have spun their threads, with which, as with cords, the caterpillars are fastened down, and so perish miserably. The ichneumons performed special service in the years 1731 and 1732: by multiplying in the same proportion

VOL. IV.

as did the caterpillars, their larvæ destroyed more of them than could be effected by human industry. Those larvæ, when on the point of turning into chrysalids, spin a silky cocoon. Nothing is more surprising and singular than to see those cods leap when placed on the table or hand. Plant-lice, the larvæ of the cuculiones, and spiders' eggs, are also sometimes the cradle of the ichneumon fly. Carcases of plant-lice, void of motion, are often found on rose tree leaves; they are the habitation of a small larva, which, after having eaten up the entrails, destroys the springs and inward economy of the plant-lice, performs its metamorphosis under shelter of the pellicle which enfolds it, contrives itself a small circular outlet, and sallies forth into open air. There are ichneumons in the woods, who dare attack spiders, run them through with their sting, tear them to pieces, and thus avenge the whole nation of flies of so formidable a foe: others, destitute of wings (and those are females), deposit their eggs in spiders' nests. The ichneumon of the bedeguar, or sweet-briar sponge, and that of the rose-tree, perhaps only deposit their eggs in those places; because they find other insects on which they feed. The genus of the ichneumon-flies might with propriety be termed a race of diminutive canibals.

ICHNOGRAPHY, in perspective, the view of any thing cut off by a plane, parallel to the horizon, just at the base of it. The word is derived from the Greek *ἰχνογραφία*, *footstep*, and *γράφω* *I write*, as being a description of the footsteps or traces of a work. Among painters it signifies a description of images or of ancient statues of marble and copper, of busts and semi-busts, of paintings in fresco, mosaic works, and ancient pieces of miniature.

ICHOGLANS, the grand signior's pages serving in the seraglio. These are the children of Christian parents, either taken in war, purchased, or sent in presents from the viceroys and governors of distant provinces; they are the most sprightly, beautiful, and well-made that can be met with; and are always reviewed and approved of by the grand signior himself before they are admitted into the seraglios of Pera, Constantinople, or Adrianople, being the three colleges where they are educated, or fitted for employments, according to the opinion the court entertains of them.

ICHOR, in surgery, properly signifies a thin watery humour like serum, but is sometimes used for a thicker kind flowing from ulcers, called also *sanies*.

ICHTHYOCOLLA, ISINGLASS, a preparation from the fish known by the name of *bufo*. See ACCIPENSER. The word is Greek, formed of *ἰχθυος*, *fish*, and *κόλλα*, *glue*.—The method of making isinglass was long a secret in the hands of the Russians, but was at length discovered, and the following account of it published by Humphrey Jackson, Esq. in the 63d volume of the Philosophical Transactions.

“All authors who have hitherto delivered processes for making ichthyocolla, fish-glué, or isinglass, have greatly mistaken both its constituent matter and preparation.

“To prove this assertion, it may not be improper to recite what Pomet says upon the subject, as he appears to be the principal author whom the rest have copied. After describing the fish, and referring to a cut engraved from an original in his custody, he says: ‘As to the manner of making the isinglass, the finewy parts of the fish are boiled in water till all of them be dissolved that will dissolve; then the gluey liquor is strained, and set to cool. Being cold, the fat is carefully taken off, and the liquor itself boiled to a just consistency, then cut to pieces, and made into a twist, bent in form of a crescent, as commonly sold; then hung upon a string, and carefully dried.’

“From this account it might be rationally concluded, that every species of fish which contained gelatinous principles would yield isinglass: and this parity of reasoning seems to have

given rise to the hasty conclusions of those who strenuously vouch for the extraction of isinglass from sturgeon; but as that fish is easily procurable, the negligence of ascertaining the fact by experiment seems inexcusable.

“ In my first attempt to discover the constituent parts and manufacture of isinglass, relying too much upon the authority of some chemical authors whose veracity I had experienced in many other instances, I found myself constantly disappointed. Glue, not isinglass, was the result of every process; and although, in the same view, a journey to Russia proved fruitless, yet a steady perseverance in the research proved not only successful as to this object, but, in the pursuit, to discover a resinous matter plentifully procurable in the British fisheries, which has been found by ample experience to answer similar purposes. It is now no longer a secret, that our lakes and rivers in North America are stocked with immense quantities of fish, said to be the same species with those in Muscovy, and yielding the finest isinglass; the fisheries whereof, under due encouragement, would doubtless supply all Europe with this valuable article.

“ No artificial heat is necessary to the production of isinglass, neither is the matter dissolved for this purpose; for, as the continuity of its fibres would be destroyed by solution, the mass would become brittle in drying, and snap short asunder, which is always the case with glue, but never with isinglass. The latter, indeed, may be dissolved into glue with boiling water; but its fibrous recomposition would be found impracticable afterwards, and a fibrous texture is one of the most distinguishing characteristics of genuine isinglass.

“ A due consideration that an imperfect solution of isinglass, called *fining* by the brewers, possessed a peculiar property of clarifying malt-liquors, induced me to attempt its analysis in cold subacid menstrua. One ounce and an half of good isinglass, steeped a few days in a gallon of stale beer, was converted into good fining, of a remarkably thick consistence: the same quantity of glue, under similar treatment, yielded only a mucilaginous liquor, resembling diluted gum-water, which, instead of clarifying beer, increased both its tenacity and turbidness, and communicated other properties in no respect corresponding with those of genuine fining. On commixing three spoonfuls of the solution of isinglass with a gallon of malt liquor, in a tall cylindrical glass, a vast number of curdly masses became presently formed, by the reciprocal attraction of the particles of isinglass and the feculencies of the beer, which, increasing in magnitude and specific gravity, arranged themselves accordingly, and fell in a combined state to the bottom, through the well known laws of gravitation; for, in this case, there is no elective attraction, as some have imagined, which bears the least affinity with what frequently occurs in chemical decompositions.

“ If what is commercially termed *long* or *short stapled isinglass* be steeped a few hours in fair cold water, the entwisted membranes will expand, and reassume their original beautiful hue, and, by a dexterous address, may be perfectly unfolded. By this simple operation, we find that isinglass is nothing more than certain membranous parts of fishes, divested of their native mucosity, rolled and twisted into the forms above mentioned, and dried in open air.

“ The sounds, or air-bladders, of fresh-water fish in general are preferred for this purpose, as being the most transparent, flexible, delicate substances. These constitute the finest sorts of isinglass; those called *book* and *ordinary staple* are made of the intestines, and probably of the peritonæum of the fish. The belluga yields the greatest quantity, as being the largest and most plentiful fish in the Muscovy rivers; but the sounds of all fresh-water fish yield, more or less, fine isinglass, particularly the smaller sorts, found in prodigious quantities in the Caspian sea, and several hundred miles beyond Astracan, in the

Wolga, Yaik, Don, and even as far as Siberia, where it is called *kle* or *kla* by the natives, which implies a glutinous matter; it is the basis of the Russian glue, which is preferred to all other kinds for its strength.

“ The sounds, which yield the finer isinglass, consist of parallel fibres, and are easily rent longitudinally; but the ordinary sorts are found composed of double membranes, whose fibres cross each other obliquely, resembling the coats of a bladder: hence the former are more readily pervaded and divided with subacid liquors; but the latter, through a peculiar kind of interwoven texture, are with great difficulty torn asunder, and long resist the power of the same menstruum; yet, when duly resolved, are found to act with equal energy in clarifying liquors.

“ Isinglass receives its different shapes in the following manner: The parts of which it is composed, particularly the sounds, are taken from the fish while sweet and fresh, slit open, washed from their slimy *fordes*, divested of every thin membrane which envelops the sound, and then exposed to stiffen a little in the air. In this state, they are formed into rolls about the thickness of a finger, and in length according to the intended size of the staple: a thin membrane is generally selected for the centre of the roll, round which the rest are folded alternately, and about half an inch of each extremity of the roll is turned inwards. The due dimensions being thus obtained, the two ends of what is called *short staple* are pinned together with a small wooden peg; the middle of the roll is then pressed a little downwards, which gives it the resemblance of a heart-shape; and thus it is laid on boards, or hung up in the air to dry. The sounds which compose the long staple are longer than the former; but the operator lengthens this sort at pleasure, by interfolding the ends of one or more pieces of the sound with each other. The extremities are fastened with a peg, like the former; but the middle part of the roll is bent more considerably downwards; and, in order to preserve the shape of the three obtuse angles thus formed, a piece of round stick, about a quarter of an inch diameter, is fastened in each angle with small wooden pegs, in the same manner as the ends. In this state, it is permitted to dry long enough to retain its form, when the pegs and sticks are taken out, and the drying completed: lastly, the pieces of isinglass are colligated in rows, by running packthread through the peg-holes, for convenience of package and exportation.

“ The membranes of the *book* sort, being thick and refractory, will not admit a similar formation with the preceding; the pieces, therefore, after their sides are folded inwardly, are bent in the centre in such manner that the opposite sides resemble the cover of a book; from whence its name: a peg being run across the middle, fastens the sides together, and thus it is dried like the former. This sort is interleaved, and the pegs run across the ends, the better to prevent its unfolding.

“ That called *cake isinglass* is formed of the bits and fragments of the staple sorts, put into a flat metalline pan, with a very little water, and heated just enough to make the parts cohere like a pancake when it is dried; but frequently it is overheated, and such pieces, as before observed, are useless in the business of fining. Experience has taught the consumers to reject them.

“ Isinglass is best made in the summer, as frost gives it a disagreeable colour, deprives it of weight, and impairs its gelatinous principles; its fashionable forms are unnecessary, and frequently injurious to its native qualities. It is common to find oily putrid matter, and *exuvie* of insects, between the implicated membranes, which, through the inattention of the cellarman, often contaminate wines and malt liquors in the act of clarification. These peculiar shapes might, probably, be introduced originally with a view to conceal and disguise.

the real substance of isinglass, and preserve the monopoly; but, as the mask is now taken off, it cannot be doubted to answer every purpose more effectually in its native state, without any subsequent manufacture whatever, especially to the principal consumers, who hence will be enabled to procure sufficient supply from the British colonies. Until this laudable end can be fully accomplished, and as a species of isinglass, more easily producible from the marine fisheries, may probably be more immediately encouraged, it may be manufactured as follows:

“The sounds of cod and ling bear great analogy with those of the *accipenser* genus of Linnæus and Artedi; and are in general so well known as to require no particular description. The Newfoundland and Iceland fishermen split open the fish as soon as taken, and throw the back bones, with the sounds annexed, in a heap; but previous to incipient putrefaction, the sounds are cut out, washed from their slimes, and salted for use. In cutting out the sounds, the intercostal parts are left behind, which are much the best: the Iceland fishermen are so sensible of this, that they beat the bone upon a block with a thick stick, till the pockets, as they term them, come out easily, and thus preserve the sound entire. If the sounds have been cured with salt, that must be dissolved by steeping them in water before they are prepared for isinglass; the fresh sound must then be laid upon a block of wood, whose surface is a little elliptical, to the end of which a small hair-brush is nailed, and with a saw-knife the membranes on each side of the sound must be scraped off. The knife is rubbed upon the brush occasionally, to clear its teeth; the pockets are cut open with scissors, and perfectly cleansed of the mucous matter with a coarse cloth; the sounds are afterwards washed a few minutes in lime-water in order to absorb their oily principle, and lastly in clear water. They are then laid upon nets to dry in the air; but if intended to resemble the foreign isinglass, the sounds of cod will only admit of that called *book*, but those of ling both shapes. The thicker the sounds are, the better the isinglass, colour excepted; but that is immaterial to the brewer, who is its chief consumer.

“This isinglass resolves into fining, like the other sorts, in subacid liquors, as stale beer, cyder, old hock, &c. and in equal quantities produces similar effects upon turbid liquors, except that it falls speedier and closer to the bottom of the vessel, as may be demonstrated in tall cylindrical glasses; but foreign isinglass retains the consistency of fining preferably in warm weather, owing to the greater tenacity of its native mucilage.

“Vegetable acids are, in every respect, best adapted to fining: the mineral acids are too corrosive, and even insalubrious, in common beverage.

“It is remarkable, that, during the conversion of isinglass into fining, the acidity of the menstruum seems greatly diminished, at least to taste; not on account of any alkaline property in the isinglass, probably, but by its enveloping the acid particles. It is likewise reducible into jelly with alkaline liquors, which indeed are solvents of all animal matters; even cold lime-water dissolves it into a pulpy *magma*. Notwithstanding this is inadmissible as fining, on account of the menstruum, it produces admirable effects in other respects: for, on commixture with compositions of plaster, lime, &c. for ornamenting walls exposed to vicissitudes of weather, it adds firmness and permanency to the cement; and if common brick-mortar be worked up with this jelly, it soon becomes almost as hard as the brick itself: but for this purpose it is more commodiously prepared, by dissolving it in cold water acidulated with vitriolic acid; in which case the acid quits the jelly, and forms with the lime a *selenitic mass*, while, at the same time, the jelly being deprived in some measure of its moisture, through the formation of an indissoluble concrete amongst its

parts, soon dries, and hardens into a firm body; whence its superior strength and durability are easily comprehended.

“It has long been a prevalent opinion, that sturgeon, on account of its cartilaginous nature, would yield great quantities of isinglass; but, on examination, no part of this fish, except the inner coat of the sound, promised the least success. This being full of *rugæ*, adheres so firmly to the external membrane, which is useless, that the labour of separating them supercedes the advantage. The intestines, however, which in the larger fish extend several yards in length, being cleansed from their mucus, and dried, were found surprisingly strong and elastic, resembling cords made with the intestines of other animals, commonly called *cat gut*, and, from some trials, promised superior advantages when applied to mechanic operations.”

Isinglass is sometimes used in medicine; but its effects are trifling, and merely to be attributed to its nutritious properties. Women subject to the *fluor albus* are in the habit of taking it dissolved in milk.

ICHTHYOLOGY, the science of fishes, or that part of zoology which treats of fishes. See FISH. Fishes form the fourth class of animals in the Linnæan system. This class is there arranged into six orders, under three great divisions; none of which, however, include the cetaceous tribes, or the whale, dolphin, &c. these forming an order of the class MAMMALIA in the same system. See ZOOLOGY.

Mr. Pennant, in his British Zoology, makes a different and very judicious arrangement, by which the cetæ are restored to their proper rank. He distributes fish into three divisions, comprehending six orders. His divisions are, into *Cetaceous*, *Cartilaginous*, and *Bony*.

Div. I. CETACEOUS Fish; the characters of which are the following: No gills; an orifice on the top of the head, through which they breathe and eject water; a flat or horizontal tail; exemplified under *Ichthyology* in Plate 23, by the Beaked Whale, figure 1, borrowed from Dale's Hist. Harw. 411. Tab. xiv.—This division comprehends three genera; the Whale, Cachalot, and Dolphin.

Div. II. CARTILAGINOUS Fish; the characters of which are: Breathing through certain apertures, generally placed on each side the neck; but in some instances beneath, in some above, and from one to seven in number on each part, except in the pipe-fish, which has only one; the muscles supported by cartilages instead of bones. Example, the Picked Dog-fish, fig. 2. a, The lateral apertures.—The genera are, the Lamprey, Skate, Shark, Fishing-frog, Sturgeon, Sun-fish, Lump-fish, Pipe-fish.

Div. III. BONY Fish; includes those whose muscles are supported by bones or spines, which breathe through gills covered or guarded by thin bony plates, open on the side, and dilatable by means of a certain row of bones on their lower part, each separated by a thin web; which bones are called the *radii brachioستيגי*, or the *gill-covering rays*. The tails of all the fish that form this division are placed in a situation perpendicular to the body; and this is an invariable character.

The great sections of the Bony Fish into *Apodal*, *Thoracic*, *Jugular*, and *Abdominal*, he copies from Linnæus, who founds this system on a comparison of the ventral fins to the feet of land-animals or reptiles; and either from the want of them, or their particular situation in respect to the other fins, establishes his sections.—In order to render them perfectly intelligible, it is necessary to refer to those several organs of movement, and some other parts, in a perfect fish, or one taken out of the three last sections. In fig. 4. (the Haddock), *a*, is the pectoral fins; *b*, ventral fins; *c*, anal fins; *d*, caudal fin, or the tail; *e, e, e*, dorsal fins; *f*, bony plates that cover the gills; *g*, branchiostegous rays and their membranes; *h*, the lateral or side line.

SECT. 1. APODAL : The most imperfect, wanting the ventral fins ; illustrated by the Conger, fig. 3. This also expresses the union of the dorsal and anal fins with the tail, as is found in some few fish.—Genera : The Eel, Wolf-fish, Launce, Morris, Sword fish.

SECT. 2. JUGULAR : The ventral fins *b*, placed before the pectoral fins *a*, as in the Haddock, fig. 4.—Genera : The Dragonet, Weever, Codfish, Blenny.

SECT. 3. THORAGIC : The ventral fins *a*, placed beneath the pectoral fins *b*, as in the Father Lasher, fig. 5.—Genera : The Goby, Bull-head, Doree, Flounder, Gilt-head, Wrasse, Perch, Stickleback, Mackarel, Surmullet, Gurnard.

SECT. 4. ABDOMINAL : The ventral fins placed behind the pectoral fins, as in the Minow, fig. 6.—Genera : The Loche, Salmon, Pike, Argentine, Atherine, Mullet, Flying-fish, Her-ring, Carp.

Naturalists observe an exceeding great degree of wisdom in the structure of fishes, and in their conformation to the element in which they are to live. Most of them have the same external form, sharp at either end, and swelling in the middle, by which they are enabled to traverse the fluid in which they reside with greater velocity and ease. This shape is in some measure imitated by men in those vessels which they design to sail with the greatest swiftness ; but the progress of the swiftest sailing ship is far inferior to that of fishes. Any of the large fishes overtake a ship in full sail with the greatest ease, play round it as though it did not move at all, and can get before it at pleasure.

The chief instruments of a fish's motion have been supposed to be the fins ; which in some are much more numerous than in others. A fish completely fitted for swimming with rapidity, is generally furnished with two pair of fins on the sides, and three single ones, two above and one below. But it does not always happen that the fish which has the greatest number of fins is the swiftest swimmer. The shark is thought to be one of the swiftest fishes, and yet it has no fins on its belly ; the haddock seems to be more completely fitted for motion, and yet it does not move so swiftly. It is even observable, that some fishes which have no fins at all, such as lobsters, dart forward with prodigious rapidity, by means of their tail ; and the instrument of progressive motion, in all fishes, is now found to be the tail. The great use of the fins is to keep the body *in equilibrio* : and if the fins are cut off, the fish can still swim ; but will turn upon its sides or its back, without being able to keep itself in an erect posture as before. If the fish desires to turn, a blow from the tail sends it about in an instant ; but if the tail strikes both ways, then the motion is progressive.

All fishes are furnished with a slimy glutinous matter, which defends their bodies from the immediate contact of the surrounding fluid, and which likewise, in all probability, assists their motion through the water. Beneath this, in many kinds, is found a strong covering of scales, which like a coat of mail defends it still more powerfully ; and under that, before we come to the muscular parts of the body, lies an oily substance, which also tends to preserve the requisite warmth and vigour.

By many naturalists fishes are considered as of a nature very much inferior to land animals, whether beasts or birds. Their sense of feeling, it is thought, must be very obscure on account of the scaly coat of mail in which they are wrapped up. The sense of smelling also, it is said, they can have only in a very small degree. All fishes, indeed, have one or more nostrils ; and even those that have not the holes perceptible without, yet have the bones within properly formed for smelling. But as the air is the only medium we know proper for the distribution of odours, it cannot be supposed that these animals which reside constantly in the water can be affected by them. As to tasting, they seem to make very little distinction. The palate of most fishes is hard

and bony, and consequently incapable of the powers of relishing different substances ; and accordingly these voracious animals have often been observed to swallow the fishermen's plummet instead of the bait. Hearing is generally thought to be totally deficient in fishes, notwithstanding the discoveries of some anatomists, who pretend to have found out the bones designed for the organ of hearing in their heads. They have no voice, it is said, to communicate with each other, and consequently have no need of an organ for hearing. Sight seems to be that sense of which they are possessed in the greatest degree ; and yet even this seems obscure, if we compare it with that of other animals. The eye, in almost all fishes, is covered with the same transparent skin which covers the rest of the head, and which probably serves to defend it in the water, as they are without eyelids. The globe is more depressed anteriorly, and is furnished behind with a muscle which serves to lengthen or flatten it as there is occasion. The crystalline humour, which in quadrupeds is flat, and of the shape of a button-mould, or like a very convex lens, in fishes is quite round, or sometimes oblong like an egg. Hence it is thought that fishes are extremely near-sighted ; and that, even in the water, they can perceive objects only at a very small distance. Hence, say they, it is evident how far fishes are below terrestrial animals in their sensations, and consequently in their enjoyments. Even their brain, which is by some supposed to be of a size with every creature's understanding, shows that fishes are very much inferior to birds in this respect.

Others argue differently with regard to the nature of fishes. With respect to the sense of feeling, say they, it cannot be justly argued that fishes are deficient merely because they are covered with scales, as it is possible these scales may be endued with as great a power of sensation as we can imagine. The sense of feeling is not properly connected with *softness* in any organ, more than with *hardness* in it. A similar argument may be used with regard to smelling ; for though we do not know how smells can be propagated in water, that is by no means a proof that they are not so. On the contrary, as water is found to be capable of absorbing putrid effluvia from the air, nothing is more probable than that these putrid effluvia, when mixed with the water, would affect the olfactory organs of fishes, as well as they affect ours when mixed with the air. With regard to taste, it certainly appears, that fishes are able to distinguish their proper food from what is improper, as well as other animals. Indeed no voracious animal seems to be endued with much sensibility in this respect ; nor would it probably be consistent with that way of promiscuously devouring every creature that comes within its reach, without which these kinds of animals could not subsist.

With respect to the *bearing of fishes*, it is urged, that, when kept in a pond, they may be made to answer at the call of a whistle or the ringing of a bell ; and they will even be terrified at any sudden and violent noise, such as thunder, the firing of guns, &c. and shrink to the bottom of the water. Among the ancients, many were of opinion that fishes had the sense of hearing, though they were by no means satisfied about the ways or passages by which they heard. Placentini afterwards discovered some bones in the head of the pike, which had very much the appearance of being organs of hearing, though he could never discover any external passage to them. Klein affirmed, from his own experiments and observations, that all fishes have the organs of hearing ; and have also passages from without to these organs, though in many species they are difficult to be seen ; and that even the most minute and obscure of these are capable of communicating a tremulous motion to those organs, from sounds issuing from without. This is likewise asserted by M. Geoffroy, (*Dissertation sur l'organe de l'ouie*, p. 97 et seq.) who gives a particular description of the organs of hearing belonging to several species. These organs are a set of little bones ex-

tremely hard, and white, like fine porcelain, which are to be found in the heads of all fishes: the external auditory passages are very small, being scarcely sufficient to admit a hog's bristle; though with care they may be distinguished in almost all fishes. It can by no means be thought that the water is an improper medium of sound, seeing daily experience shows us that sounds may be conveyed not only through water, but through the most solid bodies. See *ACOUSTICS*. It seems indeed very difficult to determine the matter by experiment. Mr. Gouan, who kept some gold fishes in a vase, informs us, that whatever noise he made, he could neither terrify nor disturb them: he holla'd as loud as he could, putting a piece of paper between his mouth and the water, to prevent the vibrations from affecting the surface, and the fishes still seemed insensible; but when the paper was removed, and the sound had its full effect on the water, the case was then altered, and the fishes instantly sunk to the bottom. This experiment, however, or others similar to it, cannot prove that the fishes did not hear the sounds before the paper was removed; it only shows that they were not alarmed till a sensible vibration was introduced into the water. The call of a whistle may also be supposed to affect the water in a fish-pond with a vibratory motion: but this certainly must be very obscure; and if fishes can be assembled in this manner when no person is in sight, it amounts to a demonstration that they actually do hear. See *COMPARATIVE Anatomy*, p. 657.

The arguments used against the sight of fishes are the weakest of all. Many instances, which daily occur, show that fishes have a very acute sight, not only of objects in the water, but of those in the air. Their jumping out of the water in order to catch flies is an abundant proof of this: and this they will continue to do in a fine summer evening, even after it is so dark that we cannot distinguish the insects they attempt to catch.

Though fishes are formed for living entirely in the water, yet they cannot subsist without air. On this subject Mr. Hawksbee made several experiments, which are recorded in the *Philosophical Transactions*. The fishes he employed were gudgeons; a species that are very lively in the water, and can live a considerable time out of it. Three of them were put into a glass vessel with about three pints of fresh water, which was designed as a standard to compare the others by. Into another glass, to a like quantity of water, were put three more gudgeons, and thus the water filled the glass to the very brim. Upon this he screwed down a brass-plate with a leather below, to prevent any communication between the water and the external air; and, that it might the better resemble a pond frozen over, he suffered as little air as possible to remain on the surface of the water. A third glass had the same quantity of water put into it; which, first by boiling, and then by continuing it a whole night *in vacuo*, was purged of its air as well as possible; and into this also were put three gudgeons. In about half an hour, the fishes in the water from whence the air had been exhausted, began to discover some signs of uneasiness by a more than ordinary motion in their mouths and gills. Those who had no communication with the external air would at this time also frequently ascend to the top, and suddenly swim down again: and in this state they continued for a considerable time, without any sensible alteration. About five hours after this observation, the fishes in the exhausted water were not so active as before, upon shaking the glass which contained them. In three hours more, the included fishes lay all at the bottom of the glass with their bellies upwards; nor could they be made to shake their fins or tail by any motion given to the glass. They had a motion with their mouths, however, which showed that they were not perfectly dead. On uncovering the vessel which contained them, they revived in two or three hours, and were perfectly well next morning; at which time those in the exhausted water were also recovered. The vessel containing these last being put under the

receiver of an air-pump, and the air exhausted, they all instantly died. They continued at top while the air remained exhausted, but sunk to the bottom on the admission of the atmosphere.

The use of air to fishes is very difficult to be explained; and indeed their method of obtaining the supply of which they stand constantly in need, is not easily accounted for. The motion of the gills in fishes is certainly analogous to our breathing, and seems to be the operation by which they separate the air from the water. Their manner of breathing is as follows: The fish first takes a quantity of water by the mouth, which is driven to the gills; these close, and keep the water which is swallowed from returning by the mouth, while the bony covering of the gills prevents it from going through them till the animal has drawn the proper quantity of air from it: then the bony covers open, and give it a free passage; by which means also the gills are again opened, and admit a fresh quantity of water. If the fish is prevented from the free play of its gills, it soon falls into convulsions, and dies. But though this is a pretty plausible explanation of the respiration of fishes, it remains a difficulty not easily solved what is done with this air. There seems to be no receptacle for containing it, except the air-bladder or swim; which, by the generality of modern philosophers, is destined not to answer any vital purpose, but only to enable the fish to rise or sink at pleasure.

The *air-bladder* is a bag filled with air, composed sometimes of one, sometimes of two, and sometimes of three divisions, situated towards the back of the fish, and opening into the maw or the gullet. The use of this in raising or depressing the fish is proved by the following experiment: A carp being put into the air-pump, and the air exhausted, the bladder is said to burst by the expansion of the air contained in it; after which, the fish can no more rise to the top, but ever afterwards crawls at the bottom. The same thing also happens when the air-bladder is pricked or wounded in such a manner as to let the air out; in these cases also the fish continues at the bottom, without a possibility of rising to the top. From this it is inferred, that the use of the air-bladder is, by swelling at the will of the animal, to increase the surface of the fish's body, and, thence diminishing its specific gravity, to enable it to rise to the top of the water, and to keep there at pleasure. On the contrary, when the fish wants to descend, it is thought to contract the air-bladder; and being thus rendered specifically heavier, it descends to the bottom.

The ancients were of opinion, that the air-bladder in fishes served for some purposes essentially necessary to life: and Dr. Priestley also conjectures, that the raising or depressing the fish is not the only use of these air-bladders, but that they also may serve some other purposes in the œconomy of fishes. There are many arguments indeed to be used on this side of the question: the most conclusive of which is, that all the cartilaginous kind of fishes want air-bladders, and yet they rise to the top or sink to the bottom of the water without any difficulty; and though most of the eel-kind have air bladders, yet they cannot raise themselves in the water without great difficulty.

Fishes are remarkable for their *longevity*. "Most of the disorders incident to mankind (says Bacon) arise from the changes and alterations in the atmosphere; but fishes reside in an element little subject to change: theirs is an uniform existence; their movements are without effort, and their life without labour. Their bones also, which are united by cartilages, admit of indefinite extension; and the different sizes of animals of the same kind, among fishes, is very various. They still keep growing: their bodies, instead of insinuating the rigidity of age, which is the cause of the natural decay of land animals, still continue increasing with fresh supplies; and as the body grows, the conduits of life furnish their stores in greater abundance.

How long a fish, that seems to have scarce any bounds put to its growth, continues to live, is not ascertained; perhaps the life of a man would not be sufficient to measure that of the smallest." There have been two methods fallen upon for determining the age of fishes; the one is by the circles of the scales, the other by the transverse section of the back bone. When a fish's scale is examined by a microscope, it is found to consist of a number of circles one within another, in some measure resembling those which appear on the transverse section of a tree, and is supposed to give the same information. For, as in trees, we can tell their age by the number of their circles; so, in fishes, we can tell theirs by the number of circles in every scale, reckoning one ring for every year of the animal's existence. The age of fishes that want scales may be known by the other method, namely, by separating the joints of the back-bone, and then minutely observing the number of rings which the surface, where it was joined, exhibits.

Fishes are, in general, the most voracious animals in nature. In most of them, the maw is placed next the mouth; and, though possessed of no sensible heat, is endowed with a very surprising faculty of digestion. Its digestive power seems, in some measure, to increase in proportion to the quantity of food with which the fish is supplied. A single pike has been known to devour 100 roaches in three days. Whatever is possessed of life seems to be the most desirable prey for fishes. Some that have very small mouths feed upon worms, and the spawn of other fish: others, whose mouths are larger, seek larger prey; it matters not of what kind, whether of their own species or any other. Those with the largest mouths pursue almost every thing that hath life; and often meeting each other in fierce opposition, the fish with the largest swallow comes off with the victory, and devours its antagonist. As a counterbalance to this great voracity, however, fishes are incredibly prolific. Some bring forth their young alive, others produce only eggs: the former are rather the least fruitful; yet even these produce in great abundance. The viviparous blenny, for instance, brings forth 200 or 300 at a time. Those which produce eggs, which they are obliged to leave to chance, either on the bottom where the water is shallow, or floating on the surface where it is deeper, are all much more prolific, and seem to proportion their stock to the danger there is of consumption. Lewenhoeck assures us, that the cod spawns above nine millions in a season. The flounder commonly produces above one million, and the mackerel above 500,000. Scarce one in 100 of these eggs, however, brings forth an animal: they are devoured by all the lesser fry that frequent the shores, by water-fowl in shallow waters, and by the larger fishes in deep waters. Such a prodigious increase, if permitted to come to maturity, would overstock nature; even the ocean itself would not be able to contain, much less provide for, one-half of its inhabitants. But two wise purposes are answered by this amazing increase; it preserves the species in the midst of numberless enemies, and serves to furnish the rest with a sustenance adapted to their nature.

With respect to the generation of many kinds of fishes, the common opinion is, that the female deposits her spawn or eggs, and that the male afterwards ejects his sperm or male semen upon it in the water. The want of the organs of generation in fishes gives an apparent probability to this: but it is strenuously opposed by Linnæus. He affirms, that there can be no possibility of impregnating the eggs of any animal out of its body. To confirm this, the general course of nature, not only in birds, quadrupeds, and insects, but even in the vegetable world, has been called in to his assistance, as proving that all impregnation is performed while the egg is in the body of its parent: and he supplies the want of the organs of generation by a very strange process, affirming, that the males eject their semen always some days before the females deposit their ova or

spawn; and that the females swallow this, and thus have their eggs impregnated with it. He says, that he has frequently seen at this time three or four females gathered about a male, and greedily snatching up into their mouths the semen he ejects. He mentions some of the efores, some perch, and some of the cyprini, in which he had seen this process. But see *COMPARATIVE Anatomy*, p. 256.

Many opinions have been started in order to account how it happens that fishes are found in pools and ditches on high mountains and elsewhere. But Gmelin observes, that the duck-kind swallow the eggs of fishes; and that some of these eggs go down and come out of their bodies unhurt, and so are propagated just in the same manner as has been observed of plants. For a more particular view of the structure of fishes, see *COMPARATIVE Anatomy*, Part III.

ICHTHYOPHAGI, FISH-EATERS, a name given to a people, or rather to several different people, who lived wholly on fishes. The word is Greek, compounded of *ἰχθυος* *piscis*, "fish," and *φαγεῖν edere*, "to eat." The Ichthyophagi spoken of by Ptolemy are placed by Sanson in the provinces of Nanquin and Xantong. Agatharcides calls all the inhabitants between Carmania and Gedrosia by the name *Ichthyophagi*. From the accounts given us of the Ichthyophagi by Herodotus, Strabo, Solinus, Plutarch, &c. it appears indeed that they had cattle, but that they made no use of them, excepting to feed their fish withal. They made their houses of large fish-bones, the ribs of whales serving them for their beams. The jaws of these animals served them for doors; and the mortars wherein they pounded their fish, and baked it at the sun, were nothing else but their vertebræ.

ICHTHYPERIA, in natural history, a name given by Dr. Hill to the bony palates and mouths of fishes, usually met with either fossil, in single pieces, or in fragments. They are of the same substance with the bufontiæ; and are of very various figures, some broad and short, others longer and slender; some very gibbose, and others plainly arched. They are likewise of various sizes, from the tenth of an inch to two inches in length, and an inch in breadth.

ICKENILD-STREET, is that old Roman highway, denominated from the Icenians, which extended from Yarmouth in Norfolk, the east part of the kingdom of the Iceni, to Barley in Hertfordshire, giving name in the way to several villages, as Ickworth, Icklingham, and Ickleton in that kingdom. From Barley to Roydon it divides the counties of Cambridge and Hertford. From Ickleford it runs by Tring, crosses Bucks and Oxfordshire, passes the Thames at Goring, and extends to the west part of England.

ICOLMKILL, formerly IONA, a noted little island, one of the Hebrides, near the S. W. point of the Isle of Mull. It is about three miles long and one broad. On this island, which is very fertile, are a mean village, and the ruins of an august monastery and cathedral, said to have been founded by St. Columba, where there are three royal chapels, or rather cemeteries, in which several ancient kings of Scotland, Ireland, and Norway are buried. In former times, this island was the place where the archives of Scotland, and many valuable and ancient MSS. were kept. Many of these, it is said, were carried to the Scotch College at Douay in France. This once celebrated seat of royalty and learning is now almost destitute of an instructor to teach the people the common duties of religion.

ICONIUM, at present COGNÉ, formerly the capital city of Lycaonia in Asia Minor. St. Paul coming to Iconium (Acts xiii. 51. xiv. 1. &c.) in the year of Christ 45, converted many Jews and Gentiles there. It is believed that, in his first journey to this city, he converted St. Thecla, so celebrated in the writings of the ancient fathers. But some incredulous Jews excited the Gentiles to rise against Paul and Barnabas, so that they were upon the point of offering violence to them; which obliged

St. Paul and St. Barnabas to fly for security to the neighbouring cities. St. Paul undertook a second journey to Iconium in the year 51; but we know no particulars of his journey, which relate peculiarly to Iconium.

ICONOCLASTES, or **ICONOCLASTÆ**, breakers of images; a name which the church of Rome gives to all who reject the use of images in religious matters. The word is Greek, formed from εἰκὼν *imago*, and κλάζειν *rumperere*, "to break." In this sense, not only the reformed but some of the eastern churches are called *Iconoclastes*, and esteemed by them heretics, as opposing the worship of the images of God and the Saints, and breaking their figures and representations in churches.

The opposition to images began in Greece under the reign of Bardanes, who was created emperor of the Greeks a little after the commencement of the eighth century, when the worship of them became common. See **IMAGE**. But the tumults occasioned by it were quelled by a revolution, which in 713 deprived Bardanes of the imperial throne. The dispute, however, broke out with redoubled fury under Leo the Isaurian, who issued out an edict in the year 726, abrogating, as some say, the worship of images, and ordering all the images, except that of Christ's crucifixion, to be removed out of the churches; but according to others, this edict only prohibited the paying to them any kind of adoration or worship. This edict occasioned a civil war, which broke out in the islands of the Archipelago, and, by the suggestions of the priests and monks, ravaged a part of Asia, and afterwards reached Italy. The civil commotions and insurrections in Italy were chiefly promoted by the Roman pontiffs Gregory I. and II. Leo was excommunicated, and his subjects in the Italian provinces violated their allegiance, and, rising in arms, either massacred or banished all the emperor's deputies and officers. In consequence of these proceedings, Leo assembled a council at Constantinople in 730, which degraded Germanus, the bishop of that city, who was a patron of images; and he ordered all the images to be publicly burnt, and inflicted a variety of severe punishments upon such as were attached to that idolatrous worship. Hence arose two factions; one of which adopted the adoration and worship of images, and on that account were called *iconoduli* or *iconolitræ*; and the other maintained that such worship was unlawful, and that nothing was more worthy the zeal of Christians than to demolish and destroy those statues and pictures which were the occasions of this gross idolatry; and hence they were distinguished by the titles of *iconomachi* (from εἰκὼν *image*, and μάχω *I contend*;) and *iconoclastæ*. The zeal of Gregory II. in favour of image worship was not only imitated, but even surpassed, by his successor Gregory III. in consequence of which the Italian provinces were torn from the Grecian empire.

Constantine, called *C pronymus*, from κρησος "stercus," and ονομα "name," because he was said to have defiled the sacred font at his baptism, succeeded his father Leo in 741, and in 754 convened a council at Constantinople, regarded by the Greeks as the seventh œcumenical council, which solemnly condemned the worship and use of images. Those who, notwithstanding this decree of the council, raised commotions in the state, were severely punished; and new laws were enacted, to set bounds to the violence of monastic rage. Leo IV. who was declared emperor in 775, pursued the same measures, and had recourse to the coercive influence of penal laws, in order to extirpate idolatry out of the Christian church. Irene, the wife of Leo, poisoned her husband in 780, assumed the reins of empire during the minority of her son Constantine, and in 786 summoned a council at Nice in Bithynia, known by the name of the *second Nicene council*, which abrogated the laws and decrees against the new idolatry, restored the worship of images and of the cross, and denounced severe punishments against those who maintained that God was the only object of religious

adoration. In this contest, the Britons, Germans, and Gauls, were of opinion, that images might be lawfully continued in churches, but they considered the worship of them as highly injurious and offensive to the Supreme Being. Charlemagne distinguished himself as a mediator in this controversy: he ordered four books concerning images to be composed, refuting the reasons urged by the Nicene bishops to justify the worship of images, which he sent to Adrian the Roman pontiff in 790, in order to engage him to withdraw his approbation of the decrees of the last council of Nice. Adrian wrote an answer; and in 794 a council of 300 bishops, assembled by Charlemagne at Francfort on the Maine, confirmed the opinion contained in the four books, and solemnly condemned the worship of images. In the Greek church, after the banishment of Irene, the controversy concerning images broke out anew, and was carried on by the contending parties, during the half of the ninth century, with various and uncertain success. The emperor Nicephorus appears upon the whole to have been an enemy to this idolatrous worship. His successor, Michael Curopalates, surnamed *Rhangabe*, patronized and encouraged it. But the scene changed on the accession of Leo the Armenian to the empire; who assembled a council at Constantinople in 814, that abolished the decrees of the Nicene council. His successor Michael, surnamed *Balbus*, disapproved the worship of images, and his son Theophilus treated them with great severity. However, the empress Theodora, after his death, and during the minority of her son, assembled a council at Constantinople in 842, which reinstated the decrees of the second Nicene council, and encouraged image worship by a law. The council held at the same place under Photius, in 879, and reckoned by the Greeks the eighth general council, confirmed and renewed the Nicene decrees. In commemoration of this council, a festival was instituted by the superstitious Greeks, called the *feast of orthodoxy*. The Latins were generally of opinion, that images might be suffered as the means of a living the memory of the faithful, and of calling to their remembrance the pious exploits and virtuous actions of the persons whom they represented; but they detested all thoughts of paying them the least marks of religious homage or adoration. The council of Paris, assembled in 824 by Louis the Meek, resolved to allow the use of images in the churches, but severely prohibited rendering them religious worship. Nevertheless, towards the conclusion of this century, the Gallican clergy began to pay a kind of religious homage to the images of saints, and their example was followed by the Germans and other nations. However, the iconoclasts still had their adherents among the Latins; the most eminent of whom was Claudius bishop of Turin, who in 823 ordered all images, and even the cross, to be cast out of the churches, and committed to the flames; and he wrote a treatise, in which he declared both against the use and worship of them. He condemned relics, pilgrimages to the holy land, and all voyages to the tombs of saints; and to his writings and labours it was owing, that the city of Turin, and the adjacent country, was, for a long time after his death, much less infected with superstition than the other parts of Europe. The controversy concerning the sanctity of images was again revived by Leo bishop of Chalcedon, in the 11th century, on occasion of the emperor Alexius's converting the figures of silver that adorned the portals of the churches into money, in order to supply the exigencies of the state. The bishop obstinately maintained that he had been guilty of sacrilege; and published a treatise, in which he affirmed, that in these images there resided an inherent sanctity, and that the adoration of Christians ought not to be confined to the persons represented by these images, but extended to the images themselves. The emperor assembled a council at Constantinople, which determined, that the images of Christ and of the Saints were to be honoured only with a relative

worship; and that invocation and worship were to be addressed to the Saints only as the servants of Christ, and on account of their relation to him as their master. Leo, dissatisfied even with these absurd and superstitious decisions, was sent into banishment. In the western church, the worship of images was disapproved and opposed by several considerable parties, as the Petrobrussians, Albigenses, Waldenses, &c. till at length this idolatrous practice was entirely abolished in many parts of the Christian world by the Reformation. See IMAGE.

ICONOGRAPHIA, from εἰκών "image," and γράφω "I describe," the description of images or ancient statues of marble and copper; also of busts and semi-busts, penates, paintings in fresco, mosaic works, and ancient pieces of miniature.

ICONOLATRÆ, or ICONOLATERS (from εἰκών, and λατρεῖν "I worship,") or ICONODULI (from εἰκών and δούλω "I serve,") those who worship images: a name which the iconoclasts give to those of the Romish communion, on account of their adoring images, and of rendering to them the worship only due to God. See ICONOCLASTS and IMAGE.

ICOSAHEDRON, in geometry, a regular solid, consisting of 20 triangular pyramids, whose vertices meet in the centre of a sphere supposed to circumscribe it; and therefore have their height and bases equal: wherefore the solidity of one of these pyramids multiplied by 20, the number of bases, gives the solid contents of the icosaedron.

ICOSANDRIA, from εἰκοσι "twenty," and ἀνήρ "a man or husband;" the name of the 12th class in Linnæus's sexual method, consisting of plants with hermaphrodite flowers, which are furnished with 20 or more stamina, that are inserted into the inner side of the calyx or petals. See BOTANY, p. 41.

ICTINUS, a celebrated Greek architect who lived about 430 B. C. built several magnificent temples, and among others that of Minerva at Athens.

IDA, in ancient geography, a mountain situated in the heart of Crete where broadest; the highest of all in the island; round, and in compass 60 stadia (Strabo); the nursing place of Jupiter, and where his tomb was visited in Varro's time. Another *Ida*, a mountain of Mysia, or rather a chain of mountains (Homer, Virgil), extending from Zeleia on the south of the territory of Cyzicus to Lectum the utmost promontory of Troas. The abundance of its waters became the source of many rivers, and particularly of the Simois, Scamander, Ætæops, Granicus, &c. It was covered with green wood, and the elevation of its top opened a fine extensive view of the Hellespont and the adjacent countries; for which reason it was frequented by the gods during the Trojan war, according to Homer. The top was called *Gargara* (Homer, Strabo); and celebrated by the poets for the judgment of Paris on the beauty of the three goddesses, Minerva, Juno, and Venus, to the last of whom he gave the preference.

IDALIUM, in ancient geography, a promontory on the east side of Cyprus. Now *Capo di Griego*; with a high rugged eminence rising over it, in the form of a table. It was sacred to Venus; and hence the epithet *Idalia* given her by the poets. The eminence was covered with a grove: and in the grove was a little town, in Pliny's time extinct. *Idalia*, according to Bochart, denotes the place or spot sacred to the goddesses.

IDEA, the reflex perception of objects, after the original perception or impression has been felt by the mind. See METAPHYSICS, and LOGIC.

IDENTITY, denotes that by which a thing is itself, and not any thing else; in which sense *identity* differs from *similitude*, as well as *diversity*. See METAPHYSICS.

IDES, in the ancient Roman kalendar, were eight days in each month; the first of which fell on the 15th of March, May, July, and October; and on the 13th day of the other months. The origin of the word is contended. Some will have

it formed from *ιδεῖν* "to see;" by reason the full moon was commonly seen on the days of the ides: others from *εἶδος* "species, figure," on account of the image of the full moon then visible: others from *idulium*, or *ovis idulis*, a name given by the Hetrurians to a victim offered on that day to Jupiter: others from the Hetrurian word *iduo*, i. e. *divido*; by reason the ides divided the moon into two nearly equal parts.

The ides came between the KALENDS and the NONES; and were reckoned backwards. Thus they called the 14th day of March, May, July, and October, and the 12th of the other months, the *pridie idus*, or the day before the ides; the next preceding day they called the *tertia idus*; and so on, reckoning always backwards till they came to the NONES. This method of reckoning time is still retained in the chancery of Rome, and in the kalendar of the Breviary. The ides of May were consecrated to Mercury: the ides of March were ever esteemed unhappy, after Cæsar's murder on that day: the time after the ides of June was reckoned fortunate for those who entered into matrimony: the ides of August were consecrated to Diana, and were observed as a feast-day by the slaves. On the ides of September, auguries were taken for appointing the magistrates, who formerly entered into their offices on the ides of May, afterwards on those of March.

IDIOCY, a defect of understanding. Both idiocy and LUNACY excuse from the guilt of crimes: (see CRIME.) For the rule of law as to lunatics, which also may be easily adapted to idiots, is, that *furiosus furore solum puniitur*. In criminal cases, therefore, (says Judge Blackstone,) idiots and lunatics are not chargeable for their own acts, if committed when under these incapacities: no, not even for treason itself. Also, if a man in his sound memory commits a capital offence, and before arraignment for it he becomes mad, he ought not to be arraigned for it: because he is not able to plead to it with that advice and caution that he ought. And if, after he has pleaded, the prisoner becomes mad, he shall not be tried: for how can he make his defence? If, after he be tried and found guilty, he loses his senses before judgment, judgment shall not be pronounced; and if, after judgment, he becomes of nonsane memory, execution shall be stayed; for, peradventure, says the humanity of the English law, had the prisoner been of sound memory, he might have alleged something in stay of judgment or execution. Indeed, in the bloody reign of Henry VIII. a statute was made, which enacted, that if a person, being *compos mentis*, should commit high treason, and after fall into madness, he might be tried in his absence, and should suffer death, as if he were of perfect memory. But this savage and inhuman law was repealed by the statute 1 & 2 Ph. & M. c. 17. For, as is observed by Sir Edward Coke, "the execution of an offender is for example, *ut poena ad paucos, metus ad omnes perveniat*: but so it is not when a madman is executed; but should be a miserable spectacle, both against law, and of extreme inhumanity and cruelty, and can be no example to others." But if there be any doubt whether the party be *compos* or not, this shall be tried by a jury. And if he be so found, a total idiocy, or absolute insanity, excuses from the guilt, and of course from the punishment, of any criminal action committed under such deprivation of the senses: but if a lunatic hath lucid intervals of understanding, he shall answer for what he does in those intervals as if he had no deficiency. Yet, in the case of absolute madmen, as they are not answerable for their actions, they should not be permitted the liberty of acting unless under proper control; and, in particular, they ought not to be suffered to go loose, to the terror of the king's subjects. It was the doctrine of our ancient law, that persons deprived of their reason might be confined till they recovered their senses, without waiting for the forms of a commission or other special authority from the crown: and now, by the

vagrant acts, a method is chalked out for imprisoning, chaining, and sending them to their proper homes.

The matrimonial contract likewise cannot take place in a state of idiocy. It was formerly adjudged, that the issue of an idiot was legitimate, and his marriage valid. A strange determination! since consent is absolutely requisite to matrimony, and neither idiots nor lunatics are capable of consenting to any thing. And therefore the civil law judged much more sensibly when it made such deprivations of reason a previous impediment, though not a cause of divorce if they happened after marriage. And modern resolutions have adhered to the sense of the civil law, by determining that the marriage of a lunatic, not being in a lucid interval, was absolutely void. But as it might be difficult to prove the exact state of the party's mind at the actual celebration of the nuptials, upon this account (concurring with some private family reasons—for which see Private Acts 23 Geo. II. c. 6.) the statute 15 Geo. II. c. 30. has provided that the marriage of lunatics and persons under phrenies (if found lunatics under a commission, or committed to the care of trustees under any act of parliament), before they are declared of sound mind by the lord chancellor, or the majority of such trustees, shall be totally void.

Idiots and persons of nonsane memory, as well as infants and persons under duress, are not totally disabled either to convey or purchase, but *sub modo* only. For their conveyances and purchases are voidable, but not actually void. The king, indeed, on behalf of an idiot, may avoid his grants or other acts. But it hath been said, that a *non compos* himself, though he be afterwards brought to a right mind, shall not be permitted to allege his own insanity in order to avoid such grant: for that no man shall be allowed to stupefy himself, or plead his own disability. The progress of this notion is somewhat curious. In the time of Edward I. *non compos* was a sufficient plea to avoid a man's own bond: and there is a writ in the register for the alienor himself to recover lands aliened by him during his insanity, *dum fuit non compos mentis sue, ut dicit, &c.* But under Edward III. a scruple began to arise, whether a man should be permitted to *blemish* himself, by pleading his own insanity: and, afterwards, a defendant in assize having pleaded a release by the plaintiff since the last continuance, to which the plaintiff replied (*ore tenus*, as the manner then was) that he was out of his mind when he gave it, the court adjourned the assize; doubting whether, as the plaintiff was sane both then and at the commencement of the suit, he should be permitted to plead an intermediate deprivation of reason; and the question was asked, how he came to remember the release, if out of his senses when he gave it? Under Henry VI. this way of reasoning (that a man shall not be allowed to disable himself by pleading his own incapacity, because he cannot know what he did under such a situation) was seriously adopted by the judges in argument, upon a question, whether the heir was barred of his right of entry by the feoffment of his insane ancestor? And from these loose authorities, which Fitzherbert does not scruple to reject as being contrary to reason, the maxim, that a man shall not stultify himself, hath been handed down as settled law: though later opinions, feeling the inconvenience of the rule, have in many points endeavoured to restrain it. And, clearly, the next heir, or other person interested, may, after the death of the idiot or *non compos*, take advantage of his incapacity and avoid the grant. And so too, if he purchases under this disability, and does not afterwards, upon recovering his senses, agree to the purchase, his heir may either waive or accept the estate at his option. In like manner an infant may waive such purchase or conveyance, when he comes to full age; or, if he does not then actually agree to it, his heirs may waive it after him. Persons also, who purchase or convey under duress, may affirm or avoid such transaction, whenever the duress is

VOL. IV.

ceased. For all these are under the protection of the law; which will not suffer them to be imposed upon through the imbecility of their present condition; so that their acts are only binding in case they be afterwards agreed to when such imbecility ceases. Yet the guardians or committees of a lunatic, by the statute 11 Geo. III. c. 20. are empowered to renew in his right, under the directions of the court of chancery, any lease for lives or years, and apply the profits of such renewal for the benefit of such lunatic, his heirs or executors. See LUNACY.

IDIOM, among grammarians, properly signifies the peculiar genius of each language, but is often used in a synonymous sense with dialect. The word is Greek, *ιδιωμα* "propriety," formed of *ιδιος* "proper, own."

IDIOPATHY, in physic, a disorder peculiar to a certain part of the body, and not arising from any preceding disease; in which sense it is opposed to sympathy. Thus, an epilepsy is idiopathic when it happens merely through some fault in the brain, and sympathetic when it is the consequence of some other disorder.

IDIOSYNCRASY, among physicians, denotes a peculiar temperament of body, whereby it is rendered more liable to certain disorders than persons of a different constitution usually are.

IDIOT, or IDEOT, in our laws, denotes a natural fool, or a fool from his birth. See IDIOCY. The word is originally Greek, *ιδιωτης*, which primarily imports a *private person*, or one who leads a private life, without any share or concern in the government of affairs. A person who has understanding enough to measure a yard of cloth, number twenty rightly, and tell the days of the week, &c. is not an idiot in the eye of the law: but a man who is born deaf, dumb, and blind, is considered by the law in the same state as an idiot.

IDIOT is also used, by ancient writers, for a person ignorant or unlearned; answering to *illiteratus* or *imperitus*. In this sense, Victor tells us, in his Chronicon, that in the consulship of Messala, the Holy Gospels, by command of the emperor Anastasius, were corrected and amended, as having been written by idiot evangelists: *tanquam ab idiotis evangelistis composita*.

IDLENESS, a reluctance in people to be employed in any kind of work. Idleness in any person whatsoever is a high offence against the public economy. In China it is a maxim, that if there be a man who does not work, or a woman that is idle, in the empire, somebody must suffer cold or hunger: the produce of the lands not being more than sufficient, with culture, to maintain the inhabitants; and therefore, though the idle person may shift off the want from himself, yet it must in the end fall somewhere. The court also of A reopagus at Athens punished idleness, and exerted a right of examining every citizen in what manner he spent his time; the intention of which was, that the Athenians, knowing they were to give an account of their occupations, should follow only such as were laudable, and that there might be no room left for such as lived by unlawful arts. The civil law expelled all sturdy vagrants from the city: and, in our own law, all idle persons or vagabonds, whom our ancient statutes describe to be "such as wake on the night, and sleep on the day, and haunt customable taverns and ale-houses, and routs about; and no man wot from whence they come, ne whether they go;" or such as are more particularly described by statute 17 Geo. II. c. 5. and divided into three classes, *idle* and *disorderly* persons, *rogues* and *vagabonds*, and *incorrigible rogues*;—all these are offenders against the good order, and blemishes in the government, of any kingdom. They are therefore all punished, by the statute last mentioned; that is to say, idle and disorderly persons with one month's imprisonment in the house of correction; rogues and vagabonds with whipping,

and imprisonment not exceeding six months; and incorrigible rogues with the like discipline, and confinement not exceeding two years: the breach and escape from which confinement in one of an inferior class ranks him among incorrigible rogues; and in a rogue (before incorrigible) makes him a felon, and liable to be transported for seven years. Persons harbouring vagrants are liable to a fine of forty shillings, and to pay all expences brought upon the parish thereby; in the same manner as, by our ancient laws, whoever harboured any stranger for more than two nights, was answerable to the public for any offence that such his inmate might commit.

IDOL, in pagan theology, an image or fancied representation of any of the heathen gods. This image, of whatever materials it consisted, was, by certain ceremonies called *consecration*, converted into a god. While under the artificer's hands, it was only a mere statue. Three things were necessary to turn it into a god; proper ornaments, consecration, and oration. The ornaments were various, and wholly designed to blind the eyes of the ignorant and stupid multitude, who are chiefly taken with show and pageantry. Then followed the consecration and oration, which were performed with great solemnity among the Romans. See **IMAGE**.

IDOLATRY, or the worship of idols, may be distinguished into two sorts. By the first, men adore the works of God, the sun, the moon, the stars, angels, dæmons, men, and animals: by the second, men worship the work of their own hands, as statues, pictures, and the like: and to these may be added a third, that by which men have worshipped the true God under sensible figures and representations. This indeed may have been the case with respect to each of the above kinds of idolatry; and thus the Israelites adored God under the figure of a calf.

The stars were the first objects of idolatrous worship, on account of their beauty, their influence on the productions of the earth, and the regularity of their motions, particularly the sun and moon, which are considered as the most glorious and resplendent images of the Deity: afterwards, as their sentiments became more corrupted, they began to form images, and to entertain the opinion, that, by virtue of consecration, the gods were called down to inhabit or dwell in their statues. Hence Arnobius takes occasion to rally the pagans for guarding so carefully the statues of their gods, who, if they were really present in their images, might save their worshippers the trouble of securing them from thieves and robbers.

As to the adoration which the ancient pagans paid to the statues of their gods, it is certain, that the wiser and more sensible heathens considered them only as simple representations or figures designed to recall to their minds the memory of their gods. This was the opinion of Varro and Seneca: and the same sentiment is clearly laid down in Plato, who maintains, that images are inanimate, and that all the honour paid to them has respect to the gods whom they represent. But as to the vulgar, they were stupid enough to believe the statues themselves to be gods, and to pay divine worship to stocks and stones.

Soon after the flood, idolatry seems to have been the prevailing religion of all the world; for, wherever we cast our eyes at the time of Abraham, we scarcely see any thing but false worship and idolatry. And it appears from Scripture, that Abraham's forefathers, and even Abraham himself, were for a time idolaters. The Hebrews were indeed expressly forbidden to make any representation of God; they were not so much as to look upon an idol: and from the time of the Maccabees to the destruction of Jerusalem, the Jews extended this precept to the making the figure of any man: by the law of Moses, they were obliged to destroy all the images they found, and were forbidden to apply any of the gold or silver to their own use, that no one might receive the least profit from any thing belonging to an idol. Of this the Jews, after they had smarted for their idola-

try, were so sensible, that they thought it unlawful to use any vessel that had been employed in sacrificing to a false god, to warm themselves with the wood of a grove after it was cut down, or to shelter themselves under its shade.

But the preaching of the Christian religion, wherever it prevailed, entirely rooted out idolatry; as did also that of Mahomet, which is built on the worship of one God. It must not, however, be forgotten, that the Protestant Christians charge those of the church of Rome with paying an idolatrous kind of worship to the pictures or images of saints and martyrs: before these, they burn lamps and wax-candles; before these, they burn incense, and, kneeling, offer up their vows and petitions: they, like the Pagans, believe that the saint to whom the image is dedicated, presides in a particular manner about its shrine, and works miracles by the intervention of its image; and that, if the image was destroyed or taken away, the saint would no longer perform any miracle in that place.

IDOMENEUS, in fabulous history, succeeded his father Deucalion on the throne of Crete. He accompanied the Greeks to the Trojan war with a fleet of 90 ships. During this celebrated war he rendered himself famous by his valour, and slaughtered many of the enemy. At his return from the Trojan war, he made a vow to Neptune in a dangerous tempest, that if he escaped from the fury of the seas and storms, he would offer to the god whatever living creature first presented itself to his eye on the Cretan shore. This was no other than his son, who came to congratulate his father upon his safe return. Idomeneus performed his promise to the god; and the inhumanity and rashness of this sacrifice rendered him so odious in the eyes of his subjects, that he left Crete, and migrated in quest of a settlement. He came to Italy, and founded a city on the coast of Calabria, which he called *Salentum*. He died in an extreme old age, after he had had the satisfaction of seeing his new kingdom flourish, and his subjects happy. According to the Greek scholiast of Lycophron, v. 1217, Idomeneus, during his absence in the Trojan war, entrusted the management of his kingdom to Leucos, to whom he promised his daughter Clisithere in marriage at his return. Leucos at first governed with moderation; but he was persuaded by Nauplius king of Eubœa to put to death Meda the wife of his master, with her daughter Clisithere, and to seize the kingdom. After these violent measures he strengthened himself on the throne of Crete, and Idomeneus at his return found it impossible to expel the usurper.

IDUMÆA. See **EDOM**.

JEALOUSY, in ethics, is that peculiar uneasiness which arises from the fear that some rival may rob us of the affection of one whom we greatly love, or suspicion that he has already done it. The first sort of jealousy is inseparable from love before it is in possession of its object: the latter is often unjust, generally mischievous, always troublesome.

IDYLLION, in ancient poetry, is only a diminutive of the word **EIDOS**, and properly signifies any poem of moderate extent, without considering the subject. But as the collection of Theocritus's poems were called *idyllia*, and the pastoral pieces being by far the best in that collection, the term *idyllion* seems to be now appropriated to pastoral pieces.

JEARS or **GEERS**, in the sea-language, an assemblage of tackles, by which the lower yards of a ship are hoisted along the mast to their usual station, or lowered from thence as occasion requires; the former of which operations is called *swaying*, and the latter *striking*.

JEBUSÆI, one of the seven ancient people of Canaan, descendants of Jebusi, Canaan's son; so warlike and brave as to have stood their ground, especially in Jebus, afterwards called *Jerusalem*, down to the time of David. Judges i. 21. 1 Sam. v. 6.

JEDBURGH, a considerable borough of Roxburghshire, situated almost in the centre of the county, on the banks of the Jed, and near its confluence with the Teviot. It has a good market for corn and cattle, and is the seat of the courts of justice for the county. It is 36 miles S. E. of Edinburgh. W. lon. 2. 25. N. lat. 55. 35.

JEDDO, the capital of the empire of Japan. It is situated in Nippon, the largest of the Japanese islands: it is open on all sides, having neither walls nor ramparts; and the houses are built of earth, and boarded on the outside, to prevent the rain from destroying the walls. In every street is an iron gate, which is shut up in the night, and a kind of custom-house, or magazine, for merchandize. It is nine miles in length and six in breadth, and contains 1,000,000 inhabitants. A fire happened in 1658, which in the space of 48 hours burnt down 100,000 houses, in which a vast number of inhabitants perished, and the emperor's palace was reduced to ashes; but the whole is rebuilt. The imperial palace is in the middle of the town, and is defended by walls, ditches, towers, and bastions. Where the emperor resides are three towers, nine stories high, each covered with plates of gold; and the hall of audience is supported by pillars of massy gold. Near the palace are several others, where the relations of the emperor live. The empress has a palace of her own, and there are 20 small ones for the concubines. Besides, all the vassal kings have each a palace in the city, with a handsome garden, and stables for 2000 horses. The houses of the common sort are nothing but a ground-floor, the rooms parted by folding skreens; so that they can be made larger or smaller at pleasure. Jeddo is seated in a plain, at the bottom of a fine bay; and the river which crosses it is divided into several canals. E. lon. 139. 30. N. lat. 36. 10.

JEFFERY. See **GEOFFREY**.

JEFFREYS (**SIR GEORGE**), baron Wem, commonly called *Judge Jeffreys*, was the sixth son of John Jeffreys, Esq. of Acton in Denbighshire; and was educated at Westminster-school, whence he removed to the Inner Temple, where he applied himself to the study of the law. Alderman Jeffreys, who was probably related to him, introduced him among the citizens of London; and he being a merry bottle-companion, soon came into great business, and was chosen their recorder. He was afterwards chosen solicitor to the duke of York; and in 1680 was knighted, and made chief-justice of Chester. At length, resigning the recordership, he obtained the post of chief-justice of the king's bench, and, soon after the accession of James II. the great seal. During the reign of king Charles II. he showed himself a bitter enemy to those dissenting ministers who, in that time of persecution, were tried by him: he was one of the greatest advisers and promoters of all the oppressions and arbitrary measures carried on in the reign of James II.; and his sanguinary and inhuman proceedings against Monmouth's unhappy adherents in the west, will ever render his name infamous. Whenever the prisoner was of a different party, or he could please the court by condemning him, instead of appearing, according to the duty of his office, as his counsel, he would scarcely allow him to speak for himself; but would load him with the grossest and most vulgar abuse; browbeat, insult, and turn to ridicule the witnesses that spoke in his behalf; and even threaten the jury with fines and imprisonment, if they made the least hesitation about bringing in the prisoner guilty. Yet it is said, that when he was in temper, and matters perfectly indifferent came before him, no one became a seat of justice better. Nay, it even appears, that, when he was under no state-influence, he was sometimes inclined to protect the natural and civil rights of mankind, of which the following instance has been given:—The mayor and aldermen of Bristol had been used to transport convicted criminals to the American

plantations, and sell them by way of trade. This turning to good account, when any pilferers or petty rogues were brought before them, they threatened them with hanging; and then some officers who attended earnestly persuaded the ignorant intimidated creatures to beg for transportation, as the only way to save them; and in general their advice was followed. Then, without more form, each alderman in course took one, and sold him for his own benefit; and sometimes warm disputes arose between them about the next turn. This infamous trade, which had been carried on many years, coming to the knowledge of the lord chief-justice, he made the mayor descend from the bench, and stand at the bar in his scarlet and fur, with his guilty brethren the aldermen, and plead as common criminals. He then obliged them to give securities to answer informations; but the proceedings were stopped by the Revolution.—However, the brutality Jeffreys commonly showed on the bench, where his voice and visage were equally terrible, at length exposed him to a severe mortification. A scrivener of Wapping having a cause before him, one of the opponent's counsel said he was a strange fellow, and sometimes went to church, and sometimes to conventicles; and it was thought he was a trimmer. At this the chancellor fired; A trimmer? (said he); I have heard much of that monster, but never saw one. Come forth, Mr. Trimmer, and let me see your shape." He then treated the poor fellow so roughly, that, on his leaving the hall, he declared he would not undergo the terrors of that man's face again to save his life, and he should certainly retain the frightful impressions of it as long as he lived. Soon after, the prince of Orange coming, the lord chancellor, dreading the public resentment, disguised himself in a seaman's dress, in order to leave the kingdom; and was drinking in a cellar, when this scrivener coming into the cellar, and seeing again the face which had filled him with such horror, started; on which Jeffreys, fearing he was known, feigned a cough, and turned to the wall with his pot of beer in his hand. But Mr. Trimmer going out, gave notice that he was there; and the mob rushing in, seized him, and carried him before the lord mayor, who sent him with a strong guard to the lords of the council, by whom he was committed to the Tower, where he died in 1689.—It is remarkable that the late countess of Pomfret met with very rude insults from the populace on the western road, only because she was grand daughter of the inhuman Jeffreys.

JEHOVAH, one of the scripture names of God, signifying the Being who is self-existent and gives existence to others. So great a veneration had the Jews for this name, that they left off the custom of pronouncing it, whereby its true pronunciation was forgotten. They call it *tetragrammaton*, or "the name with four letters;" and believe, that whoever knows the true pronunciation of it cannot fail to be heard by God.

JEHUD, or **Joud**, mountains in the N. W. part of Hindoostan Proper, extending from Attock eastward to Bember. They are part of the territory of the mountaineers, called Gickers, Gehkers, or Kakares. After Timur had passed the Indus, in 1398, the chiefs of these mountains came to make their submission to him; as Ambisares, the king of the same country, did to Alexander about 1730 years before.

JEJUNUM, the second of the small intestines; thus called from the Latin *jejunus*, "hungry;" because always found empty. See **ANATOMY**, p. 189.

JEKYL, a small island of N. America, at the mouth of the river Alatomaha, in Georgia.

JELLALÆAN, or **GELALÆAN** *Calendar, epocha, and year*. See **CALENDAR**, **EPOCHA**, and **YEAR**.

JELLY, a form of food, or medicine, prepared from the juices of ripe fruits boiled to a proper consistence with sugar, or the strong decoctions of the horns, bones, or extremities of animals, boiled to such a height as to be stiff and firm when

cold, without the addition of any sugar. The jellies of fruits are cooling, aponaceous, and acefcent, and therefore are good as medicines in all disorders of the primæ viæ, arising from alkalescent juices, especially when not given alone, but diluted with water. On the contrary, the jellies made from animal substances are all alkalescent, and are therefore good in all cases in which an acidity of the humours prevails: the alkalescent quality of these is, however, in a great measure taken off by the adding lemon juice and sugar to them. There were formerly a sort of jellies much in use, called *compound jellies*; these had the restorative medicinal drugs added to them, but they are now scarce ever heard of.

Oat JELLY, a preparation of common oats, recommended by many of the German physicians in all hectic disorders, to be taken with broth of snails or cray fish. It is made by boiling a large quantity of oats with the husk taken off, with some hartshorn shavings and currants together, with a leg of veal cut to pieces, and with the bones all broken; these are to be set over the fire with a large quantity of water, till the whole is reduced to a sort of jelly; which when strained and cold will be very firm and hard. A few spoonfuls of this are to be taken every morning, diluted with a basin of either of the above-mentioned broths, or any other warm liquor.

JEMTERLAND, a province of Sweden, bounded on the north by Angermania, on the east by Medaipadia, on the south by Helsingia, and on the west by No way. It is full of mountains: and the principal towns are Reslundt, Lich, and Docra.

JENA, or **GENO**, a town of Upper Hungary, 20 miles S. of Great Waradin, and 48 N. E. of Segedin. E. lon. 21. 5. N. lat. 46. 40.

JENCALORE a town of Asia, in Indoostan, and in the dominions of the Great Mogul, capital of a territory of the same name. It is seated on the river Chaul, in E. lon. 76. 25. N. lat. 30. 30.

JENISA, a river of the Russian empire, that runs from north to south through Siberia, and falls into the Frozen Ocean.

JENISKOL, a town of the Russian empire in Siberia, seated on the river Jenisa. It is large, populous, and pretty strong; and there are villages for several miles round it. It is subject to the Tungusians, who are pagans, and chiefly live on the above river. They pay a tribute to the emperor for every bow, reckoning a man and a woman for one. The climate is extremely cold; and no other fruits grow there but black and red currants, strawberries, and gooseberries. Corn, butchers meat, and wild fowls, are very cheap. E. lon. 86. 25. N. lat. 58. 40.

JENCOPING, a town of Sweden, in the province of Smaland, seated on the south side of the lake Werter, with a strong citadel. The houses are all built with wood. E. lon. 14. 20. N. lat. 57. 22.

JENKIN (ROBERT), a learned English divine in the 18th century, was bred at Cambridge, became master of St. John's college, and wrote several books much esteemed, *viz.* 1. An historical examination of the authority of General Councils, 4to. 2. The reasonableness and certainty of the Christian religion, 2 vols. 8vo. 3. *Defensio S. Augustini*. This book is written against M. Le Clerc. 4. Remarks on some books lately published, *viz.* Mr. Whiston's eight sermons, Locke's paraphrase, &c. 5. A translation from the French of the Life of Apollonius Tyaneus.

JENKINS (HENRY). See **LONGEVITY**.

JENKINS (Sir Leoline), a learned civilian and able statesman of the last century, born in Glamorganshire about the year 1623. Being rendered obnoxious to the parliament during the civil war by adhering to the king's cause, he consulted his safety by flight; but returning on the restoration, he was admitted an advocate in the court of arches, and succeeded

Dr. Exton as judge. When the queen-mother Henrietta died in 1669 at Paris, her whole estate, real and personal, was claimed by her nephew Louis XIV: upon which Dr. Jenkins's opinion being called for and approved, he went to Paris, with three others joined with him in a commission, and recovered her effects; for which he received the honour of knighthood. He officiated as one of the mediators at the treaty of Nimeguen, in which tedious negotiation he was engaged about four years and a half; and was afterwards made a privy counsellor and secretary of state. He died in 1685; and, as he never married, bequeathed his whole estate to charitable uses: he was so great a benefactor to Jesus college, Oxford, that he is generally looked on as the second founder. All his letters and papers were collected and printed in 1724, in 2 vols. folio.

JENNY-WREN, a name given by writers on song-birds to the wren. See **WREN**.

JENTACULUM was, amongst the Romans, a morning refreshment like our breakfast. It was exceedingly simple, consisting, for the most part, of bread alone; labouring people indeed had something more substantial to enable them to support the fatigues of their employment. What has been here said may be observed of the Jews and Grecians also. The Greeks distinguished this morning-meal by the several names of *αριστον*, *ακρατισμος* or *ακρατισμα*, though *αριστον* is generally applied to dinner. See **EATING** and **DINNER**.

JEOFAILE, (compounded of three French words, *J'ay failli*, "I have failed,") a term in law, used for an oversight in pleading or other proceedings at law. The showing of these defects or oversights was formerly often practised by the counsel; and when the jury came into court in order to try the issue, they said, This inquest you ought not to take; and after verdict they would say to the court, To judgment you ought not to go. But several statutes have been made to avoid these delays occasioned by such suggestions; and a judgment is not to be stayed after verdict for mistaking the Christian or surname of either of the parties, or in a sum of money, or in the day, month, year, &c. where the same are rightly named in any preceding record.

JERBOA. See **MUS**.

JEREMIAH (the Prophecy of), a canonical book of the Old Testament. This divine writer was of the race of the priests, the son of Hilkia of Anathoth, of the tribe of Benjamin. He was called to the prophetic office when very young, about the 13th year of Josiah, and continued in the discharge of it about 40 years. He was not carried captive to Babylon with the other Jews, but remained in Judea to lament the desolation of his country. He was afterwards a prisoner in Egypt with his disciple Baruch, where it is supposed he died in a very advanced age. Some of the Christian fathers tell us he was stoned to death by their Jews, for preaching against their idolatry; and some say he was put to death by Pharaoh Hophra, because of his prophecy against him. Part of the prophecy of Jeremiah relates to the time after the captivity of Israel, and before that of Judah, from the first chapter to the 44th; and part of it was in the time of the latter captivity, from the 44th chapter to the end.

JERICHO, or **HIERICHUS**, in ancient geography, a city of Judea; situated between Jordan and Jerusalem, at the distance of 150 stadia from the latter, and 60 from the former. Josephus says, "the whole space from Jerusalem is desert and rocky, and equally barren and uncultivated from Jericho to the lake Asphaltites; yet the places near the town and above it are extremely fertile and delicious, so that it may be justly called a *divine plain*, surpassing the rest of the land of Canaan, no unfruitful country, and surrounded by hills in the manner of an amphitheatre. It produces opobalsamum myrobalsans, and dates; from the last of which it is called the *city of palm trees*,

by Moses. The place is now called *Raha*; and is situated, M. Volney informs us, "in a plain six or seven leagues long by three wide, around which are a number of barren mountains that render it extremely hot. Here formerly was cultivated the balm of Mecca. From the description of the Hadjes, this is a shrub similar to the pomegranate-tree, with leaves like those of rue: it bears a pulpy nut, in which is contained a kernel that yields the resinous juice we call *balm* or *balsam*. At present there is not a plant of it remaining at Raha; but another species is to be found there, called *Zakkoun*, which produces a sweet oil, also celebrated for healing wounds. This *zakkoun* resembles a plum-tree; it has thorns four inches long, with leaves like those of the olive-tree, but narrower and greener, and prickly at the end; its fruit is a kind of acorn, without a calyx, under the bark of which is a pulp, and then a nut, the kernel of which gives an oil that the Arabs sell very dear: this is the sole commerce of Raha, which is no more than a ruinous village.

JERIMOTH. See JARIMUTH.

JEROME (ST.), in Latin *Hieronymus*, a famous doctor of the church, and the most learned of all the Latin fathers, was the son of Eusebius, and was born at Stridon, a city of the ancient Pannonia, about the year 340. He studied at Rome under Donatus, the learned grammarian. After having received baptism, he went into Gaul, and there transcribed St. Hilary's book *de Synodis*. He then went into Aquileia, where he contracted a friendship with Heliodorus, who prevailed on him to travel with him into Thrace, Pontus, Bithynia, Galatia, and Cappadocia. In 372 St. Jerome retired into a desert in Syria, where he was persecuted by the orthodox of Melittus's party for being a Sabellian, because he made use of the word *Hypostasis*, which had been used by the council of Rome in 369. This obliged him to go to Jerusalem; where he applied himself to the study of the Hebrew language, in order to receive a more perfect knowledge of the Holy Scriptures; and about this time he consented to be ordained, on condition that he should not be confined to any particular church. In 381 he went to Constantinople to hear St. Gregory of Nazianzen; and the following year returned to Rome, where he was made secretary to pope Damasus. He then instructed many Roman ladies in piety and the knowledge of the sciences, which exposed him to the calumnies of those whom he zealously reprov'd for their irregularities; and pope Siricius not having all the esteem for him which his learning and piety justly entitled him to, this learned doctor left Rome, and returned to the monastery of Bethlehem, where he employed himself in writing against those whom he called *heretics*, especially against Vigilantius and Jovinian. He had a quarrel with John of Jerusalem and Rufinus about the Origenists. He was the first who wrote against Pelagius; and died on the 30th of September 420, at about 80 years of age. There have been several editions of his works; the last, which is that of Verona, is in 11 vols. folio. His principal works are, 1. A Latin version of the Holy Scriptures, distinguished by the name of the *Vulgate*. 2. Commentaries on the Prophets, Ecclesiastes, St. Matthew's Gospel, and the Epistle to the Galatians, Ephesians, Titus, and Philemon. 3. Polemical treatises against Montanus, Helvidius, Jovinian, Vigilantius, and Pelagius. 4. Several letters. 5. A treatise on the lives and writings of the ecclesiastical authors who had flourished before his time. St. Jerome's style is lively and animated, and sometimes sublime.

JEROME of Prague, so called from the place of his birth, in Bohemia. He was neither a monk nor clergyman, but had a learned education. Having embraced the opinions of John Hus, he began to propagate them in the year 1480. In the mean time the council of Nice kept a watchful eye over him, and, considering him as a dangerous person, cited him to appear

before them and give an account of his faith. In obedience to this citation, he went to Constance; but on his arrival in 1415, finding Hus in prison, he set out for his own country. Being seized however on the way, imprisoned and examined, he was so intimidated that he retracted, and pretended to approve of the condemnation of Wickliff's and Hus's opinions; but on the 26th of May 1416, he condemned that recantation in these terms: "I am not ashamed to confess here publicly my weakness. Yes, with horror I confess my base cowardice. It was only the dread of the punishment by fire which drew me to consent, against my conscience, to the condemnation of the doctrine of Wickliff and Hus." Accordingly sentence was passed on him; in pursuance of which he was delivered to the secular arm, and burnt, in 1416. He was a person of great parts, learning, and elocution.

JERONYMITES, or HIERONYMITES, a denomination given to divers orders or congregations of religious; otherwise called *Hermits of St. Jerome*.

JERSEY, an island in the English channel, 18 miles from the coast of Normandy in France, and 84 S. of Portland in Dorsetshire, subject to the English. It is about thirty miles in circumference, and difficult of access on account of the rocks, sands, and forts erected for its defence. It contains twelve parishes; and the chief town is St. Helier, in the south part of the island. It lies extremely well for trade in time of peace, and to annoy the French, by privateers, in time of war. It is well watered with rivulets, and is well stocked with fruit-trees. They have a noted manufacture for woollen stockings and caps, and are still governed by the ancient Norman laws. In 1781 a body of French troops landed on this island, surpris'd the lieutenant-governor, made him prisoner, and compelled him to sign a capitulation: but major Pierston, the commander of the English troops, refused to abide by this forced capitulation, and attacked the French in the town of St. Helier. The French were compelled to surrender prisoners of war; but the gallant major was killed in the moment of victory. W. lon. 2. 10. N. lat. 49. 11.

New JERSEY, one of the United States of North America, bounded on the E. by Hudson's River and the Atlantic Ocean, on the S. by Delaware Bay, on the W. by Pennsylvania, and on the N. by a line drawn from the mouth of Mahakkamak River in lat. 41. 24. to a point in Hudson's River in lat. 41. It is 161 miles long and 52 broad. It is divided into 13 counties. Its produce is much the same as that of the neighbouring states. Trenton is the capital.

JERSEY, among woolcombers, denotes the finest wool, taken from the rest by dressing it with a Jersey comb.

JERUSALEM, an ancient and famous town of Asia, formerly capital of Judea, after David had conquered the Jebusites. It was taken by Nebuchadnezzar in the eleventh year of the reign of Zedekiah, and the Jews were led captives to Babylon. It was afterwards taken by the Romans, and ruined, together with the Temple, 70 years after the birth of Christ, being one of the most remarkable sieges in history. The emperor Adrian built a new city, near the ruins of ancient Jerusalem. It was taken by the Persians in 614, and by the Saracens in 636. In 1099 it was retaken by the Crusaders, who founded a new kingdom which lasted 88 years, under nine kings. Saladin king of Egypt and Syria got possession of it in 1187. The Turks drove away the Saracens in 1217, have kept possession of it ever since, and call it *Heteods*, that is, The Holy City. It is now inhabited by Turks, Arabs, Jews, and Christians. It stands on a high rock, with steep ascents on every side except to the north. It is almost surrounded by valleys encompassed with mountains, so that it seems to stand in the middle of an amphitheatre. It is about three miles in circumference, and includes Mount Calvary, which was formerly without the walls. The

only thing that renders it considerable is the great resort of pilgrims; for the inhabitants accommodate them with lodgings and provisions, which is their chief business. A bashaw, with a guard of Janizaries, always resides here, to protect them from the insults of the Arabs. The church of the Holy Sepulchre, which the pilgrims come chiefly to visit, is a large structure, with a round nave, which has no light but what comes through the top, like the Pantheon at Rome. The dome is covered on the outside with lead, and within with cedar wood. The opening of the dome is closed with a net of wire, to hinder the birds from coming into the church. In the middle of the nave, and directly under the opening of the dome, is the Holy Sepulchre, which is placed in a chapel, whose door is three feet high and two broad. It is so small, that it will hold but three persons on their knees at a time. At the entrance, on the right hand, is the place where the body of our Saviour was laid. The table on which he was said to have been laid at first is two feet and a half high from the pavement, which is now covered with white marble, because the Christians who came to visit it were all for carrying away a small bit. This chapel is cut out of the rock, and there are three holes in the roof, to let out the smoke of the lamps, which are 44 in number, and always kept lighted. The whole is covered with white marble, both within and without; and on the outside there are 10 fine columns of the same. It is covered with a platform, the middle of which is exactly above the three holes, and forms a small dome, six feet in height, covered with lead, and supported by 12 columns of porphyry, placed by pairs on the platform, and so making six arches, having three lamps under each. Before the gate of the sepulchre is a silver lamp, so large that two men cannot fathom it. Every year, on Good Friday, all the parts of our Saviour's passion are solemnized and acted here. They have first a sermon, and then every one takes a lighted taper in his hand, with crucifixes, &c. to begin the procession. Among the crucifixes is one as large as life, being crowned with thorns, and besmeared with blood. They visit first the pillar of flagellation; next the prison; afterward the altar of the division of Christ's garments; then they advance to the chapel of derision, and thence to Mount Calvary, leaving their shoes at the bottom of the stairs. Here are two altars; one where our Lord was supposed to be nailed to the cross; and another where it was erected; and where they set up the crucified image, which finishes the ceremony: only they pull out the nails, take down the body, and wrap it in a winding-sheet. Jerusalem is 112 miles S. W. of Damascus, and 45 from the Mediterranean. E. lon. 35. 25. N. lat. 31. 55.

JESI, an ancient town of Italy, in the marquisate of Ancona, with a bishop's see. It is seated on a mountain near the river Jesi, 17 miles S. W. of Ancona, and 112 N. E. of Rome. E. lon. 13. 16. N. lat. 43. 30.

JESSO, JESO, or *Yedso*, a large island of Asia, to the N. of the island of Nippon, governed by a tributary prince dependent on the empire of Japan. It is full of woods, and the inhabitants are strong, robust, savage, and slovenly, when compared to the Japanese. They live by fishing and hunting, and are very little known to the Europeans.

JESSOP'S WELL, in Surry, in the parish of Stoke Dabernon, a sulphureous spring, four miles S. W. of Epsom, something of the same kind as that of Harrowgate in Yorkshire.

JESSES, ribbons that hang down from garlands or crowns in falconry; also short straps of leather fastened to the hawk's legs, and so to vervels.

JESTING, or *concise wit*, as distinguished from continued wit or humour, lies either in the thought or the language, or both. In the first case, it does not depend upon any particular words or turn of the expression. But the greatest fund of jests lies in the language, *i. e.* in tropes or verbal figures; those af-

forded by tropes consist in the metaphorical sense of the words; and those of verbal figures principally turn upon a double sense of the same word, or a similitude of sound in different words. The third kind of jokes, which lie both in the sense and language, arise from figures of sentences, where the figure itself consists in the sense, but the wit turns upon the choice of the words.

JESUITS, or *the Society of Jesus*; a famous religious order of the Romish church, founded by Ignatius Loyola. See IGNA-TIUS. The plan which this fanatic formed of its constitution and laws was suggested, as he gave out, and as his followers still teach, by the immediate inspiration of heaven. But notwithstanding this high pretension, his design met at first with violent opposition. The pope, to whom Loyola had applied for the sanction of his authority to confirm the institution, referred his petition to a committee of cardinals. They represented the establishment to be unnecessary as well as dangerous, and Paul refused to grant his approbation of it. At last, Loyola removed all his scruples by an offer which it was impossible for any pope to resist. He proposed, that besides the three vows of poverty, of chastity, and of monastic obedience, which are common to all the orders of regulars, the members of his society should take a fourth vow of obedience to the pope, binding themselves to go whithersoever he should command for the service of religion, and without requiring any thing from the holy see for their support. At a time when the papal authority had received such a shock by the revolt of so many nations from the Romish church; at a time when every part of the popish system was attacked with so much violence and success, the acquisition of a body of men, thus peculiarly devoted to the see of Rome, and whom it might set in opposition to all its enemies, was an object of the highest consequence. Paul instantly perceiving this, confirmed the institution of the Jesuits by his bull, granted the most ample privileges to the members of the society, and appointed Loyola to be the first general of the order. The event hath fully justified Paul's discernment, in expecting such beneficial consequences to the see of Rome from this institution. In less than half a century, the society obtained establishments in every country that adhered to the Roman-catholic church: its power and wealth increased amazingly; the number of its members became great; their character as well as accomplishments were still greater; and the Jesuits were celebrated by the friends and dreaded by the enemies of the Romish faith, as the most able and enterprising order in the church.

The constitution and laws of the society were perfected by Laynez and Aquaviva, the two generals who succeeded Loyola, men far superior to their master in abilities and in the science of government. They framed that system of profound and artful policy which distinguishes the order. The large infusion of fanaticism mingled with its regulation should be imputed to Loyola its founder. Many circumstances concurred in giving a peculiarity of character to the order of Jesuits, and in forming the members of it not only to take greater part in the affairs of the world than any other body of monks, but to acquire superior influence in the conduct of them.

The primary object of almost all the monastic orders is to separate men from the world, and from any concern in its affairs. In the solitude and silence of the cloister, the monk is called to work out his own salvation by extraordinary acts of mortification and piety. He is dead to the world, and ought not to mingle in its transactions. He can be of no benefit to mankind but by his example and by his prayers. On the contrary, the Jesuits are taught to consider themselves as formed for action. They are chosen soldiers, bound to exert themselves continually in the service of God, and of the pope his vicar on earth. Whatever tends to instruct the ignorant, whatever can be of

use to reclaim or to oppose the enemies of the holy see, is their proper object. That they may have full leisure for this active service, they are totally exempted from those functions the performance of which is the chief business of other monks. They appear in no processions; they practise no rigorous austerities; they do not consume one half of their time in the repetition of tedious offices; but they are required to attend to all the transactions of the world, on account of the influence which these may have upon religion; they are directed to study the dispositions of persons in high rank, and to cultivate their friendship; and by the very constitution as well as genius of the order, a spirit of action and intrigue is infused into all its members.

As the object of the society of Jesuits differed from that of the other monastic orders, the diversity was no less in the form of its government. The other orders are to be considered as voluntary associations, in which whatever affects the whole body is regulated by the common suffrage of all its members. The executive power is vested in the persons placed at the head of each convent or of the whole society; the legislative authority resides in the community. Affairs of moment, relating to particular convents, are determined in conventual chapters; such as respect the whole order are considered in general congregations. But Loyola, full of the ideas of implicit obedience, which he had derived from his military profession, appointed that the government of his order should be purely monarchical. A general, chosen for life by deputies from the several provinces, possessed power that was supreme and independent, extending to every person and to every case. He, by his sole authority, nominated provincials, rectors, and every other officer employed in the government of the society, and could remove them at pleasure. In him was vested the sovereign administration of the revenues and funds of the order. Every member belonging to it was at his disposal; and by his uncontrollable mandate he could impose on them any task, or employ them in what service soever he pleased. To his commands they were required to yield not only outward obedience, but to resign up to him the inclinations of their own wills and the sentiments of their own understandings. They were to listen to his injunctions as if they had been uttered by Christ himself. Under his direction they were to be mere passive instruments, like clay in the hands of the potter, or like dead carcases incapable of resistance. Such a singular form of policy could not fail to impress its character on all the members of the order, and to give a peculiar force to all its operations. There is not, in the annals of mankind, any example of such a perfect despotism exercised not over monks shut up in the cells of a convent, but over men dispersed among all the nations of the earth.

As the constitutions of the order vest in the general such absolute dominion over all its members, they carefully provide for his being perfectly informed with respect to the character and abilities of his subjects. Every novice who offers himself as a candidate for entering into the order, is obliged to manifest his conscience to the superior, or a person appointed by him; and is required to confess not only his sins and defects, but to discover the inclinations, the passions, and the bent of his soul. This manifestation must be renewed every six months. The society, not satisfied with penetrating in this manner into the innermost recesses of the heart, directs each member to observe the words and actions of the novices: they are constituted spies upon their conduct, and are bound to disclose every thing of importance concerning them to the superior. In order that this scrutiny into their character may be as complete as possible, a long novitiate must expire, during which they pass through the several gradations of rank in the society; and they must have attained the full age of thirty-three years before they can be admitted to take the final vows, by which they become professed members. By these various methods, the superiors, under whose

immediate inspection the novices are placed, acquire a thorough knowledge of their dispositions and talents. In order that the general, who is the soul that animates and moves the whole society, may have under his eye every thing necessary to inform or direct him, the provincials and heads of the several houses are obliged to transmit to him regular and frequent reports concerning the members under their inspection. In these they descend into minute details with respect to the character of each person, his abilities natural or acquired, his temper, his experience in affairs, and the particular department for which he is best fitted. These reports, when digested and arranged, are entered into registers kept on purpose, that the general may, at one comprehensive view, survey the state of the society in every corner of the earth; observe the qualifications and talents of its members; and thus choose, with perfect information, the instruments which his absolute power can employ in any service for which he thinks meet to destine them.

As it was the professed intention of the order of Jesuits to labour with unwearied zeal in promoting the salvation of men, this engaged them of course in many active functions. From their first institution, they considered the education of youth as their peculiar province; they aimed at being spiritual guides and confessors; they preached frequently in order to instruct the people; they set out as missionaries to convert unbelieving nations. The novelty of the institution, as well as the singularity of its objects, procured the order many admirers and patrons. The governors of the society had the address to avail themselves of every circumstance in its favour; and in a short time the number as well as influence of its members increased wonderfully. Before the expiration of the sixteenth century, the Jesuits had obtained the chief direction of the education of youth in every catholic country in Europe. They had become the confessors of almost all its monarchs; a function of no small importance in any reign, but, under a weak prince, superior even to that of minister. They were the spiritual guides of almost every person eminent for rank or power. They possessed the highest degree of confidence and interest with the papal court, as the most zealous and able champions for its authority. The advantages which an active and enterprising body of men might derive from all these circumstances are obvious. They formed the minds of men in their youth. They retained an ascendancy over them in their advanced years. They possessed, at different periods, the direction of the most considerable courts in Europe. They mingled in all affairs. They took part in every intrigue and revolution. The general, by means of the extensive intelligence which he received, could regulate the operations of the order with the most perfect discernment; and, by means of his absolute power, could carry them on with the utmost vigour and effect.

Together with the power of the order, its wealth continued to increase. Various expedients were devised for eluding the obligation of the vow of poverty. The order acquired ample possessions in every catholic country; and by the number as well as magnificence of its public buildings, together with the value of its property, moveable or real, it vied with the most opulent of the monastic fraternities. Besides the sources of wealth common to all the regular clergy, the Jesuits possessed one which was peculiar to themselves. Under pretext of promoting the success of their missions, and of facilitating the support of their missionaries, they obtained a special licence from the court of Rome to trade with the nations which they laboured to convert. In consequence of this, they engaged in an extensive and lucrative commerce both in the East and West Indies. They opened warehouses in different parts of Europe, in which they vended their commodities. Not satisfied with trade alone, they imitated the example of other commercial societies, and aimed at obtaining settlements. They acquired

possession accordingly of a large and fertile province in the southern continent of America, and reigned as sovereigns over some hundred thousand subjects.

Unhappily for mankind, the vast influence which the order of Jesuits acquired by all these different means, has been often exerted with the most pernicious effect. Such was the tendency of that discipline observed by the society in forming its members, and such the fundamental maxims in its constitution, that every Jesuit was taught to regard the interest of the order as the capital object to which every consideration was to be sacrificed. This spirit of attachment to their order, the most ardent perhaps that ever influenced any body of men, is the characteristic principle of the Jesuits, and serves as a key to the genius of their policy as well as the peculiarities in their sentiments and conduct.

As it was for the honour and advantage of the society that its members should possess an ascendant over persons in high rank or of great power; the desire of acquiring and preserving such a direction of their conduct with greater facility, has led the Jesuits to propagate a system of relaxed and pliant morality, which accommodates itself to the passions of men, which justifies their vices, which tolerates their imperfections, which authorises almost every action that the most audacious or crafty politician would wish to perpetrate.

As the prosperity of the order was intimately connected with the preservation of the papal authority, the Jesuits, influenced by the same principle of attachment to the interests of their society, have been the most zealous patrons of those doctrines which tend to exalt ecclesiastical power on the ruins of civil government. They have attributed to the court of Rome a jurisdiction as extensive and absolute as was claimed by the most presumptuous pontiffs in the dark ages. They have contended for the entire independence of ecclesiastics on the civil magistrates. They have published such tenets concerning the duty of opposing princes who were enemies of the Catholic faith, as countenanced the most atrocious crimes, and tended to dissolve all the ties which connect subjects with their rulers.

As the order derived both reputation and authority from the zeal with which it stood forth in defence of the Romish church against the attacks of the reformers, its members, proud of this distinction, have considered it as their peculiar function to combat the opinions and to check the progress of the Protestants. They have made use of every art, and have employed every weapon against them. They have set themselves in opposition to every gentle or tolerating measure in their favour. They have incessantly stirred up against them all the rage of ecclesiastical and civil persecution.

Monks of other denominations have indeed ventured to teach the same pernicious doctrines, and have held opinions equally inconsistent with the order and happiness of civil society. But they, from reasons which are obvious, have either delivered such opinions with greater reserve, or have propagated them with less success. Whoever recollects the events which have happened in Europe during two centuries, will find that the Jesuits may justly be considered as responsible for most of the pernicious effects arising from that corrupt and dangerous casuistry, from those extravagant tenets concerning ecclesiastical power, and from that intolerant spirit, which have been the disgrace of the church of Rome throughout that period, and which have brought so many calamities upon civil society.

But, amidst many bad consequences flowing from the institution of this order, mankind, it must be acknowledged, have derived from it some considerable advantages. As the Jesuits made the education of youth one of their capital objects, and as their first attempts to establish colleges for the reception of students were violently opposed by the universities in different countries, it became necessary for them, as the most effectual

method of acquiring the public favour, to surpass their rivals in science and industry. This prompted them to cultivate the study of ancient literature with extraordinary ardour. This put them upon various methods for facilitating the instruction of youth; and, by the improvements which they made in it, they have contributed so much towards the progress of polite learning, that on this account they have merited well of society. Nor has the order of Jesuits been successful only in teaching the elements of literature; it has produced likewise eminent masters in many branches of science, and can alone boast of a greater number of ingenious authors than all the other religious fraternities taken together.

But it is in the New World that the Jesuits have exhibited the most wonderful display of their abilities, and have contributed most effectually to the benefit of the human species. The conquerors of that unfortunate quarter of the globe had nothing in view but to plunder, to enslave, and to exterminate its inhabitants. The Jesuits alone have made humanity and civilization the objects of their settling there. About the beginning of the last century, they obtained admission into the fertile province of Paraguay, which stretches across the southern continent of America, from the bottom of the mountains of Potosi to the confines of the Spanish and Portuguese settlements on the banks of the river de la Plata.

The pernicious effects, however, of the spirit and constitution of this order rendered it early obnoxious to some of the principal powers in Europe, and gradually brought on its downfall. The emperor Charles V. saw it expedient to check its progress in his dominions; it was expelled England, by proclamation 2 James I. in 1604; Venice, in 1606; Portugal, in 1759; France, in 1764; Spain and Sicily, in 1767; and totally suppressed and abolished by the late Pope Clement XIV. in 1773.

JESUITS BARK. Under the article BARK we have given a general account of this invaluable article of the *Materia Medica*, and of its effects in diseases. We shall here give a more precise enumeration of the species and botanical distinctions, as they are set forth by the latest writers on the subject, particularly Mr. Lambert, in a "Description of the Genus *Cinchona* and the various Species of Vegetables which supply the Peruvian and other Barks."

"1. *CINCHONA OFFICINALIS* (*Quinquina Condam. Acta Gallic. 1738*), **PERUVIAN-BARK Tree.** The characters as follows. See 2d pl. 45. vol. 1.

"*Cal.* Perianthium monophyllum, superum, quinquefidum, minimum, persistens. *Cor.* monopetala, infundibuliformis; tubus cylindricus, longus; limbus patulus, quinquefidus, acutus.

"*Stam.* Filamenta quinque, minima; antheræ oblongæ, intra faucem corollæ. *Pist.* Germen subrotundum, inferum; stylus longitudine corollæ; stigma crassiusculum, oblongum, simplex. *Per.* Capsula subrotunda; calyce coronata, bilocularis, à basi versus apicem bifariam dehiscens. *Sem.* plurima, oblonga, compressa, marginata. *Observ.* Flos interdum demit quintam partem numeri in singulis partibus."

In Vol. XL. of the *Phil. Transf.* p. 81. No 446. there is an account of the Jesuits-bark tree of Peru by Mr. William Arrot. — M. de la Condamine afterwards gave a more particular and scientific account of this tree: since which, specimens of the fructification have been sent to Europe; and Dr. Pulteney has given an excellent figure in his inaugural dissertation *De Cortice Peruviano*, in 1764, from which our figure is copied.

A preparation of this bark has been recommended by M. Lunnel, who directs us to "boil six grains of salt of tartar with an ounce of bark in a pint of water; and, after filtering the decoction, another pint of water is to be boiled with the same quantity of salt and the remaining bark. In this way no bitterness remains; at the same time that the strength of the bark appears

to be completely exhausted, as alcohol only extracted two grains of resin from it."

2. *CINCHONA CARIBÆA seu JAMAICENSIS*. Of this bark Dr. Wright has given an accurate description with an elegant engraving in the *Phil. Transf.* vol. lxxvii. p. 504, from which we shall extract the botanic characters so as to distinguish it from other species. See the plate last referred to, and pl. 24, where we have given a view of the plant from Mr. Lambert.

"*Fol.* ovata, integerrima, acuta, enervia, opposita. *Flor.* singulares, axillares. *Cal.* Perianthium monophyllum, quinquefidum, minimum, persistens, campanulatum, obsolete quinqueidentatum. *Cor.* monopetala, infundibuliformis; tubus cylindraceus, longissimus; limbus quinquepartitus, tubo æqualis; laciniis ovatis, oblongis, reflexis, quandoque pendulis. *Stam.* Filamenta quinque, filiformia, erecta e medio tubi, longitudine corollæ; antheræ longissimæ, obtusæ, erectæ supra basin exteriorem, affixæ in fauce corollæ. *Capf.* bipartibilis, in duas partes dissepimento parallelo, latere inferiore dehiscens. *Sem.* plurima, compressa, marginata, oblonga."

Dr. Wright at first found this tree of a small size; since which he discovered it 50 feet high, and of a proportional thickness. The bark from the larger trunk is very fibrous and woody; that from the limbs and roots, when dry, breaks short off, and powders easier than the Peruvian bark. The Jesuits bark of Jamaica is one of the most agreeable bitters; and, infused in wine or spirits with a little lemon-peel, makes a rich and elegant tincture. In the north side of Jamaica, where this bark is produced in the greatest perfection, it is held in high esteem, and answers every purpose of the Jesuits bark. It sits easy on the stomach, and never occasions vomiting or nausea, but checks them in remitting fevers, or where the stomach is weak or disordered.

3. *CINCHONA TRIFLORA*: "*Fol.* oppositis, ovatis, acutis, integerrimis, petiolatis; *Floribus* tribus, axillaribus." The leaves are like the *Cinchona Caribæa*, but larger. The flowers three in number from the axillæ of the leaves, and of a fine red colour. The laciniæ are reflected. The seed-vessels are larger than any of the other species we have yet seen.

Mr. Roberts discovered this bark-tree about the year 1781, but found it no where else than in that district of Jamaica called *Manchioncel*. It grows by the side of a small rapid river near the Bath, and is about 35 feet high, but not thick in proportion. Towards the bottom of the trunk the bark is rough and furrowed; but higher up it is smooth, and has much the appearance of the Peruvian bark. It is thinner, more fibrous, and redder, than either the Peruvian or the Jamaica bark already mentioned. When powdered, it is of a cinnamon colour, inclining more to red. The taste is musty, bitter, and astringent. It yields its qualities either infused in wine or spirits, but with some difficulty to cold infusion by water. Trials have been made with this bark in the cure of fevers, and in several with advantage. But few people could bear more than 20 grains; and even that quantity sometimes occasioned so distressing a sickness and nausea that its exhibition has been in general left off.

4. *CINCHONA FLORIBUNDA*. "*Panicula terminali, capsulis turbinatis lævibus, foliis ellipticis acuminatis.*" Swartz. *Prod.* 41. Vahl. in *Act. Havn.* 1. 23. *Phil. Transf.* vol. 74. p. 452—456. t. 19. This bark is externally smooth, thin, and very fibrous. Its taste is a most nauseous bitter, that lasts long in the mouth; its astringent quality is more than the Peruvian bark. It is violently emetic when fresh; but, on long keeping, it loses this quality in part only, as no more than 20 grains can be ventured on, and its repetition must take place at several hours distance. Intermitting and remitting fevers have been cured by this bark, after resisting the use of the Peruvian bark. But it is probable that in those cases the cure was effected more from its emetic powers than by its tonic virtues. At present,

VOL. IV.

however, it has fallen into disuse, except perhaps in the islands where it grows, or where the Peruvian bark has either failed, or cannot easily be got. See pl. 24.

5. *CINCHONA MACROCARPA*. "*Cinchona foliis oblongis sub-tus pubescentibus.*" Lambert, p. 22.

6. *CINCHONA BRACHYCARPA*. "*Panicula terminali, capsulis obovatis costatis, foliis ellipticis obtusis.*" Vahl. in *Act. Havn.* 1. p. 24. Swartz. *Prod.* 42. *Mill. Dict. Mart.* See pl. 24. — Mr. John Lindsay, surgeon, Westmoreland, Jamaica, discovered this species about the year 1785. It grew on the side of a steep hill or eminence running from east to west, and the tree was only about eight or ten feet high. The leaves in a recent state are oval, shining, and rigid; the sprig dries with great difficulty, and turns to a rusty brown. The spike has many white flowers, similar in figure to those of the St. Lucia bark-tree. The seed-vessels are larger than those of the Peruvian. The seeds are small and scaly. The trunks of this small tree are much furrowed; the cuticle very thick; the bark farther up smooth and brown; that of the inside is of the colour of the Peruvian bark, but more fibrous. It has no aroma, and is less bitter, but more astringent, than the *Cinchona officinalis*. Mr. Lindsay, who made trial of this bark in the cure of intermitting and remitting fevers, found that the stomach will bear 25 or 30 grains very well. He used it also in tincture and decoction, in various cases of dyspepsia, with advantage. On the whole, were this bark to be had in sufficient quantity, it promises to be an useful succedaneum to the Peruvian bark. See pl. 24.

7. *CINCHONA ANGUSTIFOLIA*: "*Angustifolia panicula terminali, capsulis oblongis pentagonis, foliis linearilanceolatis pubescentibus.*" Swartz. *Prod.* 42. *Act. Holm.* 1781. p. 117—123. t. 3. Vahl. in *Act. Havn.* 1. p. 25. See the plate.

8. *CINCHONA MONTANA*. This species, which is a native of Guadaloupe and Martinico, was first described by M. Mallet, in the *Journal de Physique* for March 1781, under the name of *Quinquina Pion*; and is said to have been employed by the author with the happiest effects in intermitting fevers, even after the Peruvian bark had failed. It has since been scientifically described, and a figure of it given, by M. Badiet, in the *Journal de Physique*, Feb. 1789, under the name of "*Cinchona Montana, foliis ovatis utrinque glabris, stipulis basi connato-vaginantibus, corymbo terminali, corollis glabris.*" It is described as a very beautiful tree, growing more than 40 feet high, and having a large regular head of branches with a thick foliage. The bark, when the epidermis is removed, is of a grey-brown colour, and its taste very bitter. It would seem to contain no resin, all its extract being soluble in water. It is however represented as a very quick and powerful febrifuge, as we have already noticed; at the same time that it possesses an emetic and cathartic property. To these possibly its effect on fever may be in part owing; though whether its evacuating qualities will admit of its ever becoming a good substitute for the officinalis, or whether it possesses any tonic power, remains yet to be determined.

9. *CINCHONA LINEATA*: "*Panicula terminali, foliis ovatis acuminatis glabris. Capsulis pentagonis.*" Vahl. in *Act. Havn.* 1. p. 22. t. 4. *Mill. Dict. Mart.* See pl. 24.

10. *CINCHONA SPINOSA*; thus described in the *Journal de Physique* for October 1790. "*Folii minimis subrotundis, pedunculis unifloris, corollis glabris quadrifidis tetrandris, seminibus submarginatis. Folia aliquando bina opposita, aliquando terna verticillata.*" It is a native of St. Domingo. The flowers are like those of the *Caribæa*, but smaller by a half. It is but a shrubby plant, not exceeding eight or ten feet in height. The leaves are small and very glabrous, and the branches terminated by a spine. The peculiar properties of this bark, or its comparative efficacy as a medicine, have not yet been ascertained.

11. An account of the new species of BARK of *Ticamez*, an Indian village in the province of Quito, situated in 46 deg. N. lat.

and near 80 deg. W. lon. is given by Mr. Brown. A view of the leaves of this plant is shewn in the plate. Vide Lambert's Description of the Genus Cinchona.

12. CINCHONA LONGIFLORA: "Pedunculis axillaribus unifloris, foliis lineari-lanceolatis glabris, corolla longissima." Lambert's Descrip.

In the *Manuel des Vegetaux* by M. de St. Germain, we find two species mentioned under the names of *Cinchona Antillana* and *Cinchona Herbacea*; but as no descriptions are added, we can say nothing concerning them.

A bark under the name of ANGSTURA BARK has been introduced into practice as a substitute for the Peruvian bark. See London Medical Journal, vol. x. p. 154. This bark is of much the same colour and thickness as the canella aromatica, and powders very freely. It has a good deal of the aromatic taste joined to bitterness and astringency; and has been supposed a true species of cinchona, different from the blanca or white sort mentioned by Mr. William Arrot in Phil. Trans. vol. xl. n^o 446. Mr. Bruce, however, is said to have pronounced it to be the bark of the *Brucea antisyphenterica*; to which indeed the resemblance is very considerable in its effects.

The Angustura bark was supposed at first to be the production of a tree growing on the coast of Africa; but is now found to come from the Spanish Main. According to *Experiments and Observations on the Angustura Bark*, by Augustus Everard Brande, just published, it is said to excel the Peruvian bark in some of its properties, and in other diseases to have different qualities. It is a powerful bitter, joined with an aroma not more pungent than the cascarilla, having a portion of pure oil which approaches in its nature to camphor. It differs from the Peruvian bark, by possessing a narcotic principle; and seems more powerful than it both as a tonic and an antiseptic. Various experiments on the antiseptic power of different substances are related, in which the columbo seems the least efficacious, and the Angustura bark to claim the highest rank.

According to Mr. Brande this bark seems to have excelled the Peruvian in curing intermittents: Dr. Pearson, however, found that in these it was scarcely superior in any instance, and sometimes not equal; but in low fevers, and putrid fevers, it seemed more powerful. In the headach, attended with fever, but arising from the stomach, Mr. Brande found it useful; and serviceable also in dysentery and dyspepsia.

JESUS the Son of SIRACH, a native of Jerusalem, composed, about 200 B. C. the book of Ecclesiasticus, called by the Greeks *Παραπύσις*, "replenished with virtue;" who also quote it under the title of *The Wisdom of Solomon the Son of Sirach*. His grandson, who was also of the same name, and a native of Jerusalem, translated it from the Hebrew into Greek about 121 B. C. We have this Greek version, but the Hebrew text is lost.

JESUS CHRIST, the Son of God, and Saviour of mankind, descended from heaven, and took upon him the human nature in Judæa, towards the conclusion of the reign of Herod the Great, king of that country. The place of his birth was Bethlehem, a flourishing city of Judah; but the year in which he was born is not precisely ascertained. The most general opinion is, that it happened about the year of Rome 748 or 749, and about 18 months before the death of Herod. The history of Jesus Christ, and the means by which the truth of his religion was made manifest to the world, are amply detailed in the holy scriptures. See CHRISTIAN Religion.

JET, a black inflammable substance of the bituminous kind, harder than asphaltum, and susceptible of a good polish. It becomes electrical by rubbing, attracting light bodies like yellow amber. It swims on water, so that its specific gravity must be less than 100; notwithstanding which it has been frequently confounded with the *lapis obsidiannus*, the specific gravity of which, according to Kirwan, is no less than 1744. It also

resembles cannel-coal extremely in its hardness, receiving a polish, not soiling the fingers, &c. so that it has also been confounded with this. The distinction, however, is easily made betwixt the two; for cannel-coal wants the electrical properties of jet, and is likewise so heavy as to sink in water; its specific gravity being no less than 1273; whereas that of jet, as has already been said, is less than 1000. M. Magellan is of opinion that jet is a true amber, differing from the yellow kind only in the mere circumstance of colour, and being lighter on account of the greater quantity of bituminous matter which enters into its composition. When burning, it emits a bituminous smell. It is never found in strata or continued masses like the true amber. Great quantities of it have been dug up in the Pyrenean mountains; also near *Batalba*, a small town of Portugal; and in Galicia in Spain. It is found also in Ireland, Sweden, Prussia, Germany and Italy. It is used in making small boxes, buttons, bracelets, mourning-jewels, &c. Sometimes also it is employed in conjunction with proper oils in making varnishes. When mixed with lime in powder, it is said to make an extraordinary hard and durable cement.

JET *d'Eau*, a French term, frequently also used with us, for a fountain that casts up water to a considerable height in the air. See HYDROSTATICS, p. 564.

JETTY-HEAD, a name usually given in the royal dock-yards to that part of a wharf which projects beyond the rest; but more particularly the front of a wharf, whose side forms one of the cheeks of a dry or wet dock.

JEVER, a town of Germany, in the circle of Westphalia, and capital of Jeverland, with a citadel; 17 miles N. E. of Aurick, and 28 N. E. of Embden. E. lon. 7. 41. N. lat. 53. 33.

JEVERLAND, a territory of Germany, in Westphalia, belonging to the house of Anhalt Zerbst.

JEWEL, any precious stone, or ornament beset with them. See DIAMOND, RUBY, &c. Jewels made a part of the ornaments with which the Jews, Greeks and Romans, especially their ladies of distinction, adorned themselves. So prodigious was the extravagance of the Roman ladies, in particular, that Pliny the elder says he saw Lollia Paulina with an equipage of this kind, amounting, according to Dr. Arbuthnot's calculation, to 322,916l. 13s. 4d. of our money. It is worthy of observation, that precious stones amongst the Romans and all the ancients were much scarcer, and consequently in higher esteem, than they are amongst us since a commerce has been opened with the Indies. The ancients did not know how to cut and polish them to much perfection; but coloured stones were not scarce, and they cut them very well either hollow or in relief. When luxury had gained ground amongst them, the Romans hung pendants and pearls in their ears; and for this purpose the ears of both sexes were frequently bored. See EARS.

JEWEL (John) a learned English writer and bishop, was born in 1522, and educated at Oxford. This excellent prelate (says the Rev. Mr. Granger) was one of the greatest champions of the reformed religion, as he was to the church of England what Bellarmine was to that of Rome. His admirable Apology was translated from the Latin by Anne, the second of the four learned daughters of Sir Anthony Coke, and mother of Sir Francis Bacon. It was published, as it came from her pen, in 1564, with the approbation of the queen and the prelates. The same Apology was printed in Greek at Constantinople, under the direction of St. Cyril the patriarch. His defence of his Apology, against Harding and other Popish divines, was in such esteem, that Queen Elizabeth, King James I. King Charles I. and four successive archbishops, ordered it to be kept chained in all parish-churches for public use." His death happened at Monkton-Failey, in 1571, in the 50th year of his

age. He wrote, 1. A view of a seditious bull sent into England by Pope Pius V. in 1569. 2. A treatise on the Holy Scriptures. 3. An exposition of St. Paul's two epistles to the Thessalonians. 4. A treatise on the sacrament. 5. An apology for the national church. 6. Several sermons, controversial treatises, and other works.

JEWEL-Blocks, in the sea language, a name given to two small blocks which are suspended at the extremity of the main and fore-top sail yards, by means of an eye-bolt driven from without into the middle of the yard-arm, parallel to its axis. The use of these blocks is, to retain the upper part of the top-mast studding-sails beyond the skirts of the top-sails, so that each of those sails may have its full force of action, which would be diminished by the encroachment of the other over its surface. The *ba'iards*, by which those studding-sails are hoisted, are accordingly passed through the jewel-blocks; whence, communicating with a block on the top-mast head, they lead downwards to the top or decks, where they may be conveniently hoisted. See **SAIL**.

JEWS, a name derived from the patriarch Judah, and given to the descendants of Abraham by his eldest son Isaac, who for a long time possessed the land of Palestine in Asia, and are now dispersed through all nations in the world. The history of this people, as it is the most singular, so is it also the most ancient in the world; and the greatest part being before the beginning of profane history, depends entirely on the authenticity of the Old Testament, where it is only to be found. With regard to the religious doctrines and rites of the *Jews*, we shall here observe, that *Judaism* was but a temporary dispensation, and was to give way, at least the ceremonial part of it, at the coming of the Messiah. We have a complete system of *Judaism* in the books of Moses. The Jews were anciently divided into several sects; the principal whereof were the Pharisees, Sadducees, and Essenians. At present there are two sects among the Jews, viz. the Caraites, who admit of no rule of religion but the law written by Moses; and the Rabbinites, who add to the law the traditions of the Talmud.

It has been observed, that *Judaism*, of all religions, is that which is the most rarely abjured. In the 18th of Edward I. the parliament granted the king a fifteenth for the expulsion of *Judaism*.

In England formerly, the Jews, and all their goods, belonged to the chief lord where they lived; and he had such absolute property in them that he might sell them, for they had not liberty to remove to another lord without leave. Mat. Paris tells us, that Henry III. sold the Jews to earl Richard, his brother, for a term of years, that *quos rex excoriaverat comes evisceraret*.

They were distinguished from the Christians, both living and dying; for they had proper judges and courts wherein their causes were tried: and they wore a badge on their breast over their clothes, in shape of a table; and they were fined if they stirred abroad without such badges. They were never buried in the country, but always brought up to London, and interred without the walls.

In this enlightened period, however, a more generous system is taking place. France has allowed them the rights of citizens; which induces numbers of the most wealthy Jews to fix their residence in that country. England, Holland, and Prussia tolerate and protect them; and the emperor has revoked some restrictions; for which an edict has lately passed: Spain, Portugal, and some of the Italian states, are still, however, totally averse to their dwelling among them. By stat. 1 Ann. 1. c. 30. if Jewish parents refuse to allow their protestant children a fitting maintenance, suitable to the fortune of the parent, the lord chancellor, on complaint, may make such an order as he shall see proper.

Jew-bill, in *Law*, is the famous statute 26 Geo. II. cap. 26. which enabled all *Jews* to prefer bills of naturalization in parliament, without receiving the sacrament as ordained by stat. 7 Jac. 1. This act was repealed by 27 Geo. II. c. 1.

JEZIDES, among the Mahometans; a term of similar import with heretics among Christians. The Jezides are a numerous sect inhabiting Turkey and Persia, so called from their head Jezid, an Arabian prince, who slew the sons of Ali, Mahomet's father-in-law; for which reason he is reckoned a parricide, and his followers heretics. There are about 20,000 Jezides in Turkey and Persia; who are of two sorts, black and white. The white are clad like Turks; and distinguished only by their shirts, which are not slit at the neck like those of others, but have only a round hole to thrust their heads through. This is in memory of a golden ring, or circle of light, which descended from heaven upon the neck of their cheq, the head of their religion, after his undergoing a fast of forty days. The black Jezides, though married, are the monks or religious of the order; and these are called *Fakirs*.

The Turks exact excessive taxes from the Jezides, who hate the Turks as their mortal enemies; and when, in their wrath, they curse any creature, they call it *musulman*: but they are great lovers of the Christians, being more fond of Jesus Christ than of Mahomet, and are never circumcised but when they are forced to it. They are extremely ignorant, and believe both the bible and the koran without reading either of them: they make vows and pilgrimages, but have no places of religious worship.

All the adoration they pay to God consists of some songs in honour of Jesus Christ, the Virgin, Moses, and sometimes Mahomet; and it is a principal point of their religion never to speak ill of the Devil, lest he should resent the injury, if ever he should come to be in favour with God again, which they think possible; whenever they speak of him, they call him the *angel Peacock*. They bury their dead in the first place they come at, rejoicing as at a festival, and celebrating the entry of the deceased into heaven. They go in companies like the Arabians, and change their habitations every 15 days. When they get wine, they drink it to excess; and it is said that they sometimes do this with a religious purpose, calling it the blood of Christ. They buy their wives: and the market-price is 200 crowns for all women, handsome or not, without distinction.

JEZRAEL, or **JEZREEL**, a town in the north of Samaria, towards mount Carmel, where stood a palace of the kings of Israel, 1 Kings xxi. 18: on the borders of Galilee, (Joshua xix.) said to be one of the towns of Issachar. The valley of Jezreel (Judges vi. 17.) was situated to the north of the town, running from west to east for ten miles, between two mountains; the one to the north, commonly called *Herman*; near mount Tabor; the other, *Gilboa*: in breadth two miles.

IF, an island of France, the most eastern of the three before the harbour of Marseilles. It is very well fortified, and its port one of the best in the Mediterranean.

IGIS, a town of the country of the Grisons, in Caddea, with a magnificent castle, in which is a cabinet of curiosities, and a handsome library; 23 miles south-west of Choira; and 23 south of Glaris. E. lon. 9. 0. N. lat. 46. 33.

IGLAW, a considerable and populous town of Germany, in Moravia, where they have a manufactory of good cloth, and excellent beer. It is seated on the river Iгла, 40 miles west of Brin, and 62 south-east of Prague. E. lon. 15. 42. N. lat. 49. 8.

IGLESIAS, a town in the south part of the island of Sardinia, with a bishop's see. E. lon. 8. 59. N. lat. 38. 30.

IGNATIA, in botany, a genus of the monogynia order, belonging to the pentandria class of plants. The calyx is five-toothed; the corolla is long; the fruit an unilocular plum,

with many seeds. There is but one species, the *ansara*, a native of India. The fruit of this tree contains the seeds called *St. Ignatius's beans*.

The best account of the plant that has yet appeared, is that sent by father Camelli to Ray and Petiver, and published in the *Philosophical Transactions* for the year 1699: he observes, that it grows in the Philippine islands, and winds itself about the tallest trees to the top; that it has large, ribbed, bitter leaves, a flower like that of the pomegranate, and a fruit larger than a melon. Some resemble the fruit to a pomegranate, probably from misapplying Camelli's words. The fruit is covered with a thin, glossy, blackish green, and as it were marbled shell, under which is lodged another of a stony hardness: within this is contained a soft, yellow, bitterish pulp, in which lie the seeds or beans, to the number commonly of 24, each covered with a silvery down.

The same gentleman gives an account of the virtues attributed to these seeds by the Indians; but experience has shown that they are dangerous. Konig relates, that a person, by drinking some of a spirituous tincture of them instead of aqua vitæ, was thrown into strong convulsions; and Dr. Gurn, that a dram of the seed in substance occasioned, for a time, a total deprivation of the senses. Others mention violent vomitings and purgings from its use. Neumann hath observed intermitting fevers removed by drinking, on the approach of a paroxysm, an infusion of some grains of the bean made in carduus water: we are not, however, from hence to look upon this medicine as an universal febrifuge, or to use it indiscriminately.

These beans (for so custom requires that we should call them) are about the size of a moderately large nutmeg; in figure somewhat roundish, but extremely irregular, scarcely any two being entirely alike, full of unequal depressions and prominences; in colour, externally yellowish brown, but when the outer skin is taken off, of a blackish brown, and in part quite blackish; in consistence, hard and compact as horn, so as not to be reducible into a powdery form, but by cutting or rasping: for all their hardness, however, they are not proof against worms. When fresh, they have somewhat of a musky smell, which by age is lost: their taste is very bitter, resembled by some to that of centaury.—According to some, it is from this plant that the *COLUMBO* root is obtained.

IGNATIUS LOYOLA, (canonized,) the founder of the well-known order of the *JESUITS*, was born at the castle of Loyola, in Biscay, 1491; and became first page to Ferdinand V. king of Spain, and then an officer in his army. In this last capacity, he signalized himself by his valour; and was wounded in both legs at the siege of Pampeluna, in 1521. To this circumstance the Jesuits owe their origin; for, while he was under cure of his wound, a *Life of the Saints* was put into his hands, which determined him to forsake the military for the ecclesiastical profession. His first devout exercise was to dedicate himself to the Blessed Virgin as her knight: he then went a pilgrimage to the Holy Land; and on his return to Europe, he continued his theological studies in the universities of Spain, though he was then 33 years of age. After this he went to Paris; and in France laid the foundation of this new order, the institutes of which he presented to Pope Paul III. who made many objections to them, but at last confirmed the institution in 1540. The founder died in 1555, and left his disciples two famous books: 1. *Spiritual exercises*; 2. *Constitutions or rules of the order*. But it must be remembered, that though these avowed institutes contain many privileges obnoxious to the welfare of society, the most diabolical are contained in the private rules intitled *Munita secreta*, which were not discovered till towards the close of the last century; and most writers attribute

these, and even the constitutions, to Laynez, the second general of the order.

IGNATIUS (St.) surnamed *Theophrastus*, one of the apostolical fathers of the church, was born in Syria, and educated under the apostle and evangelist St. John, and intimately acquainted with some other of the apostles, especially St. Peter and St. Paul. Being fully instructed in the doctrines of Christianity, he was, for his eminent parts and piety, ordained by St. John, and confirmed about the year 67 bishop of Antioch, by those two apostles, who first planted Christianity in that city, where the disciples also were first called *Christians*. Antioch was then not only the metropolis of Syria, but a city the most famous and renowned of any in the East, and the ancient seat of the Roman emperors, as well as of the viceroys and governors. In this important seat he continued to sit somewhat above 40 years, both an honour and safeguard of the Christian religion, till the year 107, when Trajan the emperor, flushed with a victory which he had lately obtained over the Scythians and Daci, about the ninth year of his reign, came to Antioch to make preparations for a war against the Parthians and Armenians. He entered the city with the pomp and solemnities of a triumph; and as his first care usually was about the concerns of religion, he began presently to inquire into that affair. Christianity had by this time made such a progress, that the Romans grew jealous and uneasy at it. The prince, therefore, had already commenced a persecution against the Christians in other parts of the empire, which he now resolved to carry on here. However, as he was naturally of a mild disposition, though he ordered the laws to be put in force against them if convicted, yet he forbade them to be fought after.

In this state of affairs, Ignatius, thinking it more prudent to go himself than stay to be sent for, of his own accord presented himself to the emperor; and, it is said, there passed a long and particular discourse between them, wherein the emperor expressing a surprise how he dared to transgress the laws, the bishop took the opportunity to assert his own innocence, and to explain and vindicate his faith with freedom. The issue of this was, that he was cast into prison, and this sentence passed upon him, That, being incurably overrun with superstition, he should be carried bound by soldiers to Rome, and there thrown as a prey to wild beasts.

He was first conducted to Seleucia, a port of Syria, at about 16 miles distance, the place where Paul and Barnabas set sail for Cyprus. Arriving at Smyrna in Ionia, he went to visit Polycarp bishop of that place, and was himself visited by the clergy of the Asian churches round the country. In return for that kindness, he wrote letters to several churches, as the Ephesians, Magnesians, and Trallians, besides the Romans, for their instruction and establishment in the faith; one of these was addressed to the Christians at Rome, to acquaint them with his present state, and passionate desire not to be hindered in the course of martyrdom which he was now hastening to accomplish.

His guard, a little impatient of their stay, set sail with him for Troas, a noted city of the Lesser Phrygia, not far from the ruins of old Troy; where, at his arrival, he was much refreshed with the news he received of the persecution ceasing in the church of Antioch: hither also several churches sent their messengers to pay their respects to him; and hence too he dispatched two epistles, one to the church of Philadelphia, and the other to that of Smyrna; and, together with this last, as Eusebius relates, he wrote privately to Polycarp, recommending to him the care and inspection of the church of Antioch.

From Troas they sailed to Neapolis, a maritime town in Macedonia; thence to Philippi, a Roman colony, where they were entertained with all imaginable kindness and courtesy, and conducted forwards on their journey, passing on foot through Ma-

cedonia and Epirus, till they came to Epidanium, a city of Dalmatia; where again taking shipping, they sailed through the Adriatic, and arrived at Rhegium, a port-town in Italy; directing their course thence through the Tyrrhenian sea to Puteoli, whence Ignatius desired to proceed by land, ambitious to trace the same way by which St. Paul went to Rome. But this wish was not complied with; and after a stay of 24 hours, a prosperous wind quickly carried them to the Roman port, the great harbour and station for their navy, built near Ostia, at the mouth of the Tyber, about 16 miles from Rome; whither the martyr longed to come, as much desirous to be at the end of his race, as his keepers, weary of their voyage, were to be at the end of their journey.

The Christians at Rome, daily expecting his arrival, were come out to meet and entertain him, and accordingly received him with a mixture of joy and sorrow; but when some of them intimated, that possibly the populace might be taken off from desiring his death, he expressed a pious indignation, entreating them to cast no rubs in his way, nor do any thing that might hinder him now he was hastening to his crown. There are many such expressions as this in his epistle to the Romans, which plainly show that he was highly ambitious of the crown of martyrdom. Yet it does not appear that he rashly sought or provoked danger. Among other expressions of his ardour for suffering, he said, that the wild beasts had feared and refused to touch some that had been thrown to them; which he hoped would not happen to him. Being conducted to Rome, he was presented to the præfect, and the emperor's letters probably delivered concerning him. The interval before his martyrdom was spent in prayers for the peace and prosperity of the church. That his punishment might be the more pompous and public, one of their solemn festivals, the time of their Saturnalia, and that part of it when they celebrated their Sigillaria, was pitched on for his execution; at which time it was their custom to entertain the people with the bloody conflicts of gladiators, and the hunting and fighting with wild beasts. Accordingly, on the 13th kal. January, i. e. December 20, he was brought out into the amphitheatre; and the lions being let loose upon him, quickly dispatched their meal, leaving nothing but a few of the hardest of his bones. These remains were gathered up by two deacons who had been the companions of his journey; and, being transported to Antioch, were interred in the cemetery, without the gate that leads to Daphne; whence, by the command of the emperor Theodosius, they were removed with great pomp and solemnity to the Tycheon, a temple within the city, dedicated to the public genius of it, but now consecrated to the memory of the martyr.

St. Ignatius stands at the head of those Antinicensian fathers, who have occasionally delivered their opinions in defence of the true divinity of Christ, whom he calls the *Son of God, and his eternal Word*. He is also reckoned the great champion of the doctrine of the episcopal order, as distinct and superior to that of priest and deacon. And one, the most important, use of his writings respects the authenticity of the holy Scriptures, which he frequently alludes to, in the very expressions as they stand at this day. -- Archbishop Usher's edition of his works, printed in 1647, is thought the best: yet there is a fresher edition extant at Amsterdam, where, beside the best notes, there are the dissertations of Usher and Pearson.

St. IGNATIUS'S *Bean*. See IGNATIA.

IGNIS FATUUS, a kind of light, of an electric nature, appearing frequently in mines, marshy places, and near stagnating waters. It was formerly thought by the superstitious to have something ominous in its nature, and to presage death and other misfortunes: and it is even said that there have been instances of people being decoyed by these lights into marshy places, where

VOL. IV.

they have perished. Hence it took the names of *Ignis fatuus*, *Will-witb-a-wisp*, and *Jack-witb-a-lantern*, as if this appearance was an evil spirit which took delight in doing mischief of that kind. See the articles LIGHT and METEOR.

IGNITION, properly signifies the setting fire to any substance; but the sense is commonly restrained to that kind of burning which is not accompanied with flame, such as that of charcoal, cinders, metals, stones, and other solid substances. The effects of ignition are first to dissipate what is called the *phlogiston* of the ignited substance, after which it is reduced to ashes. Vitrification next follows; and, lastly, the substance is totally dissipated in vapour. All these effects, however, depend on the presence of the air; for *in vacuo* the phlogiston of any substance cannot be dissipated. Neither can a body which is totally destitute of phlogiston be ignited in such a manner as those which are not deprived of it: for, as long as the phlogiston remains, the heat is kept up in the body by the action of the external air upon it; but when the phlogiston is totally gone, the air always destroys, instead of augmenting, the heat. Philosophers have therefore been greatly embarrassed in explaining the phenomena of ignition. See PHLOGISTON.

IGNOBILES, amongst the Romans, was the designation of such persons as had no right of using pictures and statues. See *Jus Imaginis*.

IGNOMINIA, a species of punishment amongst the Romans, whereby the offender suffered public shame, either by virtue of the prætor's edict, or by order of the censor. This punishment, besides the scandal, deprived the party of the privilege of bearing any offices, and almost all other liberties of a Roman citizen.

IGNORAMUS, in law, is a word properly used by the grand inquest empanelled in the inquisition of causes criminal and public, and written upon the bill whereby any crime is offered to their consideration, whenas they dislike their evidence as defective or too weak to make good the presentment; the effect of which word so written is, that all further inquiry upon that party for that fault is thereby stopped, and he delivered without further answer. It hath a resemblance with that custom of the ancient Romans, where the judges, when they absolved a person accused, did write *A.* upon a little table provided for that purpose, i. e. *absolvimus*; if they judged him guilty, they wrote *C.* i. e. *condemnamus*; if they found the cause difficult and doubtful, they wrote *N. L.* i. e. *non liquet*.

IGNORANCE, the privation or absence of knowledge. The causes of ignorance, according to Locke, are chiefly these three. 1. Want of ideas. 2. Want of a discoverable connection between the ideas we have. 3. Want of tracing and examining our ideas. See METAPHYSICS.

IGNORANCE, in a more particular sense, is used to denote illiteracy. Previous to the taking of Rome by the Gauls, such gross ignorance prevailed among the Romans, that few of the citizens could read or write, and the alphabet was almost unknown. During three ages there were no public schools, but the little learning their children had was taught them by their parents; and how little that was may be partly concluded from this circumstance, that a nail was usually driven into the wall of the temple of *Jupiter Capitolinus*, on the 15th of September, to assist the ignorance of the people in reckoning the years, because they were unacquainted with letters or figures. The driving of the nail was afterwards converted into a religious ceremony, and performed by the *Dictator*, to avert public calamities.

IGNORANCE, or mistake, in law, a defect of will, whereby a person is excused from the guilt of a crime, when, intending to do a lawful act, he does that which is unlawful. For here the deed and the will acting separately, there is not that conjunction between them which is necessary to form a criminal act.

But this must be an ignorance or mistake of fact, and not an error in point of law. As if a man intending to kill a thief or house-breaker in his own house, by mistake kills one of his own family, this is no criminal action; but if a man thinks he has a right to kill a person excommunicated or outlawed wherever he meets him, and does so, this is wilful murder. For a mistake in point of law, which every person of discretion not only may, but is bound and presumed to know, is, in criminal cases, no sort of defence. *Ignorantia juris quod quisque tenetur scire, neminem excusat*, is as well the maxim of our own law as it was of the Roman.

IGUANA, in zoology, a species of LACERPA. See the article BASILISCUS.

Mud-IGUANA. See MURÆNA.

JHOR, JOHOR, or *Jor*, a town of Asia, in Malacca, and capital of a province of the same name in the peninsula beyond the Gauges. It was taken by the Portuguese in 1603, who destroyed it, and carried off the cannon; but it has since been rebuilt, and is now in possession of the Dutch. E. lon. 93. 55. N. lat. 1. 15.

JIB, the foremost sail of a ship, being a large stay sail extended from the outer end of the bowsprit prolonged by the jib-boom, towards the fore-top-mast head. See SAIL. The jib is a sail of great command with any side wind, but especially when the ship is *close hauled*, or has the wind upon her beam; and its effort in *casting* the ship, or turning her head to leeward, is very powerful, and of great utility, particularly when the ship is working through a narrow channel.

JIB-Boom, a boom run out from the extremity of the bowsprit, parallel to its length, and serving to extend the bottom of the jib, and the stay of the fore-top-gallant mast. This boom, which is nothing more than a continuation of the bowsprit forward, to which it may be considered as a top-mast, is usually attached to the bowsprit by means of two large boom irons, or by one boom iron, and a cap on the outer end of the bowsprit; or, finally, by the cap without and a strong lashing within, instead of a boom iron, which is generally the method of securing it in small merchant ships. It may therefore be drawn in upon the bowsprit as occasion requires; which is usually practised when the ship enters a harbour, where it might very soon be broken or carried away by the vessels which are moored therein, or passing by under sail.

JIBBEL AUREZ, the mons auraceus of the middle age, an assemblage of many very rocky mountains in Africa, in the kingdom of Algiers. Here Mr. Bruce met with a race of people much fairer in the complexion than any of the nations to the southward of Britain: their hair was red, and their eyes blue: they maintain their independence, and are of a savage disposition, so that our traveller found it difficult to approach them with safety. They are called Neardia; and each of them has a Greek cross in the middle between the eyes, marked with antimony. They are divided into tribes, but, unlike the other Arabs, have huts in the mountains, built of mud and straw; and are, by our author, supposed to be a remnant of the Vandals. He even thinks that they may be descended from the remainder of an army of Vandals mentioned by Procopius, which was defeated among these mountains. They live in perpetual war with the Moors, and boast that their ancestors were Christians. They pay no taxes.

JIDDA, a town of Arabia, situated, according to Mr. Bruce, in N. lat. 28° 0' 1". E. lon. 39° 16' 45". It is situated in a very unwholesome, barren, and desert part of the country. Immediately without the gate to the eastward is a desert plain filled with the huts of the Bedowens or country Arabs, built of long bundles of spartum or bent-grass put together like fascines. These people supply the town with milk and butter. "There is no stirring out of the town (says Mr. Bruce) even for a walk,

unless for about half a mile on the south-side by the sea, where there is a number of stinking pools of stagnant water, which contributes to make the town very unwholesome."

From the disagreeable and inconvenient situation of this port, it is probable that it would have been long ago abandoned, had it not been for its vicinity to Mecca, and the vast annual influx of wealth occasioned by the India trade; which, however, does not continue, but passes on to Mecca, whence it is dispersed all over the east. The town of Jidda itself receives but little advantage, for all the customs are immediately sent to the needy and rapacious sheriff of Mecca and his dependents. "The gold (says Mr. Bruce) is returned in bags and boxes, and passes on as rapidly to the ships as the goods do to the market, and leaves as little profit behind. In the mean time provisions rise to a prodigious price; and this falls upon the townsmen, while all the profit of the traffic is in the hands of strangers; most of whom, after the market is over (which does not last six weeks), retire to Yemen and other neighbouring countries, which abound in every sort of provision.

From this scarcity Mr. Bruce supposes it is that polygamy is less common here than in any other part of Arabia. "Few of the inhabitants of Jidda, (says our author) can avail themselves of the privilege granted by Mahomet. He cannot marry more than one wife, because he cannot maintain more; and from this cause arise the want of people and the number of unmarried women."

The trade at Jidda is carried on in a manner which appeared very strange to our traveller. "Nine ships (says he) were there from India; some of them worth, I suppose, 200,000l. One merchant, a Turk, living at Mecca, 30 hours journey off, where no Christian dares go, whilst the continent is open to the Turk for escape, offers to purchase the cargoes of four out of these nine ships himself; another of the same cast comes and says he will buy none unless he has them all. The samples are shown, and the cargoes of the whole nine ships are carried into the wildest parts of Arabia by men with whom one would not wish to trust himself alone in the field. This is not all; two India brokers come into the room to settle the price; one on the part of the India Captain, the other on that of the buyer the Turk. They are neither Mahometans nor Christians, but have credit with both. They sit down on the carpet, and take an India shawl, which they carry on their shoulder like a napkin, and spread it over their hands. They talk in the mean time indifferent conversation, as if they were employed in no serious business whatever. After about 20 minutes spent in handling each other's fingers below the shawl, the bargain is concluded, say for nine ships, without one word ever having been spoken on the subject, or pen or ink used in any shape whatever. There never was one instance of a dispute happening in these sales. But this is not all; the money is yet to be paid. A private Moor, who has nothing to support him but his character, becomes responsible for the payment of these cargoes. This man delivers a number of coarse hempen bags full of what is supposed to be money. He marks the contents upon the bag, and puts his seal upon the string that ties the mouth of it. This is received for what is marked upon it, without any one ever having opened one of the bags; and in India it is current for the value marked upon it as long as the bag lasts."

The port of Jidda is very extensive, and contains numberless shoals, small islands, and sunk rocks, with deep channels, however, between them; but in the harbour itself ships may ride secure, whatever wind blows. The only danger is in the coming in or going out; but as the pilots are very skilful, accidents are never known to happen. The charts of this harbour, as Mr. Bruce informs us, are exceedingly erroneous. While he staid here, he was desired by Captain Thornhill to make a new chart of the harbour; but finding that it had been undertaken by ano-

ther gentleman, Captain Newland, he dropped it. He argues in the strongest terms against the old maps, which he says can be of no use, but the contrary; and he gives it as a characteristic of the Red sea, "scarce to have soundings in any part of the channel, and often on neither side; whilst ashore, soundings are hardly found a boat length from the main. To this, says he, I will add, that there is scarce one island on which I ever was, where the bolt-spirit was not over the land, while there were no soundings by a line heaved over the stern. Of all the vessels in Jidda, only two had their log-lines properly divided; and yet all were so fond of their supposed accuracy, as to aver they had kept their course within five leagues between India and Babel-mandel. Yet they had made no estimation of the currents without the straits, nor the different very strong ones soon after passing Socotra; their half minute glasses, upon a medium, ran 57 seconds: they had made no observations on the tides or currents in the Red sea, either in the channel or in the inward passage; yet there is delineated in this map a course of Captain Newland's which he kept in the middle of the channel, full of sharp angles and short stretches; you would think every yard was measured and sounded!"

JIG, a well known lively tune to which people dance. See MUSIC.

JIN. See GENII.

JIONPOUR, a small city of Hindoostan Proper, capital of a circar of the same name, in the district of Benares. It is seated on the Goomty; and not far from the confluence of that river with the Ganges, stands the fort of Jionpour, a building of considerable extent, on a high bank commanding the bridge over the Goomty. It is now chiefly in ruins; although formerly it commanded the country from the Ganges quite to Lucknow. This place was at one time the seat of an empire. Chaja Jehan, vizier to sultan Mahummud Shah, during the minority of his son Mamood Shah assumed the title of sultan Shirki, or king of the East, took possession of Bahar, and fixed his residence at Jionpour, where he built the great musjud, or mausoleum, which is still remaining, for himself and family. The bridge over the Goomty is built of stone, and consists of 16 pointed arches. On the top of the bridge are many little shops on both sides, built of stone. It was built in 1567, upon such found principles, as to have withstood, for such a length of time, the force of the stream, which, in the time of the rains, is very great. The inundations have been known to rise frequently over the bridge, insomuch that in the year 1774 a whole brigade of the British army (that is, 10,000 men) passed over it in boats. Jionpour is 49 miles N. W. of Benares. E. lon. 84. 7. N. lat. 25. 45.

IKENILD STREET, one of the four famous ways which the Romans made in England, called *Stratum Icenorum*, because it began in the country of the *Iceni*, who inhabited Norfolk, Suffolk, and Cambridgeshire.

ILA, or ISLAY, an island of Scotland, one of the Hebrides, to the S. W. of Jura. Its greatest length is 25 miles; its breadth 18. The principal village is Bowmore, which is in a manner a new town, and has a convenient harbour. The face of the country is hilly. Several mines are wrought to great advantage; and the lead ore is very rich and productive. Here likewise are copper, emery, native quicksilver, and black lead: with immense stores of limestone, marl, coral, and shell-sand, for manure. Much corn and flax is raised here, and a great number of cattle exported. In this, and some of the neighbouring islands, multitudes of adders infest the heath. On the N. W. side of the island is the cave of Saneymore, which is a grotto, divided into a number of far-winding passages, sometimes opening into fine expanses; again closing; for a long space, into galleries, and forming a curious subterraneous labyrinth. There are also many other caverns, the haunts of numerous wild pigeons,

that lodge and breed in them. The goats that feed among the rocks are so wild that they are obliged to be shot like deer. Some vestiges of antiquity are on this island; particularly, the remains of a circular dry stone building, on the hill of Loffet, near the Sound of Islay. This hill contains fine iron ore and emery.

ILANTS, a town in the country of the Grisons, capital of the Grey League. It contains about 60 houses, and is partly surrounded by walls; being the only walled town, except Coire, among the Grisons. It is remarkable for being the place where the general diet of the Three Leagues assembles every third year. It is seated on the Rhine, 17 miles S. W. of Coire.

ILCHESTER, a town of Somersetshire, with a market on Wednesday. It is seated on the river Yeovil, and is a town of great antiquity, as appears by the Roman coins dug up. It once had sixteen churches, now only two; is a corporation, sends two members to parliament, and here the county gaol is kept. It is 16 miles S. of Wells, and 123 W. by S. of London. W. lon. 2. 37. N. lat. 50. 56.

ILDEFONSO, ST. a magnificent palace of the king of Spain, in New Castile, and in the territory of Segovia, built by Philip V. It has very fine water-works and gardens.

ILDEFONSO DE LOS ZAPOTACOS, ST. a town of N. America, in New Spain, seated on a mountain, 50 miles N. E. of Antequera. W. lon. 27. 30. N. lat. 17. 5.

ILDERTON, a village in Northumberland, situated S. of Woller. On a hill near it is a semicircular encampment, defended by two high rampires of earth, and a deep fosse, with an inner circle of stones, which appear uncemented. The area is about 100 yards diameter, and contains many remains of buildings.

ILERDA, in ancient geography, the capital of the Iligertes, situated on an eminence between the rivers Sicoris and Cinga: an unhappy city, often besieged, and often taken, because lying exposed to the incursions from Gaul; and under Gallienus it was destroyed by the Germans. Now LERIDA, in Catalonia, on the river Segra.

ILESUGAGUEN, a strong town of Africa, in the kingdom of Morocco, and province of Hea, seated on a mountain.

ILEX, the HOLM or HOLLY Tree; a genus of the tetragynia order, belonging to the tetrandria class of plants; and in the natural method ranking under the 43d order, *Dumose*. The calyx is quadridentated; the corolla rotaceous; there is no style; the berry is monospermous. There are several species of this genus; but the most remarkable is the aquifolium, or common holly. Of this there are a great number of varieties with variegated leaves, which are propagated by the nursery gardeners for sale, and some years past were in very great esteem; but at present are but little regarded, the old taste of filling gardens with shorn evergreens being pretty well abolished: however, in the disposition of clumps, or rather plantations, of evergreen trees and shrubs, a few of the most lively colours may be admitted, which will have a good effect in the winter season, if they are properly disposed. The best of these varieties are the painted lady-holly, British holly, Bradley's best holly, phyllis or cream-holly, milkmaid holly, Pricet's best holly, gold-edged hedgehog holly, Chyney's holly, glory-of-the-west holly, Broaderick's holly, Partridge's holly, Herefordshire white holly, Blind's cream holly, Longstaff's holly, Eales's holly, silver-edged hedgehog holly. All these varieties are propagated by budding or grafting them upon stocks of the common green holly: there is also a variety of the common holly with smooth leaves; but this is frequently found intermixed with the prickly-leaved on the same tree, and often on the same branch there are both sorts of leaves.

The common holly grows naturally in woods and forests in many parts of England, where it rises from 20 to 30 feet high, and sometimes more, but their ordinary height is not above 25 feet;

the stem by age becomes large, and is covered with a greyish smooth bark; and those trees which are not lopped, or browsed by cattle, are commonly furnished with branches the greatest part of their length, to form a sort of cone; the branches are garrished with oblong oval leaves, of a lucid green on their upper surface, but are pale on their under, having a strong midrib: the edges are indented and waved, with sharp thorns terminating each of the points, so that some of the thorns are raised upward, and others are bent downward; and being very stiff, they are troublesome to handle. The leaves are placed alternate on every side of the branches; and from the base of their footstalks come out the flowers in clusters, standing on very short footstalks; each of these sustains five, six, or more flowers. They are of a dirty white, and appear in May; but are succeeded by roundish berries, which turn to a beautiful red about Michaelmas, and continue on the trees, if they are not destroyed, till after Christmas.

The common holly is a very beautiful tree in winter, therefore deserves a place in all plantations of evergreen trees and shrubs, where its shining leaves and red berries make a fine variety; and if a few of the best variegated kinds are properly intermixed, they will enliven the scene. It is propagated by seeds, which never come up the first year, but lie in the ground as the haws do; therefore the berries should be buried in the ground one year, and then taken up and sown at Michaelmas, upon a bed exposed only to the morning sun: the following spring the plants will appear, which must be kept clean from weeds; and if the spring should prove dry, it will be of great service to the plants if they are watered once a week; but they must not have it oftener, nor in too great quantity, for too much moisture is very injurious to these plants when young. In this seed-bed the plants may remain two years; and then should be transplanted in the autumn, into beds at about six inches asunder, where they may stand two years longer; during which time they must be constantly kept clean from weeds; and if the plants have thriven well, they will be strong enough to transplant where they are designed to remain: for when they are transplanted at that age, there will be less danger of their failing, and they will grow to a larger size than those which are removed when they are much larger; but if the ground is not ready to receive them at that time, they should be transplanted into a nursery, in rows at two feet distance, and one foot asunder in the rows, in which place the plants may remain two years longer; and if they are designed to be grafted or budded with any of the variegated kinds, that should be performed after the plants have grown one year in the nursery: but the plants so budded or grafted should continue two years after in the nursery, that they may make good shoots before they are removed; though the plain ones should not stand longer than two years in the nursery, because when they are older they do not transplant so well. The best time for removing hollies is in the autumn, especially in dry land; but where the soil is cold and moist, they may be transplanted with great safety in the spring, if the plants are not too old, or have not stood long unremoved; for, if they have, there is great doubt of their growing when removed.

Sheep in the winter are fed with croppings of holly. Birds eat the berries. The bark fermented and afterwards washed from the woody fibres, makes the common bird-lime. The plant makes an impenetrable fence, and bears cropping: however, it is not found in all respects to answer for this purpose equally well with the hawthorn. The wood is used in lineering, and is sometimes stained black to imitate ebony. Handles for knives and cogs for mill-wheels are made of it. It is also made into hones for whetting of razors. Mr. Miller says, he has seen the floor of a room laid with compartments of holly and mahogany, which had a very pretty effect.

ILFORD, GREAT, a village of Essex, 'on the river Roding,

which is navigable hence to the Thames. This place, and Little Ilford adjoining, are hamlets to the town of Barking. It is seven miles N. E. by E. of London.

ILFRACOMBE, a seaport of Devonshire, with a market on Saturday. It has a spacious basin, formed by a good pier projecting into the Bristol Channel. The high tides here allow large vessels to enter the harbour. This port employs a number of brigs and sloops, chiefly in carrying ore from Cornwall, coal from Wales, and corn to Bristol. A number of fishing skiffs belong to this place, which, with those of Minehead, fish on a bank off the coast during the summer, and take a number of soals, turbot, &c. for the Bristol market. It is seated almost opposite Swansea, in Glamorganshire, and is 49 miles N. N. W. of Exeter, and 181 W. by S. of London. W. lon. 4. 5. N. lat. 51. 14.

ILHEOS, a seaport of S. America, capital of Rio-dos-Ilheos, in Brasil. It is seated in a fertile country. W. lon. 41. 25. S. lat. 15. 5.

ILIAC PASSION, a violent and dangerous kind of colic; called also *volvulus*, *miserere mei*, and *chordapsus*. It takes its name from the intestine *ilion*, on account of its being usually affected; or perhaps from the Greek verb *ειλειν* "to wind or twist;" whence also it is the Latins call it *volvulus*. See MEDICINE.

ILIAD, the name of an ancient epic poem, the first and finest of those composed by Homer. The poet's design in the Iliad was to show the Greeks, who were divided into several little states, how much it was their interest to preserve a harmony and good understanding among themselves; for which end he sets before them the calamities that beset their ancestors from the wrath of Achilles, and his misunderstanding with Agamemnon; and the advantages that afterwards accrued to them from their union. The Iliad is divided into 24 books or rhapsodies, which are marked with the letters of the alphabet.

ILISSUS, a river running to the east of Athens; which, with the Eridanus running on the west side, falls below the city into the sea. Sacred to the muses, called *Iliades*; on whose bank their altar stood, and where the lustration in the less mysteries was usually performed.

ILIUM, ILION, or *Ilios*, in ancient geography, a name for the city of Troy, but most commonly used by the poets and distinguished by the epithet *Vetus*; at a greater distance from the sea than what was afterwards called *Ilium Novum*, and thought to be the *Iliensium Pagus* of Strabo. New or modern Ilium was a village nearer the sea, with a temple of Minerva; where Alexander, after the battle of Granicus, offered gifts, and called it a city, which he ordered to be enlarged. His orders were executed by Lyfimachus, who encompassed it with a wall of 40 stadia. It was afterwards adorned by the Romans, who granted it immunities as to their mother city. From this city the *Ilias* of Homer takes its name, containing an account of the war carried on between the Greeks and Trojans on account of the rape of Helen: a variety of disasters being the consequence, gave rise to the proverb *Ilias Malorum*.

ILKUCH, a former royal town of Poland, in the palatinate of Cracow, remarkable for its silver-mines mixed with lead. It is seated in a barren and mountainous country, in E. lon. 20. 0. N. lat. 50. 26.

ILLECEBRUM, in botany; a genus of the monogynia order, belonging to the pentandria class of plants; and in the natural method ranking under the 12th order, *Holoracea*. The calyx is pentaphyllous, and cartilaginous; there is no corolla; the stigma is simple; the capsule quinquevalved, and monospermous. There are several species, of which the most remarkable are the *paronychia* and the *capitatum*. Both these have trailing stalks near two feet long, which spread on the ground, garnished with small leaves like those of knot-grass. The heads

of the flowers come out from the joints of the stalks, having neat silvery bractæe surrounding them, which make a pretty appearance. Their flowers appear in June, and there is generally a succession of them for at least two months; and when the autumn proves warm, they will ripen their seeds in October. They are propagated by seeds, which should be sown in a bed of light earth in the beginning of April; the plants will come up in May, when they should be kept clean from weeds till they are fit to remove. Some should be planted in small pots, and the rest in a warm border, observing to water and shade them till they have taken new root. These plants are sometimes killed in severe winters; for which reason it is directed to plant some of them in pots, that they may be sheltered during that season.

ILLINOIS, a large river of N. America, which rises in the western territory, near the S. end of lake Michigan, and, taking a S. W. course, falls into the Mississippi. Between the Illinois and the Ohio is the country of a noted Indian nation, called the Illinois.

ILLICIUM, in botany; a genus of the pentagynia order, belonging to the dodecandria class of plants; and in the natural method ranking with those of which the order is doubtful. The calyx is tetraphyllous, and deciduous; there are eight petals, and eight petaloid subulated nectaria. There are 16 stamina with bifid antheræ; the capsules are ovate, compressed, and monospermous. There are two species, viz. 1. The *floridanum*, with red flowers, and very odorous fruit. It is a native of China. 2. The *anisatum*, a native of the woods of China and Japan. It rises with an erect branched stem to the height of a cherry-tree; and is covered with an ash-coloured bark, under which is another bark that is green, fleshy, somewhat mucous, and of an aromatic taste, combined with a small degree of astringency. The wood is hard and brittle; the pith small in quantity, fungous, and of a green herbaceous colour. The leaves resemble those of laurel; the flowers, in some sort, those of narcissus. These last generally stand single, are of a pale white, and consist of 16 petals, which differ in their form. The extremity of the flower-stalk being continued into the germen or seed-bud of the flower, forms eight conjoined capsules, or one deeply divided into eight parts. Of these capsules, some frequently decay; the rest inclose each a single seed, somewhat resembling that of palma christi, and which, when the hardish corticle that closely covers and involves it is broken, exhibits a kernel that is white, fleshy, soft, and of a vapid taste. The bonzes, or priests, of China and Japan infuse into the inhabitants a superstitious belief, that the gods are delighted with the presence of this tree. Hence they generally place before their idols garlands and bundles made of the branches. A similar opinion the Bramins inculcate into the Indians, of the Malabar fig, or *scus religiosa*. The bark of the anise-tree, reduced to powder, and equally burnt, the public watchmen in Japan, by a very curious contrivance described by Kempfer, render useful in the measuring of time during the darkness of the night. The same powder is frequently burnt in brazen vessels on the Japanese altars, as incense is in other countries, from a belief that the idols in whose honour the ceremony is performed are greatly refreshed with the agreeable fragrauncy of its odour. It is remarkable, that a branch of this tree being added to the decoction of the poisonous fish, termed by the Dutch *de opblaser* (a fish the most delicate for eating, if the poisonous matter be first properly expelled), increases its noxious quality, and exasperates the poison to an astonishing degree of activity and power.

ILLUMINATING, a kind of miniature-painting, anciently much practised for illustrating and adorning books. Besides the writers of books, there were artists whose profession was to ornament and paint manuscripts, who were called *illuminators*: the writers of books first finished their part, and the illuminators embellished them with ornamented letters and

paintings. We frequently find blanks left in manuscripts for the illuminators, which were never filled up. Some of the ancient manuscripts are gilt and burnished in a style superior to later times. Their colours were excellent, and their skill in preparing them must have been very great.

The practice of introducing ornaments, drawings, emblematical figures, and even portraits, into manuscripts, is of great antiquity. Varro wrote the lives of seven hundred illustrious Romans, which he enriched with their portraits, as Pliny attests in his Natural History (lib. xxxv. cap. 2.). Pomponius Atticus, the friend of Cicero, was the author of a work on the actions of the great men amongst the Romans, which he ornamented with their portraits, as appears in his Life by Cornelius Nepos (cap. 18.). But these works have not been transmitted to posterity. There are, however, many precious documents remaining, which exhibit the advancement and decline of the arts in different ages and countries. These inestimable paintings and illuminations display the manners, customs, habits, ecclesiastical, civil, and military, weapons and instruments of war, utensils and architecture of the ancients; they are of the greatest use in illustrating many important facts relative to the history of the times in which they were executed. In these treasures of antiquity are preserved a great number of specimens of Grecian and Roman art, which were executed before the arts and sciences fell into neglect and contempt. The manuscripts containing these specimens form a valuable part of the riches preserved in the principal libraries of Europe: the Royal, Cottonian, and Harleian libraries, as also those in the two universities in England, the Vatican at Rome, the Imperial at Vienna, the National at Paris, St. Mark's at Venice, and many others.

A very ancient MS. of Genesis, which was in the Cottonian library, and almost destroyed by a fire in 1731, contained two hundred and fifty curious paintings in water colours. Twenty-one fragments, which escaped the fire, are engraven by the society of antiquaries of London. Several specimens of curious paintings also appear in Lambecius's catalogue of the imperial library at Vienna, particularly in vol. iii. where forty-eight drawings of nearly equal antiquity with those in the Cottonian library are engraven; and several others may be found in various catalogues of the Italian libraries. The drawings in the Vatican Virgil, made in the fourth century, before the arts were entirely neglected, illustrate the different subjects treated of by the Roman poet. A miniature drawing is prefixed to each of the gospels brought over to England by St. Augustin in the sixth century, which is preserved in the library of Corpus Christi college, Cambridge; in the compartments of those drawings are depicted representations of several transactions in each gospel. The curious drawings and elaborate ornaments in St. Cuthbert's gospels made by St. Ethelwald, and now in the Cottonian library, exhibit a striking specimen of the state of the arts in England in the seventh century. The same may be observed with respect to the drawings in the ancient copy of the four gospels preserved in the cathedral church of Litchfield, and those in the Codex Rushworthianus in the Bodleian library at Oxford. The life of St. Paul the hermit, now remaining in Corpus Christi college, Cambridge, (G. 2.), affords an example of the style of drawing and ornamenting letters in England in the eighth century; and the copy of Prudentius's *Psycomachia* in the Cottonian library (Cleop. c. 8.) exhibits the style of drawing in Italy in the ninth century. Of the tenth century there are Roman drawings of a singular kind in the Harleian library (N^o 2820.) N^o 5280, 1802, and 437, in the same library, contain specimens of ornamented letters, which are to be found in Irish MSS. from the twelfth to the fourteenth century. Cædmon's Poetical Paraphrase of the book of Genesis, written in the eleventh century, which is preserved amongst F. Junius's MSS. in the Bodleian library, exhibits many speci-

mens of utensils, weapons, instruments of music, and implements of husbandry used by the Anglo-Saxons. The like may be seen in extracts from the Pentateuch of the same age, in the Cottonian library (Claud. B. 4.). The manuscript copy of Terence in the Bodleian library (D. 17.) displays the dresses, masks, &c. worn by comedians in the twelfth century, if not earlier. The very elegant Psalter in the library of Trinity College, Cambridge, exhibits specimens of the art of drawing in England in the same century. The Virgil in the Lambeth library of the 13th century (N^o 471.), written in Italy, shows, both by the drawings and writing, that the Italians produced works much inferior to ours at that period. The copy of the Apocalypse in the same library (N^o 209) contains a curious example of the manner of painting in the fourteenth century. The beautiful paintings in the history of the latter part of the reign of king Richard II. in the Harleian library (N^o 1319), afford curious specimens of manners and customs, both civil and military, at the close of the fourteenth and in the beginning of the fifteenth century; as does N^o 2278 in the same library. Many other instances might be produced; but those who desire farther information may consult Strutt's *Regal and Ecclesiastical Antiquities*, 4to, and his *Horda-Angel cynnan* published in three vols.

This art was much practised by the clergy, and even by some in the highest stations in the church. "The famous Osmund (says Bromton), who was consecrated bishop of Salisbury A. D. 1076, did not disdain to spend some part of his time in writing, binding, and *illuminating* books." Mr. Strutt, as already noticed, has given the public an opportunity of forming some judgment of the degree of delicacy and art with which these illuminations were executed, by publishing prints of a prodigious number of them, in his *Regal and ecclesiastical antiquities of England*, and *View of the customs, &c. of England*. In the first of these works we are presented with the genuine portraits, in miniature, of all the kings, and several of the queens of England, from Edward the Confessor to Henry VII. mostly in their crowns and royal robes, together with the portraits of many other eminent persons of both sexes.

The illuminators and painters of this period seem to have been in possession of a considerable number of colouring materials, and to have known the arts of preparing and mixing them, so as to form a great variety of colours: for, in the specimens of their miniature paintings that are still extant, we perceive not only the five primary colours, but also various combinations of them. Though Strutt's prints do not exhibit the bright and vivid colours of the originals, they give us equally a view, not only of the persons and dresses of our ancestors, but also of their customs, manners, arts, and employments, their arms, ships, houses, furniture, &c. and enable us to judge of their skill in drawing. The figures in those paintings are often stiff and formal; but the ornaments are in general fine and delicate, and the colours clear and bright, particularly the gold and azure. In some of these illuminations the passions are strongly painted. How strongly, for example, is terror painted in the faces of the earl of Warwick's sailors, when they were threatened with a shipwreck, and grief in the countenances of those who were present at the death of that hero! See *Strutt*, vol. ii. plates 56 and 58. After the introduction of printing, this elegant art of illuminating gradually declined, and at length was quite neglected.

Before concluding, it may not be improper to observe, that from the fifth to the tenth century the miniature paintings which we meet with in Greek MSS. are generally good, as are some which we find among those of Italy, England, and France. From the tenth to the middle of the fourteenth century they are commonly very bad, and may be considered as so many monuments of the barbarity of those ages: towards the

latter end of the fourteenth, the paintings in manuscripts were much improved; and in the two succeeding centuries many excellent performances were produced, especially after the happy period of the restoration of the arts, when great attention was paid to the works of the ancients, and the study of antiquity became fashionable.

ILLUMINED, ILLUMINATI, a church term, anciently applied to such persons as had received baptism. This name was occasioned by a ceremony in the baptism of adults; which consisted in putting a lighted taper in the hand of the person baptized, as a symbol of the faith and grace he had received in the sacrament.

ILLUMINED, *Illuminati*, is also the name of a sect of heretics, who sprang up in Spain about the year 1575, and were called by the Spaniards *Alambrados*. Their principal doctrines were, that by means of a sublime manner of prayer, which they had attained to, they entered into so perfect a state, that they had no occasion for ordinances, sacraments, nor good works; and that they could give way even to the vilest actions without sin. The sect of Illumined were revived in France in the year 1634, and were soon after joined by the Guerinets, or disciples of Peter Guerin, who together made but one body, called also ILLUMINED: but they were so hotly pursued by Louis XIII. that they were soon destroyed. The brothers of the Rosy Cross are sometimes also called Illumined. See RO-SYCRUSIAN.

ILLUSTRIOUS, ILLUSTRIS, was heretofore, in the Roman empire, a title of honour peculiar to people of a certain rank. It was first given to the most distinguished among the knights, who had a right to bear the *latus clavus*: afterwards those were entitled *illustrious* who held the first rank among those called *honorati*; that is, the *præfecti prætorii*, *præfecti urbis*, *treasurers*, *comites*, &c. There were, however, different degrees among the *illustrious*: as in Spain they have *grandees* of the first and second class, so in Rome they had their *illustres*, whom they called great, *majores*; and others less, called *illustres minores*. For instance, the *præfectus prætorii* was a degree below the master of the offices, though they were both *illustres*. The Novels of Valentinian distinguish as far as five kinds of *illustres*; among whom, the *illustres administratores* bear the first rank.

ILLYRICUM, (*Solum* perhaps understood) *Livy*, *Herodian*, *St. Paul*; called *Illyris* by the Greeks, and sometimes *Illyria*: the country extending from the Adriatic to Pannonia thus called. Its boundaries are variously assigned. *Pliny* makes it extend in length from the river *Arfia* to the *Drinius*, thus including *Liburnia* to the west, and *Dalmatia* to the east: which is also the opinion of *Ptolemy*; who settles its limits from mount *Scardus* and the Upper *Mœsia* on the east, to *Istria* in the west. A Roman province, divided by *Augustus* into the Superior and Inferior, but of which the limits are left undetermined both by ancient historians and geographers. *Illyrii* the people; called *Illyres* by the Greeks. The country is now called *Slavonia*.

ILLYRIUS, (MATTHIAS, FLACCUS, or FRANOWITZ), one of the most learned divines of the Augsburgh confession, born in *Istria*, anciently called *Illyria*, in 1520. He is said to have been a man of vast genius, extensive learning, of great zeal against Popery; but of such a restless and passionate temper, as overbalanced all his good qualities, and occasioned much disturbance in the Protestant church. He published a great number of books, and died in 1575.

IMAGE, in a religious sense, is an artificial representation or similitude of some person or thing, used either by way of decoration and ornament, or as an object of religious worship and adoration; in which last sense it is used indifferently with the word *Idol*.

The noble Romans preserved the *images* of their ancestors with a great deal of care and concern, and had them carried in procession at their funerals and triumphs: these were commonly made of wax, or wood, though sometimes of marble or brass. They placed them in the vestibules of their houses; and they were to stay there, even if the houses happened to be sold, it being accounted impious to displace them. Appius Claudius was the first who brought them into the temples, in the year of Rome 259; and he added inscriptions to them, showing the origin of the persons represented, and their brave and virtuous achievements. It was not, however, allowed for all, who had the *images* of their ancestors in their houses, to have them carried at their funerals; this was a thing only granted to such as had honourably discharged themselves of their offices: for those who failed in this respect forfeited that privilege; and in case they had been guilty of any great crime, their *images* were broken in pieces. See *IGNOBILES* and *JUS*.

The Jews absolutely condemn all *images*, and do not so much as suffer any statues or figures in their houses, much less in their synagogues or places of worship.

The use and adoration of *images* have been a long time subjects of controversy in the world.

It is plain, from the practice of the primitive church, recorded by the earlier fathers, that Christians, for the first three centuries after Christ, and the greater part of the fourth, neither worshipped *images* nor used them in their worship. However, the greater part of the Popish divines maintain, that the use and worship of *images* were as ancient as the Christian religion itself: to prove this, they allege a decree, said to have been made in a council held by the Apostles at Antioch, commanding the faithful, that they may not err about the object of their worship, to make *images* of Christ and worship them. Baron. ad ann. 102. But no notice is taken of this decree, till 700 years after the Apostolic times, after the dispute about *images* had commenced. The first instance that occurs in any credible author of *images* among Christians, is recorded by Tertullian de Pudicit. c. 10. of certain cups, or chalices, as Bellarmine pretends, on which was represented the parable of the good shepherd carrying the lost sheep on his shoulders: but this instance only proves, that the church, at that time, did not think emblematical figures unlawful ornaments of cups or chalices. Another instance is taken from Eusebius, Hist. Eccl. lib. vii. cap. 18. who says, that in his time there were to be seen two brass statues in the city of Paneas or Cæsarea Philippi; the one of a woman on her knees, with her arm stretched out; the other of a man over against her, with his hand extended to receive her: these statues were said to be the *images* of our Saviour and the woman whom he cured of an issue of blood. From the foot of the statue representing our Saviour, says the historian, sprung up an exotic plant, which, as soon as it grew to touch the border of his garment, was said to cure all sorts of distempers. Eusebius, however, vouches none of these things; nay, he supposes that the woman who erected this statue of our Saviour was a pagan, and ascribes it to a pagan custom. Further, Philostorgius, Eccl. Hist. lib. vii. c. 3. expressly says, that this statue was carefully preserved by the Christians, but that they paid no kind of worship to it, because it is not lawful for Christians to worship brass or any other matter. The primitive Christians abstained from the worship of *images*, not, as the Papists pretend, from tenderness to heathen idolaters, but because they thought it unlawful in itself to make any *images* of the Deity. Justin. Mart. Apol. ii. p. 44. Clem. Alex. Strom. 5. Strom. 7. and Protr. p. 6. Aug. de Civit. Dei, lib. vii. c. 5. and lib. iv. c. 32. Id. de Fide et Symb. c. 7. Lactant. lib. ii. c. 3. Tertull. Apol. c. 12. Arnob. lib. vi. p. 202. Some of the fathers, as Tertullian, Clemens Alexandrinus, and Origen, were of opinion, that, by the second commandment, the arts of painting

and engraving were rendered unlawful to a Christian, styling them evil and wicked arts. Tert. de Idol. cap. 3. Clem. Alex. Admon. ad Gent. p. 41. Orig. contra Celsum, lib. vi. p. 182. The use of *images* in churches as ornaments, was first introduced by some Christians in Spain, in the beginning of the fourth century; but the practice was condemned as a dangerous innovation, in a council held at Eliberis in 307. Epiphanius, in a letter preserved by Jerom, tom. ii. ep. 6. bears strong testimony against *images*, and may be considered as one of the first *ICONOCLASTS*. The custom of admitting pictures of saints and martyrs into the churches (for this was the first source of *image-worship*) was rare in the latter end of the fourth century; but became common in the fifth: however, they were still considered only as ornaments; and even in this view they met with very considerable opposition. In the following century the custom of thus adorning churches became almost universal, both in the east and west. Petavius expressly says, (de Incar. lib. xv. cap. 14.) that no statues were yet allowed in the churches; because they bore too near a resemblance to the idols of the Gentiles. Towards the close of the fourth or beginning of the fifth century, *images*, which were introduced by way of ornament, and then used as an aid to devotion, began to be actually worshipped. However, it continued to be the doctrine of the church in the sixth and in the beginning of the seventh century, that *images* were to be used only as helps to devotion, and not as objects of worship. The worship of them was condemned in the strongest terms by Pope Gregory the Great; as appears by two letters of his written in 601. From this time to the beginning of the eighth century, there occurs no single instance of any worship given or allowed to be given to *images* by any council or assembly of bishops whatever. But they were commonly worshipped by the monks and populace in the beginning of the eighth century; insomuch that in the year 726, when Leo published his famous edict, it had already spread into all the provinces subject to the empire.

The Lutherans condemn the Calvinists for breaking the *images* in the churches of the Catholics, looking on it as a kind of sacrilege; and yet they condemn the Romanists (who are professed *image worshippers*) as idolaters: nor can these last keep pace with the Greeks, who go far beyond them in this point; which has occasioned abundance of disputes among them. See *ICONOCLASTS*.

The Mahometans have a perfect aversion to *images*; which was what led them to destroy most of the beautiful monuments of antiquity, both sacred and profane, at Constantinople.

IMAGE, in *Rhetoric*, signifies a lively description of any thing in a discourse. *Images*, in *discourse*, are defined by Longinus, to be, in general, any thoughts proper to produce expressions, and which present a kind of picture to the mind. But, in the more limited sense, he says, *images* are such discourses as come from us, when, by a kind of enthusiasm, or an extraordinary emotion of the soul, we seem to see the things whereof we speak, and present them before the eyes of those who hear us.

Images, in *rhetoric*, have a very different use from what they have among the poets: the end principally proposed in poetry is, astonishment and surprise; whereas the thing chiefly aimed at in prose is, to paint things naturally, and to show them clearly. They have this, however, in common, that they both tend to move, each in its kind.

These *images*, or *pictures*, are of the utmost use, to give weight, magnificence, and strength, to a discourse. They warm and animate it; and, when managed with art, according to Longinus, seem, as it were, to tame and subdue the hearer, and put him in the power of the speaker.

IMAGE, in *Optics*, a figure in the form of any object, made

by the rays of light issuing from the several points of it, and meeting in so many other points, either at the bottom of the eye, or on any other ground, or on any transparent medium, where there is no surface to reflect them. Thus we are said to see all objects by means of their images formed in the eye.

IMAGINATION, a power or faculty of the mind, whereby it conceives and forms ideas of things communicated to it by the outward organs of sense. See METAPHYSICS.

Force of IMAGINATION. See MONSTER.

IMAGO, in *Natural History*, is a name given by Linnæus to the third state of insects, when they appear in their proper shape and colours, and undergo no more transformation.

IMAM, or IMAN, a minister in the Mahometan church, answering to a parish priest among us. The word properly signifies what we call a prelate, *antistes*, one who presides over others; but the Mussulmen frequently apply it to a person who has the care and intendency of a mosque, who is always there at first, and reads prayers to the people, which they repeat after him.

IMAM is also applied, by way of excellence, to the four chiefs or founders of the four principal sects in the Mahometan religion. Thus Ali is the *imam* of the Persian, or of the sect of the Schiaites; Abu-beker the *imam* of the Sunnites, which is the sect followed by the Turks; Saphii, or Saffiy, the *imam* of another sect, &c. The Mahometans do not agree among themselves about this *imamate* or dignity of the *imam*. Some think it of divine right, and attached to a single family, as the pontificate of Aaron. Others hold, that it is indeed of divine right, but deny it to be so attached to any single family as that it may not be transferred to another. They add, that the *imam* is to be clear of all gross sins; and that otherwise he may be deposed, and his dignity may be conferred on another. However this be, it is certain, that after an *imam* has once been owned as such by the Mussulmen, he who denies that his authority comes immediately from God is accounted impious; he who does not obey him is a rebel; and he who pretends to contradict what he says is esteemed a fool, among the orthodox of that religion. The *Imams* have no outward mark of distinction; their habit is the same with that of the Turks in common, except that the turban is a little larger, and folded somewhat differently.

IMAUS, in ancient geography, the largest mountain of Asia, (Strabo); and a part of Taurus, (Pliny); from which the whole of India runs off into a vast plain, resembling Egypt. It extends far and wide through Scythia, as far as to the Mare Glaciale, dividing it into the Hither or *Scythia intra Imaum*, and into the Farther or *Scythia extra Imaum*, (Ptolemy); and also stretching out along the north of India to the eastern ocean, separates it from Scythia. It had various names according to the different countries it ran through: Postellus thinks it is the *Sephar* of Scripture.

IMBECILITY, a languid, infirm state of body, which, being greatly impaired, is not able to perform its usual exercises and functions. Imbecility may also happen to the mind, after a long attention to any abstruse subject.

IMBRICATED, is used, by some botanists, to express the figure of the leaves of some plants, which are hollowed like an *imbrex*, or gutter-tile, or are laid in close series over one another like the tiles of an house.

IMERITIA, a county of Asia, between the Black Sea and the Caspian; bounded on the S. by the Turkish dominions, on the W. by Mingrelia, on the N. by Ossétia, and on the E. by Georgia, of which it is, properly speaking, a part. The late sovereign, the czar Solomon, having forbidden the scandalous traffic of the noblemen in their peasants, offended the Turks so much, that he was driven from his throne, and compelled to live like a wild man, for 16 years, in the woods and caverns of

the mountains, till the Russians reinstated him in his dominions. The revenues arise from a contribution of the peasants in wine, grain, and cattle, and from the tribute of the neighbouring princes. Among the extraordinary sources of revenue, confiscations have a considerable share; but as all this is insufficient for the subsistence of the prince, he usually travels from house to house, living on his vassals, and never changing his quarters till he has consumed every thing eatable. It will, of course, be understood, that the court of Imeritia is not remarkable for splendour, nor the prince's table sumptuously served. His usual fare consists of gom (a species of millet, ground and boiled into a paste), a piece of roasted meat, and some pressed caviare. These he eats with his fingers; forks and spoons being unknown in Imeritia. At table he is frequently employed in judging causes, which he decides at his discretion, there being no law but his own will. He usually wears a coarse dress of a brown colour, with a musket upon his shoulder; but upon solemn occasions he puts on a robe of rich gold brocade, and hangs round his neck a silver chain. He is distinguished from his subjects by riding upon an ass, perhaps the only one in Imeritia, and by wearing boots. He has no regular troops, but can collect an undisciplined army of 6000 men, with no artillery. These troops are drawn together by the sound of trumpet. His civil ordinances are issued every Friday (which is the market day) by one of his servants, who ascends a tree, and with a loud voice proclaims the edict, which is communicated to the people, by each person, upon his return to the place of his abode. The inhabitants, estimated at about 20,000 families, are not collected into towns or villages, but scattered over the country in small hamlets. They are less mixed with foreigners, and handsomer than the other Georgians. They are likewise bolder, and more industrious: they send yearly considerable quantities of wine to the neighbouring parts of Georgia, in leathern bags, carried by horses: but they are without manufactures, very poor and miserable, and cruelly oppressed by their landlords. The Imeritians are of the Greek religion. Their patriarch is generally of the royal family, and can seldom read or write; and the inferior clergy are not better instructed. Their churches are wretched buildings, scarcely to be distinguished from common cottages, but from a paper cross over the principal door, and some paintings of the Virgin and the saints. Cutais is the capital of the present prince, the czar David.

IMITATION, derived from the Latin *imitare*, to "represent or repeat," a sound or action, either exactly or nearly in the same manner as they were originally exhibited.

IMITATION, in music, admits of two different senses. Sound and motion are either capable of imitating themselves by a repetition of their own particular modes; or of imitating other objects of a nobler and more abstracted nature. Nothing perhaps is so purely mental, nothing so remote from external sense, as not to be imitable by music.

"Dramatic or theatrical music (says M. Rousseau) contributes to imitation no less than painting or poetry: it is in this common principle that we must investigate both the origin and the final cause of all the fine arts; as M. le Batteaux has shown. But this imitation is not equally extensive in all the imitative arts. Whatever the imagination can represent to itself is in the department of poetry. Painting, which does not present its pictures to the imagination immediately, but to external sense and to one sense alone, paints only such objects as are discoverable by sight. Music might appear subjected to the same limits with respect to the ear; yet it is capable of painting every thing, even such images as are objects of ocular perception alone: by a magic almost inconceivable, it seems to transform the ears into eyes, and endow them with the double function of perceiving visible objects by the mediums of their own; and it is the greatest miracle of an art, which can only act by mo-

tion, that it can make that very motion represent absolute quiescence. Night, sleep, silence, solitude, are the noble efforts, the grand images, represented by a picturesque music. We know that noise can produce the same effect with silence, and silence the same effect with noise; as when one sleeps at a lecture insipidly and monotonically delivered, but wakes the instant when it ends. But music acts more intimately upon our spirits, in exciting by one sense dispositions similar to those which we find excited by another; and, as the relation between these images cannot be sensible unless the impression be strong, painting, when divested of this energy, cannot restore to music that assistance in imitations which she borrows from it. Though all nature should be asleep, he who contemplates her does not sleep; and the art of the musician consists in substituting, for this image of insensibility in the object, those emotions which its presence excites in the heart of the contemplator. He not only ferments and agitates the ocean, animates the flame to conflagration, makes the fountain murmur in his harmony, calls the rattling shower from heaven, and swells the torrent to relentless rage; but he paints the horrors of a boundless and frightful desert, involves the subterraneous dungeon in tenfold gloom, soothes the tempest, tranquillizes the disturbed elements, and from the orchestra diffuses a recent fragrance through imaginary groves; nay, he excites in the soul the same emotions which we feel from the immediate perception and full influence of these objects."

Under the word *Harmony*, Rousseau has said, that no assistance can be drawn from thence, no original principle which leads to musical imitation; since there cannot be any relation between chords and the objects which the composer would paint, or the passions which he would express. In the article *Melody*, he imagines he has discovered that principle of imitation which harmony cannot yield, and what resources of nature are employed by music in representing these objects and these passions. To this, however, many objections might be urged.

"Imitation (continues Rousseau), in its technical sense, is a reiteration of the same air, or of one which is similar, in several parts where it is repeated by one after the other, either in unison, or at the distance of a fourth, a fifth, a third, or any other interval whatever. The imitation may be happily enough pursued even though several notes should be changed; provided the same air may always be recognised, and that the composer does not deviate from the laws of proper modulation. Frequently, in order to render the imitation more sensible, it is preceded by a general rest, or by long notes which seem to obliterate the impression formerly made by the air till it is renewed with greater force and vivacity by the commencement of the imitation. The imitation may be treated as the composer chooses; it may be abandoned, resumed, or another begun, at pleasure; in a word, its rules are as much relaxed as those of the fugue are severe: for this reason, it is despised by the most eminent masters; and every imitation of this kind too much affected, almost always betrays a novice in composition."

IMITATION, in oratory, is an endeavour to resemble a speaker or writer in those qualities with regard to which we propose them to ourselves as patterns. The first historians among the Romans, says Cicero, were very dry and jejune, till they began to imitate the Greeks, and then they became their rivals. It is well known how clo'ely Virgil has imitated Homer in his *Aeneid*, Hesiod in his *Georgics*, and Theocritus in his *Eclogues*. Terence copied after Menander; and Plautus after Epicarmus, as we learn from Horace, lib. ii. Ep. ad August. who himself owes many of his beauties to the Greek lyric poets. Cicero appears, from many passages in his writings, to have imitated the Greek orators. Thus Quintilian says of him, that he has expressed the strength and sublimity of Demosthenes, the copiousness of Plato, and the delicacy of Isocrates.

VOL. IV.

IMMACULATE, something without stain, chiefly applied to the conception of the holy Virgin. See *Immaculate CONCEPTION*.

IMMATERIAL, something devoid of matter, or that is pure spirit. See *METAPHYSICS*.

IMMEMORIAL, an epithet given to the time or duration of any thing whose beginning we know nothing of. In a legal sense, a thing is said to be *of time immemorial*, or *time out of mind*, that was before the reign of our king Edward II.

IMMER, the most easterly island of all the New Hebrides in the South Sea. It lies about four leagues from Tanna, and seems to be about five leagues in circumference; it is of a considerable height, with a flat top.

IMMERETTA, or IMERITIA. See *IMERITIA*.

IMMERSION, in astronomy, is when a star or planet is so near the sun with regard to our observations, that we cannot see it; being, as it were, enveloped and hid in the rays of that luminary. It also denotes the beginning of an eclipse of the moon, or that moment when the moon begins to be darkened, and to enter into the shadow of the earth.

IMMOLATION, a ceremony used in the Roman sacrifices; in consisted in throwing upon the head of the victim some sort of corn and frankincense, together with the *mola*, or salt cake, and a little wine.

IMMUNITY, a privilege or exemption from some office, duty, or imposition, as an exemption from tolls, &c. Immunity is more particularly understood of the liberties granted to cities and communities.

IMOLA, a populous town of Italy, in Romagna, with a bishop's see; seated on the river Santerno, 45 miles N. by E. of Florence. E. lon. 11. 45. N. lat. 44. 28.

IMPALE, in heraldry, is to conjoin two coats of arms pale-wise. Women impale their coats of arms with those of their husbands. See *HERALDRY*. To impale cities, camps, fortifications, &c. is to inclose them with palisadoes.

To IMPALE, or *Empale*, signifies also to put to death by spitting a criminal on a stake fixed upright.

IMPANATION, a term used by divines to signify the opinion of the Lutherans with regard to the eucharist, who believe that the species of bread and wine remain together with the body of our Saviour after consecration.

IMPANNELLING, in law, signifies the writing down or entering into a parchment, list, or schedule, the names of a jury summoned by the sheriff to appear for such public services as juries are employed in.

IMPARLANCE, in law, a petition in court for a day to consider or advise what answer the defendant shall make to the plaintiff's action; and is the continuance of the cause till another day, or a longer time given by the court.

IMPASSIBLE, that which is exempt from suffering; or which cannot undergo pain, or alteration. The Stoics place the soul of their wise man in an impassible, imperturbable state. See *APATHY*.

IMPASTATION, the mixture of various materials of different colours and consistencies, baked or bound together with some cement, and hardened either by the air or by fire.

IMPATIENS, TOUCH-ME-NOT, and *Balsamine*. See *BALSAMINE*.

IMPEACHMENT, an accusation and prosecution for treason and other crimes and misdemeanors. Any member of the lower house of parliament may impeach any one belonging either to that body or to the house of lords. The method of proceeding is to exhibit articles on the behalf of the commons, by whom managers are appointed to make good their charge. These articles are carried to the lords, by whom every person impeached by the commons is always tried; and if they find

him guilty, no pardon under the great seal can be pleaded to such an impeachment. 12 Will. III. cap. ii.

IMPECCABLES, in church history, a name given to those heretics who boasted that they were impeccable, and that there was no need of repentance: such were the Gnostics, Priscillianists, &c.

IMPECCABILITY, the state of a person who cannot sin: or a grace, privilege, or principle, which puts him out of a possibility of sinning. The schoolmen distinguish several kinds and degrees of impeccability: that of God belongs to him by nature: that of Jesus Christ, considered as man, belongs to him by the hypostatical union: that of the blessed is a consequence of their condition: that of men is the effect of a confirmation in grace, and is rather called *impeccance* than *impeccability*: accordingly divines distinguish between these two: this distinction is found necessary in the disputes against the Pelagians, in order to explain certain terms in the Greek and Latin fathers, which without this distinction are easily confounded.

IMPEDIMENTS, in law, are such hindrances as put a stop or stay to a person's seeking for his right by a due course of law. Persons under impediments are those under age or coverture, *non compos mentis*, in prison, beyond sea, &c. who, by a saving in our laws, have time to claim and prosecute their rights, after the impediments are removed, in case of fines levied, &c.

IMPENETRABILITY, in philosophy, that property of body, whereby it cannot be pierced by another: thus, a body which so fills a space as to exclude all others, is said to be impenetrable.

IMPERATIVE, one of the moods of a verb, used when we would command, entreat, or advise: thus, *go read, take pity, be advised*, are imperatives in our language. But in the learned languages this mood has a peculiar termination to distinguish it from others, as *i*, or *ito*, "go;" *lege*, or *legito*, "read," &c. and not only so, but the termination varies, according as you address one or more persons, as *audi* and *audite*; *αγγελω*, *αγγελων*, *αγγελωσαν*, &c.

IMPERATOR, in Roman antiquity, a title of honour conferred on victorious generals by their armies, and afterwards confirmed by the senate. *Imperator* was also the title adopted by the Roman emperors.

IMPERATORIA, MASTERWORT; a genus of the digynia order, belonging to the pentandria class of plants; and in the natural method ranking under the 45th order *Umbellatæ*. The fruit is roundish, compressed in the middle, gibbous, and surrounded with a border; the petals are inflexo-emarginated. There is but one species, *viz.* the ostruthium, a native of the Austrian and Styrian Alps, and other mountainous places of Italy. Mr. Lightfoot informs us, that he has found it in several places on the banks of the Clyde in Scotland; but whether indigenous or not, is uncertain. The root is as thick as a man's thumb, running obliquely in the ground; it is fleshy, aromatic, and has a strong acrid taste, biting the tongue like pellitory of Spain: the leaves arise immediately from the root; they have long foot-stalks, dividing into three very short ones at the top, each sustaining a trilobate leaf indented on the border. The footstalks are deeply channelled, and, when broken, emit a rank odour. The flower-stalks rise about two feet high, dividing into two or three branches, each being terminated by a pretty large umbel of white flowers whose petals are split; these are succeeded by oval compressed seeds, somewhat like those of dill, but larger. The plant is cultivated in gardens for the sake of its roots, which are used in medicine. It may be propagated either by seeds, or by parting the roots in autumn. They thrive best in a shady situation. The root has a flavour similar to that of angelica, and is esteemed a good sudorific. There are instances of its having cured the ague when the bark had failed. It should be dug up in winter, and a strong infusion made in wine.

IMPERFECT TENSE, in grammar, a tense that denotes some preterite case, or denotes the thing to be at that time present, and not quite finished; as *scribebam*, "I was writing." See GRAMMAR.

IMPERIAL, something belonging to an emperor, or empire. See EMPEROR and EMPIRE. Thus we say, his *imperial* majesty, the *imperial* crown, an *imperial* city, &c.

IMPERIAL Crown. See HERALDRY, p. 216.

IMPERIAL Chamber, is a sovereign court, established for the affairs of the immediate states of the Empire. See CHAMBER and GERMANY.

IMPERIAL Cities, in Germany, are those which own no other head but the Emperor. These are a kind of little commonwealths; the chief magistrate whereof does homage to the emperor, but in other respects, and in the administration of justice, is sovereign. Imperial cities have a right of coining money, and of keeping forces and fortified places. Their deputies assist at the imperial diets, where they are divided into two branches, that of the Rhine and that of Suabia. There were formerly 22 in the former, and 37 in the latter; but there are now only 48 in all.

IMPERIAL Diet, is an assembly or convention of all the states of the Empire. See DIET and GERMANY.

IMPERIALI (JOHN BAPTIST), a celebrated physician of Vicenza, where he was born in 1568. He composed several esteemed works both in prose and verse, written in good Latin; and died in 1623.

IMPERSONAL VERB, in grammar, a verb to which the nominative of any certain person cannot be prefixed; or, as others define it, a verb destitute of the two first and primary persons, as *decet*, *oportet*, &c. The impersonal verbs of the active voice end in *t*, and those of the passive in *tur*; they are conjugated through the third person singular of almost all the tenses and moods: they want the imperative, instead of which we use the present of the subjunctive; as *paniteat*, *pugnetur*, &c. nor, but a few excepted, are they to be met with in the supines, participles, or gerunds.

IMPETIGO, in Surgery, an extreme roughness and foulness of the skin, attended with an itching and plentiful eruption. The *impetigo* is a species of dry pruriginous itch, wherein scales or scurf appear on the skin, of which, strictly speaking, it is a disease, though connected with a peculiar state of the constitution. For the cure, both internal and external means must be adopted.

IMPETRATION, the act of obtaining any thing by request or prayer. This term, however, was more particularly used in our statutes for the pre-obtaining of benefices and church-offices in England from the court of Rome, which did belong to the disposal of the king and other lay-patrons of the realm; the penalty whereof is the same with that of provisors, 25 Edw. III.

IMPETUS, in mechanics, the force with which one body strikes or impels another.

IMPLICATION, in law, is where something is implied that is not expressed by the parties themselves in their deeds, contracts, or agreements.

To IMPLY, or CARRY, in Music. Authors have used these as synonymous terms in music. They are intended to signify those sounds which ought to be the proper concomitants of any note, whether by its own nature, or by its position in artificial harmony. Thus every note, considered as an independent sound, may be said to *carry* or *imply* its natural harmonics, that is to say, its octave, its twelfth, and its seventeenth; or, when reduced, its eighth, its fifth, and its third. But the same sound, when considered as constituting any part of harmony, is subjected to other laws and different limitations. It can then only be said to *carry* or *imply* such simple sounds, or complications.

of sound, as the preceding and subsequent chords admit or require. For these the laws of melody and harmony must be consulted. See MELODY and HARMONY.

IMPORTATION, in commerce, the bringing merchandise into a kingdom from foreign countries; in contradistinction to exportation. See EXPORTATION. Respecting the laws which relate to importation, see *Custom-house* LAWS.

IMPOSITION of hands, an ecclesiastical action by which a bishop lays his hand on the head of a person, in ordination, confirmation, or in uttering a blessing. This practice is also frequently observed by the dissenters at the ordination of their ministers, when all the ministers present place their hands on the head of him whom they are ordaining, while one of them prays for a blessing on him and his future labours. This some of them retain as an ancient practice, justified by the example of the apostles, when no extraordinary gifts are conveyed. However, they are not agreed as to the propriety of this ceremony; nor do they consider it as an essential part of ordination. Imposition of hands was a Jewish ceremony, introduced not by any divine authority, but by custom; it being the practice among those people, whenever they prayed to God for any person, to lay their hands on his head. Our Saviour observed the same custom, both when he conferred his blessing on children and when he cured the sick; adding prayer to the ceremony. The apostles likewise laid hands on those upon whom they bestowed the Holy Ghost. The priests observed the same custom when any one was received into their body. And the apostles themselves underwent the imposition of hands afresh every time they entered upon any new design. In the ancient church, imposition of hands was even practised on persons when they married, which custom the Abyssinians still observe.

IMPOSSIBLE, that which is not possible, or which cannot be done or effected. A proposition is said to be impossible, when it contains two ideas which mutually destroy each other, and which can neither be conceived nor united together. Thus it is impossible that a circle should be a square; because we conceive clearly that squareness and roundness destroy each other by the contrariety of their figure. There are two kinds of impossibilities, *physical* and *moral*. Physical impossibility is that which is contrary to the law of nature. A thing is morally impossible, when of its own nature it is possible, but yet is attended with such difficulties, as that, all things considered, it appears impossible. Thus it is morally impossible that all men should be virtuous; or that a man should throw the same number with three dice a hundred times successively. A thing which is impossible in law, is the same with a thing impossible in nature: and if any thing in a bond or deed be impossible to be done, such deed, &c. is void. 21 Car. I.

IMPOST, in law, signifies in general a tribute or custom, but is more particularly applied to signify that tax which the crown receives for merchandizes imported into any port or haven.

IMPOSTHUME, or abscess, a collection of matter or pus in any part of the body, either owing to previous inflammation in that part, or to a translocation of it from some other part. See SURGERY.

IMPOSTOR, in a general sense, denotes a person who cheats by a fictitious character. Thus, *religious impostors* are such as falsely pretend to an extraordinary commission from heaven; and who terrify and abuse the people with false denunciations of judgements. These are punishable in the temporal courts with fine, imprisonment, and infamous corporal punishment.

IMPOTENCE, or IMPOTENCY, in general, denotes want of strength, power, or means, to perform any thing.

Divines and philosophers distinguish two sorts of impotency; natural and moral. The first is a want of some physical princi-

ple, necessary to an action; or where a being is absolutely defective, or not free and at liberty to act: The second only imports a great difficulty; as a strong habit to the contrary, a violent passion, or the like.

IMPOTENCY is a term more particularly used for an inability to coition. Impotence with respect to men is the same as sterility in women, that is, an inability of propagating the species. There are many causes of impotence; as, a natural defect in the organs of generation, which seldom admits of a cure: accidents or diseases; and in such cases the impotence may or may not be remedied, according as these are curable or otherwise. The most common causes, and almost the only, are, early and immoderate venery, or the practice of masturbation in youth. We have instances, however, of unfitness for generation in men by an impediment to the ejection of the semen in coition, from a wrong direction which the orifice at the *verumontanum* got, whereby the seed was thrown up into the bladder. M. Petit cured one patient under such a difficulty of emission, by making an incision like to that commonly made in the great operation for the stone.

On this subject we have some curious and original observations by the late Mr. John Hunter in his Treatise on the Venereal Disease. He considers impotency as depending upon two causes. One he refers to the mind; the other to the organs.

1. *As to impotency depending upon the mind*, he observes, that as the "parts of generation are not necessary for the existence or support of the individual, but have a reference to something else in which the mind has a principal concern; so a complete action in those parts cannot take place without a perfect harmony of body and of mind: that is, there must be both a power of body and disposition of mind; for the mind is subject to a thousand caprices, which affect the actions of these parts.

"Copulation is an act of the body, the spring of which is in the mind; but it is not volition: and according to the state of the mind, so is the act performed. To perform this act well, the body should be in health, and the mind should be perfectly confident of the powers of the body: the mind should be in a state entirely disengaged from every thing else: it should have no difficulties, no fears, no apprehensions, not even an anxiety to perform the act well; for even this anxiety is a state of mind different from what should prevail; there should not be even a fear that the mind itself may find a difficulty at the time the act should be performed. Perhaps no function of the machine depends so much upon the state of the mind as this.

"The will and reasoning faculty have nothing to do with this power; they are only employed in the act, so far as voluntary parts are made use of: and if they ever interfere, which they sometimes do, it often produces another state of mind which destroys that which is proper for the performance of the act; it produces a desire, a wish, a hope, which are all only diffidence and uncertainty, and create in the mind the idea of a possibility of the want of success, which destroys the proper state of mind, or necessary confidence.

"There is perhaps no act in which a man feels himself more interested, or is more anxious to perform well; his pride being engaged in some degree, which if within certain bounds would produce a degree of perfection in an act depending upon the will, or an act in voluntary parts; but when it produces a state of mind contrary to that state on which the perfection of the act depends, a failure must be the consequence.

"The body is not only rendered incapable of performing this act by the mind being under the above influence, but also by the mind being, though perfectly confident of its power, yet conscious of an impropriety in performing it: this, in many cases, produces a state of mind which shall take away all power. The state of a man's mind respecting his sister takes away all power. A conscientious man has been known to lose his powers

on finding the woman he was going to be connected with unexpectedly a virgin.

“ Shedding tears arises entirely from the state of the mind, although not so much a compound action as the act in question; for none are so weak in body that they cannot shed tears; it is not so much a compound action of the mind and strength of body joined, as the other act is; yet if we are afraid of shedding tears, or are desirous of doing it, and that anxiety is kept up through the whole of an affecting scene, we certainly shall not shed tears, or at least not so freely as would have happened from our natural feelings.

“ From this account of the necessity of having the mind independent respecting the act, we must see that it may very often happen that the state of mind will be such as not to allow the animal to exert its natural powers; and every failure increases the evil. We must also see, from this state of the case, that this act must be often interrupted; and the true cause of this interruption not being known, it will be laid to the charge of the body, or want of powers. As these cases do not arise from real inability, they are to be carefully distinguished from such as do; and perhaps the only way to distinguish them is, to examine into the state of mind respecting this act. So trifling often is the circumstance which shall produce this inability depending on the mind, that the very desire to please shall have that effect, as in making the woman the sole object to be gratified.

“ Cases of this kind we see every day; one of which I shall relate as an illustration of this subject, and also of the method of cure. A gentleman told me, that he had lost his virility. After above an hour's investigation of the case, I made out the following facts: that he had at unnecessary times strong erections, which showed that he had naturally this power; that the erections were accompanied with desire, which are all the natural powers wanted; but that there was still a defect somewhere, which I supposed to be from the mind. I inquired if all women were alike to him? His answer was, No; some women he could have connection with as well as ever. This brought the defect, whatever it was, into a smaller compass: and it appeared there was but one woman that produced this inability, and that it arose from a desire to perform the act with this woman well: which desire produced in the mind a doubt or fear of the want of success, which was the cause of the inability of performing the act. As this arose entirely from the state of the mind produced by a particular circumstance, the mind was to be applied to for the cure; and I told him that he might be cured, if he could perfectly rely on his own power of self-denial. When I explained what I meant, he told me that he could depend upon every act of his will or resolution. I then told him, that if he had a perfect confidence in himself in that respect, he was to go to bed to this woman, but first promise to himself that he would not have any connection with her for six nights, let his inclinations and powers be what they would; which he engaged to do, and also to let me know the result. About a fortnight after he told me, that this resolution had produced such a total alteration in the state of his mind, that the power soon took place; for, instead of going to bed with the fear of inability, he went with fears that he should be possessed with too much desire, too much power, so as to become uneasy to him: which really happened; for he would have been happy to have shortened the time; and when he had once broke the spell, the mind and powers went on together, and his mind never returned to its former state.”

2. *Of impotency from a want of proper correspondence between the actions of the different organs.*—Our author, in a former part of his Treatise, when considering the diseases of the urethra and bladder, had remarked, that every organ in an animal body, without exception, was made up of different parts, whose functions or actions were totally different from one another, al-

though all tending to produce one ultimate effect. In all such organs when perfect (he observes), there is a succession of motions, one naturally arising out of the other, which in the end produces the ultimate effect; and an irregularity alone in these actions will constitute disease, at least will produce very disagreeable effects, and often totally frustrate the intention of the organ. This principle Mr. Hunter, on the present occasion, applies to the “actions of the testicles and penis: for we find that an irregularity in the actions of these parts sometimes happens in men, producing impotence; and something similar probably may be one cause of barrenness in women.

“ In men, the parts subservient to generation may be divided into two; the essential, and the accessory. The testicles are the essential; the penis, &c. the accessory. As this division arises from their uses or actions in health, which exactly correspond with one another, a want of exactness in the correspondence or susceptibility of those actions may also be divided into two: where the actions are reversed, the accessory taking place without the first or essential, as in erections of the penis where neither the mind nor the testicles are stimulated to action; and the second is where the testicles perform the action of secretion too readily for the penis, which has not a corresponding erection. The first is called *priapism*; and the second is what ought to be called *seminal weakness*.

“ The mind has considerable effect on the correspondence of the actions of these two parts: but it would appear in many instances, that erections of the penis depend more on the state of the mind than the secretion of the semen does; for many have the secretion, but not the erection; but in such, the want of erection appears to be owing to the mind only.

“ Priapism often arises spontaneously; and often from visible irritation of the penis, as in the venereal gonorrhœa, especially when violent. The sensation of such erections is rather uneasy than pleasant; nor is the sensation of the glans at the time similar to that arising from the erections of desire, but more like to the sensation of the parts immediately after coition. Such as arise spontaneously are of more serious consequence than those from inflammation, as they proceed probably from causes not curable in themselves or by any known methods. The priapism arising from inflammation of the parts, as in a gonorrhœa, is attended with nearly the same symptoms; but generally the sensation is that of pain, proceeding from the inflammation of the parts. It may be observed, that what is said of priapism is only applicable to it when a disease in itself, and not when a symptom of other diseases, which is frequently the case.

“ The common practice in the cure of this complaint is to order all the nervous and strengthening medicines; such as bark, valerian, musk, camphor, and also the cold bath. I have seen good effects from the cold bath; but sometimes it does not agree with the constitution, in which case I have found the warm bath of service. Opium appears to be a specific in many cases; from which circumstance I should be apt, upon the whole, to try a soothing plan.

“ Seminal weakness, or a secretion and emission of the semen without erections, is the reverse of a priapism, and is by much the worst disease of the two. There is great variety in the degrees of this disease, there being all the gradations from the exact correspondence of the actions of all the parts to the testicles acting alone; in every case of the disease, there is too quick a secretion and evacuation of the semen. Like to the priapism, it does not arise from desires and abilities; although when mild it is attended with both, but not in a due proportion; a very slight desire often producing the full effect. The secretion of the semen shall be so quick, that simple thought, or even toying, shall make it flow.

“ Dreams have produced this evacuation repeatedly in the same night; and even when the dreams have been so slight, that there has been no consciousness of them when the sleep has been bro-

ken by the act of emission. I have known cases where the testicles have been so ready to secrete, that the least friction on the glans has produced an emission: I have known the simple action of walking or riding produce this effect, and that repeatedly in a very short space of time.

"A young man, about four or five and twenty years of age, not so much given to venery as most young men, had these last-mentioned complaints upon him. Three or four times in the night he would emit; and if he walked fast, or rode on horseback, the same thing would happen. He could scarcely have connection with a woman before he emitted, and in the emission there was hardly any spasm. He tried every supposed strengthening medicine, as also the cold bath and sea-bathing, but with no effect. By taking 20 drops of laudanum on going to bed, he prevented the night emissions; and by taking the same quantity in the morning, he could walk or ride without the before-mentioned inconvenience. I directed this practice to be continued for some time, although the disease did not return, that the parts might be accustomed to this healthy state of action; and I have reason to believe the gentleman is now well. It was found necessary, as the constitution became more habituated to the opiate, to increase the dose of it.

"The spasms, upon the evacuation of the semen in such cases, are extremely slight, and a repetition of them soon takes place; the first emission not preventing a second; the constitution being all the time but little affected*. When the testicles act alone, without the accessory parts taking up the necessary and natural consequent action, it is still a more melancholy disease; for the secretion arises from no visible or sensible cause, and does not give any visible or sensible effect, but runs off similar to involuntary stools or urine. It has been observed that the semen is more fluid than natural in some of these cases.

"There is great variety in the diseased actions of these parts; of which the following case may be considered as an example: A gentleman has had a stricture in the urethra for many years, for which he has frequently used a bougie, but of late has neglected it. He has had no connection with women for a considerable time, being afraid of the consequences. He has often in his sleep involuntary emissions, which generally awake him at the paroxysm; but what surprises him most is, that often he has such without any semen passing forwards through the penis, which makes him think that at those times it goes backwards into the bladder. This is not always the case, for at other times the semen passes forwards. At the time the semen seems to pass into the bladder, he has the erection, the dream; and is awaked with the same mode of action, the same sensation, and the same pleasure, as when it passes through the urethra, whether dreaming or waking. My opinion is, that the same irritation takes place in the bulb of the urethra without the semen, that takes place there when the semen enters, in consequence of all the natural preparatory steps, whereby the very same actions are excited as if it came into the passage: from which one would suppose, that either semen is not secreted; or, if it be, that a retrograde motion takes place in the actions of the acceleratores urinæ. But if the first be the case, then we may suppose, that in the natural state the actions of those muscles do not arise simply from the stimulus of the semen in the part, but from their action being a termination of a preceding one making part of a series of actions. Thus they may depend upon the friction, or the imagination of a friction, on the penis; the testicles not doing their part, and the spasm in such cases arising from the friction and not from the secretion. In many of those cases of irregularity, when the erection is not strong, it shall go off with-

out the emission; and at other times an emission shall happen almost without an erection; but these arise not from debility, but affections of the mind.

"In many of the preceding cases, washing the penis, scrotum, and perinæum, with cold water, is often of service; and to render it colder than we find it in some seasons of the year, common salt may be added to it, and the parts washed when the salt is almost dissolved."

IMPOTENCY is a canonical disability, to avoid marriage in the spiritual court. The marriage is not void *ab initio*, but voidable only by sentence of separation during the life of the parties.

IMPRECATION, derived from *in*, and *precor* "I pray;" a curse, or wish that some evil may befall any one. The ancients had their goddesses called *Imprecations*, in Latin *Dire*, i. e. *Deorum iræ*, who were supposed to be the executioners of evil consciences. They were called *Dire* in heaven, *Furies* on earth, and *Eumenides* in hell. The Romans owned but three of these *Imprecations*, and the Greeks only two. They invoked them with prayers and pieces of verses to destroy their enemies.

IMPREGNATION, the getting a female with child. See MIDWIFERY; and ANATOMY, p. 208 and 209. The term *impregnation* is also used in pharmacy, for communicating the virtues of one medicine to another, whether by mixture, cocction, digestion, &c.

IMPRESSING SEAMEN. The power of impressing sea-faring men for the sea-service by the king's commission, has been a matter of some dispute, and submitted to with great reluctance; though it hath very clearly and learnedly been shown by Sir Michael Foster, that the practice of impressing, and granting powers to the admiralty for that purpose, is of very ancient date, and hath been uniformly continued by a regular series of precedents to the present time: whence he concludes it to be part of the common law. The difficulty arises from hence, that no statute has expressly declared this power to be in the crown, though many of them very strongly imply it. The statute 2 Ric. II. c. 4. speaks of mariners being arrested and retained for the king's service, as of a thing well known, and practised without dispute; and provides a remedy against their running away. By a later statute, if any waterman, who uses the river Thames, shall hide himself during the execution of any commission of pressing for the king's service, he is liable to heavy penalties. By another (5 Eliz. c. 5.) no fisherman shall be taken by the queen's commission to serve as a mariner; but the commission shall be first brought to two justices of the peace, inhabiting near the sea-coast where the mariners are to be taken, to the intent that the justices may choose out and return such a number of able-bodied men, as in the commission are contained, to serve her majesty. And by others, especial protections are allowed to seamen in particular circumstances, to prevent them from being impressed. Ferry-men are also said to be privileged from being impressed, at common law. All which do most evidently imply a power of impressing to reside somewhere; and if any where, it must, from the spirit of our constitution, as well as from the frequent mention of the king's commission, reside in the crown alone.—After all, however, this method of manning the navy is to be considered as only defensible from public necessity, to which all private considerations must give way.

The following persons are exempted from being impressed: Apprentices for three years; the master, mate, and carpenter, and one man for every 100 tons, of vessels employed in the coal trade; all under 18 years of age, and above 55; foreigners in merchant ships and privateers; landmen betaking themselves to sea for two years; seamen in the Greenland fishery, and har-

* "It is to be considered, that the constitution is commonly affected by the spasms only, and in proportion to their violence, independent of the secretion and evacuation of the semen. But in some cases even the erection going off without the spasms on the emission, shall produce the same debility as if they had taken place."

pooners, employed, during the interval of the fishing season, in the coal-trade, and giving security to go to the fishing next season.

IMPRESSION is applied to the species of objects which are supposed to make some mark or impression on the senses, the mind, and the memory. The Peripatetics assert, that bodies emit species resembling them, which are conveyed to the common *sensorium*, and they are rendered intelligible by the active intellect; and, when thus spiritualized, are called *expressions*, or *express species*, as being expressed from the others.

IMPRESSION also denotes the *edition* of a book, regarding the mechanical part only; whereas *edition*, besides this, takes in the care of the editor who corrected or augmented the copy, adding notes, &c. to render the work more useful.

IMPRISONMENT, the state of a person restrained of his liberty, and detained under the custody of another. No person is to be imprisoned but as the law directs, either by the command or order of a court of record, or by lawful warrant; or by the king's process, on which one may be lawfully detained. And at common law, a person could not be imprisoned unless he were guilty of some force and violence, for which his body was subject to imprisonment, as one of the highest executions. Where the law gives power to imprison, in such case it is justifiable, provided he that does it in pursuance of a statute exactly pursues the statute in the manner of doing it; for otherwise it will be deemed false imprisonment, and of consequence it is unjustifiable. Every warrant of commitment for imprisoning a person ought to run, "till delivered by due course of law," and not "until farther order;" which has been held ill: and thus it also is, where one is imprisoned on a warrant not mentioning any cause for which he is committed. See ARREST and COMMITMENT.

False Imprisonment. Every confinement of the person is an imprisonment, whether it be in a common prison, or in a private house, or in the stocks, or even by forcibly detaining one in the public streets. Unlawful or *false imprisonment* consists in such confinement or detention without sufficient authority: which authority may arise either from some process from the courts of justice; or from some warrant from a legal power to commit, under his hand and seal, and expressing the cause of such commitment; or from some other special cause warranted, for the necessity of the thing, either by common law or act of parliament: such as the arresting of a felon by a private person without warrant, the impressing of mariners for misbehaviour in the public highways. False imprisonment also may arise by executing a lawful warrant or process at an unlawful time, as on a Sunday; or in a place privileged from arrests, as in the verge of the king's court. This is the injury. The remedy is of two sorts; the one *removing* the injury, the other *making satisfaction* for it.

The means of *removing* the actual injury of false imprisonment are four-fold, 1. By writ of MAINPRIZE. 2. By writ *De ODIO et Atia*. 3. By writ *De HOMINE Replegiando*. 4. By writ of HABEAS Corpus. See those articles.

The *satisfactory* remedy for this injury for false imprisonment is by an action of trespass *vi et armis*, usually called an *action of false imprisonment*; which is generally, and almost unavoidably, accompanied with a charge of assault and battery also: and therein the party shall recover damages for the injuries he has received; and also the defendant is, as for all other injuries committed with force, or *vi et armis*, liable to pay a fine to the king for the violation of the public peace.

IMPROMPTU, or IMPROMPTU, a Latin word frequently used among the French, and sometimes in English, to signify a piece made off-hand, or *extempore*, without any previous meditation, by mere force and vivacity of imagination.

IMPROPRIATION, in ecclesiastical law. See APPROPRIATION.

IMPURITY, in the law of Moses, is any legal defilement.

Of these there were several sorts. Some were voluntary, as the touching a dead body, or any animal that died of itself, or any creature that was esteemed unclean; or the touching things holy by one who was not clean, or was not a priest; the touching one who had a leprosy, one who had a gonorrhœa, or who was polluted by a dead carcase, &c. Sometimes these impurities were involuntary; as when any one inadvertently touched bones, or a sepulchre, or any thing polluted; or fell into such diseases as pollute, as the leprosy, &c.

The beds, clothes, and moveables, which had touched any thing unclean, contracted also a kind of impurity, and in some cases communicated it to others. These legal pollutions were generally removed by bathing, and lasted no longer than the evening. The person polluted plunged over head in the water, and either had his clothes on when he did so, or washed himself and his clothes separately. Other pollutions continued seven days, as that which was contracted by touching a dead body. That of women in their monthly courses lasted till this was over with them. Other impurities lasted 40 or 50 days; as that of women who were recently delivered, who were unclean 40 days after the birth of a boy, and 50 after the birth of a girl. Others again lasted till the person was cured.

Many of these pollutions were expiated by sacrifices; and others by a certain water or lye made with the ashes of a red heifer, sacrificed on the great day of expiation. When the leper was cured, he went to the temple, and offered a sacrifice of two birds, one of which was killed and the other set at liberty. He who had touched a dead body, or had been present at a funeral, was to be purified with the water of expiation, and this upon pain of death. The woman who had been delivered, offered a turtle and a lamb for her expiation; or, if she was poor, two turtles or two young pigeons.

These impurities, which the law of Moses has expressed with the greatest accuracy and care, were only figures of other more important impurities, such as the sins and iniquities committed against God, or faults committed against our neighbour. The saints and prophets of the Old Testament were sensible of this; and our Saviour, in the gospel, has strongly inculcated, that they are not outward and corporeal pollutions which render us unacceptable to God, but such inward pollutions as infect the soul, and are violations of justice, truth, and charity.

INALIENABLE, that which cannot be legally alienated or made over to another: thus the dominions of the king, the revenues of the church, the estates of a minor, &c. are inalienable, otherwise than with a reserve of the right of redemption.

INANITION, among physicians, denotes the state of the stomach when empty, in opposition to repletion.

INANITY, the school term for emptiness or absolute vacuity, and implies the absence of all body and matter whatsoever, so that nothing remains but mere space.

INARCHING, in gardening, is a method of grafting, commonly called *grafting by approach*; and is used when the stock intended to graft on, and the tree from which the graft is to be taken, stand so near, or can be brought so near, that they may be joined together. The branch to be inarched is to be fitted to that part of the stock where it is to be joined; the rind and wood are to be pared away on one side for the length of three inches, and the stock or branch where the graft is to be united must be served in the same manner, so that the two may join equally and the sap meet. A little tongue is then to be cut upwards in the graft, and a notch made in the stock to admit it; so that when they are joined, the tongue will prevent their slipping, and the graft will more closely unite to the stock. Having thus brought them exactly together, they must be tied with some bafs, or worked, or other soft tying: and then the place must be covered with some grafting clay, to prevent the air from drying the wound, and the wet from rotting the stock. A stake must be

fixed in the ground, to which both the stock and the graft must be tied to prevent the winds from displacing them. When they have remained in this state for four months, they will be sufficiently united, and the graft may then be cut off from the mother-tree, observing to slope it close to the stock; and at this time there should be fresh clay laid all round the part. This operation should be performed in April or May, that the graft may be perfectly united to the stock before the ensuing winter. Inarching is chiefly practised upon oranges, myrtles, jessamines, walnuts, firs, and some other trees which do not succeed well in the common way of grafting. But it is a wrong practice when orange-trees are designed to grow large, for these are seldom long-lived after the operation.

INAUGURATION, the coronation of an emperor or king, or the consecration of a prelate: so called from the ceremonies used by the Romans when they were received into the college of augurs.

INCA, or **YNCA**, a name given by the natives of Peru to their kings and the princes of the blood. Pedro de Cieca, in his Chronicles of Peru, gives the origin of the incas; and says, that that country was for a long time the theatre of all manner of crimes, of war, dissension, and the most dreadful disorders, till at last two brothers appeared, one of whom was called *Mangoapa*. Of this person the Peruvians relate many wonderful stories. He built the city of Cusco, made laws, established order and harmony by his wife regulations; and he and his descendants took the name of *inca*, which signifies king or great lord. These incas became so powerful, that they rendered themselves masters of all the country from Pasto to Chili, and from the river Maule on the south to the river Augasmago on the north; these two rivers forming the bounds of their empire, which extended above thirteen hundred leagues in length. This they enjoyed till the divisions between Inca Guascar and Atabalipa; which the Spaniards laying hold of, made themselves masters of the country, and destroyed the empire of the incas.

INCAMERATION, a term used in the chancery of Rome, for the uniting of lands, revenues, or other rights, to the pope's domain.

INCANTATION, denotes certain ceremonies, accompanied with a formula of words, and supposed to be capable of raising devils, spirits, &c. See **CHARM**, &c.

INCAPACITY, in the canon-law, is of two kinds: 1. The want of a dispensation for age in a minor, for legitimization in a bastard, and the like: this renders the provision of a benefice void in its original. 2. Crimes and heinous offences, which annual provisions at first valid.

INCARNATION, in theology, signifies the act whereby the Son of God assumed the human nature; or the mystery by which Jesus Christ, the eternal word, was made man, in order to accomplish the work of our salvation. The era used among Christians, whence they number their years, is the time of the incarnation, that is, of Christ's conception in the virgin's womb. This era was first established by Dionysius Exiguus, about the beginning of the sixth century, till which time the era of Dioclesian had been in use. Some time after this, it was considered, that the years of a man's life were not numbered from the time of his conception, but from that of his birth: which occasioned them to postpone the beginning of this era for the space of one year, retaining the cycle of Dionysius entire in every thing else. At Rome they reckon their years from the incarnation or birth of Christ, that is, from the 25th of December, which custom has obtained from the year 1431. In France, and several other countries, they also reckon from the incarnation: but then they differ from each other in the day of the incarnation, fixing it, after the primitive manner, not to the day of the birth, but conception of our Saviour. Though the Florentines retain the day of the birth, and begin their year from Christmas.

INCARNATION, formed from *in*, and *caro* "flesh," in sur-

gery, signifies the healing and filling up of ulcers and wounds with new flesh. See **SURGERY**.

INCARNATIVES, in surgery, medicines which assist nature in filling up wounds or ulcers with flesh; or rather remove the obstructions thereto. The term is now obsolete.

INCENDIARY, in law, is applied to one who is guilty of maliciously setting fire to another's dwelling-house, and all out-houses that are parcel thereof, thought not contiguous to it or under the same roof, as barns and stables. A bare intent or attempt to do this, by actually setting fire to a house, unless it absolutely burns, does not fall within the description of *incendit et combussit*. But the burning and consuming of any part is sufficient; though the fire be afterwards extinguished. It must also be a malicious burning; otherwise it is only a trespass. This offence is called *arson* in our law.

Among the ancients, criminals of this kind were to be burnt. *Qui ædes, acera ungue frumenti juxta domum posita, sciens, frudensque dolo malo combussit, vinctus igni necatur*. The punishment of *arson* was death by our ancient Saxon laws and by the Gothic constitutions: and in the reign of Edward I. incendiaries were burnt to death. The stat. 8 Hen. VI. c. 6. made the wilful burning of houses, under special circumstances, high treason; but it was reduced to felony by the general acts of Edward VI. and Queen Mary. This offence was denied the benefit of clergy by 21 Hen. VIII. c. 1. which statute was repealed by 1 Edw. VI. c. 12; and arson was held to be ousted of clergy, with respect to the principal, by inference from the stat. 4 and 5 P. and M. c. 4. which expressly denied it to the accessory; though now it is expressly denied to the principal also, by 9 Geo. I. c. 27.

INCENSE, or **FRANKINCENSE**, in the materia medica, &c. a dry resinous substance, known among authors by the names **THUS** and **OLIBANUM**. Incense is a rich perfume, with which the Pagans, and the Roman Catholics still, perfume their temples, altars, &c. The word comes from the Latin *incensum*, q. d. *burnt*; as taking the effect for the thing itself.

The burning of incense made part of the daily service of the ancient Jewish church. The priests drew lots to know who should offer it: the destined person took a large silver dish, in which was a censer full of incense, and, being accompanied by another priest carrying some live coals from the altar, went into the temple. There, in order to give notice to the people, they struck upon an instrument of brass placed between the temple and the altar; and being returned to the altar, he who brought the fire left it there, and went away. Then the offerer of incense, having said a prayer or two, waited the signal, which was the burning of the holocaust; immediately upon which he set fire to the incense, the whole multitude continuing all the time in prayer. The quantity of incense offered each day was half a pound in the morning, and as much at night. One reason of this continual burning of incense might be, that the multitude of victims that were continually offered up, would have made the temple smell like a slaughter-house, and consequently have inspired the comers rather with disgust and aversion, than awe and reverence, had it not been overpowered by the agreeable fragrance of those perfumes.

INCEPTIVE, a word used by Dr. Wallis to express such moments, or first principles, which, though of no magnitude themselves, are yet capable of producing such as are. Thus a point has no magnitude itself, but is inceptive of a line which it produces by its motion. So a line, though it have no breadth, is yet inceptive of breadth; that is, it is capable, by its motion, of producing a surface which has breadth, &c.

INCEST, the crime of venereal commerce between persons who are related in a degree wherein marriage is prohibited by the law of the country. Some are of opinion, that marriage ought to be permitted between kinsfolks, to the end that the at-

fection so necessary in marriage might be heightened by this double tie : yet the rules of the church have formerly extended this prohibition to the seventh degree ; but time has now brought it down to the third or fourth degree.

Most nations look on incest with horror, Persia and Egypt alone excepted. In the history of the ancient kings of those countries we meet with instances of the brother's marrying the sister : the reason was, because they thought it too mean to join in alliance with their own subjects, and still more so to marry into any foreign family.

Spiritual INCEST, a crime committed in like manner between persons who have a spiritual alliance by means of baptism or confirmation. Spiritual incest is also understood of a vicar, or other beneficiary, who enjoys both the mother and daughter ; that is, holds two benefices, the one whereof depends upon the collation of the other. This renders both the one and the other of these benefices vacant.

INCH, a well known measure of length ; being the twelfth part of a foot, and equal to three barley-corns in length.

INCH, contracted from the Gaelic *innis* "an island," a word prefixed to the names of different places in Scotland and Ireland.

INCH-COLM or *Columba*, an island of Scotland, lying in the frith of Forth, near the coast of Fife, but within the county of Edinburgh. Here are the fine ruins of a once celebrated monastery, founded in 1123, by Alexander I. in gratitude, it is said, for his escape, when driven on this island in a violent tempest, and for the hospitable treatment he received here, for three days, from a hermit, who entertained him with the milk of his cow, and a few shell fish. It was of the order of Augustines, and dedicated to St. Columba. At present, some fowls that haunt the ancient tower, and the rabbits that lodge in the mouldering soil, have full possession of this neglected spot.

INCH-KEITH, a desolate little island of Edinburghshire, in Scotland, in the frith of Forth, lying midway between the ports of Leith and Kinghorn. Here is a ruinous fort. The shore of this island, like that of Inchcolm, is bold and rugged, exhibiting several deep caverns, shelving cliffs, and towering rocks.

INCH-MARNOC, a beautiful little island of Scotland, to the S. W. of the isle of Bute. It is about a mile long ; and on the W. side are vast strata of coral and shells. It derives its name of Inchmarnoc (Marnoc's Isle) from a chapel dedicated to St. Marnoc, the ruins of which are still to be seen here.

INCHANTMENT. See WITCHCRAFT.

INCHOATIVE, a term signifying the beginning of a thing or action ; the same with what is otherwise called *inceptive*. Inchoative verbs denote, according to Priscian and other grammarians, verbs that are characterised by the termination *scio* or *scor*, added to their primitives : as *augeo* from *augere*, *caleo* from *calere*, *dulcesco* from *dulcis*, *irascor* from *ira*, &c.

INCIDENCE, denotes the direction in which one body strikes on another. See OPTICS and MECHANICS.

Angle of INCIDENCE. See ANGLE.

INCIDENT, in a general sense, denotes an event, or a particular circumstance of some event.

INCIDENT, in law, is a thing appertaining to, or following another, that is more worthy or principal. A court-baron is inseparably incident to a manor ; and a court of pie-powders to a fair.

INCIDENT, in a poem, is an episode, or particular action, joined to the principal action, or depending on it. A good comedy should be full of agreeable incidents, which divert the spectators, and form the intrigue. The poet ought always to make choice of such incidents as are susceptible of ornament suitable to the nature of his poem. The variety of incidents well conducted makes the beauty of an heroic poem, which ought always to take in a certain number of incidents to suspend the catastrophe, that would otherwise break out too soon,

INCINERATION, from *in*, and *cinis* "ashes," in chemistry, the reduction of vegetables into ashes, by burning them gently.

INCISIVE, an appellation given to whatever cuts or divides ; thus, the fore teeth are called *dentes incisivi* or cutters ; and medicines of an attenuating nature were formerly named incidents, or incisive medicines.

INCLE, a coarse and narrow kind of tape made of linen yarn.

INCLINATION, is a word frequently used by mathematicians, and signifies the mutual approach, tendency, or leaning of two lines or two planes towards each other, so as to make an angle.

INCLINATION in a moral sense. See APPETITE.

INCLINED PLANE, in mechanics, one that makes an oblique angle with the horizon. See MECHANICS.

INCOGNITO, or INCOG, is applied to a person who is in any place where he would not be known : but it is more particularly applied to princes, or great men, who enter towns, or walk the streets, without their ordinary train or the usual marks of their distinction and quality.

INCOMBUSTIBLE CLOTH. See ASBESTOS. On this Cronstedt observes, that the natural store of the asbestos is in proportion to their economical use, both being very inconsiderable. "It is an old tradition (says he), that in former ages they made clothes of the fibrous asbestos, which is said to be composed by the word *byffus* ; but it is not very probable, since, if one may conclude from some trifles now made of it, as bags, ribbons, and other things, such a dress could neither have an agreeable appearance, nor be of any conveniency or advantage. It is more probable that the Scythians dressed their dead bodies, which were to be burned, in a cloth manufactured of this stone ; and this perhaps has occasioned the above fable." M. Magellan confirms this opinion of Cronstedt's, and informs us that some of the Romans also inclosed dead bodies in cloth of this kind. In the year 1756 or 1757, he tells us that he saw a large piece of asbestos cloth found in a stone tomb, with the ashes of a Roman, as appeared by the epitaph. It was kept, with the tomb also, if our author remembers rightly, in the right hand wing of the Vatican library at Rome. The under librarian, in order to show that it was incombustible, lighted a candle, and let some drops of wax fall on the cloth, which he set on fire with a candle in his presence without any detriment to the cloth. Its texture was coarse, but much softer than he could have expected.

INCOMMENSURABLE, a term in geometry, used where two lines, when compared to each other, have no common measure, how small soever, that will exactly measure them both. And in general, two quantities are said to be incommensurable, when no third quantity can be found that is an aliquot part of both.

INCOMMENSURABLE Numbers, are such as have no common divisor that will divide them both equally.

INCONTINENCE, inordinacy of the sexual appetite ; lust. It is the opposite of chastity. See CHASTITY and CONTINENCE.

INCONTINENCE, in the eye of law, is of divers kinds ; as in cases of bigamy, rapes, sodomy, or buggery, getting bastards ; all which are punished by statute. See 25 Hen. VIII. cap. 6. 18 Eliz. cap. 7. 1 Jac. I. cap. 11. Incontinency of priests is punishable by the ordinary, by imprisonment, &c. 1 Hen. VII. cap. 4.

INCONTINENCE, in medicine, signifies an inability in any of the organs to retain what should not be discharged without the concurrence of the will. But incontinence is most frequently used with regard to an involuntary discharge of urine.

INCORPORATION, in pharmacy, is much the same as impastation, being a reduction of dry substances to the consistence of a paste, by the admixture of some fluid : thus pills,

boles, troches, and plasters, are made by incorporation. Another incorporation is when things of different consistencies are by digestion reduced to one common consistence.

INCORPORATION OF *Body-Corporate*. See CORPORATION.

INCORPOREAL, (spiritual; a thing, or substance, which has no body. Thus the soul of man is incorporeal, and may subsist independent of the body. See METAPHYSICS.

INCORRUPTIBLE, that which cannot be corrupted. Thus spiritual substances, as angels, human souls, &c. and thus also glass, gold, mercury, &c. may be called *incorruptible*.

INCORRUPTIBLES, INCORRUPTIBLES, the name of a sect which sprang out of the Eutychians. Their distinguishing tenet was, that the body of Jesus Christ was incorruptible; by which they meant, that after and from the time wherein he was formed in the womb of his holy mother, he was not susceptible of any change or alteration; not even of any natural and innocent passions, as of hunger, thirst, &c. so that he ate without any occasion, before his death, as well as after his resurrection. And hence it was that they took their name.

INCRASSATING, in pharmacy, &c. the rendering of fluids thicker by the mixture of other substances less fluid, or by the evaporation of the thinner parts.

INCUBATION, the action of a hen, or other fowl, brooding on her eggs. See HATCHING.

INCUBUS, NIGHT-MAKE, a disease consisting in an oppression of the breast, so very violent, that the patient cannot speak or even breathe. The word is derived from the Latin *incubare*, to "lie down" on any thing and press it: the Greeks call it εβ.αλλης, q. d. *saltator*, "leaper," or one that rusheth on a person. In this disease the senses are not quite lost, but drowned and astonished, as are the understanding and imagination; so that the patient seems to think some huge weight thrown on him, ready to strangle him. Children are very liable to this distemper; so are fat people, and men of much study and application of mind. The stomach in all these is materially concerned; as the complaint is most liable to occur after eating too great a supper, or preferring such articles of food as are known to be difficult of digestion.

INCUMBENT, a clerk or minister who is resident on his benefice; he is called *incumbent*, because he does, or at least ought to, bend his whole study to discharge the cure of his church.

INCURVATION of the RAYS of LIGHT, their bending out of a rectilinear straight course, occasioned by refraction. See OPTICS.

INCUS, in anatomy, a bone of the internal ear, somewhat resembling one of the anterior dentes molares.

INDEFEASIBLE, a term in law for what cannot be defeated or made void; as an indefeasible estate of inheritance, &c.

INDEFEASIBLE *Right to the Throne*. See HEREDITARY *Right*.

INDEFINITE, that which has no certain bounds, or to which the human mind cannot affix any.

INDEFINITE, in grammar, is understood of nouns, pronouns, verbs, participles, articles, &c. which are left in an uncertain indeterminate sense, and not fixed to any particular time, thing, or other circumstance.

INDELIBLE, something that cannot be cancelled or effaced.

INDEMNIFY, in law, the saving harmless; or a writing to secure one from all damage and danger that may ensue from any act.

INDENTED, in heraldry, is when the outline of an ordinary is notched like the teeth of a saw.

INDENTURE, in law, a writing which comprises some contract between two at least; being indented at top, answerable to another part which has the same contents. See DEED.

INDEPENDENTS, a sect of protestants in England and Holland: so called, as denying not only any subordination among their clergy, but also all *dependency* on any other assembly.

bly. They maintain, that every separate church, or particular congregation, has in itself radically and essentially every thing necessary for its own government; that it has all ecclesiastical power and jurisdiction; and is not at all subject to other churches, or their deputies, nor to their assemblies, or synods.

Robinson, the founder of the sect, makes express use of this term in explaining his doctrine relating to ecclesiastical government: *Cœum quemlibet particularem*, (says he, in his *Apoloogia*, cap. v. p. 22.) *esse totam, integram et perfectam ecclesiam ex suis partibus constantem, immediate et independentem (quoad alias ecclesias) sub ipso Christo*. It may probably have been from this very passage that the title of *Independents* was originally derived. The disciples of Robinson, originally called Brownists, because John Robinson, the founder of this sect, was pastor of a congregation of Brownists that had settled at Leyden, did not reject the appellation of *Independents*. It was certainly utterly unknown in England before the year 1640; at least it is not once mentioned in the ecclesiastical canons and constitutions that were drawn up during that year, in the synods or visitations held by the archbishops of Canterbury, York, and other prelates, in which canons all the various sects that then subsisted in England are particularly mentioned. See Wilkins's *Concilia Magnæ Britanniae et Hiberniæ*, vol. iv. cap. 5. p. 548.

It is true, that not long after this period, and more particularly from the year 1642, we find this denomination very frequently in the English annals. The English *Independents* were so far from being displeased with it, that they assumed it publicly in a piece which they published in their own defence at London, in the year 1644, entitled *Apologetical Narration of the Independents*. But in process of time, in order to avoid the odium of sedition and anarchy charged on this sect, the true and genuine *Independents* renounced this title, and called themselves *Congregational Brethren*, and their religious assemblies *congregational churches*. The first *Independent* or congregational church in England was set up in the year 1616, by Mr. Jacob, who had adopted the religious sentiments of Robinson. The *Independents*, though sprung originally from a congregation of Brownists, were much more commendable than the latter, both in the moderation of their sentiments and the order of their discipline. The Brownists, as we have already mentioned under BARROWISTS, allowed all ranks and orders of men promiscuously to teach in public, and to perform the other pastoral functions; whereas the *Independents* had, and still have, a certain number of ministers, for the most part regularly educated, chosen respectively by the congregations where they are fixed; nor is any person among them permitted to speak in public, before he has submitted to a proper examination of his capacity and talents, and been approved of by the congregation to which he ministers. The charge alleged against them by our historian Rapin, (*Hist. of England*; vol. ii. p. 514. fol. ed.) who says, that they could not so much as endure ordinary ministers in the church, &c. is, therefore, evidently false and groundless. He was led into his mistake by confounding the *Independents* and Brownists. There are other charges, no less unjustifiable, that have been urged against the *Independents*, by this celebrated historian, and others of less note. Rapin says, that with regard to the state, they abhorred monarchy, and approved only a republican government. This might have been true with regard to several persons among the *Independents*, in common with those of other sects; but it does not appear from any of their public writings, that republican principles formed the distinguishing characteristic of this sect. On the contrary, in a public memorial drawn up by them in 1647, they declare, that they do not disapprove of any form of civil government, but do freely acknowledge, that a kingly government, bounded by just and wholesome laws, is both allowed by God, and also a good accommodation unto men. The *In-*

dependents, however, have been generally distinguished by the denomination of regicides; under a notion, that they were chargeable with the death of Charles I. Whether this fact be admitted or denied, and this is not a place proper for the investigation of it, no conclusion can be fairly drawn from the greater prevalence of republican principles, or from violent proceedings at that period, that can affect the distinguishing tenets and conduct of the *Independents* in general; and especially of the sect that bears this denomination in our times. It is certain, that our *Independents* are steady friends to a limited monarchy. Rapin is farther mistaken, when he represents the religious principles of the *Independents* as contrary to those of all the rest of the world. It appears from two confessions of faith, one composed by Robinson, on behalf of the English *Independents* in Holland, and published at Leyden in 1619, entitled, *Apologia pro Exulibus Anglis, qui Brownistæ vulgo appellantur*; and another drawn up in London in the year 1658, by the principal members of this community in England, entitled, *A Declaration of the Faith and Order owned and practised by the Congregational Churches in England, agreed upon and consented unto by their Elders and Messengers, in their Meeting at the Savoy, Oct. 12, 1658*; as well as from other writings of the *Independents*, that they differed from the sect of the reformed in no single point of any consequence, except that of ecclesiastical government; and their religious doctrines were almost entirely the same with those that are adopted by the church of Geneva. During the administration of Cromwell, the *Independents* acquired very considerable reputation and influence; and he made use of them as a check to the ambition of the Presbyterians, who aimed at a very high degree of ecclesiastical power, and who had succeeded, soon after the elevation of Cromwell, in obtaining a parliamentary establishment of their own church government. But after the restoration of Charles II. their cause declined; and in the year 1691, under the reign of king William, they entered into an association with the Presbyterians residing in and about London, under certain heads of agreement, comprised in nine articles, that tended to the maintenance of their respective institutions. These may be found in the second volume of Whiston's *Memoirs of his Life and Writings*; and the substance of them in Mosheim.

At this time the *Independents* and Presbyterians, called from this association the United Brethren, were agreed with regard to doctrines, being generally Calvinists, and differed only with respect to ecclesiastical discipline. But at present, though the English *Independents* and Presbyterians form two distinct parties of Protestant Dissenters, they are distinguished by very trifling differences with regard to church government; and the denominations are more arbitrarily used to comprehend those who differ in theological opinions. The *Independents* are generally more attached to the tenets distinguished by the term *ORTHODOXY* or *CALVINISM*, than the *PRESBYTERIANS*.

Independence is peculiar to Great Britain; the British colonies of America, whither it was carried first in 1620, and by successive Puritan emigrants in 1629 and 1633, from England, and the United Provinces. One Morel, in the sixteenth century, endeavoured to introduce it into France; but it was condemned at the synod of Rochelle, where Beza presided; and again at the synod of Rochelle, in 1644.

On the subject of this article, see Mosheim's *Eccl. Hist.* by Maclean, vol. iv. p. 522, &c. 8vo. Neal's *Hist. of the Puritans*, vol. ii. p. 107, &c. vol. iii. p. 547, &c. vol. iv. p. 187, &c. Burnet's *Hist. of his Own Times*, vol. i. p. 46, &c.

INDEX, in anatomy, denotes the fore-finger. It is thus called from *indico*, *I point* or *direct*; because that finger is generally so used: whence also the extensor indicis is called *indicator*.

INDEX, in arithmetic and algebra, shows to what power any quantity is involved, and is otherwise called its *exponent*. See *ALGEBRA*, p. 104.

INDEX of a Book, is that part annexed to a book, referring to the particular matters or passages therein contained.

INDEX of a Globe, is a little style fitted on to the north pole, and turning round with it, pointing to certain divisions in the hour-circle. It is sometimes also called *gnomon*. See *GLOBE*.

Expurgatory INDEX, a catalogue of prohibited books in the church of Rome. The first catalogues of this kind were made by the inquisitors; and these were afterwards approved of by the council of Trent, after some alteration was made in them by way of retrenchment or addition. Thus an index of heretical books being formed, it was confirmed by a bull of Clement VIII. in 1595, and printed with several introductory rules; by the fourth of which, the use of the Scriptures in the vulgar tongue is forbidden to all persons without a particular licence; and by the tenth rule it is ordained, that no book shall be printed at Rome without the approbation of the Pope's vicar, or some person delegated by the Pope; nor in any other places, unless allowed by the bishop of the diocese, or some person deputed by him, or by the inquisitor of heretical pravity.

The Trent index being thus published, Philip II. of Spain ordered another to be printed at Antwerp, in 1571, with considerable enlargements. Another index was published in Spain in 1584; a copy of which was snatched out of the fire when the English plundered Cadiz. Afterwards there were several expurgatory indexes printed at Rome and Naples, and particularly in Spain.

INDIA, an extensive region in Asia, which lies between 66° and 93° E. lon. and 7° and 35° N. lat. But, under this name, the Europeans have erroneously understood all the countries which lie S. of Tartary, and extend from the eastern frontiers of Persia to the eastern coasts of China; and they have included likewise under the denomination of the E. Indies the islands of Japan, with all the islands in the Eastern and Indian Oceans, as far S. as New Holland. But the name of India can be applied, with propriety, to that country only which is distinguished in Asia as well as in Europe by the name of Hindoostan. The countries to the E. of the river Burrampooter (namely, Aracan, Assam, Burmah, Cambodia, Cochinchina, Laos, Malacca, Pegu, Siam, and Tonquin), which geographers have hitherto distinguished by the name of the Peninsula beyond the Ganges, are no more to be considered as belonging to India, than the bordering countries of China, Thibet, Tartary, or Persia. See *HINDOOSTAN*.

INDIA Company. See *COMPANY*.

INDIA Rubber. See *CAOUTCHOUC*.

INDIAN, in a general sense, denotes any thing belonging to the Indies, East or West.

INDIAN Berry. See *MENISPERMUM*.

INDIAN Bread. See *JATROPHA*.

INDIAN Corn, or Maize. See *ZEA*.

INDIAN Cresses. See *TROPÆOLUM*.

INDIAN Fig. See *BANIAN Tree*.

INDIAN Pagod-tree. See *CACTUS*.

INDIAN Ink. See *INK*.

INDIAN Reed. See *CANNA*.

INDIANS. See the articles *INDIA*, *HINDOOSTAN*, and *AMERICA*.

INDICATION, in physic, whatever serves to direct the physician how to act in the treatment of a disease.

INDICATIVE, in grammar, the first mood or manner of conjugating a verb, by which we simply affirm, deny, or ask something: as, *amant*, they love; *non amant*, they do not love; *amantne?* do they not love? See *GRAMMAR*.

INDICTION, in chronology, a cycle of 15 years. See *CYCLE*.

INDICTMENT, in law, one of the modes of prosecuting an offender. See PROSECUTION. In English law, it is a written accusation of one or more persons of a crime or misdemeanor, preferred to, and presented upon oath by, a grand jury. To this end, (Judge Blackstone observes,) the sheriff of every county is bound to return to every session of the peace, and every commission of *oyer and terminer*, and of general gaol-delivery, twenty-four good and lawful men of the county, some out of every hundred, to inquire, present, do, and execute all those things, which on the part of our lord the king shall then and there be commanded them. They ought to be freeholders; but to what amount is uncertain: which seems to be *casus omnifusus*, and as proper to be supplied by the legislature as the qualifications of the petit jury; which were formerly equally vague and uncertain, but are now settled by several acts of parliament. However, they are usually gentlemen of the best figure in the county. As many as appear upon this pannel, are sworn upon the grand jury, to the amount of twelve at the least, and not more than twenty-three; that twelve may be a majority. Which number, as well as the constitution itself, we find exactly described so early as the laws of king Ethelred: *Exeat seniores duodecim thani, et praefectus cum eis, ut jurent super sanctuarium quod eis in manus datur, quod non int ullum innocentem accusare, nec aliquem noxium celare.* Wilk. L. L. Ann. Lex. 117. In the time of king Richard I. (according to Hoveden) the process of electing the grand jury, ordained by that prince, was as follows: Four knights were to be taken from the county at large, who chose two more out of every hundred; which two associated to themselves ten other principal freemen, and those twelve were to answer concerning all particulars relating to their own district. This number was probably found too large and inconvenient; but the traces of this institution still remain, in that some of the jury must be summoned out of every hundred. This grand jury are previously instructed in the articles of their inquiry, by a charge from the judge who presides upon the bench. They then withdraw to sit and receive indictments, which are preferred to them in the name of the king, but at the suit of any private prosecutor; and they are only to hear evidence on behalf of the prosecution: for the finding of an indictment is only in the nature of an inquiry or accusation, which is afterwards to be tried and determined; and the grand jury are only to inquire upon their oaths, whether there be sufficient cause to call upon the party to answer it. A grand jury, however, ought to be thoroughly persuaded of the truth of an indictment, so far as their evidence goes; and not to rest satisfied merely with remote probabilities: a doctrine that might be applied to very oppressive purposes.

The grand jury are sworn to inquire only for the body of the county, *pro corpore comitatús*; and therefore they cannot regularly inquire of a fact done out of that county for which they are sworn, unless particularly enabled by act of parliament. And to so high a nicety was this matter anciently carried, that where a man was wounded in one county, and died in another, the offender was at common law indictable in neither, because no complete act of felony was done in any one of them: but by statute 2 and 3 Ed. VI. c. 24. he is now indictable in the county where the party died. And by statute 2 Geo. II. c. 21. if the stroke or poisoning be in England, and the death upon the sea or out of England, or *vice versa*, the offenders, and their accessories, may be indicted in the county where either the death, poisoning, or stroke shall happen. And so in some other cases; as particularly, where treason is committed out of the realm, it may be inquired of in any county within the realm, as the king shall direct, in pursuance of statutes 26 Hen. VIII. c. 13; 33 Hen. VIII. c. 23; 35 Hen. VIII. c. 2; 5 and 6 Edw. VI. c. 11. And counterfeiters, washers, or ministers

of the current coin, together with all manner of felons and their accessories, may, by statute 26 Hen. VIII. c. 6. (confirmed and explained by 34 and 35 Hen. VIII. c. 26. § 75. 76.) be indicted and tried for those offences, if committed in any part of Wales, before the justices of gaol-delivery and of the peace, in the next adjoining county of England, where the king's writ runneth: that is, at present in the county of Hereford or Salop; and not, as it should seem, in the county of Chester or Monmouth: the one being a county palatine, where the king's writ did not run; and the other a part of Wales, in 26 Hen. VIII. Murders also, whether committed in England or in foreign parts, may, by virtue of the statute 33 Hen. VIII. c. 23. be inquired of and tried by the king's special commission in any shire or place in the kingdom. By statute 10 and 11 W. III. c. 25. all robberies, and other capital crimes, committed in Newfoundland, may be inquired of and tried in any county in England. Offences against the black act, 9 Geo. I. c. 22. may be inquired of and tried in any county of England, at the option of the prosecutor. So felonies, in destroying turnpikes, or works upon navigable rivers, erected by authority of parliament, may, by statutes 8 Geo. II. c. 20. and 13 Geo. III. c. 84. be inquired of and tried in any adjacent county. By statute 26 Geo. II. c. 19. plundering or stealing from any vessel in distress or wrecked, or breaking any ship contrary to 12 Ann. st. 2. c. 18. may be prosecuted either in the county where the fact is committed, or in any county next adjoining; and if committed in Wales, then in the next adjoining English county: by which is understood to be meant, such English county as, by the statute 26 Hen. VIII. above mentioned, had before a concurrent jurisdiction of felonies committed in Wales. Felonies committed out of the realm, in burning or destroying the king's ships, magazines, or stores, may, by statute 12 Geo. III. c. 24. be inquired of and tried in any county of England, or in the place where the offence is committed. By statute 13 Geo. III. c. 63. misdemeanors committed in India may be tried upon information or indictment in the court of king's bench in England; and a mode is marked out for examining witnesses by commission, and transmitting their depositions to the court. But, in general, all offences must be inquired into, as well as tried, in the county where the fact is committed. Yet if larceny be committed in one county, and the goods carried into another, the offender may be indicted in either; for the offence is complete in both. Or he may be indicted in England for larceny in Scotland, and carrying the goods with him into England, or *vice versa*; or for receiving in one part of the united kingdom goods that have been stolen in another. But for robbery, burglary, and the like, he can only be indicted where the fact was actually committed: for though the carrying away and keeping of the goods is a continuation of the original taking, and is therefore larceny in the second county, yet it is not a robbery or burglary in that jurisdiction. And if a person be indicted in one county for larceny of goods originally taken in another, and be thereof convicted, or stands mute, he shall not be admitted to his clergy; provided the original taking be attended with such circumstances as would have ousted him of his clergy by virtue of any statute made previous to the year 1691.

When the grand jury have heard the evidence, if they think it a groundless accusation, they used formerly to endorse on the back of the bill, *Ignoramus*; or, We know nothing of it: intimating, that though the facts might possibly be true, that truth did not appear to them. But now they assert in English more absolutely, *Not a true bill*; or (which is the better way) *Not found*: and then the party is discharged without farther answer. But a fresh bill may afterwards be preferred to a subsequent grand jury. If they are satisfied of the truth of the accusation, they then endorse upon it, "A true bill;" anciently.

Billa vera. The indictment is then said to be found, and the party stands indicted. But to find a bill, there must at least twelve of the jury agree: for so tender is the law of England of the lives of the subjects, that no man can be convicted at the suit of the king, of any capital offence, unless by the unanimous voice of twenty-four of his equals and neighbours; that is, by twelve at least of the grand jury, in the first place, assenting to the accusation; and afterwards by the whole petit jury of twelve more, finding him guilty upon his trial. But if twelve of the grand jury assent, it is a good presentment, though some of the rest disagree. And the indictment, when so found, is publicly delivered into court.

Indictments must have a precise and sufficient certainty. By statute 1 Hen. V. c. 5. all indictments must set forth the christian name, surname, and addition of the state and degree, mystery, town, or place, and the county of the offender; and all this to identify his *person*. The *time* and *place* are also to be ascertained, by naming the day and township in which the fact was committed: though a mistake in these points is in general notheld to be material, provided the *time* be laid previous to the finding of the indictment, and the *place* to be within the jurisdiction of the court; unless where the place is laid, not merely as a *venue*, but as part of the description of the fact. But sometimes the *time* may be very material, where there is any limitation in point of time assigned for the prosecution of offenders; as by the statute 7 Will. III. c. 3. which enacts, that no prosecution shall be had for any of the treasons or misdemeanors therein mentioned (except an assassination designed or attempted on the person of the king), unless the bill of indictment be found within three years after the offence committed; and, in case of murder, the time of the death must be laid within a year and a day after the mortal stroke was given. The offence itself must also be set forth with clearness and certainty; and in some crimes particular words of art must be used, which are so appropriated by the law to express the precise idea which it entertains of the offence, that no other words, however synonymous they may seem, are capable of doing it. Thus, in treason, the facts must be laid to be done "treasonably, and against his allegiance;" anciently *proditorie et contra ligantia sue debitum*; else the indictment is void. In indictments for murder, it is necessary to say that the party indicted "murdered," not "killed" or "slew," the other; which, till the late statute, was expressed in Latin by the word *murdravit*. In all indictments for felonies, the adverb "feloniously," *felonice*, must be used; and for burglaries also, *burglariter*, or, in English, "burglariously;" and all these to ascertain the intent. In rapes, the word *rapuit*, or "ravished," is necessary, and must not be expressed by any periphrasis, in order to render the crime certain. So in larcenies also, the words *felonice cepit et asportavit*, "feloniously took and carried away," are necessary to every indictment; for these only can express the very offence. Also, in indictments for murder, the length and depth of the wound should in general be expressed, in order that it may appear to the court to have been of a mortal nature: but if it goes through the body, then its dimensions are immaterial; for that is apparently sufficient to have been the cause of the death. Also, where a limb, or the like, is absolutely cut off, there such description is needless. Lastly, in indictments, the *value* of the thing which is the subject or instrument of the offence must sometimes be expressed. In indictments for larcenies this is necessary, that it may appear whether it be grand or petit larceny; and whether entitled or not to the benefit of clergy. In homicides of all sorts it is necessary; as the weapon with which it is committed is forfeited to the king as a deodand. For the manner of process upon an indictment, see PROCESS.

Plea to INDICTMENT. See PLEA.

East INDIES. See HINDOOSTAN, and plate 9.

West INDIES, the name given to a great number of islands in the Atlantic Ocean, which extend across the entrance of the gulf of Mexico, from the N. W. extremity of the Bahama Islands, off the coast of Florida, in N. lat. 27. 45, in a south-easterly direction, to the island of Tobago, which is 120 miles from the coast of Terra Firma, in N. lat. 11. 30. They lie between 59° and 86° W. lon. Cuba being the most western, and Barbadoes the most eastern of all these islands. When Columbus discovered them in 1492, he considered them as part of those vast regions in Asia, comprehended under the general name of India, to reach which, by a course due W. across the Atlantic Ocean, had been the grand object of his voyage; and this opinion was so general, that Ferdinand and Isabella, king and queen of Castile, in their ratification of an agreement, granted to Columbus, upon his return, gave them the name of *Indes*. Even after the error which gave rise to this opinion was detected, and the true position of the New World was ascertained, the name has remained, and the appellation of the *West Indies* is given by all the people of Europe to these islands, and that of *Indians* to the inhabitants, not only of these islands, but of the two continents of America. They are likewise called the Caribbee islands, from the aborigines of the country; and the sea in which they lie, is sometimes called, by modern geographers, the Archipelago of the Caribbees. By the French they are called the Antilles; and nautical men distinguish them, from the different courses taken by ships, into the Leeward and Windward Islands; which see. The name of Caribbee should properly be confined to the smaller islands, which lie between Porto Rico and Tobago. These were inhabited by the Caribbees, a fierce race of men, no wise resembling their feeble and timid neighbours in the larger islands. Columbus, in his second voyage, was a witness to their intrepid valour. The same character they have maintained invariably in all subsequent contests with the people of Europe; and, even in our times, we have seen them make a gallant stand in defence of the last territory (the island of St. Vincent) which the rapacity of their invaders had left in their possession. The British Islands are Jamaica, Barbadoes, St. Christopher, Antigua, Nevis, Montserrat, Barbuda, Anguilla, Dominica, St. Vincent, Granada, the Bahama Islands, part of the Virgin Islands, and Tobago; which last was taken from the French, April 15, 1793. Cuba, Porto Rico, Trinidad, and Margareta belong to the Spaniards, who likewise have the eastern part of Hispaniola. To the French belong Martinico, Guadaloupe, St. Lucia, Marigalante, Desada, and the western part of Hispaniola. The Dutch have St. Eustatia, Curacao, Saba, and St. Martin; the Danes, St. Thomas, St. Croix, and part of the Virgin Islands; and the Swedes, St. Bartholomew.

INDIGENOUS, of *indigena*, denotes a native of a country, or that which was originally born or produced in the country where it is found: In this sense, particular species of animals and plants are said to be *indigenous* in the country where they are native, in opposition to EXOTIC.

INDIGESTION, a crudity, or want of due coction of the food in the stomach. See DIGESTION.

INDIGETES, a name which the ancients gave to some of their gods. There are various opinions about the origin and signification of this word. Some pretend it was given to all the gods in general; and others, only to the demigods, or great men deified. Others say, it was given to such gods as were originally of the country, or rather such as were the gods of the country that bore this name; and others again hold it was ascribed to such gods as were patrons and protectors of particular cities. Lastly, others hold *indigetes* to be derived from *inde genitus* or *in loco degens*, or from *inde* and *ago*, for *dego*, "I live, I inhabit;" which last opinion seems the most probable.

In effect it appears, 1. That these *indigetes* were also called *local gods*, (*dii locales*), or *topical gods*, which is the same thing.

WEST
INDIES

British Statute Miles
0 50 100 200

West Longitude from London. 95

Barlow sculp.

2. The *indigetes* were ordinarily men deified, who indeed were in effect local gods, being esteemed the protectors of those places where they were deified; so that the second and third opinions are very consistent. 3. Virgil joins *patrii* with *indigetes*, as being the same thing, *Georg.* i. ver. 498. "*Dii patrii, indigetes.*"

4. The gods to whom the Romans gave the name *indigetes* were, Faunus, Vesta, Æneas, Romulus, all the gods of Italy; and at Athens, Minerva, says Servius; and at Carthage, Dido. It is true, we meet with Jupiter *indiges*: but that Jupiter *indiges* is Æneas, not the great Jupiter; as we may see in Livy, lib. i. cap. 3. in which last sense, Servius assures us, *indiges* comes from the Latin *in diis ago*, "I am among the gods."

Among these *indigetes* gods, there was none more celebrated, nor more extensively worshipped, than HERCULES.

INDIGO, a dye prepared from the leaves and small branches of the *Indigofera Tinctoria*. See the next article.

INDIGOFERA, the INDIGO PLANT: A genus of the dicandria order, belonging to the diadelphia class of plants; and in the natural method ranking under the 32d order, *Papilionaceæ*. The calyx is patent; the carina of the corolla furnished with a subulated patulous spur on each side; the legumen is linear.— There are five species; the most remarkable of which is the *tinctoria*, a native of the warm parts of Asia, Africa, and America, and from which the indigo dye is made. The root of this plant is three or four lines thick, and more than a foot long, of a faint smell something like parsley. From this root issues a single stem nearly of the same thickness, about two feet high, straight, hard, almost woody, covered with a bark slightly split, of a grey ash-colour towards the bottom, green in the middle, reddish at the extremity, and without appearance of pith in the inside. The leaves, ranged in pairs around the stalk, are of an oval form, smooth, soft to the touch, furrowed above, of a deep green on the under-side, and connected by a very short peduncle. From about one-third of the stem to the extremity there are ears that are loaded with very small flowers from a dozen to 15, but destitute of smell. The pistil, which is in the midst of each flower, changes into a pod, in which the seeds are inclosed.

This plant requires a smooth rich soil, well tilled, and not too dry. The seed of it, which, as to figure and colour, resembles gun-powder, is sown in little furrows that are about the breadth of the hoe, two or three inches deep, at a foot distance from each other, and in as straight a line as possible. Continual attention is required to pluck up the weeds, which would soon choke the plant. Though it may be sown in all seasons, the spring is commonly preferred. Moisture causes this plant to shoot above the surface in three or four days. It is ripe at the end of two months. When it begins to flower, it is cut with pruning-knives; and cut again at the end of every six weeks, if the weather is a little rainy. It lasts about two years, after which term it degenerates; it is then plucked up, and planted afresh. As this plant soon exhausts the soil, because it does not absorb a sufficient quantity of air and dew to moisten the earth, it is of advantage to the planter to have a vast space which may remain covered with trees, till it becomes necessary to fell them in order to make room for the indigo.

Indigo is distinguished into two kinds, the *trus* and the *bastard*. Though the first is sold at a higher price on account of its superiority, it is usually advantageous to cultivate the other, because it is heavier. The first will grow in many different soils; the second succeeds best in those which are most exposed to the rain. Both are liable to great accidents. Sometimes the plant becomes dry, and is destroyed by an insect frequently found on it; at other times, the leaves, which are the valuable part of the plant, are devoured in the space of 24 hours by caterpillars. This last misfortune, which is but too common, has given occasion to the saying, "that the planters of indigo go to bed rich, and rise in the morning totally ruined." This production ought

to be gathered in with great precaution, for fear of making the farina that lies on the leaves, and is very valuable, fall off by shaking it. M. Berthollet, in his "Elements of the Art of Dyeing," has many valuable remarks on the process of making indigo, and particularly of its chemical properties. We shall therefore continue this article by the following extracts from the work of that ingenious chemist:

"When the indigofera (says he) appears to be ripe, it is cut, and carried to the vats, where it is to undergo a fermentation, to which it is greatly disposed. If it be perfectly ripe when cut, the indigo it affords is of a finer colour, but much less in quantity, than if it be not arrived at a state of maturity: if it be over ripe, the quantity is still less, and its quality is bad.

"There are three vats placed one over another at different heights, and near a reservoir of water. The first is called the *steeping vat*. Into this the plant is put, after having filled it with water to a certain height: a brisk fermentation soon commences, and much scum is formed. Mr. Quatremere says, that the disengaged gas is inflammable.

"When the indigo-maker finds the fermentation sufficiently advanced, and the colouring particles beginning to unite, he draws off the liquor into the second vat, called the *beating vat*, in which the liquor is beaten with instruments contrived for that purpose. Mr. Le Blond asserts, in the observations sent by him to the academy of sciences, that this operation is intended to dissipate the carbonic acid formed by the fermentation, which would prevent the precipitation of the colouring particles. He says, that the beating is not sufficient to procure the precipitation of all the colouring particles, and that a method has been tried in French Guiana, which, by producing a much more copious precipitate, revived the hopes of the colourists, who were abandoning this manufacture. This method consists in mixing with the liquor a quantity of lime-water, which absorbs its carbonic acid: but he thinks that this should not be carried beyond a certain proportion, and that an excess of lime-water is prejudicial. This method is not new: it is mentioned by father Labat. Mr. Struve also has thought, that lime-water would favour the precipitation of the indigo, by seizing the carbonic acid which held it in solution.

"When it is judged, from the blue colour, that the liquor is sufficiently beaten, it is left at rest about two hours, that the colouring particles may begin to separate from the liquor, which contains a yellow extractive matter, and it is then drawn off into a third vat, called the *settling vat*. The colouring particles are left to settle in this vat, the supernatant liquor of which is drawn off by two cocks placed one above the other; after which the colouring particles, then in a state of semifluidity, are drawn off by a third cock into a linen strainer in the shape of a jelly-bag; and when they are reduced to the consistence of a paste, they are turned out into square boxes, placed in the open air, under sheds which shelter them from the sun.

"The indigo produced in these operations differs, not only according to the quality of the plant which afforded it, but according to the care employed in its preparation. Its colouring part, however, appears to be invariably the same; so that the difference of its quality is entirely owing to the heterogeneous substances mixed with it, and the degree of consistence which it acquires in dyeing.

"There is a light sort that comes from Guatemala, of a fine blue colour, and called *light indigo*, or *flower indigo* (indigo flore). It swims on water, whilst all the other kinds sink in it. This sort is the finest and most valuable. There is a sort known by the name of *coppery indigo*, because its surface assumes a copper colour when rubbed against a hard body; and there are other sorts much less pure, as that which comes from Carolina.

"In the experiments of Bergman, one part in nine of indigo was found to be soluble in water by boiling. This part appeared to consist of mucilaginous, astringent, and saponaceous particles. The astringent particles are precipitable by solutions of alum, of sulphat of iron, and of copper.

"M. Quatremere also has separated the soluble parts by means of water. He asserts, that their quantity is greater in proportion as the indigo is inferior in quality; and that the residuum, after this operation, is equal to the finest indigo: whence he proposes, to purify indigo of inferior quality by boiling it in a bag, renewing the water till it will take no more colour. Unquestionably this operation would be of advantage, as it would deprive the indigo of the yellow matter capable of altering its colour: still however its quality might differ, on account of the earthy particles not soluble in water, which, it is true, could not affect its colour, but would vary the proportion of the colouring matter.

"Powdered indigo digested in *alcohol* gave a tincture at first yellow, then red, and at last brown. By this operation several times repeated, it lost about a seventeenth of its weight. From this tincture water separated a brownish resinous substance. *Ether* acts on indigo nearly in the same manner as alcohol; but oils, either fixed or volatile, have little action on it.

"Bergman mixed one part of indigo finely powdered, with eight parts of colourless *sulphuric acid*, so concentrated that its specific gravity was to that of distilled water as 1900 to 1000. The glass vessel in which these were mixed was slightly stopped. The acid attacked the indigo readily, and excited great heat. After twenty-four hours digestion, the indigo was dissolved, but the mixture was opaque and black: by the addition of water it was rendered clear, passing successively through the various shades of blue, in proportion to the quantity of water. At least twenty pounds of water are required to render the smallest drop of the solution imperceptible, in a cylindrical glass vessel of seven inches diameter. If the sulphuric acid be diluted with water, it attacks only the earthy principle mixed with the indigo, and some mucilaginous particles.

"Several bottles in which a drop of this solution was mixed with liquors containing different substances, as acids, alkalis, and neutral salts, were exposed for some time to a temperature of from fifteen degrees to twenty degrees (65 to 77 Fahr.). In some the colour remained unaltered; in others it became green, and, was destroyed more or less readily. Bergman accounted for the changes he observed, by the property some substances possess of taking away phlogiston, and others of affording it: but they may be happily explained by the attractions of oxygen, which some substances yield, or take away, or acquire from the atmosphere.

"*Fixed alkalis* saturated with carbonic acid separate from the solution of indigo a very fine blue powder, which is deposited very slowly. Bergman distinguishes this blue powder by the appellation of *precipitated indigo*. It may be obtained also by dropping the solution into alcohol, or into saturated solutions of alum, sulphat of soda, or other salts containing the sulphuric acid; but the liquor remains always in some degree coloured.

"Concentrated *nitric acid* attacks indigo with such violence as to set it on fire. If it be diluted to a proper degree, it acts with less vehemence, the colour of the indigo becomes rusty, and the residuum, which amounts only to one-third of the indigo employed, has the appearance of umber. Fixed alkali precipitates from the nitric acid which has acted on the indigo, a little oxyd of iron, mixed with barytes and calcareous earth: but if too much alkali be added, a part of the precipitate is redissolved, and the colour of the liquor becomes deeper than before.

"Bergman says, that the nitrous acid which has been *phlogisticated* by indigo, and has at the same time taken up a portion of its mucilage, may be employed for dyeing wool or silk

of different shades, of a very permanent yellow: but here that great chemist mistakes for a particular effect, the action always exerted by nitric acid on wool or silk, to which it gives a yellow colour, more or less deep according to its degree of concentration, and which he has himself described in his notes on Scheffer's essay on dyeing.

"Mr. Hauffman has given a more regular series of observations on the changes produced in indigo by nitric acid, in his interesting "*Dissertation sur l'indigo & ses dissolvants*, inserted in the *Journal de Physique* for March 1788. After all the indigo which he had exposed to the action of that acid appeared to be destroyed, he found in the vessel a coagulum, which, being perfectly freed from nitric acid by washing, formed a brown viscous mass, having all the appearance of a gummy resinous substance: it was soluble in alcohol, which indigo is not, and was not soluble in water, except in a large quantity, though more so in hot water than in cold: and it was very bitter to the taste. The water with which the coagulum had been washed, yielded on evaporation small crystals, which exhibited many properties of the tartarous and oxalic acids, but the nature of which our author did not precisely ascertain.

"*Muriatic acid*, digested and even boiled on indigo, takes up the earthy part, the iron, and a little extractive matter, which colours it of a yellowish brown, but has not the least action on the blue colour. If the indigo be precipitated from sulphuric acid, the muriatic acid will readily dissolve a certain portion of it, and form a deep blue liquor.

"The other acids, as the *tartarous, formic, acetic, and phosphoric*, act on indigo like the muriatic; they dissolve precipitated indigo very well. Sulphuric acid too much diluted with water to dissolve indigo, and nitric acid also when too weak to decompose it, dissolve only the earthy part and the extractive matter, which are altogether foreign to the colouring substance.

"The *oxygenated muriatic acid* shews little action on indigo in substance, but destroys its colour when in a state of solution. I employed the solution in sulphuric acid to ascertain the alterations it would induce in it. With this I mixed oxygenated muriatic acid, till its blue colour was entirely destroyed: it was then of a brown yellow. In this state I evaporated it, and a blackish viscous substance was gradually deposited, which appeared to be of the same nature as that Mr. Hauffman obtained by means of the nitric acid.

"This effect of the oxygenated muriatic acid on the solution of indigo in sulphuric acid, affords a very accurate method of determining the goodness of indigo. All the colouring particles contained in it are soluble in the sulphuric acid, and form perfectly similar solutions; for there is no difference between the colouring particles. The relative quantities therefore of these particles contained in different specimens of indigo may be found, by the proportions of oxygenated muriatic acid required to destroy the colouring particles extracted by sulphuric acid from equal weights." In the second section of the first part of his work, M. Berthollet mentions the precautions necessary in making this experiment.

"Pure or *caustic fixed alkali* dissolves some substances foreign to the colouring matter of indigo, but acts little on the colouring matter itself. Caustic volatile alkali, or *ammoniac*, acts nearly in the same manner. Precipitated indigo dissolves readily without heat, in alkalis, fixed or volatile. If they be pure or caustic, the blue colour changes gradually to a green, and is at length destroyed: but if they be combined with carbonic acid the colour is not altered. Lime-water has little action on indigo itself, but it dissolves precipitated indigo. This solution changes its colour, which is ultimately destroyed, nearly in the same manner as those in caustic alkalis.

"Indigo exposed to the action of *fire* in an open crucible, or

under a muffle, fumes, swells, grows red, and sometimes takes fire, emitting a white flame. A hundred parts of indigo leave thirty-three or thirty-four parts of ashes. These ashes afford no fixed alkali when lixiviated with distilled water. Muriatic acid dissolves the greater part of them with a slight effervescence: the residuum, which is insoluble, constitutes an eleventh part, and has the characters of siliceous earth.

“ The solution in muriatic acid produces prussian blue, on mixing with it prussiat of pot-ash. From thirty-to thirty-two grains (25 to 27 English) are obtained from the ounce of indigo. Bergman concluded that the ounce contained eighteen or twenty grains (15 or 16) of iron; but he has ascertained in various subsequent works, that prussian blue formed by means of prussiat of pot-ash, contained only about a sixth of its weight of iron; so that from the above experiment we should reckon only five or six grains (4 or 5) in the ounce.—Beside the iron and siliceous earth, the ashes contain calcareous earth and barytes.

“ Indigo detonates strongly with *nitre*. In distillation it affords carbonic acid, a liquor containing a little volatile alkali, and an oil resembling the empyreumatic oil of tobacco, and readily soluble in alcohol.

“ Bergman concludes from his analysis, that a hundred parts of good indigo contain

Mucilaginous matter separable by means of water	12
Resinous matter soluble in alcohol	6
Earthy matter soluble in acetous acid, which does not attack the iron here in the state of oxyd	22
Oxyd of iron soluble in muriatic acid	13

“ The forty-seven parts remaining are almost pure colouring matter, which, distilled alone, affords

Carbonic acid	2
Alkaline liquor	8
Empyreumatic oil	9
Coal	23

“ The coal burnt in the open air gave four parts of earth, about half of which was oxydated iron, and the remainder a very fine siliceous powder.

“ From these results, that great chemist considers indigo as a substance analogous to prussian blue, and the colouring parts of ink. He thinks that, like those substances, it owes its colour to iron: but it has been shewn that the method used by him to calculate the iron contained in it exaggerated its quantity. Besides, we should reckon only that iron which enters into the composition of the colouring matter; for that which the muriatic acid can dissolve without attacking the colouring matter, ought to be considered as a foreign substance, as well as the earths and extractive and resinous matters, the quantities of which vary greatly in different kinds of indigo. Now, from forty-seven parts of pure indigo Bergman obtained only two parts of oxyd of iron, which owes at least a fourth of its weight to oxygen. Hence it follows, that iron cannot be reckoned more than a thirtieth part in the composition of the colouring matter of indigo, the properties of which, moreover, appear to have but a very slight relation to those of prussian blue, and the colouring parts of ink. Iron then can have but little influence in producing the colour of indigo.

“ It is known at present that most of the principles obtained by distillation, as oil, carbonic acid, and ammoniac, did not exist in the substance from which they are disengaged by heat; but that they are new combinations, owing to principles which by their union formed the original substance. Thus, there is neither oil nor ammoniac in indigo: but from the products of its analysis we may conclude, that it contains a pretty considerable quantity of hydrogen, a little azot, a very small quantity of iron, but, above all, such a proportion of coal as is obtainable

from no other known vegetable substance, since forty-seven grains of pure indigo left twenty-three of coal, from which, it is true, we are to subtract four grains of ashes; but then, on the other hand, we must add the coaly matter contained in the oil, in the carbonic acid, and in the carbonic hydrogenous gas, which was no doubt disengaged in the operation. Other experiments will shew, that oxygen really exists in indigo, without forming such an intimate combination as when it enters into the composition of water. As to the siliceous earth, it does not appear whether it be a component part of the colouring matter, or simply mixed with it.

“ The great quantity of coal and of hydrogen which enter into the composition of indigo, accounts for its prompt inflammability, and the brisk detonation it produces with nitre. The nitric and oxygenated muriatic acids appear to me to produce the blackish viscous substance before mentioned, by forming water from a combination of their oxygen with the greater part of the hydrogen of the indigo, so that the coaly matter remains combined with only a very small portion of hydrogen.”

In the first part of the Elements of the Art of Dyeing, M. Berthollet has exhibited reasons which, in his opinion, amount to a proof, that the fixity and unchangeableness of colours are chiefly owing to the proportion of fixed principles which enter into the composition of the colouring matter, and the abundance of coal, which, combining with oxygen less readily than hydrogen does, gives them the property of resisting the action of the air.

“ In indigo (continues he) we find this abundance of coal, which must render its colour fixed and unchangeable. Forty-seven parts of pure indigo left on distillation twenty-three of coal, in Bergman's experiments: and Mr. Quatremere says, that four ounces of indigo yielded him two ounces and a half of coal. If we turn our attention to the preparation by which it is extracted, or rather formed, it appears, that the substance to which it owes its origin must have been of a resinous nature when in the organized plant: that in the preparation it has undergone, in the kind of putrefaction it has experienced, a part of its hydrogen has been consumed by a slow combustion, during which a gas escaped: and that the chief use of the beating was to favour the contact and action of the air. This theory is confirmed by the circumstances which accompany the beating: if it be continued too long, the indigo is changed, blackened, and becomes what is called burnt indigo.

“ Indigo has not indeed the brown or fawn colour, which most commonly indicates that combustion of which I have laid down the theory: but I have remarked, that this colour is not an inseparable effect of it, for colours are influenced by slight circumstances: besides, a deep blue approaches considerably the proper colour of coal.

“ I have advanced, that when colouring matter like that of flax underwent a slight combustion, a small portion of oxygen remained united with it, without combining particularly either with the hydrogen or with the coal, and that hence arose some of its qualities. It appears that we find in indigo this property, which remains to be examined; and from this it is, that the putrefaction, or rather combustion, which it undergoes in its preparation, must have a certain limit, which if exceeded, the indigo is rendered of bad quality.

“ It has been seen that indigo is not naturally soluble, either by alkalis or lime; yet, in the processes employed, it is dissolved by those substances, from which it is afterwards precipitated on the matter to be dyed. The solution of indigo by lime or alkali is greenish. At the surface it becomes blue, because there the indigo is precipitated in its natural state. The green colour is not produced by the alkalis, as it is in many other blue vegetable substances, as Bergman observes: for these, when rendered green, recover their colour as soon as the alkali is saturated with

an acid, which of itself would give them a red colour: but an alteration of the colouring matter of indigo was requisite to its solution in an alkali, and acids have not the property of making it red. It remains to enquire what change the indigo experiences previous to its solution in alkalis."

Bergman examines two processes, to deduce from them the cause of the changes produced in the indigo. We have already treated of these as operations of the dyer (see DYEING). At present it is sufficient merely to mention them.

"If sulphat of iron (observes M. Berthollet) be mixed in water with an equal weight of indigo, and double its weight of lime, the indigo soon dissolves: but Bergman has observed, that if the sulphat of iron be boiled for some hours in a large portion of water, afterwards reduced to a proper quantity by evaporation, the solution would not take place. If a solution of pure or caustic fixed alkali be taken, and to this indigo and sulphuret of arsenic or orpiment be added, the bath soon becomes green, and the indigo is dissolved. If instead of the sulphuret of arsenic we substitute the portion of arsenic it contains, the bath will never be fit for dyeing; but on adding the quantity of sulphur it ought to contain, we shall soon see marks of solution.

"Bergman attributes these effects to phlogiston, communicated to the indigo in the first instance by the precipitate of iron, in the second by the orpiment, by means of which it is rendered soluble by the alkali and the lime; so that when the precipitate of iron has been deprived of its phlogiston by a long ebullition, it is unable to occasion a solution of the indigo, because it is no longer capable of affording it phlogiston.

"In this explanation we have only to make those alterations which are pointed out by the improvements made in physics. Indigo contains a portion of oxygen, which may be taken from it by substances that have a strong attraction for it, and then it becomes soluble by lime and alkalis. The fresh precipitate of sulphat of iron is a substance of this kind: for it is known from the experiments of Dr. Priestley, that this precipitate combines with vital air with which it is placed in contact, whilst its green colour changes to a red, and then to a yellow; but by a long ebullition the iron combines with more and more oxygen, and at length becomes saturated with it, thus being rendered incapable of taking it from the indigo. Sulphuret of arsenic also, when dissolved in an alkali, has a strong attraction for oxygen; but the oxyd of arsenic has a very slight tendency to combine with that principle.

"Mr. Hauffman has proved by a direct experiment, that the solution of sulphuret of arsenic mixed with indigo absorbed vital air, with which it was in contact: for, having put some of that solution, known in the dye-house by the name of *printing blue*, in contact with air obtained by distilling nitre, seven-eighths of the air were absorbed, and the residuum was found to be azotic gas. The printing blue was entirely spoiled, and the indigo was regenerated: a portion of the alkali united with the sulphuric acid produced, and formed with it, sulphat of pot-ash: there remained some caustic alkali; and the arsenic, instead of being in the metallic state, as it is in the sulphuret of arsenic, was combined with it in the state of oxyd. Perhaps Mr. Hauffman would have found, that a part of the arsenic was in the state of an acid, had he pursued his enquiries with more accuracy.

"Though, with respect to the theory of this observation, Mr. Hauffman remains undecided whether to adopt the phlogistic hypothesis, or the natural explanation which attributes the phenomena just described to the absorption of air and the combination of oxygen, no doubts of the validity of the latter can remain at present, when it is known that the air obtained from nitre is composed of vital air, and a more or less considerable proportion of azotic gas or phlogisticated air, according to

the degree to which the decomposition of the nitre has been carried. The azotic gas, which Mr. Hauffman found as a residuum, was pre-existent then, and had no share in producing the phenomenon: the vital air was simply absorbed by the sulphur, which was converted into sulphuric acid: it combined also with the arsenic, reducing it to the state of oxyd, and perhaps even of an acid; while a portion of it united likewise with the indigo dissolved by the caustic alkali: hence the indigo resumed its blue colour, and its natural state; the caustic alkali was no longer capable of acting on it; and it was precipitated: circumstances perfectly analogous to those which take place in the solution of indigo produced by means of sulphat of iron.

"It follows from what has been said, 1st, that indigo in its natural state contains oxygen: 2dly, that while it retains this oxygen it is incapable of uniting with alkalis or lime: 3dly, that substances capable of depriving it of this portion of oxygen render it soluble by lime and alkalis: 4thly, that this solution is decomposed, and the indigo resumes its natural state, when it comes into contact with atmospheric air, and attracts the oxygen of which it had been deprived. The very same things happen when any substance is dyed in the indigo vat. In the vat it acquires a green colour; but when it is exposed to the air it becomes blue, because the indigo recombines with the oxygen it attracts from the atmosphere, by which it is restored to its natural state, and the lime or alkali is set at liberty: the latter being carried off in the washing, the indigo remains combined with the substance, which is found to be dyed by its means. I have found, that a pattern of cloth, or cotton, coming green out of the vat, acquired in like manner a blue colour, by dipping it quickly into oxygenated muriatic acid, sufficiently diluted not to decompose the indigo.

"With respect to Mr. Hauffman's experiment I shall observe, that the sulphuret of alkali and of arsenic acts much more powerfully on oxygen than the simple sulphuret of alkali; which may be owing to two causes: 1st, the arsenic, which in the sulphuret of arsenic is in the metallic state, or very slightly oxydated, may itself act on the oxygen: or 2dly, the union of the sulphur and alkali may not be so intimate in the triple compound of alkali, arsenic, and sulphur, as in the more simple sulphuret, composed of sulphur and alkali only; so that the sulphur existing in a state of equal division may act more strongly on the oxygen.

"However this may be, on the more powerful action exerted on oxygen by the sulphur of alkali and of arsenic depends the more striking effect it produces on wines that contain lead; because it thereby reduces nearer to the metallic state the oxyd of lead, which thence acquires a blacker colour.

"It has been seen, that indigo underwent from the action of the nitric and oxygenated muriatic acids a combustion, in which its hydrogen was alone, or at least principally, destroyed. Sulphuric acid, in dissolving it, appears also to produce a slight combustion, which is perceived by the smell of sulphureous acid, however gentle the heat by which the solution is effected. If the heat employed be a little too great, the signs of combustion are very evident. To this alteration I attribute the changes observed by Bergman in the indigo precipitated from sulphuric acid. Thus, pure alkali and lime dissolve the precipitate, render it green, and soon destroy its colour, so as not to be recoverable by acids, because, as I have shewn, they favour the progress of the combustion. If the liquor which is deprived of its colour were evaporated, a residuum of the nature of that left by the nitric and oxygenated muriatic acids would probably be obtained.

"Indigo, when it has undergone a slight alteration from the sulphuric acid, does not adhere so strongly to wool or silk, as when it is in its natural state. Hence the *saxen blue*, pro-

duced by a solution in sulphuric acid, is less permanent than the blue of the indigo vat; and that solution is capable of giving only a slight dye to silk, and a still slighter to thread or cotton.

"If we attend to the properties acquired by indigo when deprived of a portion of its hydrogen, as it is by the oxygenated muriatic acid, it will not be difficult to explain the greater part of the observations made by Bergman on different mixtures with solution of indigo.

"Mr. Hauffman has observed, that the sulphuret of antimony, or crude antimony, promoted the solution of indigo, in the same manner as sulphuret of arsenic; but that the oxyd of antimony mixed with sulphur would not produce the same effect. He remarked, that the solution of indigo by means of sulphuret of antimony could not be used as a *printing blue*, because the antimony was precipitated in a red state, probably remaining combined with a little sulphur. Other metallic sulphurets did not succeed with him; because, as he observes, they are not soluble in caustic alkali."

Mr. Hauffman, it appears, has made many other interesting observations, which Mr. Berthollet is not yet able to explain in a satisfactory manner. He digested a mixture of iron filings reduced to a fine powder, indigo ground with water, and concentrated caustic alkaline liquor, without being able to dissolve the colouring substance: but a very good solution was procured by means of antimony in its metallic state. The oxyds of antimony appeared to have no action on it; and zinc, though it acts strongly on oxygen, produced no solution.

The precipitate of copper with indigo exhibited to him some peculiar phenomena. Far from contributing to its solution, it effected its regeneration from all the different arsenical antimonial solutions, as well as from that obtained by means of precipitate of iron. The solution of copper in ammoniac produces the same effect. He says, that the dyers avail themselves of this property of copper, more readily to exhaust the blue vats, which, from having been too long in use, or containing originally too little indigo, give but very weak shades; but on dipping the goods to be dyed into a water very slightly impregnated with sulphat of copper, or other coppery solution, whether acid or alkaline, deeper shades of colour are readily produced.

INDIVIDUAL, a particular being of any species, or that which cannot be divided into two or more beings equal or alike. The usual division in logic is made into *genera*, or into *genuses*; those *genera* into *species*; and those *species* into *individuals*.

INDIVISIBLE, among metaphysicians. A thing is said to be absolutely *indivisible*, that is a simple being, and consists of no parts into which it may be divided. Thus, God is *indivisible* in all respects; as is also the human mind; not having extension, or other properties of body.

INDIVISIBLES, in geometry, the elements or principles into which any body or figure may be ultimately resolved; which elements are supposed to be infinitely small: thus, a line may be said to consist of points, a surface of parallel lines, and a solid of parallel and similar surfaces.

INDORE, or **ENDORE**, a modern city of Hindoostan Proper, capital of a territory in the province of Malwa, subject to one of the Poonah Mahratta chiefs. It is 30 miles S. of Ougain. E. lon. 76. 5. N. lat. 24. 31.

INDORSEMENT, in law, any thing written on the back of a deed; as a receipt for money received. There is likewise an *indorsement*, by way of assignment, on bills of exchange and notes of hand; which is done by writing a person's name on the back thereof.

INDOSTAN, or **HINDOOSTAN PROPER**, **INDIA**, or *the Empire of the Great Mogul*. See **HINDOOSTAN**.

INDRE, a department of France, which includes the late province of Berry. It has its name from a river, which rises

in this department, and, passing into that of Indre and Loire, falls into the Loire between Chinon and Saumur. Chateauroux is the capital.

INDRE and LOIRE, a department of France, which includes the late province of Touraine. Tours is the capital.

INDUCTION, in logic and rhetoric, a consequence drawn from several propositions or principles first laid down. See **LOGIC** and **ORATORY**.

INDUCTION, in law, is putting a clerk or clergyman in possession of a benefice or living to which he is collated or presented. See the article **PARSON**. Induction is performed by a mandate from the bishop to the archdeacon, who usually issues out a precept to other clergymen to perform it for him. It is done by giving the clerk corporal possession of the church, as by holding the ring of the door, tolling a bell, or the like; and is a form required by law, with intent to give all the parishioners due notice and sufficient certainty of their new minister, to whom their tythes are to be paid. This therefore is the investiture of the temporal part of the benefice, as institution is of the spiritual. And when a clerk is thus presented, instituted, and inducted into a rectory, he is then, and not before, in full and complete possession; and is called in law *persona impersonata*, or *parson impersoné*.

INDULGENCES, in the Romish church, are a remission of the punishment due to sins, granted by the church, and supposed to save the sinner from purgatory. According to the doctrine of the Romish church, all the good works of the saints over and above those which were necessary towards their own justification, are deposited, together with the infinite merits of Jesus Christ, in one inexhaustible treasury. The keys of this were committed to St. Peter, and to his successors the popes, who may open it at pleasure, and, by transferring a portion of this superabundant merit to any particular person, for a sum of money, may convey to him either the pardon of his own sins, or a release for any one in whom he is interested, from the pains of purgatory. Such indulgences were first invented in the 11th century, by Urban II. as a recompense for those who went in person upon the glorious enterprise of conquering the Holy Land. They were afterwards granted to those who hired a soldier for that purpose; and in process of time were bestowed on such as gave money for accomplishing any pious work enjoined by the pope.

The power of granting indulgences has been greatly abused in the church of Rome. Pope Leo X. in order to carry on the magnificent structure of St. Peter's at Rome, published indulgences, and a plenary remission, to all such as should contribute money towards it. Finding the project take, he granted to Albert elector of Mentz, and archbishop of Magdeburg, the benefit of the indulgences of Saxony and the neighbouring parts, and farmed out those of other countries to the highest bidders; who, to make the best of their bargain, procured the ablest preachers to cry up the value of the ware. The form of these indulgences was as follows: "May our Lord Jesus Christ have mercy upon thee, and absolve thee by the merits of his most holy passion! And I, by his authority, that of his blessed apostles Peter and Paul, and of the most holy Pope, granted and committed to me in these parts, do absolve thee, first from all ecclesiastical censures, in whatever manner they have been incurred: then from all thy sins, transgressions, and excesses, how enormous soever they may be, even from such as are reserved for the cognizance of the holy see, and as far as the keys of the holy church extend: I remit to you all punishment which you deserve in purgatory on their account; and I restore you to the holy sacraments of the church, to the unity of the faithful, and to that innocence and purity which you possessed at baptism; so that, when you die, the gates of punishment shall be shut, and the gates of the paradise of delight shall

be opened : and if you shall not die at present, this grace shall remain in full force when you are at the point of death. In the name of the Father, and of the Son, and of the Holy Ghost."

The terms in which the retailers of indulgences described their benefits and the necessity of purchasing them, are so extravagant, that they appear almost incredible. If any man (said they) purchases letters of indulgence, his soul may rest secure with respect to its salvation. The souls confined in purgatory, for whose redemption indulgences are purchased, as soon as the money tinkles in the chest, instantly escape from that place of torment, and ascend into heaven. That the efficacy of indulgences was so great, that the most heinous sins, even if one should violate (which was impossible) the mother of God, would be remitted and expiated by them, and the person be freed both from punishment and guilt. That this was the unspeakable gift of God, in order to reconcile men to himself. That the cross erected by the preachers of indulgences was equally efficacious with the cross of Christ itself. "Lo! the heavens are open; if you enter not now, when will you enter? For twelve pence you may redeem the soul of your father out of purgatory; and are you so ungrateful, that you will not rescue your parent from torment? If you had but one coat, you ought to strip yourself instantly, and sell it, in order to purchase such benefits," &c.

It was this great abuse of indulgences that contributed not a little to the first reformation of religion in Germany, where Martin Luther began first to declaim against the preachers of indulgences, and afterwards against indulgences themselves: but since that time the popes have been more sparing in the exercise of this power: however, they still carry on a great trade with them to the Indies, where they are purchased at two rials a-piece, and sometimes more:

The pope likewise grants indulgences to persons at the point of death; that is, he grants them, by a brief, power to choose what confessor they please, who is authorized thereby to absolve them from all their sins in general.

INDULT, in the church of Rome, the power of presenting to benefices granted to certain persons by the pope. Of this kind is the indult of kings and sovereign princes in the Romish communion, and that of the parliament of Paris granted by several popes. By the concordat for the abolition of the pragmatic sanction, made between Francis I. and Leo X. in 1516, the French king had the power of nominating to bishoprics, and other consistorial benefices, within his realm. At the same time, by a particular bull, the pope granted him the privilege of nominating to the churches of Brittany and Provence. In 1648 pope Alexander VIII. and in 1668 Clement IX. granted the king an indult for the bishoprics of Metz, Toul, and Verdun, which had been yielded to him by the treaty of Munster; and in 1668 the same pope Clement IX. granted him an indult for the benefices in the counties of Roussillon, Artois, and the Netherlands. The cardinals likewise have an indult granted them by agreement between pope Paul IV. and the sacred college in 1555, which is always confirmed by the popes at the time of their election. By this treaty the cardinals have the free disposal of all the benefices depending on them, and are empowered likewise to bestow a benefice *in commendam*.

INDULTO, a duty, tax, or custom, paid to the king of Spain for all such commodities as are imported from the West Indies in the galleons.

INDUS, or SINDE, a great river of Hindoostan Proper, called by the natives Sinde, or Sindeh. It is formed of about ten principal streams, which descend from the Persian and Tartarian mountains; but, according to major Rennell, the sources of these streams must be far more remote than the sides of these mountains. From the city of Attock, in about lat.

32. 27. downward to Moultan, to the conflux of the Jenaub, or Chunaub, it is commonly named the river of Attock. Below the city of Moultan, it proceeds in a S. W. direction, through the province of that name, and that of Sindy, and enters the Arabian Sea, by several months, N. W. of the gulf of Outch.

INEBRIANTS, are defined to be such things as affect the nerves in a particular and agreeable manner, and through them alter and disturb the functions of the mind. They are properly divided into native and artificial; the former chiefly in use among the oriental and other nations, the latter principally throughout Europe.

Natural Inebriants, are, 1. Opium; in use all over the East, and of which the Turks, through custom, swallow largely. 2. Peganum harmala, Syrian rue. The seeds are sold in Turkey for this purpose; and with these, as Bellonius relates, the Turkish emperor Solyman kept himself intoxicated. 3. Maslac of the Turks, or bangué of the Persians; prepared from the dust of the male flower of hemp, or from the leaves. 4. Bangué of the Indians, from the leaves of the hibiscus sabbariffa. 5. Seeds of various species of the datura, or thorny apple. 6. Pinang, or betel of the Indians. 7. Roots of black henbane. 8. The hyoscyamus physaloides. 9. Berries of the deadly nightshade. 10. Leaves of millfoil, are used by the Dalecarlians to render their beer intoxicating. 11. Tobacco, and several others less material are mentioned; such as clary, saffron, and darnel.

Artificial Inebriants, are fermented liquors from farinaceous seeds; wines, and spirits drawn by distillation. With these is ranked the nectar of the gods, and the anodyne medicine of Homer, commonly called *nepeuthes*; and the spells by which Medea and Circe produced their enchantments.

INERTIA of MATTER, in philosophy, is defined by Sir Isaac Newton to be a passive principle by which bodies persist in their motion or rest, receive motion in proportion to the force impressing it, and resist as much as they are resisted. It is also defined by the same author to be a power implanted in all matter, whereby it resists any change endeavoured to be made in its state. See MECHANICS.

INESSE is applied to things which are actually existing. Authors make a difference between a thing *in esse*, and a thing *in posse*: a thing that is not, but may be, they say is *in posse*, or *potentia*; but a thing apparent and visible, they say is *in esse*, that is, has a real being *eo instanti*; whereas the other is casual, and at best but a possibility.

INFALISTACIO, an ancient punishment of felons, by throwing them among the rocks and sands, customarily used in port towns. It is the opinion of some writers, that *infalifatus* did imply some capital punishment, by exposing the malefactor upon the sands till the next tide carried him away; of which custom, it is said, there is an old tradition. However, the penalty seems to take its name from the Norman *falese*, or *falefia*, which signified not the sands, but the rocks and cliffs adjoining, or impending on the sea-shore. *Commisit feloniam, ob quam fuit suspensus, utlegatus, vel alio modo morti damnatus, &c. vel apud Dover infalifatus, apud Southampton submersus, &c.*

INFALLIBLE, something that cannot err, or be deceived. One of the great controversies between the Protestants and Papists, is the infallibility which the latter attribute to the pope; though, in fact, they themselves are not agreed on that head, some placing this pretended infallibility in the pope and a general council.

INFAMY, in law, is a term which extends to forgery, perjury, gross cheats, &c. by which a person is rendered incapable of being a witness or juror, even though he is pardoned for his crimes.

INFANCY, the earliest period of human life. Fred. Hoffman says, that the human species are *infants* until they begin

to talk, and *children* to the age of puberty. Anatomy discovers to us, that during infancy there is much imperfection in the human frame; *e. g.* its parts are disproportioned, and its organs incapable of those functions which in future life they are designed to perform. The head is larger in proportion to the bulk of the body than that of an adult. The liver and pancreas are much larger in proportion than in advanced life; their secretions are more in quantity also. The bile is very inert; the heart is stronger and larger than in future life; the quantity of blood sent through the heart of an infant, in a given time, is also more in proportion than in adults. Though these circumstances have their important usefulness, yet the imperfection attending them subjects this age to many injuries and dangers from which a more perfect state is exempted. Dr. Percival observes, in his *Essays Medical and Experimental*, that of all the children who are born alive, two thirds do not live to be two years old.

Infants have a larger proportion of brain than adults, hence are most subject to spasmodic disorders; and hence the diagnostics of diseases are in many respects obscure or uncertain, as particularly those taken from the pulse, which, from the irritability of the tender bodies of infants, is suddenly affected by a variety of accidents too numerous, and seemingly too trivial, to gain our attention. However, no very great embarrassment arises to the practitioner from hence; for the disorders in this state are generally acute, less complicated than those in adults, and are more easily discovered than is generally apprehended.

INFANT, denotes a young child. See the article INFANCY. Infants, amongst the Jews, Greeks, and Romans, were swaddled as soon as they were born, in a manner similar to that practised by the moderns. The Jews circumcised and named their infant children on the 8th day from the birth. Upon the birth of a son, the Grecians crowned their doors with olive—of a daughter, with wool. The infant was washed in warm water, and anointed with oil—by the Spartans with wine; it was then dressed, and laid in a basket, or on a shield if the father was a warrior, particularly amongst the Spartans. At five days old they ran with it round the fire, and the mother's relations sent presents. The Greeks named their children on the tenth day, the Romans on the ninth: the naming was attended with sacrifices and other demonstrations of joy. The maternal office of suckling their own children was never declined, when circumstances would permit. How much different is this from the unnatural delicacy observed by modern mothers, a delicacy which to the child is cruelty! The 40th day was a day of solemnity for the mother. The names of children were registered both by the Greeks and Romans. See REGISTER.

For an account of the custom of exposing infants, see EXPOSING.

Infants were kept from crying in the streets by means of a sponge soaked in honey. Nurses had also their bugbears and terrible names to frighten the children into peace:—The figure with which they were principally intimidated was *Μορμολυκειον*, a sort of raw head and bloody-bones.

INFANT, in law, is a person under 21 years of age; whose capacities, incapacities, and privileges, are various.

1. In *criminal* matters. The law of England does in some cases privilege an infant under the age of 21, as to common misdemeanours; so as to escape fine, imprisonment, and the like: and particularly in the cases of omission, as not repairing a bridge, or a highway, and other similar offences; for, not having the command of his fortune till the age of 21, he wants the capacity to do those things which the law requires. But where there is any notorious breach of the peace, a riot, battery, or the like, (which infants when full grown are at least as liable as others to commit); for those, an infant above

the age of 14 is equally liable to suffer, as a person of the full age of 21.

With regard to capital crimes, the law is still more minute and circumspect; distinguishing with greater nicety the several degrees of age and discretion. By the ancient Saxon law, the age of twelve years was established for the age of possible discretion, when first the understanding might open: and from thence till the offender was 14, it was *etas pubertatis proxima*, in which he might, or might not, be guilty of a crime, according to his natural capacity or incapacity. This was the dubious stage of discretion: but under twelve, it was held, that he could not be guilty in will, neither a ter fourteen could be supposed innocent, of any capital crime which he in fact committed. But by the law, as it now stands, and has stood at least ever since the time of Edward III. the capacity of doing ill, or contracting guilt, is not so much measured by years and days, as by the strength of the delinquent's understanding and judgment. For one lad of 11 years old may have as much cunning as another of 14; and in these cases our maxim is, that *malitia supplet aetatem*. Under seven years of age, indeed, an infant cannot be guilty of felony; for then a felonious discretion is almost an impossibility in nature: but at eight years old he may be guilty of felony. Also, under 14, though an infant shall be *prima facie* adjudged to be *doli incapax*, yet if it appear to the court and jury that he was *doli capax*, and could discern between good and evil, he may be convicted and suffer death. Thus a girl of 13 has been burnt for killing her mistress: and one boy of ten, and another of nine years old, who had killed their companions, have been sentenced to death, and he of ten years actually hanged; because it appeared upon their trials, that the one hid himself, and the other hid the body he had killed; which hiding manifested a consciousness of guilt, and a discretion to discern between good and evil. And there was an instance in the last century, where a boy of eight years old was tried at Abington for firing two barns; and, it appearing that he had malice, revenge, and cunning, he was found guilty, condemned, and hanged accordingly. Thus also, in very modern times, a boy of ten years old was convicted on his own confession of murdering his bedfellow. There appearing in his whole behaviour plain tokens of a mischievous disposition; and as the sparing this boy merely on account of his tender years might be of dangerous consequence to the public, by propagating a notion that children might commit such atrocious crimes with impunity, it was unanimously agreed by all the judges, that he was a proper subject of capital punishment. But, in all such cases, the evidence of that malice which is to supply age, ought to be strong and clear beyond all doubt and contradiction.

2. In *civil* matters. The ages of male and female are different for different purposes. A male at 12 years old may take the oath of allegiance; at 14 is at the years of discretion, and therefore may consent or disagree to marriage, may choose his guardian, and, if his discretion be actually proved, may make his testament of his personal estate; at 17 may be an executor; and at 21 is at his own disposal, and may aliene his lands, goods, and chattels. A female also at seven years of age may be betrothed or given in marriage; at nine is entitled to dower, at 12 is at years of maturity, and therefore may consent or disagree to marriage, and, if proved to have sufficient discretion, may bequeath her personal estate; at 14 is at years of legal discretion, and may choose a guardian; at 17 may be executrix; and at 21 may dispose of herself and her lands. So that full age in male or female is 21 years, which age is completed on the day preceding the anniversary of a person's birth; who till that time is an infant, and so styled in law. Among the ancient Greeks and Romans, women were never of age, but subject to perpetual guardianship, unless when married, *nisi convenissent in manum viri*: and, when that

perpetual tutelage wore away in process of time, we find that, in females as well as males, full age was not till 25 years. Thus by the constitution of different kingdoms, this period, which is merely arbitrary, and *juris positivi*, is fixed at different times. Scotland agrees with England in this point (both probably copying from the old Saxon constitutions on the continent, which extended the age of minority *ad annum vigesimum primum, et eo usque juvenes sub tutelam reponunt*): but in Naples persons are of full age at 18; in France, with regard to marriage, not till 30; and in Holland at 25.

The very disabilities of infants are privileges; in order to secure them from hurting themselves by their own improvident acts. An infant cannot be sued but under the protection, and joining the name, of his guardian; for he is to defend him against all attacks as well by law as otherwise: but he may sue either by his guardian, or *prochein amy*, his next friend who is not his guardian. This *prochein amy* may be any person who will undertake the infant's cause; and it frequently happens that an infant, by his *prochein amy*, institutes a suit in equity against a fraudulent guardian.

With regard to estates and civil property, an infant hath many privileges. In general, an infant shall lose nothing by nonclaim, or neglect of demanding his right; nor shall any other *laches* or negligence be imputed to an infant, except in some very particular cases.

It is generally true, that an infant can neither aliene his lands, nor do any legal act, nor make a deed, nor indeed any manner of contract, that will bind him. But still to all these rules there are some exceptions: part of which were just now mentioned in reckoning up the different capacities which they assume at different ages: and there are others, a few of which it may not be improper to recite, as a general specimen of the whole. And, first, it is true, that infants cannot aliene their estates; but infant trustees, or mortgagges, are enabled to convey, under the direction of the court of chancery or exchequer, or other courts of equity, the estates they hold in trust or mortgage, to such person as the court shall appoint. Also it is generally true, that an infant can do no legal act: yet an infant, who has an advowson, may present to the benefice when it becomes void. For the law in this case dispenses with one rule, in order to maintain others of far greater consequence: it permits an infant to present a clerk (who, if unfit, may be rejected by the bishop), rather than either suffer the church to be unserved till he comes of age, or permit the infant to be debarred of his right by lapse to the bishop. An infant may also purchase lands, but his purchase is incomplete: for, when he comes to age, he may either agree or disagree to it, as he thinks prudent or proper, without alleging any reason; and so may his heirs after him, if he dies without having completed his agreement. It is, farther, generally true, that an infant, under 21, can make no deed but what is afterwards voidable: yet in some cases he may bind himself apprentice by deed indented or indentured, for seven years; and he may by deed or will appoint a guardian to his children, if he has any. Lastly, it is generally true, that an infant can make no other contract that will bind him: yet he may bind himself to pay for his necessary meat, drink, apparel, physic, and such other necessaries; and likewise for his good teaching and instruction, whereby he may profit himself afterwards.

INFANTE, and INFANTA, all the sons and daughters of the kings of Spain and Portugal, except the eldest; the princes being called *infantes*, and the princesses *infantas*.

INFANTRY, in military affairs, the whole body of foot-soldiers, whether independent companies or regiments. The word takes its origin from one of the *infantas* of Spain, who, finding that the army commanded by the king her father had been defeated by the Moors, assembled a body of foot-soldiers,

and with them engaged and totally routed the enemy. In memory of this event, and to distinguish the foot-soldiers, who were not before held in much consideration, they received the name of *Infantry*.

Heavy-armed INFANTRY, among the ancients, were such as wore a complete suit of armour, and engaged with broad shields and long spears. They were the flower and strength of the Grecian armies, and had the highest rank of military honour.

Light-Armed INFANTRY, among the ancients, were designed for skirmishes, and for fighting at a distance. Their weapons were arrows, darts, or slings.

Light INFANTRY, among the moderns, have only been in use since the year 1656. They have no camp-equipage to carry, and their arms and accoutrements are much lighter than those of the infantry. Light infantry are the eyes of a general, and the givers of sleep and safety to an army. Wherever there is found light cavalry, there should be light infantry. They should be accustomed to the pace of four miles an hour, as their usual marching pace, and be able to march at five miles an hour upon all particular occasions. Most of the powers on the continent have light infantry. It is no very long time since light infantry came to be used in the British army; but now every regiment has a company of them, placed on the left, the right being occupied by the grenadiers.

INFATUATE, to prepossess any one in favour of some person or thing that does not deserve it, so far as that he cannot easily be disabused. The word *infatuate* comes from the Latin *fatuus* "fool;" of *fari* "to speak out," which is borrowed from the Greek *φαω*, whence *φαρις*, which signifies the same with *vates* in Latin, or *prophet* in English; and the reason is, because their prophets or priests used to be seized with a kind of madness or folly, when they began to make their predictions, or deliver oracles. The Romans called those persons *infatuati*, who fancied they had seen visions, or imagined the god Faunus, whom they called *fatuus*, had appeared to them.

INFECTIO, among physicians. See CONTAGION.

INFERIÆ, sacrifices offered by the Romans to the *Di Manes*, or the souls of deceased heroes or other illustrious persons, or even any relation or person whose memory was held in veneration. These sacrifices consisted of honey, water, wine, milk, the blood of victims, variety of balsamic unguents, chaplets, and loose flowers. The victims upon these occasions were generally of the smaller cattle, though in ancient times they sacrificed slaves or captives: but what a shocking view does this give us of their sentiments of human nature, as if nothing but murder, cruelty, and human blood, could satisfy or prove acceptable to an human soul! The sacrifices were usually black and barren. The altars on which they were offered were holes dug in the ground. The honey, water, wine, &c. were used as libations, and were poured on the tombs of children by children, on those of virgins by virgins, and on those of married men by women. The *inferiæ* were offered on the 9th and 30th days after interment amongst the Greeks, and repeated in the month Anthesterion. The whole of this article applies equally to the Greeks and the Romans.

INFIBULATION, in antiquity. It was a custom among the Romans to infibulate their singing boys, in order to preserve their voices: for this operation, which prevented their retracting the prepuce over the glans, and is the very reverse to circumcision, kept them from injuring their voices by premature and preposterous venery; serving as a kind of padlock, if not to their inclinations, at least to their abilities. It appears by some passages in Martial, that a less decent use was made of infibulation among the luxurious Romans: for some ladies of distinction, it seems, took this method of confining their paramours to their own embraces. Juvenal also hints at some such practice. Celsus, a chaste author, says infibulation was some-

times praised for the sake of health, and that nothing destroys it more than the silly practice this operation seems intended to prevent. The method of doing it is this: The skin which is above the glans is to be extended, and marked on both sides with ink, where it is perforated, and then suffered to retract itself. If the marks recur upon the glans, too much of the skin has been taken up, and we must make the marks farther; if the glans remain free from them, they show the proper place for affixing a fibula: then pass a needle and thread through the skin where the marks are, and tie the threads together; taking care to move it every day, until the parts about the perforations are cicatrised: this being effected, take out the thread, and put in the fibula; which the lighter it is the better. Authors have not determined what the fibula of the ancient surgeon was, though, no doubt it was for different purposes. In the present case, the fibula seems to mean a ring of metal, not unlike what the country people put through the noses of swine.

INFIDEL, a term applied to such persons as are not baptized, and that do not believe the truths of the Christian religion. See DEIST.

INFIDELITY, in a general sense, denotes want of faith or belief in regard to any subject or transaction. The term however is most usually understood of religious infidelity, which signifies a disbelief of Christianity.

“Of all the methods (says Mr. Knox in his Essays) which the vanity of man has devised with a view to acquire distinction, there is none easier than that of professing a disbelief of the established religion. That which shocks the feelings of those with whom we converse, cannot fail of attracting notice; and as the vain are usually confident, they utter their doubts with an air so oracular and decisive, as induces the simple to think them profoundly wise. Audacity, with a little ingenuity, will attract the eyes of spectators; and this will sufficiently answer the purpose of many among the professed unbelievers. One might be diverted, if one were not hurt, at seeing a circle of silly admirers, gaping and fixing their eyes on some half-learned and impudent prater, who throws out oblique insinuations against the bible, the clergy, or the sacrament. These are fertile topics of wit and ingenuity; but it might mortify the vanity of some very vain writers and talkers, if they were to recollect, what is undoubtedly true, that it is a species of wit and ingenuity which not only the vilest, but the most stupid and illiterate of mankind, have frequently displayed in all its possible perfection.

“There is indeed no doubt that vanity is one of the principal causes of infidelity. It must be the sole cause of communicating it to others, by writing or conversation. For let us suppose the case of a very humane, judicious, and learned man, entertaining doubts of the truth of Christianity; if he cannot clear his doubts by examination, he will yet recollect that doubts are no certainties; and, before he endeavours to propagate his scepticism, he will ask himself these questions: “Am I quite convinced that what I doubt of cannot possibly be true? If I am convinced of it, am I sure that the publication of my opinions will not do more harm than good? Is not the disturbing of any long-established civil constitution attended with confusion, rebellion, bloodshed, and ruin? And are not the majority of men more strongly attached to the religion than the government of their forefathers? Will it serve my country to introduce discontent of any species? May not those innovations in religion, which discontent may introduce, lead to all the evils which are caused by phrensy and fanaticism? Granting that I were able to make a party formidable enough to crush opposition and to exterminate Christianity, still am I certain that I act, in this instance, like a good member of society? For is not this system, whether well or ill founded, friendly to society? I must confess

it; its greatest enemies have acknowledged it. What motive then can induce me to divulge my doubts of its authenticity? Not the good of mankind; for it is already allowed by unbelievers, that the good of mankind is interested in the belief of its divine original. Is it for my own good, and with a view to be convinced? I will not deceive myself: my motive, I suspect, is of another kind; for do I read those books which have been already written to satisfy similar doubts? Nothing but the vanity of appearing to be wiser than my credulous neighbours can induce me to interrupt the happiness of their belief. But vanity of this sort, which tends to disturb society, to injure the national morals, and to rob many thousand individuals of a copious source of sweet and solid comfort, must be pronounced extreme wickedness, even according to the obvious dictates of natural religion. I shall act the part of a good citizen and a good man, by conforming to a system whose beneficial influence I feel and confess, and by endeavouring to acquire a belief in that which has for so many centuries been established, and which promises to soothe me in distress with the sweetest consolations, and to brighten the dismal hour of death by the hope of a more glorious and happy state of existence. At all events, I shall have the satisfaction of having commanded myself so far, as not to have run the hazard of endangering the welfare of my fellow-creatures, either here or hereafter, by indulging a degree of vanity, which, in a creature so weak and so short-lived as myself, is a folly very inconsistent with the superior wisdom which I seem to arrogate.

“I will venture to repeat (continues our author), that all writers against Christianity, however they may affect even the extremes of benevolence, honour, philosophy, and enlargement of mind, are actuated by vanity and wickedness of heart. Their motives are as mean, selfish, narrow, and in every respect unjustifiable, as the tendency of their writings is mischievous. Their malice is often impotent, through the foolish sophistry of their arguments; but, if ever it be successful, it is highly injurious; and indeed, considering their motives and the probable consequences of their endeavours, the infidel writer is a greater enemy to society, and consequently guiltier, according to all the principles of social union, than the thief or the traitor. Persecution would, however, only promote his cause, and his proper punishment is contempt.

“It is certainly no derogation from the character of a man of sense, to conform, even while he is so unfortunate as to doubt their truth, to the opinions of his country. His conformity will probably lead him to a train of actions and of thought, which, in due time, will induce him to believe. But, if that should not happen, yet he will act as very wise and very great men have acted, in paying a respectful deference to the avowed conviction of others. The most intelligent and powerful men of ancient Rome not only appeared to believe a very absurd and hurtful system, but assisted in all its ceremonies as priests. Even Socrates, who evidently entertained some notions adequate to the dignity of the one great and supreme Being, yet thought it was a duty which he owed to his country, so far to conform to the wretched establishment, as to order in his dying words a sacrifice to *Æsculapius*. This external conformity to the national religion ought not to be confounded with hypocrisy. If indeed it is carried to extremes, or zealously affected, it certainly is very blameable and contemptible deceit; but while it keeps within the bounds of reason and moderation, it ought to be called a decent deference to the opinions of the majority, arising from humility, and from a desire to maintain the tranquillity of the state, and to continue an innocent and useful system, which has and will always greatly contribute to lessen the quantity and degree both of moral and of natural evil.

“The easiest, after all, or at least the most effectual method of appearing in any character, is really to be what we wish to appear. But belief, you will say, is not in our power, and how

can we believe what appears to us incredible? Certainly you cannot while it appears incredible. But let me ask you, whether you have taken any pains to believe, or have at once and at a glance persuaded yourself, that the Christian religion is totally false? It is probable that a great number of sceptical writers never gave themselves the trouble to read those scriptures which they warmly oppose. They hear objections, they read objections, and they find, that from men of reputed wit and ingenuity the objections often originate. They also wish to be reputed men of wit and ingenuity, and therefore eagerly adopt the language and sentiments of the order. Perhaps the vanity and pride of this class of men will render all attempts to convince them abortive; but to modest doubters, and to those whose good sense and good dispositions lead them to wish to adopt the religion of their country, it may not be useless to suggest advice, with a view to facilitate their conviction.

“The chief thing required is to free themselves from the pride of human reason. Humility (and surely our blindness and imperfections are sufficient to render us humble, if we would be reasonable), humility will open our hearts, and belief will find admission. Sincere endeavours, seconded by prayers, will never fail to help our unbelief. But, alas! a fine, gay, spirited, liberal, and enlarged modern philosopher would be ashamed to be found on his knees, or with a Testament in his possession. There is scarcely any vicious act, or any vicious book, which would put him so much to the blush.

“A modest well-meaning man might, however, one should think, divest himself of those prejudices which prevent the possibility of belief, by the following soliloquy: ‘I find myself placed in a world abounding with evil and misery. Under the immediate pressure of it, I feel my heart inclining, like the needle to the north, by its natural tendency, to the Deity for support. Man, of all animals, is the only one who has the sense of religion. Feeling this distinctive propensity of my nature, I look around to discover to what object, and in what manner, that part of my fellow-creatures who live in the same society with myself pay their adoration. I find a system of religion already established, and which has been established in the most enlightened countries of the earth near 2000 years. I resolve to examine it. It claims that respect from its antiquity and universality. Many difficulties appear on the first inspection. My reason is often startled, and my belief wavers. But I will not yet give up a point of so serious importance, without further and cloier attention to it. I reflect, that 2000 years is a vast space in the age of the world. How many myriads of men like myself have lived and died in the faith during that time! And were all of them fools or hypocrites? It could not have been. Can the understanding of a poor individual, just come into the world, and hardly knowing where he is, comprehend on intuition an object of such magnitude, and make the mighty discovery which has escaped millions of the wisest and most learned of mortals? Or, supposing that they all perceived the deception, am I then at last the only honest man who will confess it? I am ashamed to avow such an idea to myself. But yet, if I reject what they received, surely I avow it in the more expressive language of my conduct. Pride, I fear, is the foundation of my scepticism; and humility must form the basis of my belief. I will check my own presumption, and reject the cavils of vain and foolish philosophy. Shall a poor weak creature, who cometh up like a flower, and is cut down, who fleeth as a shadow, and never continueth in one stay, presume to pronounce decisively in that little period, in which he has scarcely time to look about him before he dies, against a system which has strong internal and external evidence of divine original, which is most useful and comfortable, and which has been admitted among a great portion of mankind during almost 20 centuries? No: it is the first wisdom to be humble. Humility will be fol-

lowed by grace, and grace by faith, and faith by salvation. It plainly appears, that I can lose nothing by belief, but some of those excessive and irregular enjoyments which would destroy my health and life; but I may possibly gain a glory and a happiness which shall continue to all eternity.”

INFINITE, that which has neither beginning nor end: in which sense God alone is infinite. Infinite is also used to signify that which has had a beginning, but will have no end, as angels and human souls. This makes what the schoolmen call *infinitum a parte post*; as, on the contrary, by *infinitum a parte ante*, they mean that which has an end, but had no beginning.

INFINITE Quantities. The very idea of magnitudes infinitely great, or such as exceed any assignable quantities, does include a negation of limits; yet if we nearly examine this notion, we shall find that such magnitudes are not equal among themselves, but that there are really, besides infinite length and infinite area, three several sorts of infinite solidity; all of which are *quantitates sui generis*, and that those of each species are in given proportions. *Infinite-length*, or a line infinitely long, is to be considered either as beginning at a point, and so infinitely extended one way, or else both ways from the same point; in which case the one, which is a beginning infinity, is the one half of the whole, which is the sum of the beginning and ceasing infinity; or, as may be said, of infinity *a parte ante* and *a parte post*, which is analogous to eternity in time and duration, in which there is always as much to follow as is past, from any point or moment of time, nor doth the addition or subtraction of finite length, or space of time, alter the case either in infinity or eternity, since both the one or the other cannot be any part of the whole.

INFINITESIMALS, among mathematicians, are defined to be infinitely small quantities. In the method of infinitesimals, the element, by which any quantity increases or decreases, is supposed to be infinitely small; and is generally expressed by two or more terms, some of which are infinitely less than the rest; which being neglected as of no importance, the remaining terms form what is called the *difference of the proposed quantity*. The terms that are neglected in this manner, as infinitely less than the other terms of the element, are the very same which arise in consequence of the acceleration, or retardation, of the generating motion, during the infinitely small time in which the element is generated; so that the remaining terms express the elements that would have been produced in that time, if the generating motion had continued uniform: therefore those differences are accurately in the same ratio to each other as the generating motions or fluxions. And hence, though in this method infinitesimal parts of the elements are neglected, the conclusions are accurately true without even an infinitely small error, and agree precisely with those that are deduced by the method of fluxions. See FLUXIONS.

INFINITIVE, in grammar, the name of one of the moods, which serve for the conjugation of verbs. See GRAMMAR.

INFINITY, the quality which denominates a thing infinite. See METAPHYSICS.

INFIRMARY, a kind of hospital, where the lame and sickly are properly taken care of.

INFLAMMABILITY, that property of bodies which opposes them to kindle or catch fire. See FIRE, FLAME, PHLOGISTON, &c.

INFLAMMATION, in medicine and surgery, a redness and swelling of any part of the body, attended with heat, pain, and symptoms of fever. See MEDICINE and SURGERY.

INFLAMMATION of Oils by concentrated Acids. See CHEMISTRY, p. 453.

Spontaneous INFLAMMATION; heat and conflagration produced in combustible bodies from adventitious causes. A paper on this subject, which appeared in vol. ii. p. 425 of the Re-

peritory, induced the Rev. Mr. W. Tooke to publish in vol. iii. p. 95 of the same work, some ingenious remarks on that subject :

“ The following observations (says he) on spontaneous inflammations were drawn up, a few years ago, in Russia; they were suggested by an accident which happened on board a frigate lying in the harbour of Cronstadt, of which mention is made in your last number. I was then at Cronstadt, and consequently had an opportunity of procuring an accurate account, not only of the accident itself, but also of the experiments made to ascertain the cause of it. If you think proper to add them to the accounts of spontaneous inflammations which you have already published, you are at liberty to do so.

“ The explication of the causes of spontaneous inflammations in certain substances and compositions, must ever be an object of consequence to the magistracy; as, by discovering the causes of such phænomena, the suspicion of felonious practices in setting fire to buildings may frequently be avoided, and many an innocent person saved from capital punishment. A bare attempt to lessen the number of victims, that may possibly be doomed to bleed at the bar of mistaken justice, can never be thought either frivolous or impertinent.

“ I intentionally pass over the *pyrophori*, at present so well known to chemists, prepared from alum, &c. as not properly belonging to my design, though deserving of notice in explaining the causes of spontaneous inflammation; nor shall I say any thing of those inflammations that happen in the mineral kingdom, in coal-mines, alum-pits, &c. as they are already sufficiently known, and their causes have often been discussed.

“ Of incomparably more importance, and far less known, are the spontaneous inflammations of substances from the animal and vegetable kingdoms; and these are what I design here briefly to bring together: as I firmly believe, that a more extensive publication of these phænomena may prove of general utility to mankind, by lessening the dangers to which they are exposed.

“ A recent instance will serve to elucidate what I now advance. A person of the name of Rûde, at that time an apothecary at Bautzen, had prepared a *pyrophorus* from rye-bran and alum. Not long after he had made the discovery, there broke out in the next village of Nauslitz a great fire, which did much mischief, and was said to have been occasioned by the treating of a sick cow in the cow-house. Mr. Rûde knew that the countrymen were used to lay an application of parched rye-bran to their cattle, for curing the thick neck; he knew also, that alum, and rye-bran, by a proper process, yielded a *pyrophorus*; and now he wished to try whether parched rye-bran alone would have the same effect. Accordingly he roasted a quantity of rye bran by the fire, till it had acquired the colour of roasted coffee. This roasted bran he wrapped up in a linen cloth; in the space of a few minutes there arose a strong smoke through the cloth, accompanied by a smell of burning. Not long afterwards the rag grew as black as tinder, and the bran, now become hot, fell through it on the ground in little balls. Mr. Rûde repeated the experiment at various times, and always with the same result. Who now will any longer doubt, that the frequency of fires in cow-houses, which, in those parts, are mostly wooden buildings, may not be occasioned by this common practice, of binding roasted bran about the necks of the cattle? The fire, after consuming the cattle and the shed, communicates itself to the adjoining buildings; great damage ensues; and the ignorant look for the cause in wilful and malicious firing, consequently in a capital crime.

“ Montet relates, in the *Mémoires de l'Académie de Paris*, 1748, that animal substances, under certain circumstances, may kindle into flame; and that he himself has been witness to the spontaneous accension of dunghills. The woollen stuff prepared

at Sevennes, which bears the name of Emperor's stuff, has kindled of itself, and burnt to a coal. It is not unusual for this to happen to woollen stuffs, when in hot summers they are laid in a heap, in a room but little aired.

“ In June, 1781, the same thing happened at a wool-comber's in a manufacturing town in Germany, where a heap of wool-combings, piled up in a close warehouse seldom aired, took fire of itself. This wool had been by little and little brought into the warehouse; and, for want of room, piled up very high, and trodden down, that more might be added to it. That this combed wool, to which, as is well known, rape oil mixed with butter is used in the combing, burnt of itself, was sworn by several witnesses. One of them affirmed that, ten years before, a similar fire happened among the flocks of wool at a clothier's, who had put them into a cask, where they were rammed hard, for their easier conveyance. This wool burnt from within outwards, and became quite a coal; it was very certain that neither fire nor light had been used at the packing, consequently the above fires arose from similar causes.

“ In like manner very credible cloth workers have certified, that after they have bought wool that was become wet, and packed it close in their warehouse, this wool has burnt of itself; and very serious consequences might have followed, if it had not been discovered in time.

“ The spontaneous accension of various matters from the vegetable kingdom, as wet hay, corn, and madder, and at times wet meal and malt, are already sufficiently known. Experiments have likewise repeatedly been made with regard to such phænomena; and it will presently appear, that hemp, or flax, and hemp-oil, have frequently given rise to dreadful conflagrations. Montet says: In the year 1757, a sort of sailcloth, called *prelart*, having one side of it smeared with ochre and oil, took fire in the magazine at Brest, where it had probably kindled of itself. It is not at all unlikely that many fires in seaports have arisen from these self-accensions; as it has often happened that, after the strictest enquiry, the real cause of them has not been discovered.

“ About twenty years ago, several fires broke out within a short space of time in a rope-walk, and in some wooden houses, at St. Petersburg; and, in all these instances, not the slightest trace of wilful firing could be found: but there was lying in the rope-walk, where the cables for the navy are made, a great heap of hemp, among which a considerable quantity of oil had been carelessly spilt, and it was therefore declared spoilt; for which reason it had been bought at a low price, and put up together, and was held to be the cause of the fire. The inferior inhabitants of that part of the town had likewise bought of this spoilt hemp, at a cheaper rate than usual, for closing the chinks and caulking the windows of their houses, which are constructed of barks laid one upon the other. At this rope-walk, coils of cable have been found hot, and the people have been obliged to separate them, to prevent farther danger.

“ It was in the spring of the year 1780, that a fire was discovered on board a frigate lying in the road off Cronstadt; which, if it had not been timely extinguished, would have endangered the whole fleet. After the severest scrutiny, no cause of the fire was to be found; and the matter was forced to remain without explanation, but with strong surmises of some wicked incendiary being at the bottom of it. In the month of August, in the same year, a fire broke out at the hemp-magazine at St. Petersburg, by which several hundred thousand poods (about 36lb. English) of hemp and flax were consumed. The walls of the magazine are of brick, the floors of stone, and the rafters and covering of iron; it stands alone on an island in the Neva, on which, as well as on board the ships lying in the Neva, no fire is permitted. In St. Petersburg, in the same year, a fire was discovered in the vaulted shop of a furrier. In these shops,

which are all vaults, neither fire nor candle is allowed, and the doors of them are all of iron. At length the probable cause was found to be, that the surrier, the evening before the fire, had got a roll of new cere-cloth, (much in use here for covering tables, counters, &c. being easily wiped and kept clean,) and had left it in his vault, where it was found almost consumed.

“ In the night between the 20th and 21st of April, 1781, a fire was seen on board the frigate *Maria*, which lay at anchor, with several other ships, in the road off the island of Cronstadt; the fire was however soon extinguished; and, by the severest examination, little or nothing could be extorted concerning the manner in which it had arisen. The garrison was threatened with a scrutiny that should cost them dear; and, while they were in this cruel suspense, the wisdom of the sovereign gave a turn to the affair, which quieted the minds of all, by pointing out the proper method to be pursued by the commissioners of inquiry, in the following order to Count Chernichef: When we perceived, by the report you have delivered in of the examination into the accident that happened on board the frigate *Maria*, that, in the cabin where the fire broke out, there were found parcels of matting, tied together with packthread, in which the foot of burnt fir-wood had been mixed with oil, for the purpose of painting the ship's bottom, it came into our mind, that, at the fire which happened last year at the hemp-warehouses, the following cause, among others, was assigned, that the fire might have proceeded from the hemp being bound up in greasy mats, or even from such mats having lain near the hemp: therefore, neglect not to guide your farther inquiries by this remark.

“ As, upon juridical examination, as well as private inquiry, it was found that, in the ship's cabin, where the smoke appeared, there lay a bundle of matting, containing Russian lamp-black, prepared from fir-foot, moistened with hemp-oil varnish, which was perceived to have sparks of fire in it at the time of the extinction, the Russian admiralty gave orders to make various experiments, in order to see whether a mixture of hemp-oil varnish and the forementioned Russian black, folded up in a mat and bound together, would kindle of itself.

“ They shook forty pounds of fir-wood foot into a tub, and poured about thirty-five pounds of hemp-oil varnish upon it; this they let stand for an hour, after which they poured off the oil. The remaining mixture they now wrapped up in a mat, and the bundle was laid close to the cabin where the midshipmen had their birth. To avoid all suspicion of treachery, two officers sealed both the mat and the door with their own seals, and stationed a watch, of four sea-officers, to take notice of all that passed the whole night through; and, as soon as any smoke should appear, immediately to give information to the commandant of the port.

“ The experiment was made the 26th of April, about 11 o'clock A. M. in presence of all the officers named in the commission. Early on the following day, about 6 o'clock A. M. a smoke appeared, of which the chief commandant was immediately informed by an officer: he came with all possible speed, and, through a small hole in the door, saw the mat smoking. Without opening the door, he dispatched a messenger to the members of the commission; but, as the smoke became stronger, and fire began to appear, the chief commandant found it necessary, without waiting for the members of the commission, to break the seals and open the door. No sooner was the air thus admitted, than the mat began to burn with greater force, and presently it burst into a flame.

“ The Russian admiralty, being now fully convinced of the self-enkindling property of this composition, transmitted their experiment to the Imperial Academy of Sciences; who appointed my friend Mr. Georgi, a very learned and able adjunct of the Academy, to make farther experiments on the subject,

and to him I am chiefly indebted for this account; though, being myself at the time upon a visit to some of my old parishioners at Cronstadt, I made myself acquainted with many of the circumstances on the spot.

“ The experiments of this ingenious chemist are of great importance, as they form a valuable addition to our knowledge on the subject, and are very remarkable from the occasion that led to these discoveries.

“ Previous to the relation of the experiments, it is necessary to observe, that the Russian fir-black is three or four times more heavy, thick, and unctuous, than that kind of painter's black which the Germans call *kien-rabm*. The former is gathered at Ochta, near St. Petersburg, at Moscow, at Archangel, and other places, in little wooden huts, from resinous fir-wood, and the unctuous bark of birch, by means of an apparatus uncommonly simple, consisting of pots without bottoms set one upon the other; and is sold very cheap. The famous fine German *kien-rabm* is called in Russia *Holland's black*. In what follows, when I speak of raw oil, it is to be understood of linseed-oil or hemp-oil; but most commonly the latter. The varnish is made of five pounds of hemp-oil boiled with two ounces and a half of minium. For wrapping up the composition, Mr. Georgi made use of coarse hemp-linen, and always single, never double. The impregnations and commixtures were made in a large wooden bowl, in which they stood open till they were wrapt up in linen.

“ That I may not be too prolix, I will select and communicate only such of the experiments as were most remarkable, and succeeded best.

“ Three pounds of Russian fir-black were slowly impregnated with five pounds of hemp-oil varnish; and when the mixture had stood open five hours, it was bound up in linen. By this process it became clotted; but some of the black remained dry. When the bundle had lain sixteen hours in a chest, it was observed to emit a very nauseous, and rather putrid, smell, not quite unlike that of boiling oil. Some parts of it became warm, and steamed much; this steam was watery, and by no means inflammable. Eighteen hours after the mixture was wrapt up, one place became brown, emitted smoke, and directly afterwards glowing fire appeared. The same thing happened in a second and a third place; though other places were scarcely warm. The fire crept slowly around, and gave a thick, grey, stinking smoke. Mr. Georgi took the bundle out of the chest, and laid it on a stone pavement; when, on being exposed to the free air, there arose a slow burring flame, a span high, with a strong body of smoke. Not long afterwards there appeared, here and there, several chaps, or clefts, as from a little volcano, the vapour issuing from which burst into flame. On his breaking the lump, it burst into a very violent flame, full three feet high, which soon grew less, and then went out. The smoking and glowing fire lasted for the space of six hours; and afterwards the remainder continued to glow without smoke for two hours longer. The grey earthy ashes, when cold, weighed five ounces and a half.

“ In another experiment perfectly similar to the foregoing, as far as relates to the composition and quantities, the enkindling did not ensue till forty-one hours after the impregnation: the heat kept increasing for three hours, and then the accension followed.

“ It is worthy of remark, that these experiments succeeded better on bright days than on such as were rainy; and the accension came on more rapidly.

“ In another experiment, three pounds of Russian fir-black were slowly impregnated with three pounds of raw hemp-oil; and the accension ensued after nine hours.

“ Three quarters of a pound of German *rabm* were slowly impregnated with a pound and a half of hemp oil varnish. The mixture remained seventy hours before it became hot and reek-

ing. It then gradually became hotter, and emitted a strong exhalation; the effluvia were moist, and not inflammable. The re-action lasted 36 hours, during which the heat was one while stronger, and then weaker, and at length quite ceased.

“ Stove or chimney soot, mostly formed from birch wood smoke, was mingled with the above-mentioned substances and tied up; the compound remained cold and quiet.

“ Russian fir-black mixed with equal parts of oil of turpentine, and bound up, exhibited not the least re-action or warmth.

“ Birch oil mixed with equal parts of Russian fir-black, and bound up, began to grow warm and to emit a volatile smell; but the warmth soon went off again.

“ From the experiments of the Admiralty, and of Mr. Georgi, we learn, not only the decisive certainty of the self-accension of soot and oil, when the two substances are mixed under certain circumstances, but also the following particulars:

“ Of the various kinds of soot or lamp-black, the experiments succeeded more frequently and surely with the coarser, more unctuous and heavier, like Russian painter's black, than with fine light German *rahm*, or with coarse chimney-soot. In regard to oils, only those experiments succeeded which were made with drying oils either raw or boiled. The proportions of the soots to the oils were, in the successful experiments, very various; the mixture kindled with a tenth, a fifth, a third, with an equal, and likewise with a double proportion of oil. In general, however, much more depends on the mode of mixture, and the manipulation; and, as Mr. Georgi often observed, on the weather: for, in moist weather, the bundles, after becoming warm, would frequently grow cold again.

“ It is in all respects remarkable, that it should never till now have been observed, that a mixture which has been made millions of times, in all proportions and quantities, for painting of ships, and the outsides of wooden houses, and sometimes intentionally, sometimes accidentally, left covered or open, a longer or a shorter time, should be capable of kindling of itself. It is highly probable, that, even on this occasion, it was entirely owing to the attention of the Empress that it was made an object of inquiry, or even that it was at all observed.

“ Before I finish this paper, I will just mention a self-accension, not noticed till of late, and that by Mr. Hagemann, an apothecary at Bremen. He prepared a boiled oil of *hyssopus*, or henbane, in the usual way, with common oil. The humidity of the herb was nearly evaporated, when he was called away by other affairs, and was obliged to leave the oil on the fire. The evaporation of the humidity was hereby carried so far, that the herb could easily be rubbed to powder. The oil had lost its green colour, and had become brownish. In this state it was laid on the straining cloth, and placed in the garden, behind the house, in the open air.

“ In the space of half an hour, on coming again to this place, he perceived a strong smoke there, though he thought the oil must have long been cooled: on closer inspection, he found that the smoke did not proceed from the oil, but from the herb on the straining-cloth; at the same time the smell betrayed a concealed fire. He stirred the herb about, and blew into it with a bellows, whereupon it broke out into a bright flame. Had this herb been placed in the house, near the fire, it might easily have been supposed that a spark had flown into it, which had caused the inflammation: but this was not the case; the herb had kindled of itself. We see from this, that those who are intrusted with the preparation of boiled oils should take care they do not give occasion to danger by fire, which may excite suspicions of felonious designs, to the ruin of innocent persons in their lives or reputations.”

The spontaneous heating and combustion of hay and other vegetable substances are very generally known in this country, as well as the means of preventing such accidents; for which

reason it is not necessary to enlarge on the subject in this place.

INFLATION, formed from *in* and *flatus*; of *flō* “ I blow;” blowing up, the act of stretching or filling any flaccid or distensible body with a statulent or windy substance.

INFLECTION, called also a *diffraction*, and *deflection*, in optics, is a property of light, by reason of which, when it comes within a certain distance of any body, it will either be bent from it or towards it; which is a kind of imperfect reflection or refraction. See OPTICS.

INFLECTION, or *Point of INFLECTION*, in the higher geometry, is a point where a curve begins to bend a contrary way.

INFLECTION, in grammar, the variation of nouns and verbs, by declension and conjugation.

INFLUENCE, a quality supposed to flow from the heavenly bodies, either with their light or heat; to which astrologers idly ascribe all sublunary events. Alchemists also, who to this ascribe the philosopher's stone, tell us, that every thing in nature is produced by the influence of the stars, which, in their passage through the atmosphere, imbibe many of its moist parts, the grossest wheteof they deposit in the sands and earths where they fall; that these, filtrating through the pores of the earth, descend even to the centre, whence they are driven, by the central fire, back again to the surface; and in their ascent, by a natural kind of sublimation, as they find earths duly disposed, they form natural bodies, as metals, minerals, and vegetables, &c. Thus it is pretended that chemistry, consisting of an artificial imitation of these natural operations, and in applying active principles to passive principles, can form natural bodies, make gold, &c.

INFORMATION, in law, is nearly the same in the crown-office, as what in other courts is called a *declaration*. See PROSECUTION. Informations are of two sorts; first, those which are partly at the suit of the king, and partly at that of a subject; and secondly, such as are only in the name of the king. The former are usually brought upon penal statutes, which inflict a penalty upon conviction of the offender, one part to the use of the king, and another to the use of the informer. By the statute of 31 Eliz. c. 5. no prosecution upon any penal statute, the suit and benefit whereof are limited in part to the king and in part to the prosecutor, can be brought by any common informer after one year is expired since the commission of the offence; nor on behalf of the crown, after the lapse of two years longer; nor, where the forfeiture is originally given only to the king, can such prosecution be had after the expiration of two years from the commission of the offence.

The informations that are exhibited in the name of the king alone, are also of two kinds: first, those which are truly and properly his own suits, and filed *ex officio* by his own immediate officer, the attorney-general: secondly, those in which though the king is the nominal prosecutor, yet it is at the relation of some private person or common informer; and they are filed by the king's coroner and attorney in the court of king's bench, usually called the *master of the crown-office*, who is for this purpose the standing officer of the public. The objects of the king's own prosecutions, filed *ex officio* by his own attorney-general, are properly such enormous misdemeanors as peculiarly tend to disturb or endanger his government, or to molest or affront him in the regular discharge of his royal functions. For offences so high and dangerous, in the punishing or preventing of which a moment's delay would be fatal, the law has given to the crown the power of an immediate prosecution, without waiting for any previous application to any other tribunal: which power, thus necessary, not only to the ease and safety, but even to the very existence, of the executive magistrate, was originally reserved in the great plan of the English

constitution, wherein provision is wisely made for the due preservation of all its parts. The objects of the other species of informations, filed by the master of the crown-office upon the complaint or relation of a private subject, are any gross and notorious misdemeanors, riots, batteries, libels, and other immoralities of an atrocious kind, not peculiarly tending to disturb the government (for those are left to the care of the attorney-general), but which, on account of their magnitude or pernicious example, deserve the most public animadversion. And when an information is filed, either thus, or by the attorney-general *ex officio*, it must be tried by a petit-jury of the county where the offence arises: after which, if the defendant be found guilty, he must resort to the court for his punishment. See Blackstone's Commentaries, vol. iv. p. 309—312.

INFORMER, *informator*, in law, a person that informs against, or prosecutes in any of the king's courts, those that offend against any law or penal statute. See INFORMATION. Informers were very common both in Greece and Rome. Every corner of the streets was pestered with swarms of turbulent rascals, who made it their constant business to pick up stories and catch at every occasion to accuse persons of credit and reputation: these by the Greeks were called *Συνοφάνται*; for a more particular account of whom, see the article SYCOPHANT. Amongst the Romans, informers were of two sorts, *mandatores* and *delatores*. These played into each other's hands; the former marking down such persons as they pretended to have found guilty of any misdemeanor, and the other prosecuting them. What tended to increase the number of these pestilent fellows was, that the informers were entitled to a fourth part of the effects of the persons convicted. Wicked princes rewarded and countenanced this mischievous tribe; but Titus set on foot a most diligent search after them, and punished such as he found with death or banishment. Trajan also is praised by Pliny for a similar conduct.

INFRACTION, formed from *in*, and the supine of *frango* "I break," a rupture or violation of a treaty, law, ordinance, or the like.

INFRALAPSARII, the name of a sect of predelinarians, who maintain, that God has created a certain number of men only to be damned, without allowing them the means necessary to save themselves, if they would; and they are thus called, because they hold that God's decrees were formed *infra lapsum*, after his knowledge of the fall, and in consequence thereof; in contradistinction to the SUPRALAPSARIANS.

INFRA-SCAPULARIS, in anatomy. See ANATOMY, *Table of the Muscles*.

INFRA-Spinatus, in anatomy. See ANATOMY, *ibid*.

INFULA, in antiquity, was a mitre worn by the Roman and Grecian priests, upon the head, from which on each side hung a ribband. The covering the head with a mitre was rather a Roman than a Grecian custom, introduced into Italy by *Aeneas*, who covered his head and face at the performance of sacrifice, lest any ill-boding omen should disturb the rites. The infulae were commonly made of wool, and were not only worn by the priests, but were put upon the horns of the victims, upon the altar and the temple. The infulae were also called *vittæ*.

INFUNDIBULIFORM, in botany, an appellation given to such monopetalous or one-leaved flowers as resemble a funnel in shape, or which have a narrow tube at one end, and gradually widen towards the limb or mouth.

INFUSION, in pharmacy, an operation whereby the virtues of plants, roots, and the like, are drawn out, by letting them steep in some convenient fluid menstruum, without boiling them therein; since boiling is found to dissipate the finer parts of many bitter and aromatic substances, without more fully extracting their medicinal principles.

INGATESTONE, a town in Essex, with a market on Wednesday. The town consists of one street, the north side of which, and half of the south side, are in the parish of Fryerning. It is 6 miles S. W. of Chelmsford, and 23 N. E. of London. E. lon. 0. 28. N. lat. 51. 39.

INGENUOUS, in a general sense, signifies *open, fair, and candid*. The epithet *ingenuus*, in Roman antiquity, was given to persons born of free parents, who had never been slaves: for the children of the *liberti*, or persons who had obtained their liberty, were called *libertini*, not *ingenui*; this appellation of *ingenuus* being reserved for their children, or the third generation.

INGESTA, is used by some authors to express all sorts of aliment taken into the body.

INGLESHEIM, a town of Germany, in the palatinate of the Rhine, remarkable for having been the residence of the emperors. It is seated on the river Salva, on an eminence, whence there is a charming prospect, five miles S. W. of Mentz, and five W. of Bingen. E. lon. 8. 15. N. lat. 49. 48.

INGLETON, a town in the W. riding of Yorkshire, eight miles N. W. of Settle, and 246 of London.

INGLIS (SIR JAMES), a Scottish poet who flourished towards the middle of the 16th century. According to Mackenzie, he was descended from an ancient family in Fifeshire, where he was born in the reign of James IV. He was educated at St. Andrew's, went to Paris, and returned in the minority of James V. into whose favour he ingratiated himself by his poetry, having written sundry tragedies and comedies, and other poems, that were much applauded by good judges. He joined the French faction against the English; and, in some skirmishes preceding the fatal battle of Pinkie, so distinguished himself that he was knighted on the field. After the loss of that day, he retired into Fife, and amused himself with his favourite studies; and in 1548 published at St. Andrew's his noted Complaint of Scotland. He appears to have read both Greek and Latin authors, and to have been well-skilled in mathematics and philosophy. Unpublished and in MS. (says Mackenzie) are Poems, consisting of Songs, Ballads, Plays, and Farces. He died at Culross in 1554.

INGLUVIES, the crop or craw of granivorous birds, serving for the immediate reception of the food, where it is macerated for some time before it is transmitted to the true stomach.

INGOLSTADT, a handsome town of Germany, in Bavaria, with a famous university, and a fine church. The houses are built of stone, and the streets are large. It is the strongest town in Bavaria, but was taken by the Austrians in 1742. It is seated on the Danube, five miles N. E. of Neuburg, and 45 N. by W. of Munich. E. lon. 11. 10. N. lat. 48. 46.

INGOT, a mass of gold or silver melted down, and cast in a mould, but not coined or wrought.

INGRAFTING, in gardening. See GRAFTING.

INGRATITUDE, the opposite of gratitude. See GRATITUDE. Ingratitude is a crime so shameful, that there never was a man found who would own himself guilty of it; and, though too frequently practised, it is so abhorred by the general voice, that to an ungrateful person is imputed the guilt or the capability of all other crimes. The ungrateful are neither fit to serve their Maker, their country, nor their friends. Ingratitude perverts all the measures of religion and society, by making it dangerous to be charitable and good-natured. A few instances from History may not be improper.

1. In a little work entitled *Friendly Cautions to Officers*, the following atrocious instance of ingratitude is related. An opulent city in the west of England, little used to have troops with them, had a regiment sent to be quartered there: the

principal inhabitants and wealthiest merchants, glad to show their hospitality and attachment to their sovereign, took the first opportunity to get acquainted with the officers, inviting them to their houses, and showing them every civility in their power. This was truly a desirable situation. A merchant, extremely easy in his circumstances, took so prodigious a liking to one officer in particular, that he gave him an apartment in his own house, and made him in a manner absolute master of it, the officer's friends being always welcome to his table. The merchant was a widower, and had only two favourite daughters: the officer in so comfortable a station cast his wanton eyes upon them; and, too fatally succeeding, ruined them both. Dreadful return to the merchant's misplaced friendship! The consequence of this ungenerous action was, that all officers ever after were shunned as a public nuisance, as a pest to society: nor have the inhabitants perhaps yet conquered their aversion to a red-coat.

2. We read in Rapin's History, that during Monmouth's rebellion, in the reign of James II. a certain person knowing the humane disposition of one Mrs. Gaunt, whose life was one continued exercise of beneficence, fled to her house, where he was concealed and maintained for some time. Hearing, however, of the proclamation, which promised an indemnity and reward to those who discovered such as harboured the rebels, he betrayed his benefactress; and such was the spirit of justice and equity which prevailed among the ministers, that he was pardoned and recompensed for his treachery, while she was burnt alive for her charity!

3. The following instance is also to be found in the same History.—Humphrey Bannister and his father were both servants to and raised by the Duke of Buckingham; who being driven to abscond, by an unfortunate accident befalling the army he had raised against the usurper Richard III. he without footman or page retired to Bannister's house near Shrewsbury, as to a place where he had all the reason in the world to expect security. Bannister, however, upon the king's proclamation promising 1000*l.* reward to him that should apprehend the duke, betrayed his master to John Merton high sheriff of Shropshire, who sent him under a strong guard to Salisbury, where the king then was, and there in the market-place the duke was beheaded. But Divine vengeance pursued the traitor Bannister; for, demanding the 1000*l.* that was the price of his master's blood, King Richard refused to pay it him, saying, "He that would be false to so good a master ought not to be encouraged." He was afterwards hanged for manslaughter, his eldest son ran mad and died in a hog-sty, his second became deformed and lame, and his third son was drowned in a small puddle of water. His eldest daughter was got with child by one of his carters, and his second was seized with a leprosy whereof she died.—*Hist. of Eng.* 8vo. vol. i. p. 304.

4. Basilus Macedo the emperor, exercising himself in hunting, a sport he took great delight in, a great stag running furiously against him, fastened one of the branches of his horns in the emperor's girdle, and, pulling him from his horse, dragged him a good distance, to the imminent danger of his life; which a gentleman of his retinue perceiving, drew his sword and cut the emperor's girdle asunder, which disengaged him from the beast, with little or no hurt to his person. But observe what reward he had for his pains. "He was sentenced to lose his head for putting his sword so near the body of the emperor;" and suffered death accordingly. *Zoner. Annal.* tom. 3. p. 155.

INGRESS, in astronomy, signifies the sun's entering the first scruple of one of the four cardinal signs, and especially Aries.

INGRIA, a province of the Russian empire, which now forms the government of St. Petersburg. It is bounded on

the N. by the river Neva and the gulph of Finland, on the E. and S. by the government of Novogorod, and on the W. by that of Livonia. It is about 130 miles long, and 50 broad. The czar Peter the Great wrested it from the Swedes, and it was confirmed to him by the treaty of Nyfladt in 1721. At this time, the inhabitants of the flat country were a Finnish people, but little different from the Fins of Carelia as to their language and manners. They were called Ischorki, and Ischortzi, from the river Ischora, which runs into the Neva. Ingria did not retain its ancient Swedish privileges: on the contrary, Peter made a present of one part of the Ischortzi to certain Russian nobles; who, on their side, were obliged to people the less cultivated cantons of Ingria with colonies of Russians from their estates; and thence it is that we often see a village of Russians surrounded by villages of Fins. These Ischortzi have long followed agriculture. Their economy is an ill-chosen mean between that of the Russians and that of the Fins. They assemble in small villages, of five or ten farms each; and live miserably in small dirty huts. Their household furniture indicates the greatest penury; and their manner of living is squalid and disgusting. Notwithstanding the land that each family occupies is of tolerable extent, their agriculture and cattle are equally poor. Their inclination to idleness and drinking leads them often to sell their stock, and the very corn they have saved for sowing the fields. The money, which that produces, they squander in a short time, and are thus reduced to the most deplorable indigence. In this state they behold their cattle die of hunger and cold with the most perfect indifference. Some of them, however, imitate the Russian villagers, who are better managers, more at their ease, and in better circumstances. The Ingrians are a stupid, suspicious, thievish race, and dangerous from their phlegmatic and pilfering temperament. Those who live along the road to Riga, resemble the gypsies, are vagabonds like them, calculate nativities, and tell fortunes. The dress of the men is exactly like that of the Fin boors; but the habit of the women betrays a vanity, which, considering the poverty of this people, and the tyranny which their husbands and fathers exercise over them, may pass for luxury. The lower part of their dress resembles that of the Fin country women. Their shift reaches down to their knees, has a neck and close wristbands, both of them pinked or wrought. The sleeves are large, and whimsically worked. The body of the shift is large, and puffed with numberless plaits; and the making of it is usually four weeks work. Instead of a petticoat, the Ingrian women tie on each side a linen apron without gathers. These aprons are sometimes of cloth, and sometimes of linen, worked with different colours. Those behind come over one another, but before they are at some distance: the open part of the petticoat then left, is concealed by a smaller apron adorned with glass beads and little shells. Several strings of these beads are worn round the neck, and fall upon the breasts. They carry, rather than wear, heavy ear-rings, with the addition generally of strings of beads. The girls wear their hair loose and uncovered: the married women, on the contrary, conceal their hair, like the Finnish women, with a piece of linen, four yards and a half in length, folded towards the middle into a kind of cap, while its extremities fall upon the back, and are supported by the girdle in such a manner that the whole makes a kind of spread sail over the shoulders. When they dress themselves to go to town, they commonly put on the Russ cap, which is ornamented with a peak in front, lined with fur, and laced round the edges: with this they wear a long gown, made of coarse stuff, and fastened down the breast with buttons. Before the Russians conquered this country, the Ingrians had Lutheran ministers for every canton; but numbers of them have been since converted to the Greek faith. They are full of absurd

notions and Pagan superstitions, which they mix with the ceremonies of Christianity. They commonly consider the figures of the saints as idols to be adored. They carry them into the woods in procession, and there pay them a formal worship. When a man is inclined to marry, he buys himself a girl, and celebrates his nuptials. All the way to the church they are accompanied by two women in veils, who sing compositions, if one may call them so, totally destitute of common sense. No sooner is the marriage ceremony performed, than the husband begins to treat his wife with the utmost severity, and thenceforward keeps her under strict discipline, though not always with the greatest attention to justice. She is often beaten for the faults of the children, and sometimes for those of the domestics. The dead are buried by the priest of the profession to which they belong: but these superstitious people return to the grave, under cover of the night, and, having taken up the sod, deposit eatables for their departed friend, which they renew during a fortnight or three weeks. Dogs and other animals easily scratch up these victuals and devour them, while the simple people that placed them there, believe they were consumed by the deceased. Their general opinion is, that they continue to live in the subterranean world in the same manner as they did on the surface of the earth; and that the grave is little more than a change of habitation: for which reason, they bury their money, that they may have it to use in the other world. They speak to their deceased friends, and go to their tomb for that purpose; but, at the same time, are much afraid of them. Among their holy places there is one on the road from St. Petersburg to Riga. It is formed by a large lime-tree, whose branches are interwoven with those of the forest that are nearest to it, and form a delightful bower. On the festival of St. John, at night, the Ischortzi assemble under this tree, and remain till morning, shrieking, and singing, and dancing, round a great fire; concluding their orgies with burning a white cock, and making the most absurd gesticulations and grimaces.

INGROSSER, or **ENGROSSER**, in common law, is one who buys up corn growing, or any provisions by wholesale, before the market, to sell again. See **FORESTALLING**. It also signifies a clerk who writes records or instruments of law on skins of parchment. See **ENGROSSING**.

INGUEN, in anatomy, the same with what is otherwise called the *groin*.

INGULPHUS, abbot of Croyland, and author of the history of that abbey, was born in London about A. D. 1030. He received the first part of his education at Westminster; and when he visited his father, who belonged to the court of Edward the Confessor, he was so fortunate as to engage the attention of queen Edgitha. That amiable and learned princess took a pleasure in examining our young scholar on his progress in grammar, and in disputing with him in logic; nor did she ever dismiss him without some present as a mark of her approbation. From Westminster he went to Oxford, where he applied to the study of rhetoric, and of the Aristotelian philosophy, in which he made greater proficiency than many of his contemporaries. When he was about 21 years of age, he was introduced to William duke of Normandy (who visited the court of England, A. D. 1051), and made himself so agreeable to that prince, that he appointed him his secretary, and carried him with him into his own dominions. In a little time he became the prime favourite of his prince, and the dispenser of all preferments, humbling some and exalting others, at his pleasure; in which difficult station, he confessed, he did not behave with a proper degree of modesty and prudence. This excited the envy and hatred of many of the courtiers; to avoid the effects of which, he obtained leave from the duke to go in pilgrimage to the Holy Land, which

was then become fashionable. With a company of 30 horsemen, he joined Sigfrid duke of Mentz, who, with many German nobles, bishops, clergy, and others, was preparing for a pilgrimage to Jerusalem. When they were all united, they formed a company of no fewer than 7000 pilgrims. In their way they spent some time at Constantinople, performing their devotions in the several churches. In their passage through Lycia, they were attacked by a tribe of Arabs, who killed and wounded many of them, and plundered them of a prodigious mass of money. Those who escaped from this disaster at length reached Jerusalem, visited all the holy places, and bedewed the ruins of many churches with their tears, giving money for their reparation. They intended to have bathed in Jordan; but being prevented by the roving Arabs, they embarked on board a Genoese fleet at Joppa, and landed at Brundisium, from whence they travelled through Apulia to Rome. Having gone through a long course of devotions in this city, at the several places distinguished for their sanctity, they separated, and every one made the best of his way into his own country. When Ingulph and his company reached Normandy, they were reduced to 20 half-starved wretches, without money, clothes, or horses: a faithful picture of the foolish disastrous journeys into the Holy Land, so common in those times. Ingulph was now so much disgusted with the world that he resolved to forsake it, and became a monk in the abbey of Fontenelle in Normandy; in which, after some years, he was advanced to the office of prior. When his old master was preparing for his expedition into England, A. D. 1066, he was sent by his abbot, with 100 merks in money, and 12 young men nobly mounted and completely armed, as a present from their abbey. Ingulph having found a favourable opportunity, presented his men and money to his prince, who received him very graciously; some part of the former affection for him reviving in his bosom. In consequence of this he raised him to the government of the rich abbey of Croyland in Lincolnshire, A. D. 1076, in which he spent the last 34 years of his life; governing that society with great prudence, and protecting their possessions from the rapacity of the neighbouring barons by the favour of his royal master. The lovers of English history and antiquities are much indebted to this learned abbot, for his excellent history of the abbey of Croyland, from its foundation, A. D. 664. to A. D. 1091, into which he hath introduced much of the general history of the kingdom, with a variety of curious anecdotes that are nowhere else to be found. Ingulph died of the gout, at his abbey, A. D. 1109, in the 79th year of his age.

INHALER, in medicine, a machine for steaming the lungs with warm water, recommended by Mr. Mudge in the cure of the catarrhus cough. The body of the instrument resembles a porter-pot, holds about a pint, and the handle, which is fixed to the side of it, is hollow. In the lower part of the vessel, where it is soldered to the handle, is a hole, by means of which and three others on the upper part of the handle, the water, when it is poured into the inhaler, will rise to the same level in both. To the middle of the cover a flexible leathern tube about six or seven inches long is fixed, with a mouth-piece of wood or ivory. In the cover there is a valve fixed, which opens and shuts the communication between the upper and internal part of the inhaler and the external air. This valve is extremely simple: being formed only of a short tube descending inwards from the cover, and having beneath a small hole upon which a ball of cork plays. When the mouth is applied to the end of the tube in the act of inspiration, the air rushes into the handle, and up through the body of warm water, and the lungs become, consequently, filled with hot vapour. In expiration, the mouth being still fixed to the tube, the breath, together with the steam on the

surface of the water in the inhaler, is forced up through the valve in the cover. In this manner, therefore, the whole act of respiration is performed through the inhaler, without the necessity, in the act of expiration, of either breathing through the nose, or removing the pipe from the mouth. See the figure in plate 25.

INHERITANCE, a perpetual right or interest in lands inherited in a person and his heirs. See **DESCENT**.

INHIBITION, a writ to inhibit or forbid a judge from farther proceeding in a cause depending before him. Sometimes prohibition and inhibition are put together, as of the same import; but inhibition is most commonly a writ issuing out of a higher court-christian to a lower; and prohibition out of the king's court to an inferior court.

INHUMATION, in chemistry, a method of digesting substances, by burying the vessel in which they are contained in horse-dung or earth.

INJECTION, the forcibly throwing a liquid, by means of a syringe or tube, into some canal or sinus, or into a vessel opened by incision. This practice, and that of transfusion, or the conveying the arterial blood of one man, or other animal, into another, were once greatly practised, then laid aside, and lately revived, though to no good purpose, by Dr. Busick Harwood at Cambridge.

Anatomical INJECTION, the filling the vessels of a human or other animal body with some coloured substance, in order to make their figures and ramifications visible.

I. The best account of the method of injecting *the sanguiferous vessels* of animals, is that by the late Dr. Monro, published in the *Medical Essays*, vol. i. p. 79.

"The instrument with which the liquor is commonly thrown into the vessels is a tight easy-going syringe of brass, to which several short pipes are fitted, and can be fixed by screws, the other extremities of these pipes being of different diameters without any screw, that they may slide into other pipes, which are so exactly adapted to them at one end, that, when they are pressed a little together, nothing can pass between them: and because their cohesion is not so great as to resist the pushing force of the injection, which would drive off this second pipe, and spoil the whole operation; therefore the extremity of this second sort of pipes, which receives the first kind, is formed on the outside into a square, bounded behind and before by a rising circle, which hinders the key that closely grasps the square part from sliding backwards or forwards; or a bar of brass must stand out from each side of it, to be held with the fingers. The other extremity of each of these second sort of pipes is of different diameter; and near it a circular notch, capable of allowing a thread to be sunk into it, is formed; by this, the thread tying the vessel at which the injection is to be made, will not be allowed to slide off.

"Besides this form described, common to all this second sort of pipes, we ought to have some of the larger ones, with an additional mechanism, for particular purposes; as, for instance, when the larger vessels are injected, the pipe fastened into the vessel ought either to have a valve or a stop-cock, that may be turned at pleasure, to hinder any thing to get out from the vessel by the pipe; otherwise, as the injection, in such a case, takes time to coagulate, the people employed in making the injection must either continue all that while in the same posture; or, if the syringe is too soon taken off, the injected liquor runs out, and the larger vessels are emptied. When the syringe is not large enough to hold at once all the liquor necessary to fill the vessels, there is a necessity of filling it again. If, in order to do this, the syringe was to be taken off from the pipe fixed in the vessel, some of the injection would be lost, and what was exposed to the air would cool and harden; therefore some of the pipes ought to have a reflected curve tube coming out of their side, with a valve so disposed, that no liquor can come from the straight

pipe into the crooked one, but, on the contrary, may be allowed to pass from the crooked to the straight one: the injector then, taking care to keep the extremity of the reflected pipe immersed in the liquor to be injected, may, as soon as he has pushed out the first syringe full, fill it again by only drawing back the sucker; and, repeating this quickly, will be able to throw several syringefuls into the vessels.

"All these different sorts of pipes are commonly made of brass.

"The liquors thrown into the vessels, with a design to fill the small capillary tubes, are either such as will incorporate with water, or such as are oily: both kinds have their advantages and inconveniences; which I shall mention in treating of each, and shall conclude with that which I have found by experience to succeed best.

"All the different kinds of glue, or ichthyocolla, fyths, common glue, &c. dissolved and pretty much diluted, mix easily with the animal-fluids, which is of great advantage, and will pass into very small vessels of a well-chosen and prepared subject, and often answer the intention sufficiently, where the design is only to prepare some very fine membrane, on which no vessels can be expected to be seen so large as the eye can discover whether the transverse sections of the vessels would be circular, or if their sides are collapsed. But when the larger vessels are also to be prepared, there is a manifest disadvantage to the usefulness and beauty of the preparation; for, if nothing but the glutinous liquor is injected, one cannot keep a subject so long as the glue takes of becoming firm; and, therefore, in dissecting the injected part, several vessels will probably be cut and emptied. To prevent this, one may indeed either soak the part well in alcohol, which coagulates the glue; but then it becomes so brittle, that the least handling makes it crack; and if the preparation is to be kept, the larger vessels appear quite shrivelled, when the watery part of the injection is evaporated: or the efflux of the injection may be prevented, by carefully tying every vessel before we are obliged to cut it; still, however, that does not hinder the vessels to contract when the glue is drying. If, to obviate these difficulties, the glutinous liquor should first be injected in such quantity as the capillary vessels will contain, and the common oily or wax injection is pushed in afterwards to keep the larger vessels distended, the wax is very apt to harden before it has run far enough; the two sorts of liquors never miss to mix irregularly, and the whole appears interrupted and broken by their soon separating from each other; which is still more remarkable afterwards, when the watery particles are evaporated.

"Spirit of wine coloured mixes with water and oils, and so far is proper to fill the very small vessels with: but, on the other hand, it coagulates any other liquor it meets, which sometimes blocks up the vessels so much, that no more injection will pass; then it scarce will suspend some of the powders that prove the most durable colours; and as it entirely evaporates, the vessels must become very small; and the small quantity of powder left, having nothing to serve for connecting its particles together, generally is seen so interrupted, that the small ramifications of vessels rather have the appearances of random scratches of a pencil, than of regular continued canals.

"Melted tallow, with a little mixture of oil of turpentine, may sometimes be made to fill very small vessels, and keeps the larger ones at a full stretch; but where any quantity of the animal liquors are still in the vessels, it is liable to stop too soon, and never can be introduced into numbers of vessels which other liquors enter; and it is so brittle, that very little handling makes it crack, and thereby renders the preparation very ugly.

"The method I have always succeeded best with, in making what may be called *subtile* or *fine injections*, is, first to throw in

coloured oil of turpentine, in such a quantity as might fill the very small vessels; and, immediately after, to push the common coarse injection into the larger ones. The oil is subtil enough to enter rather smaller capillary tubes than any colouring can; its resinous parts, which remain after the spirituous are evaporated, give a sufficient adhesion to the particles of the substance with which it is coloured, to keep them from separating, and it intimately incorporates with the coarser injection; by which, if the injection is rightly managed, it is impossible for the sharpest eye to discover that two sorts have been made use of.

“ All the liquors with which the vessels of animals are artificially filled, having very faint, and near the same colours, would not all appear in the very small vessels, because of their becoming entirely diaphanous, without a mixture of some substance to impart its colour to them; and where several sorts of even the largest vessels of any part were filled, one sort could not be distinguished from another, unless the colour of each was different; which has likewise a good effect in making preparations more beautiful. Wherefore anatomists have made use of a variety of such substances, according to their different fancies or intentions; such as gamboge, saffron, ink, burnt ivory, &c. which can be easily procured from painters. My design being only to consider those that are fit to be mixed with the injecting liquors proposed to fill capillary vessels, which is scarce ever to be done in any other, except the branches of the arteries and of some veins, I shall confine myself to the common colours employed to these last named two sorts of vessels, which colours are red, green, and sometimes blue, without mentioning the others, which require very little choice.

“ Anatomists have, I imagine, proposed to imitate the natural colours of the arteries and veins in a living creature, by filling the arteries with a red substance, and the veins with a blue or green: from which, however, there are other advantages, such as the strong reflection which such bodies make of the rays of light, and the unaptness most such bodies have to transmit these same rays, without at least a considerable reflection of the rays peculiar to themselves; or, in other words, their unfitnes to become completely pellucid; without which, the very fine vessels, after being injected, would still be imperceptible. The animal or vegetable substances made use of for colouring injections, such as cochineal, laque, *rad. anchuse*, brazil-wood, indigo, &c. have all one general fault of being liable to run into little knots which stop some of the vessels; their colour fades sooner when kept dry; they more easily yield their tincture when the parts are preserved in a liquor; and rats, mice, and insects, will take them for food: for which reasons, though I have frequently succeeded in injecting them, I rather prefer the mineral kind, such as minium or vermilion for red; of which this last is, in my opinion, the best, because it gives the brightest colour, and is commonly to be bought finely levigated. The green-coloured powder generally used is verdigrease; but I rather choose that preparation of it called *distilled verdigrease*; because its colour is brighter, and it does not so often run into small knots as the common verdigrease, but dissolves in the oily liquors.

“ The method of preparing the injection composed of these materials, is to take for the fine one, a pound of clear oil of turpentine, which is gradually poured on three ounces of vermilion, or distilled verdigrease finely powdered, or rather well levigated by grinding on marble; stir them well with a small wooden spatula till they are exactly mixed, then strain all through a fine linen rag. The separation of the grosser particles is, however, rather better made, by pouring some ounces of the oil upon the powder, and, after stirring them together strongly, stop rubbing with the spatula for a second or so, and pour off into a clean vessel the oil with the vermilion or verdigrease suspended in it; and continue this sort of operation till you observe no more of

the powder come off; and all that remains is granulated. The coarser injection is thus prepared: Take tallow, 1 pound; wax, bleached white, 5 ounces; fallad oil, 3 ounces; melt them in a skillet put over a lamp; then add Venice turpentine, 2 ounces; and as soon as this is dissolved, gradually sprinkle in of vermilion or verdigrease prepared, 3 ounces; then pass all through a clean, dry, warmed linen-cloth, to separate all the grosser particles; and, when you design to make it run far into the vessels, some oil of turpentine may be added immediately before it is used.

“ The next thing to be considered, and indeed what chiefly contributes to the success of injections, is the choice and preparation of the subject whose vessels are to be filled.

“ In choosing a fit subject, take these few general rules: 1. The younger the creature to be injected is, the injection will, *ceteris paribus*, go farthest, and *vice versa*. 2. The more the creature's fluids have been dissolved and exhausted in life, the success of the operation will be greater. 3. The less solid the part designed to be injected is, the more vessels will be filled. 4. The more membranous and transparent parts are, the injection shows better; whereas, in the solid very hard parts of a rigid old creature, that has died with its vessels full of thick strong blood, it is scarce possible to inject great numbers of small vessels.

“ Therefore, in preparing a subject for injecting, the principal things to be aimed at, are: to dissolve the fluids, empty the vessels of them, relax the solids, and prevent the injection's coagulating too soon. To answer all these intentions, authors have proposed to inject tepid or warm water by the arteries, till it returns clear and untinged by the veins; and the vessels are thereby so emptied of blood, that all the parts appear white; after which, they push out the water by forcing in air; and, lastly, by pressing with their hands, they squeeze the air also out. After this preparation, one can indeed inject very subtilly; but generally there are some inconveniences. For in all the parts where there is a remarkable *tunica cellulosa*, it never misses to be full of the water, which is apt to spoil any parts designed to be preserved either wet or dry; and some particles of the water seldom miss to be mixed in the larger as well as smaller vessels with the oily injection, and make it appear discontinued and broken: wherefore it is much better to let this injection of water alone, if it can be possibly avoided, and rather to macerate the body or part to be injected a considerable time in water made so warm as one can hold his hand easily in it; taking care to keep it of an equal warmth all the time, by taking out some of the water as it cools, and pouring in hot water in its place; by which the vessels will be sufficiently softened and relaxed, the blood will be melted down, and the injection can be in no danger of hardening too soon; whereas, if the water is too hot, the vessels shrink, and the blood coagulates. From time to time we squeeze out the liquids as much as possible at the cut vessel by which the injection is to be thrown in. The time this maceration is to be continued, is always in proportion to the age of the subject, the bulk and thicknes of what we design to inject, and the quantity of blood we observe in the vessels, which can only be learned by experience; at least, however, care ought to be taken, that the whole subject, or part macerated, is perfectly well warmed all through; and that we continue the pressure with our hands till no more blood can be brought away, whatever position we put the subject in.

When the syringe, injections, and subject, are all in readiness, one of the second sort of pipes is chosen, as near to the diameter of the vessel by which the injection is to be thrown as possible; for, if the pipe is too large, it is almost needless to tell it cannot be introduced. If the pipe is much smaller than the vessel, it is scarce possible to tie them so firmly together,

but, by the wrinkling of the coats of the vessel, some small passage will be left, by which part of the injection will spring back on the injector in the time of the operation, and the nearest vessels remain afterwards undistended, by the loss of the quantity that oozes out. Having chosen a fit pipe, it is introduced at the cut orifice of the vessel, or at an incision made in the side of it; and then a waxed thread being brought round the vessel, as near to its coats as possible, by the help of a needle or a flexible eyed probe, the surgeon's knot is made with the thread, and it is drawn as firmly as the thread can allow; taking care that it shall be sunk into the circular notch of the pipe all round; otherwise it will very easily slide off, and the pipe will be brought out probably in the time of the operation; which ruins it.

“ If there have been large vessels cut, which communicate with the vessels you design to inject, or if there are any others proceeding from the same trunk, which you do not resolve to fill, let them be all carefully now tied up, to save the injected liquor, and make the operation succeed better in the view you then have.

“ When all this is done, both sorts of injections are to be warmed over a lamp, taking care to stir them constantly, lest the colouring powder fall to the bottom and burn. The oil of turpentine needs be made no warmer than will allow the finger to remain in it, if the subject has been previously well warmed in water: when the maceration has not been made, the oil ought to be scalding hot, that it may warm all the parts which are designed to be injected. The coarse injection ought to be brought near to a boiling. In the mean time, having wrapt several folds of linen round the parts of the syringe which the operator is to gripe, and secured the linen with thread, the syringe is to be made very hot by sucking boiling water several times up, and the pipe within the vessel is to be warmed by applying a sponge dipped in boiling water to it.

“ After all is ready, the syringe being cleared of the water, the injector fills it with the finer injection; and then introducing the pipe of the syringe into that in the vessel, he presses them together, and either with one hand holds this last pipe firm, with the other gripes the syringe, and with his breast pushes the sucker; or, giving the pipe in the vessel to be held by an assistant, in any of the ways mentioned in the description of these sorts of pipes, he gripes the syringe with one hand, and pushes the sucker with the other, and consequently throws in the injection; which ought to be done slowly, and with no great force, but proportioned to the length and bulk of the part to be injected and strength of the vessels. The quantity of this fine injection to be thrown in is much to be learned by use. The only rule I could ever fix to myself in this matter was to continue pushing till I was sensible of a stop which would require a considerable force to overcome. But this will not hold where all the branches of any vessel are not injected; as for instance, when the vessels of the thorax only are to be injected: for the aorta bears too great a proportion to the branches sent from it, and therefore less fine injection is requisite here. As soon as that stop is felt, the sucker of the syringe is to be drawn back, that the nearest large vessels may be emptied. Then the syringe is taken off, emptied of the fine injection, and filled with the coarser, which is to be pushed into the vessels quickly and forcibly, having always regard to the strength and firmness of the vessels, bulk, &c. of the part. Continue to thrust the sucker, till a full stop, or a sort of push backwards, is felt, when you must beware of thrusting any more, otherwise some of the vessels will be bursted, and the whole or a considerable share of the preparation you designed will be spoiled by the extravasation; but rather immediately stop the pipe by the turn-cock, and take out the syringe to

clean it, and allow sufficient time for the coarse injection to coagulate fully before any part is dissected. Ruysch, immediately after throwing in the injection, put the body into cold water, and stirred it continually for some time, to prevent the vermilion separating from the tallow.”

11. The *injection of the lymphatic system* is much more difficult than that of the sanguiferous, on account of the extreme smallness of the vessels; so that till very lately it was almost quite impracticable. Methods indeed had been attempted for this purpose; but, by reason of the improper form of the instruments and the inferior skill of anatomists in former times, we may justly look upon this as one of the most modern improvements in anatomy.

The first thing to be considered, when the lymphatics are to be injected, is a proper method of discovering them; for this is by no means an easy matter, on account of their smallness and transparency.—To find out these vessels the subject must be viewed in a proper place, where the light is neither very strong nor very weak. Mr. Sheldon, who has written a treatise upon this subject, recommends a winter forenoon from ten to two; it being chiefly in the winter season that anatomical preparations are made, and because at that time of the day the light is more clear and steady. He says also, from his own experience, that the light passing through the glass of a window is better for this purpose than the open air, as the vessels are more distinctly seen. The injecting of the vessels is likewise rendered more difficult in the open air, by the ease with which the humidity is evaporated from them. It will likewise be necessary to incline the part in various ways to the light, as some of the vessels are most easily discoverable in one position and some in another. The lacteal trunks under the peritoneal coats of the intestines, and the lymphatics on the external surface of the liver, &c. particularly require this method. He discommends the use of magnifying glasses. “ I am persuaded (says he), that those who attempt to find them through this medium, will not acquire that *visus eruditus* which is obtained to a surprising degree by those who have been much experienced in injecting lymphatic vessels. A lateral light is likewise preferable to an horizontal, or even to an oblique sky-light.

“ The subjects must be laid upon a table of sufficient height, which might be contrived with a ledge fixed to the table in such a manner as to be water proof; which would be useful for preventing the quicksilver, which is almost always necessary for injecting these vessels, from being lost. The surface of the table should likewise be hollowed, so that the mercury which falls may be collected in the middle, where an hole with a stopper may be made to take out occasionally the quicksilver which collects. Such a table would also be convenient for holding water for the purpose of steeping membranous parts which are frequently to be injected; and which, from being exposed to the air, become dry; which also it is inconvenient and hazardous to move into water during the time of operation. Even a common table with a hole cut in the middle may answer the purpose: the hole may be round or square according to the fancy of the anatomist; but the table must be constructed of such materials as are not liable to warp in warm water. Should the anatomist not be provided with either of these tables, the parts must be laid in a tray or earthen dish, that the quicksilver may be saved.”

The materials for injecting these vessels are only quicksilver, and the ceraceous or *coarse* injection of anatomists; the former being always used in injecting the lymphatics and lacteals, it being almost impossible to fill them with another fluid in the dead body. The ceraceous injection is chiefly used for the thoracic duct; and in some particular instances, where the lymphatic trunks have been found larger than the ordinary size, a coarse injection has been made use of. It is made of mutton-suet and yellow resin, in the proportion of two thirds of resin to

one of suet. If required of a thicker consistence, we may add a small quantity of pure wax; if of a softer quality, we may augment the quantity of suet: orpiment, or king's yellow, is generally made use of; though others are equally proper, provided they be fine enough.

The instruments necessary for injecting the lymphatic vessels are the injecting tube and pipes, lancets, blow-pipes, knives, scissars, forceps, needles, and thread. The old injecting tube has been found in a manner entirely useless, the pipe being fixed in a glass tube two or three feet long; which is one of the reasons why, before the time of Hewson, so little of the lymphatic system could be injected. Tubes of such a length are entirely unmanageable by one person, and it is impossible to perform the operation properly with two. To perform it in the best manner, the instrument should be held in the hand like a pencil or pen. The instruments used by our author are tubes made either of glass or of brass; which, when filled with mercury, may be held in the hand like a pen: a glass tube, however, is preferable to the metallic one. It is somewhat in the shape of a trumpet; six inches and a half in length, an inch and a half broad where broadest, and three-eighths of an inch where narrowest. A collar of steel half an inch broad and three quarters of an inch long is cemented to this pipe, and a smaller tube of the same metal is screwed upon the end of the collar; the whole terminating in a capillary tube about an inch in length. This last is the most difficult part of the whole work to execute; it should be drilled out of a solid piece of metal, and not made of a thin bit of plate soldered, as these are apt to turn ragged in the edges, and the solder is also liable to be destroyed by the mercury. Those used by Mr. Sheldon were made by drilling a small hole lengthwise through a bit of well-tempered wire. It is cleaned by means of a very small piece of steel-wire capable of passing through the bore of the tube. This ought to be annealed, lest it should break; in which case the broken bit could not easily be got out. The very small tubes may be made of glass drawn out as fine as we choose; and though very apt to break, they are easily repaired. They ought to be very thin, that they may be easily melted. Sometimes it has been found convenient to fit the collar with a steel stop-cock.

The brass tube represented by our author is about nine inches and an half in length, and half an inch wide where widest. The collar is a full quarter of an inch broad, and three quarters of an inch long; a steel piece and capillary tube being screwed to it as in the other.

The lancets are to be exquisitely sharp, in order to cut into the lymphatic vessels. The latter are easily inflated by the small silver blow-pipes usually put up in the dissecting cases by the London chirurgical instrument makers: dissecting knives, fine-pointed scissars, accurately made dissecting forceps, with straight or crooked needles, are likewise substituted with advantage, as not being affected by the quicksilver.

The subjects chosen for injection should be as free from fat as possible. In the human subject those who have died universally dropsical, or of an ascites or anasarca, are the best, for the following reasons, viz. in such there is little or no animal oil, and but a very small quantity of red blood; both of which, when they occur in great abundance, very much impede the discovery of the lymphatic vessels; but when the cellular vessels are loaded with water, the absorbents are more readily traced, and with less risk of wounding them in dissection: the preparations also, particularly the dried ones, are more lasting. This circumstance is found to be of most consequence in preparing the absorbent vessels of the trunk and extremities of the human subject. Of all the viscera in young subjects, only the liver and lungs can be injected with success; and these may be successfully injected even in the fœtus. It will be most proper to begin the operation upon the subject immediately after death, as lymph or

chyle will then be more readily found in the vessels, than when we wait a longer time. In preparing the lacteals, previously distended with milk in the living subject, it is proper to have the intestines and mesentery plunged (with the ligature upon the root of the latter) into rectified spirit of wine. This process will coagulate the chyle; and the fluid being opaque, the vessels will be beautifully seen when we mean to prepare the parts, by preserving them in proof-spirit as wet specimens: "In this way (says Mr. Sheldon) I have made in the dog one of the most natural preparations that can be seen of the lacteals injected from their orifices by the natural absorption." We may also prepare the lacteals by the method used by Mr. Hunter, already mentioned; by which they will be very conspicuous, by the indigo absorbed from the cavity of the intestines. By tying the thoracic duct near its insertion into the angle formed between the subclavian and jugular veins on the left side, or by tying these veins on both sides, we may distend almost all the absorbents of the animal. Thus we are enabled to pursue these vessels in many parts where they have not yet been discovered, where they can scarcely be traced by injection; and even in some parts where it is utterly impossible for the injections to reach them.

Another method sometimes successfully used by our author, was first practised by Malpighi. In this the part is to be steeped in water, and the liquid changed as long as it appears tinged with blood; suffering the parts afterwards to remain in the same water till the putrefaction begins. As soon as this begins to take place, the air which is extricated will distend the lymphatics, so that they may be easily seen, and then injected with quicksilver. It is, however, remarkable, that this method will not in general answer so well in the human species as in quadrupeds; the air having never passed by putrefaction into the human lacteals in any of the subjects which Mr. Sheldon tried, though it will take place in those of the horse or ass, and many other animals: drawing of the lacteals may likewise be made in this method to very great advantage. In some parts of the human body also, this method may be employed to advantage; as the liver, heart, &c. It may likewise be useful to make ligatures on the large trunks of the vessels previous to the maceration, that thus the air may be confined as soon as it is extricated from the coats by putrefaction. Our author adds, that if ligatures were made upon the wrists and legs *in articulo mortis*, or immediately after death, the lymph would be stopped in the vessels, the latter would become distended, and might be injected with the greatest facility by the common method after taking off the ligature. Mr. Sheldon in such a case recommends the tourniquet. "I have reason (says he) to believe, that absorption goes on as long as muscular irritability remains; which last continues a considerable time after the general life of the animal is lost." On this, however, we cannot forbear to remark, that making ligatures for such purposes upon a human creature *in articulo mortis*, or even immediately after death, savours so much of barbarity, that we cannot think it will be often practised. In some cases, even in the dead subject, ligatures are useful; as when we are searching for the lymphatics in the fingers and toes. In these it is useful to stroke up the parts with the finger, by which means the small quantity of lymph remaining in the vessels will be forced upwards, and stopped by the ligature; after which the vessels may be easily injected with quicksilver, as already mentioned.

To inject the vessels; we must open one or more of them, directing the point of the lancet almost always towards the trunk or trunks of the vessels, and taking care not to carry the incision through the opposite side. If the vessels happen to lie under the peritoneum as the lacteals, or under the pleura as the lymphatics of the lungs, we may cut into their cavity through these membranes. In injecting those of the extremities, however, and in many other parts of the body, it is absolutely necessary to dis-

the vessels we design to fill away from the fat and reticular substance before we attempt to open them with the lancet. The tube with the pipe affixed to it is previously to be filled with mercury: the anatomist then inflates the vessel by means of the blow-pipe, takes the tube from the assistant, and introduces the small tube into the puncture. In this operation it will be found necessary not to carry the tube farther into the vessel than is sufficient to give the mercury a free passage; for, if we introduce it farther, the passage of the mercury will be impeded by the pipe being pushed against the side of the vessel. Should not the fluid be able to effect a passage, it will then be necessary to press upon the surface of it in the tube with our fingers. If it descend freely, and without any of it passing between the side of the vessel and small pipe, we have only to fill up the tube with mercury as the latter descends; but if it gets out, we must then tie the vessel. This, however, should always be avoided if possible; because, if not very dexterously performed, the operator will be apt to separate the tube from the vessel; and on this account the puncture ought always to be very small, no larger indeed than is necessary to allow the pipe to get in with difficulty. As the injection proceeds, the pressure upon the surface of the quicksilver must be carried on higher and higher in the course of the lymphatic, till we come near the gland or glands into which the vessels terminate; otherwise we shall seldom get the cells of the glands, or the vessels emerging from the opposite side of the glands, well injected. In injecting the lymphatic vessels of the extremities, it will be useful to raise the part where the pipe is inserted higher than the other end of the limb, and to make the assistant press with his hands along the skin in the course of the vessels, which will favour the progress of the injection. When the vessels are sufficiently filled, which may be known by the swelling of them, and by the resistance the mercury meets with, the assistant passes a ligature about the vessel, and ties it above the puncture before the anatomist withdraws the injection-pipe.

The method of injecting the larger trunks or thoracic duct with the coarse injection is exactly similar to that already described for the sanguiferous vessels. Mr. Sheldon, however, recommends the use of some pipes of a particular construction invented by himself. The improvement consists in shaping the ends of the pipes like a pen; taking care to make the edges and point blunt, to avoid cutting the vessel when we introduce them. Thus, much larger tubes than those commonly in use may be admitted; and there is no occasion to make any bulb or rising near the extremity of these small pipes to prevent the thread from slipping off: for this will certainly hinder us from inserting pipes of such diameter as might otherwise be done.

Having thus shown the method of injecting the lymphatics, our author next proceeds to describe the method of dissecting and preparing them either for immediate demonstration, or for preservation for any length of time. In the dissection, great care is requisite, on account of the exquisite thinness of their coats: but if this should happen by accident, it will then be necessary to introduce the pipe at the ruptured part, and, having secured it above and below with ligatures, to fill it again as before directed. Our author recommends, for the purpose of dissection, such knives as are made use of by the Germans and French in tracing the nerves. They must be made thin in the blade like lancets, and not much larger. A variety of different shaped blades, some single and others double-edged, will be necessary for various parts of the body; the fault of the common dissecting knives being that they are too thick in the blade, which makes them soon blunt, and occasions the trouble of perpetual grinding, which is not the case with those just recommended. A sharp-pointed forceps is necessary, in order to lay fast hold of the smallest portion of cellular substance; but they ought not to be so sharp as to endanger the puncturing of the vessels: nor should they by any means be bowed or stiff in the spring, to pre-

vent the fingers of the operator from being wearied in the operation. They should also be made in such a manner as to hold large as well as small portions of reticular substance. For dissections of this kind, fine pointed scissors and lancets fixed in handles are sometimes necessary; and it is frequently of use to plunge the parts into water, in order to loosen the reticular membrane connected with the outside of the coats of the vessels; by which means they may be dissected more easily, and with less danger of wounding them. The blood may be extracted by frequently changing the water. After being injected with quicksilver, the parts should not be allowed to remain long in the water, because the volatile alkali formed by putrefaction is apt to change the colour of the mercury.

The dissection being performed, the preparation is then to be preserved either in a wet or dry state, according to its nature. Preparations of the larger parts, as the trunk or extremities, should be preserved dry; and to dry them effectually, they should be exposed to a free current of air, but not to the rays of the sun; and the vessels should be displayed in their natural situation. When fully dried, they ought then to be varnished over with transparent spirit or copal varnish; which will not only preserve them from insects, but render them more beautiful, and the vessels more conspicuous. They should then be inclosed in glass cases, where they are to be placed in a horizontal position, and handled as little as possible.

To make preparations of the thoracic duct, we must in the first place fill the aorta, vena cava superior, and vena azygos or intercostalis, with coarse injection; then fill, with the same, the vessels below the right crus or little muscle of the diaphragm. The duct is sometimes prepared with quicksilver; but Mr. Sheldon recommends to anatomists to make drawings of any thing new or remarkable in their preparations of the lymphatic vessels with quicksilver; as most of those specimens, particularly such as are dried, become at last totally useless by reason of the drying of the vessels and the escape or blackening of the mercury; or from the varnish growing more and more opaque with age. The quicksilver injection, however, in some cases is very useful. Thus, for instance, if we wish to demonstrate the valves in the thoracic duct, or any other large absorbent vessel, we need only inject the vessels with quicksilver, dissect and dry them, then cut them open, and let the mercury run out; after which the valves will appear by making sections in the coats of the vessels. This may be done still better by varnishing the vessels three or four times before the sections are made; because the varnish will strengthen the sides of the vessel. In wet preparations the valves in the cavities of these parts may likewise be demonstrated by opening them; or by inverting the vessels, and suspending them in proof malt spirits. Thus the valves that cover the terminations of the thoracic duct on the inside of the angle formed between the jugular and subclavian veins on the left side, and those which terminate the lymphatics on the right side of the neck, arm, and lungs, may be beautifully demonstrated. Specimens of the lacteal vessels, of the absorbents of the heart, lungs, liver, spleen, diaphragm, kidneys, &c. may be kept wet or dry, according to the particular nature of the preparation, or view of the anatomist. Some preparations are the better for being dried and afterwards immersed in vials full of oil of turpentine: by which means the flesh will be rendered transparent, the injection distinctly seen, and the vessels appear extremely beautiful. The only disadvantage of this method is, that the parts on which the vessels pass do not at all preserve their natural bulk, by reason of their shrinking up: and as the wet preparations are free from this inconvenience, Mr. Sheldon does not hesitate at assigning them a decided superiority over the dry ones.—Sometimes it is necessary to fix the preparations upon stiff paper or pasteboard, on account of their weight after being injected with mercury. The paper or pasteboard on

which they are fastened ought to be of various colours, according to the nature of the preparation, in order to form a proper ground for showing the lymphatic vessels. Such small preparations as are preserved in spirits, or oil of turpentine, may be kept in bottles well closed with stoppers; and the larger in common preparation glasses. Our author describes a simple method of stopping the mouths of these preparation glasses, by which means the stopper is rendered nearly as durable as the glass itself. "In order to execute it, let the anatomist take care to have the upper surface of his bottles made plane, by desiring the workmen at the glass-house to flatten them in the making. This they will easily do in forming the round ones, but the flat bottles are attended with considerable difficulty. The right way to make them, I believe, would be to blow them in moulds of various sizes; the workmen should likewise form the bottoms of the bottles perfectly flat, that they may stand upright and steady. Bottles of this form being provided for the larger preparations, we grind the upper surface of them on a flat plate of lead, about a quarter of an inch thick, and two feet in diameter; first with fine emery and water, then with powdered rotten stone, or putty first wet with water, and at last dry; so that the surface may be reduced to an exact horizontal plane, and of as fine a polish as plate-glass. This will soon be done, as the manœuvre requires but little dexterity; and the anatomist should be provided with a considerable number of these glasses prepared as above directed. To the top of each bottle a piece of plate-glass, cut by a diamond, is to be adapted so as completely to cover, but not project over, the edge of the bottle. When these two smooth surfaces are put upon each other, with a drop of water between, the attraction of cohesion is so considerable, that it requires great force to separate them.

Many preparations of the lymphatics, and other parts preserved in bottles, do not require any strings to suspend them; particularly when fixed on pasteboard or paper: such as require suspension should be tied to strings fixed to the preparation below, and to small holes drilled in the substance of the glass at the bottom of the neck; or to small bits of glass that may be fixed on the inside of the same part. The preparation is thus suspended in limpid proof malt-spirit, the bottle being almost completely filled; the upper and polished surface of the bottle, and the plate of glass, are to be wiped clean and dry; a drop of solution of gum arabic is to be put on the polished surface of the bottle, the top strongly and steadily pressed upon it, so as to bring the two surfaces into as close contact as possible; after which the bottle is to be placed in a cool airy place to dry. A piece of wet ox bladder, freed from fat, and soaked in water till it becomes mucilaginous, is then to be placed over the top, the air pressed out from between it and the glass; after which it must be tied with a pack-thread dipped in the solution of gum arabic. The bladder being cut off neatly under the last turn of the thread, is then to be dried, the string taken cautiously off, and the top and neck painted with a composition of lamp black mixed with japanners gold size: this soon dries, and leaves a fine smooth glossy surface, from which the dirt can at any time be as readily wiped off as from a mirror. By this method large bottles are as easily and effectually secured as small ones; and it is found to answer as well as the hermetical sealing of glasses, which in large vessels is altogether impracticable. If the bottoms have any inequalities which prevent them from standing steady, they may be easily made perfectly flat by grinding them with emery on the plate above mentioned. The tops, if well gummed, will even remain perfectly fixed on the glasses without the bladder: though in the common upright ones it may be advisable to put it on as a defence. Our author informs us, that since his making this discovery he has used glass saucers, with flat tops gummed on. In these vessels

the preparations, by reason of their horizontal posture, appear to great advantage. Thus he has exhibited very early abortions in their membranes, and some other preparations that cannot be suspended or viewed conveniently in the perpendicular direction. Some very delicate preparations, particularly those intended to be viewed with the microscope, those of the ampullulæ lactææ of Liberkuhn, and of the valves of the absorbents, may be preserved either in spirits or dry in tubes closed in the manner just mentioned, and will appear to great advantage. Some of the dry ones may also be advantageously placed in square oblong boxes, made of pieces of plate or white glass neatly gummed together, with narrow slips of white or coloured paper, and the objects may be conveniently viewed in this manner. With respect to the stopper bottles, which are very convenient for holding small preparations, our author advises the stoppers to be perfectly well ground; that they pass rather lower down than the neck of the bottle, for the convenience of drilling two holes obliquely through the inferior edge of the substance of the stopper, opposite to each other, for the convenience of fixing threads to hold the subject; for, if the threads pass between the neck and stopper, a space will be left; or, if the stopper be well ground, the neck of the bottle will be broken in endeavouring to press it down. On the other hand, if any space be left, the thread, by its capillary attraction, will act in such a way as to raise the spirits from the bottle, and cause evaporation, which will likewise take place from the chink between the stopper and neck.

INSTIÖGE, a post town of Kilkenny, in the province of Leinster; 63 miles from Dublin. It is also a borough, and returns two members to parliament; patronage in the representative of Sir William Fownes. It has two fairs.

INITIATED, a term properly used in speaking of the religion of the ancient heathens; where it signifies being admitted to the participation of the sacred mysteries. The word comes from the Latin *initiatu*s, of *initiare*, *initiare*; which properly signifies to begin sacrificing, or to receive or admit a person to the beginning of the mysteries, or of ceremonies of less importance. The ancients never discovered the deeper mysteries of their religion, nor even permitted some of their temples to be open, to any but those who had been initiated. See **MYSTERY**.

INJUNCTION, in law, a writ generally grounded upon an interlocutory order or decree out of the court of chancery or exchequer, sometimes to give possession to the plaintiff, for want of the defendant's appearance; sometimes to the king's ordinary court, and sometimes to the court-christian, to stop proceedings in a cause, upon suggestion made, that the rigour of the law, if it take place, is against equity and conscience in that case; that the complainant is not able to make his defence in these courts, for want of witnesses, &c. or that they act erroneously, denying him some just advantage. The writ of injunction is directed not only to the party himself, but to all and singular his counsellors, attorneys and solicitors; and if any attorney, after having been served with an injunction, proceeds afterward contrary to it, the court of chancery will commit the attorney to the Fleet for contempt. But if an injunction be granted by the court of chancery in a criminal matter, the court of king's bench may break it, and protect any that proceed in contempt of it.

INJURY, any wrong done to a man's person, reputation, or goods. See **ASSAULT**.

INK, a black liquor used in writing, generally made of an infusion of galls, vitriolated iron, commonly called green vitriol or *copperas*, and gum arabic. The properties which this liquor ought to have, are, 1. To flow freely from the pen, and sink a little into the paper, that the writing be not easily discharged. 2. A very deep black colour, which should be as deep at first as

at any time afterwards. 3. Durability, so that the writing may not be subject to decay by age. 4. Ink should be destitute of any corrosive quality, that it may not destroy the paper, or go through it in such a manner as to render the writing illegible. No kind of ink, however, hath yet appeared which is possessed of all these qualities. The ink used by the ancients was possessed of the second, third, and fourth qualities above mentioned, but wanted the first. Dr. Lewis hath discovered its composition from some passages in ancient authors. "Pliny and Vitruvius (says he) expressly mention the preparation of foot, or what we now call *lamp black*, and the composition of writing-ink from lamp-black and gum. Dioscorides is more particular, setting down the proportions of the two ingredients, *viz.* three ounces of the foot to one of the gum. It seems the mixture was formed into cakes or rolls; which being dried in the sun, were occasionally tempered with water, as the cakes of Indian ink are among us for painting."

In Mr. Delaval's Treatise on colours, p. 37, he acquaints us, that with an infusion of galls and iron filings he had not only made an exceedingly black and durable ink, but by its means, without the addition of any acid, dyed silk and woollen cloth of a good and lasting black. This kind of ink, however, though the colour is far superior to that of any other, hath the inconvenience of being very easily discharged, either by the smallest quantity of any acid, or even by simple water; because it doth not penetrate the paper in such a manner as is necessary to preserve it from the instantaneous action of the acid or of the water. During the action of the infusion of galls upon the iron in making this kind of ink, a very considerable effervescence takes place, and a quantity of air is discharged, the nature of which hath not yet been examined.

Dr. Lewis has thought the subject of ink-making not unworthy of his attention. From many experiments he infers, that the decay of inks is chiefly owing to a deficiency of galls; that the galls are the most perishable ingredient, the quantity of these, which gives the greatest blackness at first (which is about equal parts with the vitriol), being insufficient to maintain the colour; that, for a durable ink, the quantity of galls cannot be much less than three times that of the vitriol; that it cannot be much greater without lessening the blackness of the ink: that by diminishing the quantity of water, the ink is rendered blacker and more durable; that distilled water, rain water, and hard spring water, have the same effects; that white-wine produces a deeper black colour than water; that the colour produced by vinegar is deeper than that by wine; that proof-spirit extracts only a reddish brown tinge; that the last-mentioned tincture sinks into, and spreads upon, the paper; and hence the impropriety of adding spirit of wine to ink, as is frequently directed, to prevent mouldiness or freezing: that other astringents, as oak bark, bistort, floe-bark, &c. are not so effectual as galls, nor give so good a black, the colour produced by most of these, excepting oak-bark, being greenish: that the juice of flocs does not produce a black colour with martial vitriol; but that, nevertheless, the writing made with it becomes black, and is found to be more durable than common ink: that inks made with saturated solutions of iron in nitrous, marine, or acetous acids, in tartar, or in lemon-juice, were much inferior to the ink made with martial vitriol: that the colour of ink is depraved by adding quicklime, which is done with an intention of destroying any superabundant acid which may be supposed to be the cause of the loss of the colour of ink: that the best method of preventing the effects of this superabundant acid is probably by adding pieces of iron to engage it; and that this conjecture is confirmed by an instance the author had heard, of the great durability of the colour of an ink in which pieces of iron had been long immersed: and lastly, that a decoction of logwood used instead of water, sen-

sibly improves both the beauty and deepness of the black, without disposing it to fade. The same author observes, that the addition of gum-arabic is not only useful, by keeping the colouring matter suspended in the fluid, but also by preventing the ink from spreading, by which means a greater quantity of it is collected on each stroke of the pen. Sugar, which is sometimes added to ink, is found to be much less effectual than gums, and to have the inconvenience of preventing the drying of the ink. The colour of ink is found to be greatly injured by keeping the ink in vessels made of copper or of lead, and probably of any other metal, excepting iron, which the vitriolic acid can dissolve.

The foregoing experiments point out for the best proportions of the ingredients for ink, One part of green vitriol, one part of powdered logwood, and three parts of powdered galls. The best menstruum appears to be vinegar or white wine, though for common use water is sufficient. If the ink be required to be of a full colour, a quart, or at most three pints, of liquor may be allowed to three ounces of galls, and to one ounce of each of the other two ingredients. Half an ounce of gum may be added to each pint of the liquor. The ingredients may be all put together at once in a convenient vessel, and well shaken four or five times each day. In 10 or 12 days the ink will be fit for use, though it will improve by remaining longer on the ingredients. Or it may be made more expeditiously by adding the gum and vitriol to a decoction of galls and logwood in the menstruum. To the ink, after it has been separated from the feculencies, some coarse powder of galls, from which the fine dust has been sifted, together with one or two pieces of iron, may be added, by which its durability will be secured.

This receipt differs in some respects from the following, which is recommended by Dr. Black in his lectures:

Take powdered galls, three ounces; logwood shavings and vitriolated iron, of each one ounce; water from two to three pints, according to the degree of strength required for the ink. Before the boiling is finished, throw in half an ounce of gum-arabic, and when it is dissolved strain the liquor. As a means of preserving the ink from mould, Dr. Black directs about a quarter of an ounce of spirit of wine to be added; and likewise a little powdered cloves ground in a mortar with a little of the ink.

Some attempts were made by Dr. Lewis to endow writing-ink with the great durability of that of the ancients, as well as the properties which it has at present. For this purpose, he first tried animal glues, and then oily matters. A pencil, however, dipped in water washed the former away entirely. Of the latter he says: "As oils are made miscible with watery fluids by the intervention of gum, I mixed some of the softer painters varnish with about half its weight of a thick mucilage of gum arabic, working them well together in a mortar till they united into a smooth uniform mass: this was beaten with lamp-black, and some water added by little and little, the rubbing being continued till the mixture was diluted to a due consistence for writing. It wrote freely, and of a full brownish black colour: the characters could not be discharged by rubbing, but water washed them out, though not near so readily as any of the foregoing. Instead of the painters varnish or boiled oil, I mixed raw linseed oil in the same manner with mucilage and lamp-black, and, on diluting the mixture with water, obtained an ink not greatly different from the other.

"Though these oily mixtures answered better than those with simple gums or glues, it was apprehended that their being dischargeable by water would render them unfit for the purposes intended. The only way of obviating this imperfection appeared to be, by using a paper which should admit the black liquid to sink a little into its substance. Accordingly I took

some of the more sinking kinds of paper, and common paper made damp as for printing; and had the satisfaction to find, that neither the oily nor the simple gummy mixtures spread upon them so much as might have been expected, and that the characters were as fixed as could be desired, for they could not be washed out without rubbing off part of the substance of the paper itself."

"But (continues Dr. Lewis) a further improvement may yet be made, namely, that of uniting the ancient and modern inks together; or using the common vitriolic ink, instead of water, for tempering the ancient mixture of gum and lamp-black. By this method it should seem that the writings would have all the durability of those of former times, with all the advantage that results from the vitriolic ink fixing itself in the paper. Even when the common vitriolic mixture is depended on for the ink, it may in many cases be improved by a small addition of the ancient composition, or of the common Indian ink, which answers the same purpose: when the vitriolic ink is dilute, and flows so pale from the pen, that the fine strokes, on first writing, are scarcely visible, the addition of a little Indian ink is the readiest means of giving it the due blackness. By this admixture it may be presumed also that the vitriolic ink will be made more durable, the Indian ink in some measure covering it, and defending it from the action of the air. In all cases where Indian ink or other similar compositions are employed, cotton should be used in the ink-stand, as already mentioned, to prevent the settling of the black powder."

Since the invention of printing much less attention than formerly has been paid to the making of ink, so that now the art seems to be in a great measure lost. This will appear from a comparison of some ancient manuscripts with the writings of modern times. It being of the utmost importance, however, that public records, wills, and other valuable papers, which cannot admit of being printed, should be written with ink of a durable quality, this inattention seems to have been very culpable, and a restoration of the method of making writing-ink a very valuable acquisition. "The necessity (says Mr. Astle, in his *Origin of Alphabetical Writing*) of paying greater attention to this matter may readily be seen, by comparing the rolls and records that have been written from the 15th century to the end of the 17th, with the specimens we have remaining of various writings from the 5th to the 12th centuries. Notwithstanding the superior antiquity of the latter, they are in excellent preservation; but we frequently find the former, though of more modern date, so much defaced that they are scarcely legible."

This author agrees with Dr. Lewis in the opinion that the ancient inks were composed of foot or ivory black instead of the galls, copperas, and gums, which form the composition of ours. Besides their black inks, however, the ancients used various other colours, as red, gold and silver, purple, &c. Every coloured fluid capable of being used with a pen, may not improperly be deemed an *ink*: of these we have spoken occasionally under the articles *DYEING* and *COLOUR-MAKING*. Green ink was frequently used in Latin manuscripts, especially in the latter ages; and it was frequently employed in signatures by the guardians of the Greek emperors till their wards were of age. Blue or yellow ink was seldom used except in manuscripts; but (says Mr. Astle) "the yellow has not been much in use, as far as we can learn, these 600 years." Some kinds of characters, particularly the metallic, were burnished. Wax was used by the Latins and Greeks as a varnish, but especially by the former, and particularly in the 9th century. It continued a long time in vogue.

A treatise upon inks was published by Peter Caniparius, professor of medicine at Venice; of which an edition was printed at London in 1660. It is divided into six parts. The

first treats of inks made from pyrites, stones, and metals; the second of such as are made from metals and calces; the third from foots and vitriols; the fourth of the different kinds of inks used by the librarii or book-writers, by printers, and engravers; likewise of staining or writing upon marble, stucco, or scaliolia, and of encaustic modes of writing; also of liquids for painting or colouring leather and linen or woollen cloths; restoring inks that had been decayed by time; together with many methods of effacing writing, restoring decayed paper, and different modes of secret writing. The fifth treats of writing inks made in different countries from gums, woods, the juices of plants, &c. as well as of different kinds of varnishes. The sixth treats of the different methods of extracting vitriol, and the chemical uses of it.

Weckerus de Secretis, a treatise printed at Basil in 1612, contains a number of curious particulars concerning ink. He gives also receipts for making gold and silver inks, composed both with these metals and without them; directions for making inks for secret writing, and for defacing them; though in this last part there are many particulars bordering too much on the marvellous.

In the *Philosophical Transactions* for 1787, Dr. Blagden gives some account of a method of restoring decayed inks so as to render them legible. His experiments originated from a conversation with Mr. Astle already quoted, on the question whether the inks made eight or ten centuries ago, and which are found to have preserved their colour very well, were made of the same materials now employed or not? In order to decide the question, Mr. Astle furnished the Doctor with several manuscripts on parchment and vellum from the 9th to the 15th centuries inclusively. Some of these were still very black; others of different shades, from a deep yellowish brown to a very pale yellow, in some parts so faint that it could scarcely be seen. This was tried with simple and phlogisticated alkalies, the mineral acids and infusion of galls. From these experiments it appeared that the ink anciently employed was of the same nature as at present: the letters turned of a reddish or yellowish brown, with alkalies became pale, and were at length obliterated by the dilute mineral acids. The drop of acid liquor, which had been put upon a letter, changed to a deep blue or green on the addition of phlogisticated alkali; with an infusion of galls, in some cases the letters acquired a deep tinge, in others a slight one. "Hence (says the Doctor) it is evident, that one of the ingredients was iron, which there is no reason to doubt was joined with the vitriolic acid; and the colour of the more perfect MSS. which in some was a deep black, and in others a purplish black, together with the restitution of that colour in those which had lost it by the infusion of galls, sufficiently proved that another of the ingredients was astringent matter, which from history appears to have been that of galls. No trace of a black pigment of any sort was discovered; the drop of acid, which had completely extracted a letter, appearing of an uniform pale and ferruginous colour, without an atom of black powder or other extraneous matter floating in it."

As this account differs very materially from the former extracted from Mr. Astle's writings, so the reason given for the continuance of the colour differs no less. This, according to Dr. Blagden, "seems to depend very much on a better preparation of the material upon which the writing was made, namely the parchment or vellum; the blackest letters being generally those which had sunk into it the deepest. Some degree of effervescence was commonly to be perceived when acids were in contact with the surface of these old vellums. I was led, however, to suspect, that the ancient inks contained rather a less proportion of iron than the more modern; for, in general, the tinge of colour produced by the phlogisticated alkali in the acid laid upon

them, seemed less deep: which, however, might depend in part upon the length of time they had been kept; and perhaps more gum was used in them, or they were washed over with some kind of varnish, though not such as gave any gloss."

Among the specimens with which our author was favoured by Mr. Atle, there was one which differed very materially from the rest. It was said to be a manuscript of the 15th century: the letters were of a full engrossing hand, angular without any fine strokes, broad, and very black. None of the chemical solvents above mentioned seemed to produce any effect. Most of them seemed rather to make the letters blacker, probably by cleaning the surface; and the acids, after having been rubbed strongly upon the letters, did not strike any deeper tinge with the phlogisticated alkali. Nothing could obliterate these but what took off part of the vellum; when small rolls of a dirty matter were to be perceived. "It is therefore unquestionable (says the Doctor) that no iron was used in this ink; and, from its resistance to the chemical solvents, as well as a certain clotted appearance in the letters when examined closely, and in some places a slight degree of gloss, I have little doubt that they were formed of a footy or carbonaceous powder and oil, probably something like our present printer's ink; and am not without suspicion that they were actually printed."

On examining this MS. more fully, our author was convinced that it was really a part of a very ancient printed book. In considering the methods of restoring the legibility of decayed writings, our author observes, that perhaps one of the best may be to join phlogisticated alkali with the calx of iron which remains; because the precipitate formed by these two substances greatly exceeds that of the iron alone. On this subject Dr. Blagden disagrees with Mr. Bergman; but to bring the matter to a test, the following experiments were made.

1. The phlogisticated alkali was rubbed in different quantities upon the bare writing. This, in general, produced little effect; though, in a few instances, it gave a blueish tinge to the letters, and increased their intensity; "probably (says the Doctor) where something of an acid nature had contributed to the diminution of their colour." 2. By adding, besides the alkali, a dilute mineral acid to the writing, our author found his expectations fully answered; the letters then changing quickly to a very deep and beautiful blue. It is but of little consequence whether the acid or phlogisticated alkali be first added; though upon farther consideration the Doctor inclined to begin with the alkali. The reason is, that when the alkali is first put on, the colour seems to spread less, and thus not to hurt the legibility of the writing so much as would otherwise be done. His method is to spread the alkali thin over the writing with a feather, then to touch it as gently as possible upon or nearly over the letters with the diluted acid by means of a feather or bit of stick cut to a blunt point. The moment that the acid liquor is applied, the letters turn to a fine blue, beyond comparison stronger than the original trace of the letter; and by applying a bit of blotting paper to suck up the superfluous liquid, we may in a great measure avoid the staining of the parchment: for it is this superfluous liquor which, absorbing part of the colouring matter from the letters, becomes a dye to whatever it touches. Care ought however to be taken not to allow the blotting paper to come in contact with the letters, because the colouring matter may easily be rubbed off while soft and wet. Any one of the three mineral acids will answer the purpose effectually: Dr. Blagden commonly uses the marine. But whichever of the three is used, it ought to be diluted so far as not to be in danger of corroding the parchment; after which the degree of strength seems not to be a matter of great nicety.

Another method of restoring the legibility of old writings is by wetting them with an infusion of galls in white wine; but

this is subject to the same inconvenience with the former, and is besides less efficacious. The Doctor is of opinion that the acid of the galls by itself would be better for the purpose than the infusion of the whole substance of them; and he thinks also that a preferable kind of phlogisticated alkali might be prepared either by purifying the common kind from iron as much as possible, or by making use of the volatile alkali instead of the fixed. Mr. Atle mentions a method of restoring the legibility of decayed writings; but says that it ought not to be hazarded lest a suspicion of deceit should arise.

In the Monthly Review of this volume of the Transactions, we find a method proposed of preventing ink from decaying, which seems very likely to answer the purpose. It consists in washing over the paper to be written upon with the colouring matter of prussian blue, which will not deprave it in colour, or any other respect. By writing upon it with common ink afterwards, a ground of prussian blue is formed under every stroke; and this remains strong after the black has been decayed by the weather, or destroyed by acids. Thus the ink will bear a larger proportion of vitriol at first, and will have the advantage of looking blacker when first written.

Indian Ink, a valuable black for water-colours, brought from China and other parts of the East Indies, sometimes in large rolls, but more commonly in small quadrangular cakes, and generally marked with Chinese characters. Dr. Lewis, from experiments made on this substance, hath shown that it is composed of fine-lamp-black and animal-glue: and accordingly, for the preparation of it, he directs us to mix the lamp-black with as much melted glue as is sufficient to give it a tenacity proper for being made into cakes; and these when dry, he tells us, answered as well as those imported from the East Indies, both with regard to the colour and the freedom of working. Ivory black, and other charcoal blacks, levigated to a great degree of fineness, answered as well as the lamp-black; but in the state in which ivory-black is commonly sold, it proved much too gritty, and separated too hastily from the water.

Printing Ink, a substance totally different from Indian ink, or that made use of in writing. It is an oily composition, of the consistence of a thin ointment. The method of preparing it was long kept a secret by those whose employment it was to make it, and who were interested in concealing it; and even yet is but imperfectly known. The properties of good printing ink are, to work clean and easily, without daubing the types, or tearing the paper; to have a fine black colour; to wash easily off the types; to dry soon; and to preserve its colour without turning brown. This last, which is a most necessary property, is effectually obtained by setting fire to the oil with which the printing ink is made for a few moments, and then extinguishing it by covering the vessel. It is made to wash easily off the types, by using soap as an ingredient; and its working clean depends on its having a proper degree of strength, which is given by a certain addition of rosin. A good deal, however, depends on the proportion of the ingredients to each other; for, if too much soap is added, the ink will work very foul, and daub the types to a great degree. The same thing will happen from using too much black, at the same time that both the soap and black hinder the ink from drying; while too much oil and rosin tear the paper, and hinder it from washing off. By the following receipt printing ink of a tolerable good quality may be made: "Take a Scots pint of linseed oil, and set it over a pretty brisk fire in an iron or copper vessel capable of holding three or four times as much. When it boils strongly, and emits a thick smoke, kindle it with a piece of paper, and immediately take the vessel off the fire. Let the oil burn for about a minute; then extinguish it by covering the vessel: after it has grown pretty cool, add two pounds of black rosin, and one pound of hard soap cut into

hin slices. If the oil is very hot when the soap is added, almost the whole mixture will run over the vessel. The mixture is then to be set again over the fire; and when the ingredients are thoroughly melted, a pound of lamp black, previously put through a lawn sieve, is to be stirred into it. The whole ought then to be ground on a marble stone, or in a mill like the levigating mill."

Though the above receipt is greatly superior to any that hath been hitherto published, all of which are capitally deficient in not mentioning the necessary ingredients of rosin and soap; yet it must be acknowledged, that ink made in this manner is inferior in point of colour, and is likewise more apt to daub the types and make an indistinct impression, than such as is prepared by some of those who make the manufacture of this commodity their employment; so that either a variation in the proportion of the ingredients, a nicety in the mixture, or some additional ingredient, seems necessary to bring it to the requisite perfection.

Ink for the Rolling Press, is made of linseed oil burnt in the same manner as that for common printing ink, and then mixed with Francfort-black, and finely ground. There are no certain proportions which can be determined in this kind of ink; every workman adding oil or black to his ink as he thinks proper, in order to make it suit his purpose. Some, however, mix a portion of common boiled oil which has never been burnt: but this must necessarily be a bad practice, as such oil is apt to go through the paper; a fault very common in prints, especially if the paper is not very thick. No soap is added; because the ink is not cleared off from the copper-plates with alkaline ley as in common printing, but with a brush dipped in oil.

Sympathetic Ink, a liquor with which a person may write, and yet nothing appear on the paper after it is dry, till some other means are used, such as holding the paper to the fire, rubbing it over with some other liquor, &c. These kinds of ink may be divided into seven classes, and that with respect to the means used to make them visible; viz. 1. Such as become visible by passing another liquor over them, or by exposing them to the vapour of that liquor. 2. Those that do not appear so long as they are kept close, but soon become visible on being exposed to the air. 3. Such as appear by strewing or sifting some very fine powder of any colour over them. 4. Those which become visible by being exposed to the fire. 5. Such as become visible by heat, but disappear again by cold or the moisture of the air. 6. Those which become visible by being wetted with water. 7. Such as appear of various colours, red, yellow, blue, &c.

1. The first class contains four kinds of ink, viz. solutions of lead, bismuth, gold, and green vitriol. The first two become visible in the same manner, viz. by the contact of sulphureous liquids or fumes. For the first, a solution of common sugar-of-lead in water will answer as well as more troublesome preparations. If you write with this solution with a clean pen, the writing when dry will be totally invisible; but if it be wetted with a solution of *leper sulphuris*, or of orpiment, dissolved by means of quick-lime; or if it be exposed to the strong vapours of these solutions, but especially to the vapour of volatile tincture of sulphur; the writing will appear of a brown colour, more or less deep according to the strength of the sulphureous fume. By the same means, what is wrote with the solution of bismuth in spirit of nitre will appear of a deep black.

The sympathetic ink prepared from gold depends on the property by which that metal precipitates from its solvent on the addition of a solution of tin. If you write with a solution of gold in aqua regia, and let the paper dry gently in the shade, nothing will appear for the first seven or eight hours. Dip a pencil or a small fine sponge in the solution of tin, and draw it lightly over the invisible characters, they will immediately appear of a purple colour.

Characters wrote with a solution of green vitriol carefully depurated, will likewise be invisible when the paper is dry; but if wetted with an infusion of galls, they will immediately appear as if wrote with common ink. If, instead of this infusion, a solution of the phlogisticated alkali, impregnated with the colouring matter of prussian blue, is made use of, the writing will appear of a very deep blue.

II. To the second class belong the solutions of all those metals which are apt to attract phlogiston from the air, such as lead, bismuth, silver, &c. The sympathetic ink of gold already mentioned belongs also to this class; for, if the characters wrote with it are long exposed to the air, they become by degrees of a deep violet colour, nearly approaching to black. In like manner, characters wrote with a solution of silver in aquafortis are invisible when newly dried, but, being exposed to the sun, appear of a grey colour like slate. To this class also belong solutions of lead in vinegar; copper in aquafortis; tin in aqua regia; emery, and some kinds of pyrites, in spirit of salt; mercury in aquafortis; or iron in vinegar. Each of these has a particular colour when exposed to the air; but they have the disagreeable property of corroding the paper, so that after some time the characters appear like holes cut out of the paper.

III. The third class of sympathetic inks contains such liquids as have some kind of glutinous viscosity, and at the same time are long a-drying; by which means, though the eye cannot discern the characters wrote with them upon paper, the powders strewed upon them immediately adhere, and thus make the writing become visible. Of this kind are urine, milk, the juices of some vegetables, weak solutions of the deliquescent salts, &c.

IV. This class, comprehending all those that become visible by being exposed to the fire, is very extensive, as it contains all those colourless liquids in which the matter dissolved is capable of being reduced, or of reducing the paper, into a sort of charcoal by a small heat. A very easily procured ink of this kind is oil of vitriol diluted with as much water as will prevent it from corroding the paper. Letters wrote with this fluid are perfectly invisible when dry, but instantly appear as black as if wrote with the finest ink, on being held near the fire. Juice of lemons or onions, a solution of sal-ammoniac, green vitriol, &c. will answer the same purpose, though not so easily, or with so little heat.

V. The fifth class comprehends only solutions of regulus of cobalt in spirit of salt; for the properties of which see CHEMISTRY, p. 432.

VI. This class comprehends such inks as become visible when characters wrote with them are wetted with water. They are made of all such substances as deposit a copious sediment when mixed with water, dissolving only imperfectly in that fluid. Of this kind are dried alum, sugar of lead, vitriol, &c. We have therefore only to write with a strong solution of these salts upon paper, and the characters will be invisible when dry; but when we apply water, the small portion of dried salt cannot again be dissolved in the water. Hence the insoluble part becomes visible on the paper, and shows the characters wrote in white, grey, brown, or any other colour which the precipitate assumes.

VII. Characters may be made to appear of a fine crimson, purple, or yellow, by writing on paper with solution of tin in aqua regia, and then passing over it a pencil dipped in a decoction of cochineal, Brazil wood, logwood, yellow wood, &c. Further mention of these may be traced under the articles CHEMISTRY, DYEING, and COLOUR-Making.

Ink-Stones, a kind of small round stones of a white, red, grey, yellow, or black colour, containing a quantity of native martial vitriol, whence they derive the property of making ink, and from thence their name. They are almost entirely

soluble in water, and, besides their other ingredients, contain also a portion of copper and zinc.

INIS-STONE. See *MOON-STONE*.

INLAND, a name for any part of a country at a distance from the sea.

INLAND-*Navigation*. See *CANAL* and *Inland NAVIGATION*.

INLAND *Trade*, that kind of trade carried on between the different parts of the same kingdom, whether over land, or by means of inland navigation.

INLAYING. See *VENEERING*, *MOSAIC*, and *MARQUETRY*.

INLEAVED, in our old writers, signifies entangled or ensnared. It is used in the champion's oath.

INLISTING, in a military sense. See *LISTING*.

INMATES, such persons as are admitted, for their money, to live in the same house or cottage with another man, in different rooms, but going in at the same door; being usually supposed to be poor, and not able to maintain a whole house themselves. These are inquirable in a court-leet. No owner or occupier of a cottage shall suffer any inmates therein, or more families than one to inhabit there, on pain of forfeiting 10s. per month to the lord of the leet.

INN, a river of Germany, which has its source in the country of the Grisons, and at the foot of the mountain Septimerberg. It runs N. E. through Tirol, by Inspruc, and, continuing its course N. E. through Bavaria, passes by Kufstein, Vafseburg, Braunaw, and other towns, and falls into the Danube between Passau and Instadt.

INN, a place appointed for the entertainment and relief of travellers. Inns are licensed and regulated by justices of the peace, who oblige the landlord to enter into recognizances for keeping good order. If a person who keeps a common inn refuses to receive a traveller into his house as a guest, or to find him victuals and lodging on his tendering a reasonable price for them, he is liable to an action of damages, and may be indicted and fined at the king's suit. Judge Blackstone observes, that the rates of all commodities sold by inn-keepers, according to our ancient laws, may be assessed: and inn-keepers not selling their hay, oats, beans, &c. and all manner of victuals, at reasonable prices, without taking any thing for litter, may be fined and imprisoned, &c. by 21 Jac. I. c. 21. Where an inn-keeper harbours thieves, persons of infamous character, or suffers any disorders in his house, or sets up a new inn where there is no need of one, to the hindrance of ancient and well-governed inns, he is indictable and fineable: and by statute, such inn may be suppressed. Action upon the case lies against any inn-keeper, if a theft be committed on his guest by a servant of the inn, or any other person not belonging to the guest; though it is otherwise where the guest is not a traveller, but one of the same town or village, for there the inn-keeper is not chargeable; nor is the master of a private tavern answerable for a robbery committed on his guest: it is said, that even though the travelling guest does not deliver his goods, &c. into the inn-keeper's possession, yet if they are stolen he is chargeable. An inn-keeper is not answerable for any thing out of his inn, but only for such as are within it; yet, where he of his own accord puts the guest's horse to graze, and the horse is stolen, he is answerable, he not having the guest's orders for putting such horse to graze. The inn-keeper may justify the stopping of the horse, or other thing of his guest, for his reckoning, and may retain the same till it be paid. Where a person brings his horse to an inn, and leaves him in the stable, the inn-keeper may detain him till such time as the owner pays for his keeping; and if the horse eats out as much as he is worth, after a reasonable appraisalment made, he may sell the horse and pay himself: but when a guest brings several horses to an inn, and afterwards takes them

all away except one, this horse so left may not be sold for payment of the debt for the others; for every horse is to be sold, only to make satisfaction for what is due for his own meat.

INNS, a name by which our colleges of municipal or common law professors and students are called: the old English word for houses of noblemen, bishops, and others of extraordinary note, being of the same signification with the French word *hotel*.

INNS of *Court* are so called, as some think, because the students there are to serve and attend the courts of judicature; or else, because anciently these colleges received none but the sons of noblemen and better sort of gentlemen, who were here to be qualified to serve the king in his court; as Fortescue affirms. And, in his time, he says, there were about 2000 students in the inns of court and chancery, all of whom were *fili nobilium*, or gentlemen born. But this custom has gradually fallen into disuse; so that in the reign of queen Elizabeth, Sir Edward Coke does not reckon above 1000 students, and the number at present is very considerably less; for which judge Blackstone assigns the following reasons: 1. Because the inns of chancery, being now almost totally filled by the inferior branches of the profession, are neither commodious nor proper for the resort of gentlemen of any rank or figure; so that there are very rarely any young students entered at the inns of chancery. 2. Because in the inns of court all sorts of regimen and academical superintendance, either with regard to morals or studies, are found impracticable, and therefore entirely neglected. Lastly, because persons of birth and fortune, after having finished their usual courses at the universities, have seldom leisure or resolution sufficient to enter upon a new scheme of study at a new place of instruction; wherefore few gentlemen now resort to the inns of court, but such for whom the knowledge of practice is absolutely necessary, or such as are intended for the profession.

Our inns of court, justly famed for the production of men of learning in the law, are governed by masters, principals, benchers, stewards, and other officers; and have public halls for exercises, readings, &c. which the students formerly used to attend and perform for a certain number of years, before they could be admitted to plead at the bar. These societies have not, however, any judicial authority over their members; but instead of this they have certain orders among themselves, which have by consent the force of laws. For lighter offences persons are only excommunicated, or put out of commons; for greater, they lose their chambers, and are expelled the college; and when once expelled out of one society, they are never received by any of the others. The gentlemen in these societies may be divided into benchers, outer-barristers, inner-barristers, and students.

The four principal inns of court, are the Inner Temple and Middle Temple, heretofore the dwelling of the Knights Templars, purchased by some professors of the common law about 300 years ago; Lincoln's Inn, and Gray's Inn, anciently belonging to the earls of Lincoln and Gray. The other inns are the two Serjeants Inns.

INNS of *Chancery* were probably so called, because anciently inhabited by such clerks as chiefly studied the forming of writs, which regularly belonged to the curators, who are officers of chancery. The first of these was Thavies Inn, begun in the reign of Edward III. and afterwards sold to the society of Lincoln's Inn. Besides this, we have New Inn, Symond's Inn, Clement's Inn, Clifford's Inn, anciently the house of the Lord Clifford; Staple Inn, belonging to the merchants of the staple; Lion's Inn, anciently a common inn with the sign of the lion; Furnival's Inn, and Bernard's Inn. These were heretofore preparatory colleges for younger students; and many were entered here before they were admitted into the inns of court. Now they are mostly taken up by attorneys, solicitors, &c. They all belong

to some of the inns of court, who formerly used to send yearly some of their barristers to read to them.

INNACONDA, a fortress of the Deccan of Hindoostan, in the Guntoor Circa, situate on a hill, 46 miles N. W. by N. of Onzole, and subject to the Nizam of the Deccan.

INNATE IDEAS, those supposed to be stamped on the mind from the first moment of its existence, and which it constantly brings into the world with it: a doctrine which Mr. Locke has taken great pains to refute.

INNERLEITHING, a village of the county of Peebles, in Scotland, on the N. side of the river Tweed; near which is an excellent medicinal spring rising into celebrity.

INNIS. See **INCH**.

INNISCLOCHRAN, or the **SPONEX ISLAND**, an island in Lough Ree, in the river Shannon, between the counties of Westmeath and Roscommon, at which place a monastery was founded by St. Marmod about the beginning of the 6th century.

INNISFAIL, derived from *Inis Bheal*, that is, "the island of Bheal," one of the ancient names of Ireland, so denominated from *Bheal*, the principal object of adoration among the ancient inhabitants of the British isles. Innisfail has been erroneously translated the *Island of Destiny*, as *Bheal* was sometimes taken for *Fate* or *Providence*.

INNISFALLEN, an island in the lake of Killarney, in the county of Kerry and province of Munster: in it are the ruins of a very ancient religious house, founded by St. Finian, the patron saint of these parts, and to him the cathedral of Aghadoe is also dedicated. The remains of this abbey are very extensive, its situation romantic and retired. Upon the dissolution of religious houses, the possessions of this abbey were granted to Captain Robert Collam. The island contains about 12 acres, is agreeably wooded, and has a number of fruit-trees. St. Finian flourished about the middle of the 6th century; he was surnamed in Irish *Iobbar*; his father's name was *Conail* the son of *Eschod*; descended from *Kian* the son of *Alild*, king of Munster. There was formerly a chronicle kept in this abbey, which is frequently cited by Sir J. Ware and other antiquaries under the title of the *Annals of Innisfallen*. They contain a sketch of universal history, from the creation of the world to the year 430 or thereabouts; but from thence the annalist has amply enough prosecuted the affairs of Ireland down to his own times. He lived to the year 1215. Sir J. Ware had a copy of them, whereof there is an imperfect transcript among the MSS. of the library of Trinity College, Dublin. They were continued by another hand to the year 1320. Bishop Nicholson, in his Irish historical library, informs us, that the Duke of Chandos had a complete copy of them down to 1320 in his possession. These annals tell us, that in the year 1180, the abbey, which had at that time all the gold and silver and richest goods of the whole country deposited in it, as the place of greatest security, was plundered by Mildwin son of Daniel O'Donoghoe, as was also the church of Ardferit, and many persons were slain in the very cemetery by the McCartys; but God, as it is said in this chronicle, punished this impiety by the untimely end of some of the authors of it.

INNISHANNON, a town in the county of Cork and province of Munster, 134 miles from Dublin; situated on the river Bandon six miles from Kinsale. Here is a charter-school for above 30 boys. The linen manufacture has been much encouraged by the late Mr. Adderley. The river is navigable to Collier's quay, about half a mile below the place. On the west side of the town is a stone bridge. This place was formerly walled, and of some note, as appears by the foundations of several castles and large buildings discovered in it. The town of Innishannon, together with its ferry, were granted to Philip de Barry by Henry V. by letters patent, anno 1412. It has two fairs.

INNISHIRKAN, an island situated between Cape Clear Island and Baltimore Bay, in the county of Cork and province of Munster. In this island stood the castle of Duneloug, possessed by the O'Driscolls, which was surrendered after the defeat of the Spaniards to Captain Hervey on the 23d Feb. 1652. There was afterwards a regular fortification erected on part of the island, which was garrisoned in Queen Ann's time, but it has been for several years dismantled: about a mile to the south are the remains of an ancient abbey, founded 1460, for Franciscans, by Florence O'Driscoll. This island has very good land, and is vastly preferable to that of Cape Clear islands. To the north-west of Innishirkan island lies Hare island, a large fruitful spot; and near it are four small islands called the *Schimes*: also along the coast, in the following order from east to west, are Cattle island, 19 acres; Horse island, containing 100 acres; and west of all these is a small spot called Goat island. All these islands, together with the adjacent coast, produce large crops of fine English barley.

INNISKILLING, a borough, market, fair, and post town of Ireland, in the county of Fermanagh and province of Ulster, lying between three lakes. It is about 24 miles east of Ballyshannon, and 79 north-west of Dublin. It sends two members to parliament; patron Lord Inniskilling, this place giving title of viscount to the family of Cole. Its inhabitants distinguished themselves in several considerable engagements in the wars of Ireland at the Revolution, out of which a regiment of dragoons, bearing the title of the Inniskilleners, was mostly formed. They form the 6th regiment of dragoons in the British army. It has a barrack for three companies of foot.

INNOCENT'S DAY, a festival of the Christian church, observed on December 28th, in memory of the massacre of the innocent children by the command of Herod king of Judæa. See *Jesus Christ*; and the article *Jews*. The Greek church in their kalendar, and the Abythinians of Ethiopia in their offices, commemorate 14,000 infants on this occasion.

INNTHAL, a district of Germany, in the Tirol, watered by the river Inn. Inspruc is the capital.

INNUENDO, of *innuo* "I nod or beckon," is a word frequently used in writs, declarations and pleadings, to ascertain a person or thing which was named, but left doubtful, before: as, he (*innuendo* the plaintiff) did so and so: mention being before made of another person. In common conversation or writing, an innuendo denotes an oblique hint or distant reference, in contradiction to a direct and positive charge.

INO, in fabulous history, a daughter of Cadmus and Harmonia, who nursed Bacchus. She married Athamas king of Thebes, after he had divorced Nephele, by whom he had two children, Phryxus and Helle. Ino became mother of Melicerta and Learchus; and soon conceived an implacable hatred against the children of Nephele, because they were to ascend the throne in preference to her own. Phryxus and Helle were informed of Ino's machinations, and they escaped to Colchis on a golden ram. Juno, jealous of Ino's prosperity, resolved to disturb her peace; and more particularly because she was of the descendants of her greatest enemy, Venus. Tiphone was sent by order of Juno to the house of Athamas; and she filled the whole palace with such fury, that Athamas, taking Ino to be a lioness and her children whelps, pursued her and dashed her son Learchus against a wall. Ino escaped from the fury of her husband; and from a high rock she threw herself into the sea with Melicerta in her arms. The gods pitied her fate; and Neptune made her a sea deity, which was afterwards called Leucothoe. Melicerta became also a sea god, known by the name of Palemon.

INOA, festivals in memory of Ino, celebrated yearly with sports and sacrifices at Corinth. An anniversary sacrifice was also offered to Ino at Megara, where she was first worshipped

under the name of *Leucothoe*.—Another in Laconia, in honour of the same. It was usual at the celebration to throw cakes of flour into a pond, which if they sunk were prefaces of prosperity, but if they swam on the surface of the waters they were inauspicious and very unlucky.

INOCARPUS, in botany; a genus of the monogynia order, belonging to the decandria class of plants. The corolla is funnel-shaped; the calyx bifid; the stamina are placed in a double series; the fruit is a monospermous plum.

INOCULATION, or **BUDDING**, in gardening, is commonly practised upon all sorts of stone-fruit; as nectarines, peaches, apricots, plums, cherries, as also upon oranges and jasmines: and indeed this is preferable to any sort of grafting for most sorts of fruit. The method of performing it is as follows: You must be provided with a sharp pen-knife with a flat haft, which is to raise the bark of the stock to admit the bud; and some sound bass-mat, which should be soaked in water, to increase its strength, and render it more pliable: then having taken off the cuttings from the trees you would propagate, you must choose a smooth part of the stock, about five or six inches above the surface of the ground, if designed for dwarfs; but if for standards, they should be budded six feet above ground. Then with your knife make an horizontal cut across the rind of the stock, and from the middle of that cut make a slit downwards, two inches in length, that it may be in the form of a T; but you must be careful not to cut too deep, lest you wound the stock: then having cut off the leaf from the bud, leaving the foot-stalk remaining, you should make a cross cut, about half an inch below the eye, and with your knife slit off the bud, with part of the wood to it: this done, you must with your knife pull off that part of the wood which was taken with the bud, observing whether the eye of the bud be left to it or not; for all those buds which lose their eyes in stripping, are good for nothing: then having gently raised the bark of the stock with the flat haft of your pen-knife clear to the wood, thrust the bud therein, observing to place it smooth between the rind and wood of the stock, cutting off any part of the rind belonging to the bud that may be too long for the slit made in the stock; and so having exactly fitted the bud to the stock, tie them closely round with bass-mat, beginning at the under part of the slit, and so proceeding to the top, taking care not to bind round the eye of the bud, which should be left open.

When your buds have been inoculated three weeks or a month, those which are fresh and plump you may be sure are joined: and at this time you should loosen the bandage, which if it be not done in time, will injure if not destroy the bud. The March following cut off the stock sloping, about three inches above the bud, and to what is left fasten the shoot which proceeds from the bud: but this must continue no longer than one year; after which the stock must be cut off close above the bud. The time for inoculating is from the middle of June to the middle of August: but the most general rule is, when you observe the buds formed at the extremity of the same year's shoot, which is a sign of their having finished their spring growth. The first sort commonly inoculated is the apricot; and the last the orange-tree, which should never be done till the latter end of August. And in doing this work, you should always make choice of cloudy weather; for if it be done in the middle of the day, when the weather is hot, the shoots will perspire so fast as to leave the buds destitute of moisture.

INOCULATION, in a medical sense, is used for the transplantation of diseases from one subject to another, particularly for the insertion of the small-pox, which, though of ancient use in the Eastern countries, is but a modern practice among us.

As to the origin of the art of inoculating the small-pox, as

well as the time and place in which it was performed, they are equally unknown to all by whom the practice is adopted. Accident probably gave rise to it. Pylarini says, that among the Turks it was not attended to except amongst the meaner sort. Dr. Ruffel informs us in the *Philosophical Transactions*, vol. lviii. p. 142. that no mention is made of it by any of the ancient Arabian medical writers that are known in Europe; and the physicians who are natives in and about Arabia assert, that nothing is to be found regarding it in any of those of a more modern date. He farther says, that he engaged some of his learned Turkish friends to make inquiry; but they did not discover any thing on this subject of inoculation either in the writings of physicians, historians, or poets. Until the beginning of the 18th century, all the accounts we have of inoculating the small-pox are merely traditional. The silence on this subject, observed amongst writers in the countries where the practice obtained, Dr. Ruffel supposes, with great probability, to be owing to the physicians there never countenancing or engaging in it. It is also remarkable, that before Pylarini's letter to the Royal Society in 1701, nor yet for several years after, this practice is not noticed by any of the most inquisitive travellers. On this Dr. Ruffel very justly observes, that customs, the most common in distant countries, are often the least apt to attract the observation of travellers, who, engaged in other pursuits, must be indebted to accident for the knowledge of such things as the natives seldom talk of, upon the belief that they are known to all the world.

The first accounts we have in the learned world concerning inoculation, are from two Italian physicians, *viz.* Pylarini and Timoni, whose letters on the subject may be seen in the *Philosoph. Transf. abr.* vol. v. p. 370, &c. The first is dated A. D. 1701; the next is dated A. D. 1713. Whether our inquiries are extended abroad or confined to our own country, inoculation hath been practised under one mode or other time immemorial; in Great Britain and its adjacent isles we have well authenticated accounts, extending farther backward than any from the continent. Dr. Williams of Haverfordwest, who wrote upon inoculation in 1725, proves, that it had been practised in Wales, though in a form somewhat different, time out of mind. Mr. Wright, a surgeon in the same place, says, that buying the small-pox is both a common practice and of long standing in that neighbourhood. He says, that, in Pembrokehire, there are two large villages near the harbour of Milford, more famous for this custom than any other, *viz.* St. Ishmael's and Marloes. The old inhabitants of these villages say, that it has been a common practice; and that one William Allen of St. Ishmael's, who in 1722 was 90 years of age, declared to some persons of good sense and integrity, that this practice was used all his time; that he well remembered his mother telling him, that it was a common practice all her time, and that she got the small-pox that way; so that at least we go back 160 years or more.

In the Highlands of Scotland, and some of the adjacent isles, Dr. Alexander Monro senior informs us, that the custom through ages past hath been to put their children to bed with those who laboured under a favourable small pox, and to tie worsted threads about their children's wrists, after having drawn them through variolous pustules.

According to the result of Dr. Ruffel's inquiries, the Arabians assert, that the inoculation of the small pox has been the common custom of their ancestors, and that they have no doubt of its being as ancient as the disease itself. It is remarkable, that buying the small-pox is the name universally applied in all countries to the method of procuring the disease: it is true that there are other terms; but in Wales and Arabia, as well as many other countries, this is the usual appellation. From the sameness of the name, and the little diversity observable in

the manner of performing the operation, it is probable that the practice of inoculation in these countries was originally derived from the same source. From its extensive spread, it is probably of great antiquity too.

In the year 1717, Lady Mary Wortley Montague, wife of the English ambassador at Constantinople, had her son inoculated there at the age of six years; he had but few pustules, and soon recovered. In April 1721, inoculation was successfully tried on seven condemned criminals in London, by permission of his majesty. In 1722, Lady Mary Wortley Montague had a daughter of six years old inoculated in this island; soon after which, the children of the royal family that had not had the small-pox were inoculated with success; then followed some of the nobility, and the practice soon prevailed. And here we date the commencement of inoculation under the direction of art.

From the example of the royal family in England, the practice was adopted in Germany, where the late Dr. Houlston greatly promoted it; also in Hanover and its adjacent countries.

After Mr. Maitland had succeeded with those he had inoculated in and about London, he introduced the practice into Scotland in the year 1726.

Sweden soon followed the example of the British. Russia lately engaged one of our principal promoters and improvers of this art. And now there are not many countries that do not more or less practise it.

The modes of inoculation practised in different countries have been exceedingly various.

Inoculation with the blood of variolous patients has been tried without effect: it is the variolous matter only that produces the variolous disease. This can act on a sensible part only, and the activity of the virus then is such, that the smallest atom, though imperceptible to any of our senses, conveys the disease as well as the largest quantity. Hence the most obvious method is the prick of a needle or of the point of a lancet dipped in the matter of a variolous pustule.

By some less experienced surgeons cotton or thread is used, that is previously rubbed with powdered variolous scabs; this thread is drawn with a needle through the cutis, and sometimes left in. This is the method in some parts of the East Indies. The Indians pass the thread on the outside of the hand, between any of the fingers, or between the fore finger and thumb. The Thessalian women inoculate in the forehead and chin. Some abrade the scarf-skin, and rub in the powdered dry scabs which fall from the pustules of patients with the small-pox.

Many of the Greek women make an oblique puncture with a needle, on the middle of the top of the forehead, on each cheek, the chin, each metacarpus, and each metatarsus; then drop in each a little of the pus just taken warm from a patient, and brought in a servant's bosom. Others in Greece make several little wounds with a needle in one, two, or more places, in the skin, till some drops of blood ensue; then the operator pours a drop of warm pus fresh from a pustule, and mixes it with the blood as it issues out; then the wound is covered by some with a bandage, by others with half a walnut shell placed with its concave side over each orifice.

The Chinese convey a pellet of variolated cotton, with the addition of a little musk, into the nostrils of the patient; they collect dry pustules, and keep them in a porcelain bottle well corked; and when they inoculate, they mix a grain of musk with three or four grains of the dry scales, and roll them in cotton. This method may be called *inodoration*.

About Bengal, in the East Indies, the person who intends to be inoculated, having found a house where there is a good sort of the small-pox, goes to the bed of the sick person, if he is old enough; or if a child, to one of his relations, and speaks to him as follows: "I am come to buy the small-pox." The answer is, "Buy, if you please." A sum of money is accord-

ingly given, and one, three, or five pustules, for the number must always be odd, and not exceeding five, extracted whole and full of matter. These are immediately rubbed on the skin of the outside of the hand between the fore-finger and the thumb; and this suffices to produce the disease. The same custom obtains in Algiers, Tunis, Tripoli, and other countries.

Very similar to the custom amongst the people about Bengal, &c. is that in Arabia, where on some fleshy part they make several punctures with a needle imbrued in variolous matter taken from a pustule of a favourable kind. Here they buy the small-pox too, as follows: The child to be inoculated carries a few raisins, dates, sugar-plums, or such like; and showing them to the child from whom the matter is to be taken, asks how many pocks he will give in exchange? The bargain being made, they proceed to the operation; but this buying, though still continued, is not thought necessary to the success of the operation. The Arabs say that any fleshy part is proper; but generally they insert the matter between the fore-finger and thumb on the outside of the hand.

The Georgians insert the matter on the fore-arm. The Armenians introduce the matter on the two thighs. In Wales the practice may be termed *infriction* of the small-pox. There some of the dry pustules are procured by purchase, and are rubbed hard upon the naked arm or leg.

The practice in some places is to prick the skin between some of the fingers by means of two small needles joined to one another; and after having rubbed a little of the matter on the spot, a circle is made by means of several punctures of the bigness of a common pustule, and matter is again rubbed over it. The operation is finished by dressing the wound with lint.

Incisions have been made in the arms and legs; and thread, cotton, or lint, previously dipped in the variolous matter, was lodged in them. The practice of some is to bathe the feet in warm water, and then secure lint dipped in the variolous matter on the instep, or other part of the foot, where the skin is thin. Others apply a small blistering plaster, and when the scarf-skin is elevated and slipped off, the variolous matter is applied to the surface of the true skin, and confined there by a little lint or plaster. Scratching the skin with a pin or needle, and then rubbing the part with lint previously dipped in variolous matter, is the custom in some places.

In the Highlands of Scotland they rub some part of the skin with fresh matter, or dip worsted in variolous matter, and tie it about the children's wrists. But this method is more likely to give the small-pox in the natural way, unless the cuticle happens by chance to be broken so as to allow the variolous matter to be absorbed. They observe, that if fresh matter is applied a few days successively, the infection is more certain than by one application.

The objections made by the vulgar to the salutary practice of *inoculation*, are too idle to deserve a serious refutation here. It is, however, the duty of every enlightened person, whether of the medical profession or not, to combat them on every occasion: and to hold it forth to parents as one of the first of their duties to preserve the lives of those to whom they have given existence, by a process so easy in its accomplishment, so safe in its consequences, and so laudable in its example.

Though no disease, after it is formed, baffles the powers of medicine more than the small-pox, yet more may be done before hand to render this disease favourable than in any other we know. The artificial method of producing the small-pox hath almost stripped it of its terrors; in general, hath rendered its aspect mild, its progress uniform, and nearly without hazard to the patient. Mr. Mudge, in his Dissertation on the inoculated small-pox, enumerates the following sources of possible danger from this disease, viz. 1. The patient's constitution, 2. The propensity of the patient to be infected. 3. The man-

ner or mode of the infection being communicated. 4. The constitution of the air at the time of infection. And it is the peculiar advantage of *inoculation*, almost totally to exempt its subjects from the disadvantages attendant on these sources.

1. "Respecting *the habit of body*, or state of the patient's constitution at the time of infection."—Constitutional or habitual diseases, in general, do not interfere with the course of the small-pox, whether in its natural or its artificial progress; such as scorbutic eruptions on the skin, strumous complaints, scabby eruptions, excoriated ears, &c. The variolous poison is therefore a thing *su generis*, and noways affected by these taints of the juices, or what is usually called a bad habit of body; or at least so inconsiderably as not to deprive such patients of any of the advantages of *inoculation*. But the case is much reversed with respect to some accidental diseases. *E. gr.* If, on the attack of the small-pox, the habit or its attending circumstances tend to inflammation, or, on the contrary, to a putrid acrimony, the eruptive fever in these aggravated states will load the body with variolous matter, or produce pustules of a less favourable kind; in either of these cases (not to enumerate more) the patient may chance to be severely affected. But *inoculated* subjects may be infected when the constitution is in the best condition to combat with the disease; if either of those indispositions be attendant, or any other which usually endangers, they may soon be restrained or removed.

2. "The different degrees of propensity in the patient, at different times, to be infected."—That different quantities of matter are produced in different persons in the process of the disease, we find true in fact; and there is the strongest reason to believe, that, previous to infection, the quantity of the variolous matter, or rather that principle in the constitution which eventually produces it, ebbs and flows, is more or less vigorous at different times in the same subject, under various combinations of circumstances. The instances are not uncommon, where the patient who hath withstood at one time all the ordinary means of infection, nay, who hath industriously, but ineffectually, sought it; yet at another hath had a small-pox so malignant in appearance and effect, that the whole body has been converted into an offensive variolous putrescence. If the degree of propensity to receive infection were always the same, it would be inconceivable that any one could pass unaffected when the small-pox became epidemic. From whatever causes, however, this propensity may arise, it is most reasonable to assert, that the increase or decrease of this principle takes place according as the small-pox is epidemic or not. During the continuance of any contagious epidemic disease, we always find that those constitutions which are most congenial with that character, are peculiarly obnoxious to the correspondent distemper. And we may reasonably conclude, that when the constitution of a person not past the small-pox is most saturated with the variolous principle, he is then more particularly subject to infection. Again, it is not only undoubted that the variolous principle subsists in the constitutions of persons not past the small-pox, but it is more than probable that a part of this principle is produced by the eruptive fever, and the rest of the variolous process. Agreeably to what has been said, we find that, during the epidemic tendency, those who have not passed the disease are more open to contagion than in other constitutions of air, when the small-pox is not epidemic, and is consequently a rare disease. Many who have escaped infection from *inoculation* and other means of contagion, on removal into a situation where the small-pox has been epidemic, have presently after been seized with this disorder. Events of this kind are so common as to have given rise to the ill-grounded opinion, that any change of air is hazardous to those who have not had the small-pox. If at a time when the propensity to be affected is the greatest, there should be a concurrence of those

states of the constitution above noticed, how aggravated will the condition of the patient be!

Respecting the evasion of these inconveniences by *inoculation*, it is to be observed, that, as the propensity to the disease differs at different times in the same subject, it is reasonable to suppose that the disorder is produced by downright violence, when there subsists in the patient but little of that peculiarity of constitution so essential to the production of the disease (and so general when the small-pox is epidemic), or, in other words, when the body is indisposed to be poisoned. This consideration, peculiar to the disease when artificially produced, appears to be the true cause of the small quantity of pocky matter, and that general scarcity of pustules, when compared to the natural small-pox, which has ever accompanied *inoculation*, and is one of the grand advantages of the discovery. Farther, as it is very reasonable to suppose that this propensity is the greatest when there is an epidemic constitution of the air which favours the production of the disease; and if it be as probable that the severity or mildness of the disease depends in a good degree upon the greater or lesser propensity of the subject to be infected; it will certainly be an eligible step not to bring on the disorder by *inoculation* during the continuance of an evidently prevailing tendency to the disease. Prudence in this case directs us to take advantage of the absence of such a prevailing tendency, when all the benefits of *inoculation* may be secured; and not to delay the operation, till such a constitution of air prevails as at once makes the operation necessary, and deprives it of some of its advantages. To conclude, we may add to this consideration, that, by the practice of exposure to cold, the violence of the eruptive fever is so far moderated as to prevent its forming an additional quantity of variolous matter, which, in a violent and unrestrained state, it would do, by assimilating the juices of the constitution into the nature of the variolous poison.

3. "The manner or mode of the infection being communicated."—In the natural small-pox, the disease may be produced by accidental contagion, or an epidemic influence. Dr. Mead says, that the air of this climate never produces the plague, small-pox, or measles; and Dr. Arbuthnot says, that the plague itself may be generated by some quality in the air, without any contagion. Be these opinions as they may, it is evident that contagion is sometimes so languid that it requires the agency of other causes to give it activity, so as to produce the tribe of diseases to which it belongs, and which without this agency would never be brought forth; and though the strongest epidemic tendency may not in Europe create the small-pox without the concurrence of contagious sources, yet there is, by the agency of the former, such an alteration made and propensity brought on the animal juices, as is essentially necessary to continue the existence of the disease. Variolous contagion produces its effects by the actual application of its poison, either externally through the medium of the skin; or internally, to the gullet, stomach and guts in the act of deglutition; or, lastly, to the lungs in the act of respiration. Though there may be a possible admission of the poisonous miasmata into the constitution through the skin, from the principle of absorption; yet the poison very seldom, if ever, exerts its influence upon the habit in this manner: possibly by a local actual application of the gross matter lodged in the clothes, or otherwise conveyed, the distemper may sometimes be produced by a kind of *inoculation*, and then the disorder will probably be favourable. But when the poison, in a more dilute state, only floats in or impregnates the air, it seldom enters the pores of the skin, and poisons by way of absorption; for the degrees of activity, in which this power is exerted, are most probably in proportion to the aids the constitution may stand in need of from it. However, it is more than probable that the ordinary mode of infection is by the lungs, which from their structure

they are well calculated to receive, to entangle, and to retain. When either the lungs or the stomach are first infected by the infectious effluvia, it is most reasonable to believe, that these noble parts, together with the fauces, glottis, wind-pipe, and gullet, will frequently labour under a greater load of pustules than the external surface of the body: for it is observed, that when the patient is infected artificially, the parts to which the poison is applied suffer in a greater degree than the more distant; and that the circumjacent skin, to some extent, is filled with pustules. From this particular application of the morbid matter to the fauces, &c. it is probable that the large discharge of saliva, &c. arises, which characterizes the confluent small-pox in adults; and as children swallow this saliva, it excites a diarrhœa, which in them answers to the spitting in those more aged. When the internal parts are oppressed with pustules, there is no interval between the eruptive and the subsequent symptomatic fever; and the suffering which the patient labours under from a generally inflamed skin, heightened by the diseased condition of the nobler parts, perpetuates the first fever. This informs us, that all is not so well within as otherwise the external appearances might have induced us to believe; but that the nobler parts are rendered unfit for the purposes of life, at least are labouring and lagging behind in the process, so that they have not kept pace with the apparent state of the disease on the surface of the body: this some have supposed to be the true general cause of the secondary fever, under which the patient, if he sinks, dies peripneumonic. These consequences frequently attend the infection received in the natural way; and if, superadded to these, the unhappy situation of those described under the first and second sources of danger attends the patient, the disorder will be proportionably aggravated, and the chance of life lessened.

But here again *inoculation* relieves: for by this mode the virus is applied to the external surface of the body, so that the whole constitution (excepting the part immediately surrounding the wound) being affected uniformly, the process of the disease is regularly carried on; and the nobler parts not being particularly affected by a partial application of the variolous fomes to their surface, have no distress to proclaim by a secondary fever, which therefore is scarcely ever seen in *inoculated* patients.

4. "The constitution of the *air* at the time of infection."—A powerful source of difficulty and danger in the natural small-pox is, the malignant-influence of the air at some seasons, and particularly if it happens at the time of receiving the infection. If this concurs with one or more of the other sources, how dreadful the devastation! Whether this constitution of the air produces its deleterious effects by heightening the natural malignity of the infecting poison, or acts on the constitution itself so as to render the effects of contagion more peculiarly fatal, the consequence of this state of the air is the same. The general characters of a morbid state of the air are the inflammatory and putrid; and it is uniformly observed, that whenever a person is attacked with a fever under either of these prevailing dispositions, it never fails to impress its character upon the disease.

But here also *inoculation* affords the most benign influence. The judicious practitioner does not expose his patient to the pernicious effects of an air that can stamp its baneful character on the small-pox, but chooses the season best calculated for the safety and welfare of his patient; and hence we rarely see the influence of this evil source attendant on the artificial disease.

Having seen, that from the influence of one or more of these four sources of difficulty and danger, and that from their union will result a natural small-pox complicated with horrors not to less to be dreaded than the plague; how inestimable must appear that favour of Providence, by which we are freed from the formidable attendants of this disease; viz. *inoculation*, by which the disorder is rendered mild, and in general less hazardous than a common cold! Nay, nothing can be more decisive of this

than the instances which repeatedly occur, of *thousands* being *inoculated* together in the same town or village without the loss of a *single life*.

From attention to the above sources of ill in the natural small-pox, we perceive with sufficient satisfaction the many instances of relief and security which generally we avail ourselves of by *inoculation*; a part of which we have seen, and a few others follow.

1. As already observed, it saves the lives of most who are its subjects. From a general calculation it appears, that in the hospitals for small-pox and *inoculation*, 72 die out of 400 patients having the distemper in the natural way, and only one out of this number when *inoculated*.
2. It lessens the affliction from both the degree and the number of ill symptoms, even when it proves fatal. It lessens the number of pustules; and, by moderating the virulence of the disease, the marks on the face never occur.
3. It is extremely rare that the secondary fever attends it; a symptom productive of much suffering, if the patient is happy enough to escape with life.
4. It produces the disease under the fewest disadvantages, and favours with foresight to prevent many ills not to be guarded against in the natural small-pox.
5. Instead of communicating other disorders with it, many disorders subsequent to the natural are very rarely observed after the artificial small-pox.
6. It effectually removes all just grounds of fear; a passion very injurious in this disease.
7. Soldiers, sailors, and all who would appear abroad, or in public offices, are freed from every anxiety and hazard attendant on the natural small-pox.
8. Servants, women with children at their breasts, pregnant women, magistrates, physicians, &c. are all freed from the most distressing embarrassment, by conformity to *inoculation*.

INOSCUATION, in anatomy; the same with **ANASTOMOSIS**.

INOWSLADISLOW, a strong and considerable town of Poland, capital of Cujavia, with a fort, and a palace where the bishop of Cujavia resides. It is 39 miles N. E. of Gnesna, and 90 W. of Warsaw. E. lon. 18. 50. N lat. 52. 58.

INQUEST, the investigation of a jury on any specific question. The term inquest is most frequently applied to the inquiry of a jury summoned by the coroner in cases of violent death. See **CORONER** and **JURY**.

INQUISITION, in the church of Rome, a tribunal in several Roman Catholic countries, erected by the popes for the examination and punishment of heretics. This court was founded in the 12th century by father Dominic and his followers, who were sent by Pope Innocent III. with orders to excite the Catholic princes and people to extirpate heretics, to search into their number and quality, and to transmit a faithful account thereof to Rome. Hence they were called *inquisitors*; and this gave birth to the formidable tribunal of the Inquisition, which was received in all Italy and the dominions of Spain, except the kingdom of Naples and the Low Countries.

This diabolical tribunal takes cognizance of heresy, Judaism, Mahometanism, sodomy, and polygamy; and the people stand in so much fear of it, that parents deliver up their children, husbands their wives, and masters their servants, to its officers, without daring in the least to murmur. The prisoners are kept for a long time, till they themselves turn their own accusers, and declare the cause of their imprisonment; for they are neither told their crime, nor confronted with witnesses. As soon as they are imprisoned, their friends go into mourning, and speak of them as dead, not daring to solicit their pardon, lest they should be brought in as accomplices. When there is no shadow of proof against the pretended criminal, he is discharged after suffering the most cruel torture, a tedious and dreadful imprisonment, and the loss of the greatest part of his effects. The sentence against the prisoners is pronounced publicly, and with extraor-

dinary solemnity. In Portugal, they erect a theatre capable of holding 3000 persons; in which they place a rich altar, and raise seats on each side in the form of an amphitheatre. There the prisoners are placed; and over-against them is a high chair, whither they are called, one by one; to hear their doom, from one of the inquisitors.

These unhappy people know what they are to suffer by the clothes they wear that day. Those who appear in their own clothes are discharged upon payment of a fine: those who have a *santo benito*, or strait yellow coat without sleeves, charged with St. Andrew's cross, have their lives, but forfeit all their effects; those who have the resemblance of flames, made of red serge, sewed upon their *santo benito*, without any cross, are pardoned, but threatened to be burnt if ever they relapse: but those who, besides these flames, have on their *santo benito* their own picture, surrounded with figures of devils, are condemned to expire in the flames. The inquisitors, who are ecclesiastics, do not pronounce the sentence of death; but form and read an act, in which they say, that the criminal being convicted of such a crime, by his own confession, is with much reluctance delivered to the secular power to be punished according to his demerits: and this writing they give to the seven judges who attend at the right side of the altar, who immediately pass sentence. For the conclusion of this horrid scene, see *ACT of Faith*.

INSCRIBED, in geometry. A figure is said to be inscribed in another, when all its angles touch the side or planes of the other figure.

INSCRIPTION, a title or writing affixed to any thing, to give some farther knowledge of it, or to transmit some important truth to posterity. Antiquaries are very curious in examining ancient inscriptions found on stones and other monuments of antiquity. Sanchoniathon, contemporary, as it is said, with Gideon, drew most of the memoirs whereof his history is composed, from inscriptions which he found in temples and on columns, both among the Heathens and the Hebrews.

It appears, indeed, that the ancients engraved upon pillars the principles of sciences, as well as the history of the world. Those mentioned by Herodotus show, that this was the first way of instructing people, and of transmitting histories and sciences to posterity. This is confirmed by Plato in his *Hippias*; wherein he says, that Pisistratus engraved on stone-pillars precepts useful for husbandmen. Pliny assures us, that the first public monuments were made of plates of lead; and that the treaties of confederacy concluded between the Romans and the Jews were written upon plates of brass; that (says he) the Jews might have something to put them in mind of the peace and confederacy concluded with the Romans. The Greeks and Romans were great dealers in inscriptions, and were extremely fond of being mentioned in them; and hence it is that we find so many in those countries of ancient learning, that large volumes have been composed, as the collection of Gruter, &c. Since Gruter's collection, Th. Reinesius has compiled another huge volume of inscriptions. M. Fabretti published another volume at Rome in 1679, wherein he has corrected abundance of errors which had escaped Gruter, Reinesius, and other antiquaries, &c. and added a great number of inscriptions omitted by them.—Since all these, Grævius has published a complete collection of inscriptions, in three volumes folio.

Academy of INSCRIPTIONS. See ACADEMY.

INSCRUTABLE, UNSearchable, in theology, is usually understood of the secrets of Providence, and the judgments of God, which cannot be found out, or into which human reason cannot penetrate.

INSECTS, INSECTA, in natural history, a smaller sort of animals, commonly supposed to be sanguinous; and distinguished by certain incisions, cuttings, or indentings in their bo-

dies. The word is originally Latin, formed of *in*, and *scio* "I cut;" the reason of which is, that in some of this tribe, as ants, the body seems to be cut or divided into two; or because the bodies of many, as worms, caterpillars, &c. are composed of different circles, or rings, which are a sort of incision. See ZOOLOGY and ENTOMOLOGY.

Of the Kinds of INSECTS, and where found. Insects, in general, are known to most people, the systematic distinctions but to few; nor have we any English names for the greatest part of them. The general denominations of beetles, butterflies, moths, flies, bees, wasps, and a few other common names, are all that our language supplies. It would, therefore, be in vain to enumerate the immense variety of genera and species to any person unskilled in the science of entomology; we may, however, give directions under general names, where to find each kind. The class of insects is divided by Linnæus into seven orders. See ZOOLOGY and ENTOMOLOGY.

I. The *Coleoptera* kind. Many of these (as the *scarabeus* or chaffer, *dermestes* or leather-eater, *bister* or mimick beetle, *staphylinus* or rove-beetle, &c.) are found in and under the dung of animals, especially of cows, horses, and sheep. Some (as *lucanus* or stag-beetle, *cerambyx* or capricorn-beetle, *dermestes*, &c.) are found in rotten and half-decayed wood, and under the decayed bark of trees. Others (as *bister*, *silpha* or carrion-beetle, *staphylinus*, &c.) on the carcases of animals that have been dead four or five days; on moist bones that have been gnawed by dogs or other animals; on flowers having a fetid smell; and on several kinds of fungous substances, particularly the rotten and most stinking. Others (as *byrrhus*, *curculio* or weevil, *bruchus* or seed-beetle, &c.) may be found in a morning about the bottoms of perpendicular rocks and sand-banks, and also upon the flowers of trees and herbaceous plants. Many kinds (as *gyrinus* or whirl-beetle, *dytiscus* or water-beetle, &c.) may be caught in rivers, lakes and standing pools, by means of a thread-net, with small meshes, on a round wire-hoop, fixed at the end of a long pole. In the middle of the day, when the sun shines hot, some (as the *coccinella* or lady-fly, *huprestis* or burn-cow, *chrysmela* or golden honey-beetle, *cantharis* or soft-winged beetle, *elater* or spring-beetle, *necydalis* or clipt-winged-beetle, &c.) are to be seen on plants and flowers, blighted trees and shrubs. Others (as *lampyris* or glow-worm, &c.) frequent moist meadows, and are best discovered at night, by the shining light which they emit. A great variety sit close on the leaves of plants, particularly of the burdock, elecampane, colts-foot, dock, thistle, and the like, (as the *castida* or tortoise-beetle, &c.); or feed on different kinds of tender herbs (as the *meloe* or blister-beetle). Numbers (as the *tenebrio* or stinking-beetle) may be found in houses, dark cellars, damp pits, caves and subterraneous passages; or on umbelliferous flowers (as the *aranthia*, *plana*, &c.); or on the trunks as well as on the leaves of trees, in timber-yards, and in the holes of decayed wood. Some (as the *leptura* or wood-beetle, *cinclis* or glossy beetle, &c.) inhabit wild commons, the margins of pools, marshes, and rivulets; and are likewise seen creeping on flags, reeds, and all kinds of water-plants. Multitudes (as the *carabus* or ground-beetle) live under stones, moss, rubbish, and wrecks near the shores of lakes and rivers. These are found also in bogs, marshes, moist places, pits, holes of the earth, and on stems of trees; and in an evening they crawl plentifully along path-ways after a shower of rain. Some (as the *forficula* or earwig) may be discovered in the hollow stems of decayed umbelliferous plants, and on many sorts of flowers and fruits.

II. *Hemiptera*. Some of these (as the *blatta* or cockroach) are found about bake-houses, &c.; others (as the *gryllus* or camel-cricket, *gryllus* or locust, *fulgura cicada* or flea-loenti, *cimex* or bug, &c.) on grass, and all kinds of field-herbage.

Some (as *natonella* or boat fly, *nepa* or water-scorpion, &c.) frequent rivers, lakes, and standing-pools.

III. *Lepidoptera*. In the day, when the sun is warm, butterflies are seen on many sorts of trees, shrubs, plants, and flowers. Moths may be seen in the day-time, sitting on pales, walls, trunks of trees, in shades, out-houses, dry holes, and crevices; on fine evenings, they fly about the places they inhabit in the day-time: some (as the *sphinx* or hawk-moth) are seen flying in the day-time over the flowers of honey-suckles and other plants with tubular flowers. Insects of this species seldom sit to feed, but continue vibrating on the wing, while they thrust the tongue or proboscis into the flowers.

IV. *Neuroptera*. Of these, some (as the *myrmelon*, *hemerobius* or pearl-fly, *raphidia* or camel-fly, &c.) are found in woods, hedges, meadows, land-banks, walls, pales, fruits, and umbelliferous flowers. Others (as *ibullula* or dragon-fly, *ephemera* or may-fly, *phryganea* or spring-fly, &c.) fly about lakes and rivers in the day.

V. *Hymenoptera*. These, including wasps, bees, &c. frequent hedges, shrubs, flowers, and fruits.

VI. *Diptera*. Flies of various kinds constitute this class; of which some (as *astus* or gad-fly, *musca* or fly, *tabanus* or whame) fly about the tops of trees, little hills, horses, cows, sheep, ditches, dunghills, and every offensive object. Others (as *tipula*, *an ps*, *afilus* or wasp-fly, &c.) are found on all sorts of flowers, particularly those of a fetid smell.

VII. *Aptera*, or those without wings, comprehend scorpions, spiders, ciabs, lobsters, &c.

Catching and Preserving INSECTS. In the following directions we shall relate the methods of killing them the most readily, and with the least pain, as the pursuit of this part of natural history hath been often branded with cruelty; and however reasonably the naturalist may exculpate himself by pleading the propriety of submitting to an evil which leads to useful discoveries, yet for wanton cruelty there never can be a just pretext.

1. The first class, consisting of beetles (*coleoptera*), are hard-winged. Many kinds fly about in the day, others in the evening, some at night only. They may be caught with a gauze net, or a pair of forceps covered with gauze. When they are taken, flick a pin through the middle of one of the hard wings, and pass it through the body. They may be killed instantly, by immersion in hot water, as well as in spirit of wine; then stick them on a piece of cork, and afterwards carefully place their legs in a creeping position, and let them continue exposed to the air until all the moisture is evaporated from their bodies. Beetles may also be preserved in spirit of wine, brandy, or rum, closely corked up.

2. Insects of the second class (*hemiptera*) may be killed in the same manner as beetles, and likewise by means of a drop of the ethereal oil of turpentine applied to the head; or in the manner to be described under the next class for killing moths.

3. The division of butterflies and moths (*lepidoptera*), as well as all flies with membranaceous wings, should be caught with a gauze net, or a pair of gauze forceps: when taken in the forceps, run a pin through the thorax or shoulders, between the fore-wings. After this is done, take the pin by the head, and remove the forceps, and with the other hand pinch the breast of the insect, and it will immediately die: the wings of butterflies should be expanded, and kept so by the pressure of small slips of paper for a day or two. Moths expand their wings when at rest, and they will naturally take that position.

The larger kinds of these insects will not so readily expire by this method, as by sticking them upon the bottom of a cork exactly fitted to the mouth of a bottle, into which a little sulphur had been put, and by gradually heating the bottle, till

an exhalation of the sulphur take place, when the insect instantly dies, without injuring its colour or plumage.

The best method of having the most perfect butterflies is to find out, if possible, the larva or caterpillar of each, by examining the plants, shrubs, or trees, they usually feed upon, or by beating the shrubs and trees with long poles, and thereby shaking the caterpillars into a sheet spread underneath to receive them; to put them into boxes covered with thin canvas, gauze, or cut-gut, and to feed them with the fresh leaves of the tree or herb on which they are found: when they are full grown, they will go into the pupa or chrysalis state, and require then no other care till they come out perfect butterflies, at which time they may be killed, as before directed. Sometimes these insects may be found hanging to walls, pales, and branches of trees, in the chrysalis state.

Moths might likewise be procured more perfect, by collecting the caterpillars, and breeding them in the same manner as butterflies. As the larvæ or caterpillars cannot be preserved dry, nor very well kept in spirit, it would be satisfactory if exact drawings could be made of them while they are alive and perfect. It may be necessary to observe, that in breeding these kinds of insects, some earth should be put into the boxes, as likewise some rotten wood in the corners; because, when the caterpillars change into the pupa or chrysalis state, some go into the earth, and continue under ground for many months before they come out into the moth state; and some cover themselves with a hard shell, made up of small pieces of rotten wood.

4. The fourth class of insects (*neuroptera*) may be killed with spirit of wine, oil of turpentine, or by the fumes of sulphur.

5. Those of the next class (*hymenoptera*) may be killed in the same manner. A pin may be run through one of their wing-shells and body.

6. Insects of the sixth class (*diptera*) may likewise be killed by spirit, or by fumes of sulphur.

7. Those of the last division (*aptera*) are, in general, subjects which may be kept in spirit.

When in search of insects, we should have a box suitable to carry in the pocket, lined with cork at the bottom and top to stick them upon, until they are brought home. If this box be strongly impregnated with camphor, the insects soon become stupified, and are thereby prevented from fluttering and injuring their plumage. Besides a small forceps, the collector should have a large musquito gauze-net, and also a pin-cushion with three or four different sizes of pins to suit the different sizes of insects.

In hot climates insects of every kind, but particularly the larger, are liable to be eaten by ants and other small insects; especially before they are perfectly dry; to avoid this, the piece of cork on which our insects are stuck in order to be dried, should be suspended from the ceiling of a room, by means of a slender string or thread; besmear this thread with bird-lime, or some adhesive substance, to intercept the rapacious vermin of those climes in their passage along the thread.

After our insects are properly dried, they may be placed in the cabinet or boxes where they are to remain: these boxes should be kept dry; and also made to shut very close, to prevent small insects from destroying them; the bottoms of the boxes should be covered with pitch, or green wax, over which paper may be laid; or, which is better, lined with cork, well impregnated with a solution of corrosive sublimate mercury in a saturated solution of crude sal-ammoniac in water, an ounce of which will dissolve 2 scruples of the sublimate.

The finest collections have been ruined by small insects, and it is impossible to have our cabinets too secure. Such insects as are thus attacked may be fumigated with sulphur, in the

manner described for killing moths: if this prove ineffectual, they may be immersed in spirit of wine, without much injuring their fine plumage or colours, and afterwards let them be sprinkled about their bodies and infertions of the wings with the solution above-mentioned. But baking the insects in an oven, in the manner described for BIRDS (under that article), is the most effectual method of extirpating these enemies: however, the utmost caution is requisite in this process, in regulating the heat of the oven.

All kinds of insects having no wings, may be preserved in spirits, brandy, or rum; except crabs, lobsters, and the like, which may conveniently be preserved dry.

INSECTS giving Root to Plants. Of this we have an account, by Mr. Fourgeroux, in the Memoirs of the Academy of Sciences for 1769. The plants, of which Mr. Fourgeroux gives an account, are perfectly the reverse of the worm-plant of China, described by Mr. Reaumur in the year 1726. For, in that case, a worm fixes its snout into the extremity of the plant, and derives nourishment from it. But the plants, of which an account is here given, derive their nourishment from the animals.

The greatest part of the animal-plants which he has seen, grow, he tells us, on the chrysalis of a species of cicada. The plant growing on these insects has got the generic name of *clavaria*, because its stalks and branches, when it has any, are terminated by tubercles, which give the appearance of little clubs. The root of this plant, in general, covers the body of the insect, and sometimes is even extended over its head. When these productions have for some time been preserved in spirits, the plant and animal may be separated from each other without hurting either. Small grooves, formed by the rings of the animal, may be observed running cross the roots of the plant: but no vestige can be found of the root's having any where penetrated the body of the insect. These plants produce fibres differing in length and number. The fibres are terminated by tubercles, which, before the plant arrives at maturity, are solid; but, after that period, they are found punctured, probably by worms which have suffered a metamorphosis upon escaping from them.

According to Mr. Fourgeroux, plants grow, not only on the chrysalis of the cicada, but upon the cicada itself. He saw one of this kind upon a cicada brought from Cayenne. The plant, in this case, differed from the *clavaria* already mentioned. It was a species of fungus, composed of long, white, silky fibres, covering the body of the insect, and extending from seven to eight lines above and below its belly.

The author has found the *clavaria* growing upon worms. He has found it chiefly upon worms, which, suffering a metamorphosis, become afterwards a small species of may-bug. This chrysalis, he observes, is very different from that of the cicada; and, even in its worm-state, may easily be distinguished from it.

After describing these different species of animal-plants, the author next proceeds to offer his opinion upon this subject. He first considers what had been said by Dr. Watson, in the Philosophical Transactions, concerning the vegetating-fly of the Caribbee islands (See *Vegetable FLY*). Dr. Watson's account of these flies is, that they bury themselves about the month of May, and begin to be metamorphosed in June; and that the little plant which grows upon them resembles a branch of coral, is about three inches in height, and carries small protuberances, where worms are generated, which are again converted into flies. The author imagines, that, in this account, Dr. Watson has been deceived by the worms, which he has already observed will eat into the *clavaria*, and undergo a change in the holes which they have there made. Mr. Fourgeroux is rather inclined to adopt the opinion of Dr.

Hill, founded upon observations made at Martinico. There the cicadæ are very frequent; and, during their chrysalis state, bury themselves among dead leaves, to wait their metamorphosis. Dr. Hill imagines, that the seeds of the *clavaria* are then attached to them, and are afterwards developed, much in the same manner as the *fungus in pede equino* grows upon the hoofs of dead horses.

It may appear astonishing, that the *clavaria* should attach itself so constantly to the nymphæ of the cicadæ in America, as it is not observed to do so in other countries. For this Mr. Fourgeroux attempts to account, from viewing the *clavaria* as a parasite peculiar to this species of insect; from the great number of the nymphæ of cicadæ which abound in America; and from the circumstances of the climate and soil, which may render this phenomenon very common there, although it be not observed in Europe.

INSECTS, Anatomical use of. The insect world affords us numerous uses, and those many of them such as no one would at first thought imagine, and which no other operations or operators could so well effect. In the minutiae of anatomy, where knives cannot be introduced, the maggot or the ant may be employed with great success. Skeletons of fœtuses have been prepared by burying them in an ant-hill, and that in so accurate and perfect a manner, that all who have seen them have admired by what means they could be so nicely finished; and the secret of the great Ruyisch, by which he cleared away the parenchymatous substance from his vascular preparations, was of this kind. After injecting the vessels of any part with wax, all that remained to the completing these preparations, was the taking off the parenchymatous or fleshy matter from between and among them. Other anatomists of his time did this by the knife, or by maceration in water and other liquors; but it appeared a sort of magic to them, that his were always not only much sooner executed, but to a greater nicety and perfection than theirs ever possibly could be. His method was only to put a number of the common flesh-eating maggots to the substance; and these regularly ate away all the flesh, their heads getting into crevices which no instrument could reach, and the whole substance of the injection remained unhurt, as their soft bodies could glide between its nicest parts without injuring them; and the wax, being no food for them, was in no danger of being eroded, even in its smallest pieces. The several sizes of the worms or maggots bred from the eggs of different flies were of great use in the perfecting the preparations; for while the larger sort ate the more fleshy parts, where the vessels are large and but few in number, the middle-sized maggots got into the interstices of the more vascular parts; and the most minute of all, which are usually also the most numerous, kept about the surface, and ate away between and among the capillary vessels.

The maggots produced from flies are not the only animals fit for this kind of business. There are several species of beetles of the smaller kinds, whose eggs hatch into a six-legged worm, which eats as much and as nicely as the fly-maggots. All these may be employed very successfully to the preparations of the parts of animals.

These nice anatomists are not confined to animal substances: they often exert their power also on vegetables. Many of them feed on the leaves and fruits of plants; and some species of these work so nicely, that they eat away all the outer membrane and internal parenchymatous substance of the leaves, so as only to leave the net-like plexus of vessels standing. Yet these being unhurt shew the true figure of the leaf, and are a sort of vegetable skeletons, but very poorly imitated by art in the common way, by long macerations in water; this method usually destroying and washing away many of the smaller vessels, which the tender mouths of these creatures spare. If they

exert their skill often upon leaves in this manner, they do it also sometimes with equal if not greater success upon fruits. As, in the leaves, those which have the tenderest parenchyma and the firmest ribs, succeed best; so also it is in fruits. The leaves of the rufcus or butcher's broom, are often found thus beautifully anatomised; and of all fruits, none succeeds so well as that of the stramonium, or thorn-apple. Wherever this plant grows in any plenty, the fruit towards autumn, while it is yet full of juice, is attacked by a small worm, which eats away all the parenchyma, and leaves every vessel standing in its place; and this not only in the outer coat of the fruit, but in the very inner cells of the seeds. These vessels remain exactly in the shape of the fruit, and, growing white with the air, exhibit the most elegant and beautiful skeletons imaginable, while yet standing on the plant. The animal which effects this, is a hexapode worm produced from the egg of a small beetle; and differs very little from some of those which so elegantly eat away the fleshy parts from the injected anatomical preparations. These are gregarious animals like some species of the smaller caterpillars, and numbers of them are always at work together on the same leaf or fruit, so that the skeleton is soon made. They begin by piercing a number of little holes into the substance of the leaf, and thence burrow under the integument till they meet one another; and this being done all over the leaf, they leave it, and go to work upon another.

INSECTS blown from the Nose. Of this we are furnished with many accounts in the works of medical authors. The fact is confirmed by Dr. Monro, (*Ed. Med. Com.* ii. 312.) who has received at different times some of these insects from different persons. They were all of the scolopendra kind, though not exactly answering to any description of Linnæus. One of these he received from Mr. Hill, surgeon in Dumfries. It was an inch and a half long; and lived some hours after it was discharged, creeping about slowly on a table. It was then put into ardent spirits, soon after which it died.

Noxious INSECTS; Means of destroying them. Of those substances which have been generally observed to be efficacious in driving away or in destroying insects, mercury, and its various preparations, may be reckoned one of the most generally useful. Sulphur is also useful. Oils of all kinds have been often and deservedly recommended. Tobacco is not less remarkable for its utility. Of the application of these in order,

1. Mercury is known to kill or drive away lice from the human body; and it may probably be of equal efficacy in ridding other animals of their insects. For instance, sheep having a small quantity of mercurial ointment rubbed on their skins, on the sides, between the fore-legs and the body, it may kill or drive away the insect peculiar to them. Sulphur is recommended to be added to the mercurial ointment. Thus not only the insect peculiar to them, but also the scab, may be cured: See the Transactions of the Society for the Encouragement of Arts, London, vol. vii. viii. p. 90. In the Transactions of the same Society, vol. v. vi. p. 59, Mr. Ailway directed that, in the winter, the walls, frames, &c. of his green and hot houses should be well washed with the following mixture: Take of corrosive sublimate mercury four ounces, and dissolve it in two gallons of water. These houses had been greatly infested with red spiders and ants. After having been washed with the above mixture, neither were to be seen next summer. This wash may be used on old garden walls, and to the roots of fruit-trees infested with insects, if made weaker. It may destroy the tender leaves of plants, though not the roots. This wash will effectually destroy that disagreeable insect the bug, and all other insects of a tender cuticle; and it will not in the least hurt the colour of bed-furniture or hangings. Care must be taken, that the wash be applied into every crevice or folding

of the furniture with a painter's brush. It will sometimes be necessary to repeat the wash, as some of the ova of bugs may remain concealed, notwithstanding the utmost care.

Some of the West India islands were much infested with large ants, which greatly hurt the sugar-canes. The remedy was, to dissolve corrosive sublimate mercury in rum, in the proportion of two drams to a pint of spirits. This solution was poured on dry powdered sugar; and when the sugar was dried, it was laid in the paths of the ants. They ate it, and were destroyed. Might not this practice be imitated, by laying sugar thus prepared on paper or pieces of thin boards near the roots of fruit-trees infested by insects, especially when the fruit is ripening? The papers or boards might be taken in during the night, or when it rained. The sugar should be coloured with indigo, or other substance, thereby to mark it as a substance to be avoided by curious idlers.

2. We are informed that a person in Philadelphia employed brimstone in the following manner: Having cleared all round the roots of trees infested with caterpillars or other insects, he strewed some flower of brimstone round the roots, and covered it with a thin sprinkling of fine mould, that it might not be blown away by the wind, yet so that the sun might operate through, and cause the brimstone to fumigate. Thus he destroyed the caterpillars. One pound he found sufficient for 200 trees. In that hot climate the sun may perhaps have that effect; but it scarcely will in this. He also employed sulphur in the following manner to drive insects from tall trees: He split the end of a pole, and put in the slit some matches, set them on fire, and held them under the parts of the trees chiefly affected. A pole thus armed he found would answer for three or four trees. Brimstone thus mixed with damp straw, and set on fire, for instance, in hop-grounds infested with the fly, might be of use to drive away the fly.

Sheep are liable to an eruption on the skin, known by the name of the *scab*. The brimstone, when added to the mercurial ointment recommended for that disorder in the Transactions of the Society for the Encouragement of Arts, vol. vii. p. 90, might perhaps render the application more efficacious and less dangerous.

3. The natives of hot countries are taught by experience, that an unctuous covering on their bodies prevents the bites of musquitoes and all gnats. The white inhabitants in such countries are not sufficiently careful in preventing the least stagnant water near their dwellings, in which the musquitoes are bred; even in the waste water thrown out they are produced. Dr. Franklin, by a careful attention to this circumstance, guarded his family in Philadelphia from such insects: one day seeing a number of musquitoes in his library, he found on enquiry, that one of his servants had taken the cover off a tub placed near his window for receiving rain-water. On such an occasion the remedy is easy, viz. shutting the room up for the day, so that the musquitoes cannot come at any water, in which time they die. Though this caution may seem trifling to us who live in a mild climate, it is far otherwise in hot countries.

We are informed, in the Transactions of the Society for the Encouragement of Arts, vol. v. p. 45, that Mr. Winter, among other experiments on turnip-seed, steeped the seed 24 hours in a sufficient quantity of train-oil. He then drained the oil from the seed, which he mixed with a quantity of fine sifted earth, and immediately sowed it in drills. When the plants began to appear on the surface, the ground was sown with foot. He found that seed steeped in lintseed-oil answered equally well. The turnips the least injured by the fly were those that grew from seed steeped as above, which grew so luxuriantly as to produce rough leaves several days prior to the most flourishing of any of his other experiments, and were the better enabled to withstand the fly's attack. The leaves of

these turnips were of a darker green, and appeared twice as thick in bulk and luxuriance as the other turnips, and were a considerable deal larger. The seed was drilled an inch and a half deep, and at a foot distance in the rows. Train oil is apt to kill the leaves of plants which have been injured by insects; but linseed oil has not that effect, though equally destructive to the insects. The train oil seems to act both as an oil, and by its disagreeable smell it prevents insects approaching it. In this respect it may be successfully used to prevent field-mice or other vermin preying on acorns, chestnuts, or other seeds sown in it before they are sown.

When thus giving directions for preventing the fly on turnips, a late experiment should be mentioned, by the disclosing of which a person gained a considerable reward. His secret was, running a roller over the ground early in the morning, while the dew remained on the ground, on the first appearance of the fly. The dew entangled the flies so much, that they could not make their escape, and were therefore crushed to death. As the roller may leave the surface of the earth too hard, some very properly advise to fix some boughs of elder in a gate or hurdle, to be drawn over the field; and if the boughs had been before fumigated with the smoke of tobacco, or tincture of assafoetida, the success would be the surer. The most certain method of preventing the hurt done by the fly is to raise the plants in a nursery, and at a proper age to transplant them, being carried to the ground in a wheel-barrow filled with manure softened with water so as to admit the plants. This method will secure their more speedy growth. In the nursery the attack of the fly may be prevented by sprinkling foot or quicklime on the ground. The utility of transplanting turnips is evident by the practice of transplanting the turnip-rooted cabbage. They who are discouraged from this practice by the expence attending it, do not reflect that the hoeing is prevented, and the plants grow the better, being set in fresh earth.

4. Before proceeding to direct the use of the last means mentioned, viz. tobacco, for destroying insects in turnips, it may be proper to mention an experiment made by Mr. Green, of her majesty's flower-garden at Kew. He contrived a pair of bellows, similar to that employed in recovering people seemingly drowned. It has a cavity in the nozzle, in which some tobacco is put, with a live coal over it. The bellows being then worked, the tobacco is set on fire, and the smoke is directed to any particular spot. A lady was fond of having the moss-rose in her dressing-room, but was prevented having it on account of the green insects which constantly adhere to that plant. To remedy this inconvenience, Mr. Green had a box made large enough to contain a pot in which a plant of the moss-rose grew. In one end of the box was a hole, to admit the nozzle of the bellows; the bellows was worked, and the smoke was received into the box. When the tobacco was consumed, the nozzle was withdrawn; and a cork being put into the hole, the box thus remained till morning, when the insects were all laid dead on the earth. Being swept off, the plant was in a state fit for a dressing-room. Many plants thus infested with insects may be too large, or otherwise so placed as not to be put into a box. In this case it occurred to the writer of these observations, that being sprinkled with an infusion of tobacco in water might in some degree answer the same purpose. On trial he found it answer, and he thus freed other plants of their insects. He also used it on trees of easy access with advantage. Train oil is so inimical to tender plants or leaves, that it destroys them if insects have in the least hurt them; whereas the infusion, instead of killing the leaves, promoted a fresh vegetation.

Fruit trees often become the prey of insects. Those against

a wall, or in espaliers, being easily come at, much of the mischief may be prevented by cutting off the leaves so soon as they are observed to be emble; for then fresh eggs are laid on them, probably by butterflies. If sprinkled with the infusion of tobacco, it will prevent their coming to life. After the fruit is formed, the infusion must not be used, lest the taste and smell may remain. The scissars are then the proper remedies, which ladies may employ as amusement, and may thereby present fruit to their friends of their own preserving. A ley of the ash of plants sprinkled on the leaves may have a good effect, as also on other pot-herbs, which are often the prey of caterpillars. As many insects, besides those bred on the leaves or in the walls, may destroy the fruit, the sugar with the corrosive sublimate, as already described, may be laid in the way of other insects, to all which it will prove a speedy death. Diligent inspection into their retreats is the most certain means of preventing the loss sustained by snails. Ants are prevented rising up the trees, by laying round the roots powdered chalk, or any other substance which by entangling their feet prevents their crossing it. Care should be taken to destroy their nests every where near the garden.

The hop is now become an article of so great consequence, that it deserves our particular attention. Early in its growth, when the vines begin to ascend the poles, a black fly preys on its leaves, frequently in such numbers, as, by destroying the leaves, to interrupt the vegetation, much of the food of plants being absorbed by the leaves. The infusion of tobacco destroys them, or at least drives them away so effectually that a plant almost totally stripped of its leaves has put out fresh leaves after the use of it. If care be not taken, they will again fall on the fresh leaves. As the flies lodge on the lower side of the leaves, they are protected from storms of rain, and therefore the infusion must be driven upwards by a forcing pump. As it is said that the expence of tobacco is too great, perhaps lime-water, or even water by itself, driven strongly against the leaves, might drive them away. The labour attending such experiments in a large plantation discourages others, without reflecting that, if such means are used early, the flies may more easily be got rid of. Free ventilation is undoubtedly beneficial to all plants; and hence perhaps the particular advantages of drilling corn in rows a little distant. If alleys somewhat larger than common were made in the plantations of hops, there might be sufficient spaces left where the alleys cross one another to admit of setting damp straw, or other materials mixed with brimstone, foot, &c. on fire. Smoke itself is said to prevent the fly; and if so, it will still act more powerfully when mixed with such materials. It has been observed in Sweden, that the hops grow naturally among heaps of stones or fragments of rocks. They therefore advise to cover the ground round their roots, with stones, which will prevent the insects laying their eggs near the roots in the ground, where they lay them to be protected during the winter. The stones will also preserve moisture at the roots during the summer. A rope cannot be drawn across a plantation of hops, as it can across a field of corn, in case of mildew. Here water to wash off the clammy juice that entices and feeds insects seems to be the only remedy. The plantation being well ventilated, may at least prevent the frequency of it. The forcing pump will most effectually wash off this exudation.

INSERTION, in anatomy, the close conjunction of the vessels, tendons, fibres, and membranes of the body, with some other parts. This term is particularly applied to a muscle, which is said to have its *origin* and its *insertion*.

INSINUATION of a *Will*, among civilians, is the first production of it, or the leaving it with the register in order to its probate. See *WILL*.

INSITION, **INSITIO**, in botany, denotes the same with engrafting, viz. the act of inserting and uniting a cyon, bud, or the like, in the substance of the stock.

INSOLATION, in pharmacy, a method of preparing certain fruits, drugs, &c. by exposing them to the heat of the sun's rays; either to dry, to mature, or to sharpen them; as is done in vinegar, figs, &c. The word comes from the Latin verb, *insolare*, which is used by Pliny and Columella, and signifies *to expose to the sun*.

INSOLVENT, a term applied to such persons as have not wherewithal to pay their just debts. A person dying, and not leaving estate sufficient to discharge these, is said to die insolvent.

Trial by INSPECTION, or **EXAMINATION**, is when, for the greater expedition of a cause, in some point or issue, being either the principal question, or arising collaterally out of it, but being evidently the object of sense, the judges of the court, upon the testimony of their own senses, shall decide the point in dispute. For, where the affirmative or negative of a question is matter of such obvious determination, it is not thought necessary to summon a jury to decide it, who are properly called in to inform the conscience of the court of dubious facts: and therefore, when the fact, from its nature, must be evident to the court either from ocular demonstration or other irrefragable proof, there the law departs from its usual resort, the verdict of 12 men, and relies on the judgment of the court alone. As in case of a suit to reverse a fine for non-age of the cognizor, or to set aside a statute or recognizance entered into by an infant; here, and in other cases of the like sort, a writ shall issue to the sheriff, commanding him that he constrain the said party to appear, that it may be ascertained by the view of his body by the king's justices, whether he be of full age or not: *Ut per aspectum corporis sui constare poterit justiciariis nostris, si predictus an sit plenæ ætatis necne*. If, however, the court has, upon inspection, any doubt of the age of the party (as may frequently be the case), it may proceed to take proofs of the part; and particularly may examine the infant himself upon an oath of *voir dire, veritatem dicere*; that is, to make true answers to such questions as the court shall demand of him: or the court may examine his mother, his god-father, or the like.

INSPECTOR, a person to whom the care and conduct of any work is committed. *Inspectors*, in the Roman law, were such persons as examined the quality and value of lands and effects, in order to the adjusting or proportioning taxes and impositions to every man's estate. The Jews also have an officer, in their synagogue, whom they call *inspector*, *יבבזען*. His business consists principally in inspecting or overlooking the prayers and lessons, in preparing and showing them to the reader, and in standing by him to see he reads right; and, if he makes mistakes, he is to correct him.

INSPIRATION, among divines, &c. implies the conveying of certain extraordinary and supernatural notices or motions into the soul, or it denotes any supernatural influence of God upon the mind of a rational creature, whereby he is formed to any degree of intellectual improvements, to which he could not, or would not, in fact have attained in his present circumstances in a natural way. Thus the prophets are said to have spoken by divine inspiration.

Some authors reduce the inspiration of the sacred writers to a particular care of Providence, which prevented any thing they had said from failing or coming to nought; maintaining, that they never were really inspired either with knowledge or expression. According to M. Simon, inspiration is no more than a direction of the Holy Spirit, which never permitted the sacred writers to be mistaken. It is a common opinion,

that the inspiration of the Holy Spirit regards only the matter, not the style or words; and this seems to fall in with M. Simon's doctrine of direction.

Theological writers have enumerated several kinds of inspiration: such as an inspiration of superintendency, in which God does so influence and direct the mind of any person, as to keep him more secure from error in some various and complex discourse, than he would have been merely by the use of his natural faculties; plenary superintendant inspiration, which excludes any mixture of error at all from the performance so superintended; inspiration of elevation, where the faculties act in a regular, and, as it seems, in a common manner, yet are raised to an extraordinary degree, so that the composition shall, upon the whole, have more of the true sublime or pathetic, than natural genius could have given; and inspiration of suggestion, when the use of the faculties is superseded, and God does, as it were, speak directly to the mind, making such discoveries to it as it could not otherwise have obtained, and dictating the very words in which such discoveries are to be communicated, if they are designed as a message to others. It is generally allowed that the New Testament was written by a superintendant inspiration; for without this the discourses and doctrines of Christ could not have been faithfully recorded by the evangelists and apostles: nor could they have assumed the authority of speaking the words of Christ, and evinced this authority by the actual exercise of miraculous powers: and besides, the sacred writings bear many obvious internal marks of their divine original, in the excellence of their doctrines, the spirituality and elevation of their design, the majesty and simplicity of their style, the agreement of their various parts, and their efficacy on mankind; to which may be added, that there has been in the Christian church, from its earliest ages, a constant tradition, that the sacred books were written by the extraordinary assistance of the Spirit, which must at least amount to superintendant inspiration. But it has been controverted whether this inspiration extended to every minute circumstance in their writings, so as to be in the most absolute sense plenary. Jerom, Grotius, Erasmus, Episcopius, and many others, maintain that it was not; whilst others contend, that the emphatical manner in which our Lord speaks of the agency of the Spirit upon them, and in which they themselves speak of their own writings, will justify our believing that their inspiration was plenary, unless there be very convincing evidence brought on the other side to prove that it was not: and if we allow, it is said, that there were some errors in the New Testament, as it came from the hands of the apostles, there may be great danger of subverting the main purpose and design of it; since there will be endless room to debate the importance both of facts and doctrines.

Among the Heathens, the priests and priestesses were said to be divinely inspired when they gave oracles. The poets also laid claim to it; and to this end they always invoked Apollo and the Muses at the beginning of any great work.

INSPIRATION, in physiology, is understood of that action of the breast, by which the air is admitted within the lungs; in which sense, inspiration is a branch of respiration, and stands opposed to **EXPIRATION**. This admission of the air depends immediately on its spring or elasticity, at the time when the cavity of the breast is enlarged by the elevation of the thorax and abdomen, and particularly by the motion of the diaphragm downwards: so that the air does not enter the lungs, because they are dilated; but those dilate, because the air enters within them. Nor, is it the dilation of the breast which draws in the air, as is commonly thought, though this is a condition absolutely necessary to inspiration; but an actual intrusion of the air into the lungs. See **RESPIRATION**.

INSPISSATING, in pharmacy, an operation whereby a liquor is brought to a thicker consistence, by evaporating the thinner parts.

INSPRUCK, a city of Germany, in the circle of Austria, and capital of the county of Tyrol, received its name from the river Inn, which runs by it. It has a noble castle or palace, formerly the residence of the archdukes of the house of Austria, with a cathedral where they are buried. The houses, though built in the German taste, are rather handsome; and the streets, though narrow, are remarkably well paved. For the defence of this city the inhabitants can place but little confidence in their fortifications, which are very trifling. They seem rather to depend on the natural fastnesses of their country; which appear indeed to form a barrier, so perfectly inaccessible to any enemy, that even the great Gustavus Adolphus, after having over-run with his victorious arms the other parts of Germany, could never make any impression upon this. It is seated in a pleasant valley, in E. long. 11. 27. N. lat. 47. 3.

INSTALMENT, or **INSTALLATION**, the act of giving visible possession of an order, rank, or office, by placing in the proper seat. The word is derived from the Latin *in*, and *stallum*, a term used for a seat in church, in the choir, or a seat or bench in a court of justice, &c. though Vossius is of opinion the word is of German origin. **INSTALMENT** is chiefly used for the induction of a dean, prebendary, or other ecclesiastical dignitary, into the possession of his stall, or proper seat in the cathedral church to which he belongs. This is sometimes also called *installation*.

INSTALMENT is likewise used for the ceremony whereby the knights of the garter are placed, in their rank, in the chapel of St. George at Windsor.

INSTANT, a point of duration in which we perceive no succession; or it is that which takes up the time only of one idea in our minds.

INSTAURATION, the re-establishment or restoration of a religion, a church, or the like, to its former state. The word is by some derived from the old Latin *instaurum*, which signified the "stock" of things necessary for the tilling and managing of grounds; as cattle, tools, harness, &c. But the word *instaurum* is only of the middle age; *instauratio* is of much greater antiquity, and by some derived from *instar* "like;" as importing a thing's being brought to its former likeness or appearance. See **RESTAURATION**.

INSTEP, in the manege, is that part of a horse's hind leg which reaches from the ham to the pattern-joint.

INSTINCT, a natural disposition, or sagacity, wherewith animals are endued; and by virtue whereof they are enabled to provide for themselves, and know what is good for them, and are determined to preserve and propagate their species.

INSTINCT in brutes bears some analogy to reason in men. There have been many systems adopted to explain the principles which produce and direct the spontaneous actions of brute animals. Many of the ancient philosophers ascribed to brutes an understanding differing only in degree from that of man, and attributed their inferiority to the want of proper and sufficient bodily organs. This system has been lately very strenuously supported by M. Helvetius, *De l'Esprit*, tom. i. p. 2, &c. Among the moderns, the learned Cudworth endeavoured to explain the instinct of animals by means of a certain *PLASTIC nature*. Des Cartes thought that all the actions of brute animals might be explained by the simple laws of mechanism, and considers them as machines totally devoid of life and sentiment, but so curiously constructed by the Creator, that the mere impressions of light, sound, and other external agents on their organs, produced a series of motions in them, and caused them to execute those various operations, which had before been ascribed to an internal principle of life and

spontaneity. But the actions and manners of animals, which are totally incompatible with the mere principles and laws of mechanism, evince the absurdity of this opinion. M. Buffon adopts the opinion of Des Cartes in part, but grants them life, and the faculty of distinguishing between pleasure and pain, together with a strong inclination to the former, and aversion from the latter. By these inclinations and aversions he undertakes to account for all, even the most striking operations of animals; affirming, that, in consequence of impressions made on the brain, by means of the sensitive organs, and by the re-action of the brain and nerves on the muscles, these machines acquire a motion conformable to the nature of the animal, and of the impressions of the different objects which act upon their organs, and excite desire or aversion. See **BRUTES**.

The *pre-established harmony* of Leibnitz has also been applied to explain the actions of brute animals. Others have considered the actions of animals as produced by the constant and immediate influence of the divine energy, directing all their inclinations and motions: such appears to have been the opinion, however unphilosophical it must appear, of Mr. Addison, in the second volume of the *Spectator*. The late ingenious Hermann Samuel Reimar, professor of philosophy at Hamburg, has enumerated and exposed these and other opinions, with regard to the instinct of animals, in his *Observations Physiques*, &c. published in 2 vols. 12mo. at Amsterdam and Paris, 1770; and, defining *instinct*, in the most comprehensive sense of the word, to be every natural inclination, accompanied with a power, in animals, to perform certain actions, divides instincts into three heads. The first, which he calls *mechanical instincts*, belong to the body, considered as an organized substance, and are exercised blindly and independently of the will of the animal. Such are those which produce the motion of the heart and lungs, the contraction and dilatation of the pupil, digestion, &c. This class of instincts is possessed in common both by men and brutes, and in some measure even by vegetables. The second class comprehends those which he terms *representative instincts*, which consist partly in the power of perceiving external objects by their present impression on the senses, and partly in the faculty of rendering the ideas of these objects present to the mind by the powers of imagination, or of memory, in a lax sense of the word. These are common to men and other animals, excepting that brutes possess only the faculty of imagination in common with us, and not that of memory, in the strict and proper sense of the word. Indeed this author endeavours to prove, that the knowledge of brutes does not merely differ in degree from that of man, but that it is of a kind entirely different from it; and that they are incapable both of memory and reasoning; the faculty of imagination serving to give them a confused idea of events that are past, by the view, or other impressions of objects that are present. The third and principal class of instincts is that which comprehends all those which M. Reimar call *spontaneous*. This species of instinct is not attended with any power of reflection, determining the animal to decide freely between two different modes of action present to his imagination; nor is it merely corporeal or mechanical. It is put into action by the natural and primitive principle of self-love implanted in all animated beings; or by a love of pleasure and aversion to pain, producing a voluntary inclination to perform certain actions which tend to their well-being and preservation. To the performance of these actions they are particularly prompted by their present sensations, by imagination supplying the place of memory, and by other causes. The wonderful effects produced by these instinctive appetites, are farther to be attributed to the exquisite mechanism in their bodily conformation, particularly in the structure of the various organs with which they execute their

operations, and to the superior perfection and acuteness of their external senses, by which they are quickly and distinctly informed of those qualities of objects which most materially concern them. In order to account for the more curious and surprising operations of brute animals, M. Reimar adds two other principles, viz. 1st. an internal distinct perception of the precise power and proper use of their various bodily organs, together with an innate knowledge of the qualities of those objects around them in which they are interested; and 2dly, certain innate and determinate powers and inclinations, impressed by the Author of Nature, *à priori*, on the soul itself; by which they are arbitrarily, and without their own knowledge or consciousness, directed and irresistibly impelled to the performance of these various operations which they execute with such unremitting industry and art. These determinate forces, which constitute the principal part of M. Reimar's system, are no where so visible and distinguishable as in that numerous set of instincts which he classes under the title of the *industrious* instincts of animals. For a further account of this system we must refer to the work itself, or to an abstract of it, with several of the author's illustrations, in the Monthly Review, vol. xlv. p. 533, &c.

INSTITUTES, in literary history, a book containing the elements of the Roman law. The institutes are divided into four books; and contain an abridgment of the whole body of the civil law, being designed for the use of Students. See **LAW**.

INSTITUTION, in general, signifies the establishing or founding something.—In the canon and common law, it signifies the investing a clerk with the spiritualities of a rectory, &c. which is done by the bishop, who uses the following formula: "I institute you rector of such a church with the cure of souls, and receive your care and mine."

INSTITUTIONS, in literary matters, denote a system of the elements or rules of any art or science. Thus, physical or medicinal institutions are such as teach the necessary *præcognita* to the practice of medicine, or the cure of diseases.

INSTRUMENT, in general, whatever is subservient to a cause in producing any effect.

Mathematical, Philosophical, &c. **INSTRUMENTS**. See **ASTRONOMY**, **ELECTRICITY**, **GEOMETRY**, **LEVELLING**, **MECHANICS**, **OPTICS**, **PNEUMATICS**, &c. &c.

INSTRUMENT is also used in law, to signify some public act, or authentic deed, by means whereof any truth is made apparent, or any right or title established, in a court of justice.

INSUBRIUM, **AGER**, in ancient geography, a district of the Transpadana; situated between the Ticinus to the west, the Addua to the east, the Padus to the south, and Orobii to the north. The people are called *Infabres* by Livy, *Insubri* by Ptolemy, and *Isombres* by Strabo. Now the Duchy of Milan.

INSULAR, any thing belonging to an island. Insular situations are productive of many happy consequences to the inhabitants, both with respect to the climate, security, and convenience for commerce. See **ISLAND** and **COAST**.

INSULATED, in architecture, an appellation given to such columns as stand alone, or free from any contiguous wall, like an island in the sea; whence the name.

INSULATED, in electrical experiments. When any body is prevented from communicating with the earth by the interposition of an electric body, it is said to be *insulated*. See **ELECTRICITY**.

INSURANCE, in law and commerce, a contract, whereby one party engages to pay the losses which the other may sustain, for a stipulated premium or consideration. The most common sorts are, Insurance against the dangers of the seas, insurance against fire, insurance of debts, and insurance of lives.

I. **INSURANCE against Loss at Sea**, is a most beneficial institu-

tion, for promoting the security of trade, and preventing the ruin of individuals; and is now conducted by a regular system of rules, established by the interposition of the legislature, the decision of the courts of justice, and the practice of merchants.

It is carried on to the best advantage by public companies, or by a considerable number of private persons, each of whom only engages for a small sum, on the same vessel. There are two public companies established by authority of parliament, viz. the London and Royal Exchange Insurance-Companies. For procuring subscription by private persons, brokers are generally employed, who extend the policy or contract of insurance, procure subscriptions, and assist at settling losses. They are entitled to an allowance for their trouble, generally 5 *per cent.* on premiums, and 2 *per cent.* on losses.

The parties who engage to pay the damage are called the *insurers* or *under-writers*: the parties for whose security they engage, are called the *insured*; and the premium is understood to be paid when the insurance is made. On this subject, we shall consider, What is necessary to render an insurance valid: When the risk commences, and when it terminates: What constitutes a total or a partial loss: What proof of loss is necessary: and, How the loss is adjusted.

First, In order to render an insurance valid, the insured must have property really at stake; the voyage must take place under the circumstances agreed on; the dangers insured against must not be contrary to law; and a candid account must be given of circumstances which enhance the danger.

1. The condition of possessing property was required by 19 Geo. II. c. 37. to prevent ships from being fraudulently destroyed when insured above their value; and to discourage a practice which had become common, of converting policies to the purpose of mere wagers. In transactions of this kind, as the insured had no property, and could claim no indemnification for partial damage; so the insurers, having lost their wager by the ship's being lost, could claim no abatement, though part was saved: accordingly, the policies contained clauses of interest or no interest, free from average, and without benefit of salvage. All such policies are declared invalid.

This restriction does not extend to privateers, nor to ships trading to the Spanish or Portuguese plantations.

Insurances are commonly made as interest shall appear; and it is incumbent on the insured to prove the value of his property. The value of the goods may be proved by the invoices; and the cocquet must be produced, if required, to instruct that the goods were actually shipped. It is admitted to value the ship at prime cost and charges, deducting the freights that have been drawn since purchased, if the proprietors choose to stand to that rule; but they are not restricted to it. Sometimes the value of the ship or goods is expressed in the policy; and this value must be admitted, although it be higher than the true one: but it is incumbent on the insured to prove that he had property at stake; and, if the property be trifling in comparison of the sum insured, the insurance will be set aside, as an evasion of the statute.

Expected profits, and bounty on the whale-fishery, if specified in the policy, may be insured.

When the value is less than the sum insured, the owners may claim a return of premium for the excess.

If there be several policies on the same subject, of different dates, the earlier one is valid, and the others must be vacated. If they be of the same date, they must be vacated in equal proportions.

When a policy is vacated, in whole or in part, the under-writers have a right to retain $\frac{1}{2}$ *per cent.* for their trouble.

In the case of a cargo intended for A, but afterwards sent to B, both expected it, and insured, and B claimed for the value on its being lost. The under-writers answered, that it

was a double insurance, and they ought only to pay their proportion. Judgment was given, finding them liable for the whole, and reserving to them any demand competent against the underwriters who insured for A.

Fraudulently to cast away or destroy a ship insured above its value, is felony.

2. If the ship does not proceed on the voyage, or if, being warranted to depart with convoy, it departs without convoy, the insurance must be vacated.

If the extent of a trading voyage be uncertain, the longest one in contemplation is described in the policy, and it is agreed that part of the premium shall be returned if the voyage be shortened. In like manner, in time of war, when insurance is made without condition of convoy, it is agreed that part of the premium be returned in case it sail with convoy.

When a ship is warranted to depart with convoy, it is understood from the usual place of convoy (*e. g.* the Downs), and it is insured till it arrive there.

The common proof of sailing with convoy is the production of sailing-orders; but if a ship be prevented by the weather from receiving the sailing-orders, other proof may be admitted.

A ship was insured from the Thames to Halifax, warranted to sail from Portsmouth with convoy. The convoy had failed before the ship arrived there, and the underwriters declined to insure it, without convoy, for the rest of the voyage. They were found liable to return part of the premium, retaining only in proportion to the accustomed rate from London to Portsmouth. This decision seems to establish the following principle, that, when the voyage performed is only part of that described in the policy, and when the risk can be proportioned, the underwriters are bound to return part of the premium, though there be no agreement for that purpose.

But, if a ship, insured only against the hazards of the sea, be taken by the enemy, the insured have no right to claim a return of premium, though the capture happen soon, under pretence that little sea-hazard was incurred.

If a ship deviates from the voyage described in the policy without necessity, it sets aside the insurance. An intention to deviate is not sufficient to set it aside; there must be an actual deviation; and, even in that case, the insurers are liable for damages sustained before deviation.

It is no deviation to go out of the way to the accustomed place of convoy, nor to the nearest place where necessary repairs may be had. Deviation, for the purpose of smuggling, if without the knowledge of the owners, does not set aside the insurance, nor when the master is forced by the crew to return.

In insurances to the East Indies, and home, the insurers are understood to take the risk of detention in the country, and of country voyages.

3. Insurance of prohibited goods, against the risk of seizure by the government, is unlawful, and invalid. The insurers, insured, brokers, and all accessories, are liable to the fine of 500l.

4. If the insured have any information of more than common danger, they must reveal every such circumstance to the insurers, otherwise the policy is set aside.

This rule is established for the preservation of good faith: and there are several strong decisions in support of it. If a ship be spoke to leaky at sea, or if there be a report of its being lost, these circumstances must be communicated to the insurers. Even the concealment of a false report of loss vitiates the insurance; and, if the ship be afterwards lost, though in a different manner, the insured will recover nothing. In a voyage from Carolina to London, another ship had sailed 10 days after that which was insured, and arrived seven days before the insurance was made; and the concealment of this circumstance, though the fact was not proved to the satisfaction of the jury, was considered as sufficient to set it aside. Also,

during the continuance of the American war, a ship being insured from Portugal, by the month, without condescending on the voyage, sailed for North America, and was taken by a provincial privateer. The insurers refused to pay, because the hazardous destination was concealed; and it was only upon proof of the insured being equally ignorant of it that they were found liable.

But the insured are not obliged to take notice of general perils, which the insurers are understood to have in contemplation; dangerous navigation, West-Indian hurricanes, enterprises of the enemy, and the like.

Insurance is not set aside by a mistake in the name of the ship or master, or the like,

Insurance may be made on an uncertain ship; on any ship that the goods may be loaded on; on any ship that A shall sail in from Virginia. In this last case, the policy is no transferred to a ship which A goes on board during the voyage.

Secondly, If a ship be insured at and from a port, the insurance commences immediately if the ship be there, or at its arrival there. If it be damaged when preparing for a voyage, the insurers are liable; but not if the voyage be laid aside for several years, with consent of the owners. Insurance from a port commences when the ship breaks ground; and if it set sail, and be driven back and lost in the port, the insurers are liable.

Insurance on goods generally continues till they be landed; but, if they be sold after the ship's arrival, and freight contracted to another port, the insurance is concluded. Goods sent on board another ship or lighter are not at the risk of the insurer; but goods sent ashore in the long boat are.

Insurance on freight commences when the goods are put on board.

Goods from the East Indies, insured to Gibraltar, and to be re-shipped from thence to Britain, were put on board a store-ship at Gibraltar, to wait an opportunity of re-shipping, and were lost. The custom of putting goods aboard a store-ship being proved; the insurers were found liable.

Loss of sails ashore, when the ship is repairing, is comprehended within the insurance. What is necessarily understood is insured, as well as what is expressed; the essential means, and intermediate steps, as well as the end. Ships performing quarantine are at the risk of the insurer.

Thirdly, The insurers are liable for a total loss when the subject perishes through any of the perils insured against. *Baratry*, though it properly signifies running away with the ship, extends to any kind of fraud in the master or mariners. Insurance against detention of princes does not extend to ships that are seized for transgressing the laws of foreign countries.

The insurers are also liable for a total loss, when damage is sustained, and the remaining property abandoned or vested in the insurers.

If a ship be stranded, or taken, and kept by the enemy, or detained by any foreign power, or seized for the service of the government, the proprietors have a right to abandon.

But, if a ship be taken by the enemy, and be re-taken, or makes its escape, before action against the insurers; have the insured a right to abandon, or must they only claim for the damages sustained as an average loss? There are opposite decisions, according as the circumstances of the case were strong. When the ship was long detained, the goods perishable, the voyage entirely lost, or so disturbed that the pursuit of it was not worth the freight, or when the damage exceeds half the value of the thing, they have been found entitled to abandon; (*Goss against Withers, 2 Burrow, 683*). But, if the voyage be completed with little trouble or delay, they are not entitled; (*Hamilton against Mendez, 2 Burrow, 1198*).

The insured cannot claim, as for a total loss, on an offer to abandon when the loss is, in its nature, only partial; for, if

this were permitted, they might devolve the loss occasioned by bad markets on the insurers.

And, in all cases, the insured have their option to abandon, or not. They may retain their property if they please, and claim for an average loss; and they must make their option before they claim.

If the goods be so much damaged that their value is less than the freight, the insurers are accountable as for a total loss.

The insurers are liable for general average, when the property is charged with contribution; and for particular average, when the property is damaged, or part of it destroyed.

If the damage be sustained through the fault of the ship, the owners of the goods may have recourse, either against the master or insurers; and, if the insurers be charged, they stand in the place of the owners, and have recourse against the master.

In order to prevent the insurers from being troubled with frivolous demands for average, it is generally stipulated, that none shall be charged under 5 per cent. or some other determined rate; and corn, flax, fruit, fish, and like perishable goods, are warranted, free from average, unless general, or the ship be stranded.

In order to encourage every effort to save the ship, the insurers are liable for charges laid out with that design, although the subject perish. Thus they may be charged with more than the sum insured.

In case of goods being damaged, the proportion of the sum insured, for which the underwriters are liable, is regulated by the proportion of the prices which the sound and damaged goods fetch at the port of destination. The prime cost of the goods is not considered, nor the necessity of immediate sale, in consequence of damage. Although the damaged goods sell above prime cost, the insurers are liable.

Fourthly, If a ship be lost, and the crew saved, the loss is proved by the evidence of the crew.

If damage be sustained, the extent is proved by an examination of the subject damaged, at the ship's arrival; and the cause by the evidence of the crew.

If the ship be stranded, evidence must be taken at the place where stranded.

Documents of loss must be laid before the underwriters, with all convenient speed; and, if these be sufficiently clear, the loss should be immediately settled. The underwriters generally grant their notes at a month or six weeks date for their proportions.

If a ship be not heard of for a certain time, it is presumed lost; and the underwriters are liable to pay the sums insured, the property being abandoned to them in the event of the ship's return. Six months are allowed for a voyage to any part of Europe, a year to America, and two years to the East Indies.

By the ordinance of Hamburgh, if a ship be three months beyond the usual time of performing a voyage, the underwriters may be desired to pay 92 per cent. on an abandon. If they decline it, they are allowed 14 months more, and then they must pay the full value.

A ship insured against the hazards of the sea, but not against the enemy, if never heard of, is presumed lost at sea.

Fifthly, In order that the manner of settling losses may be understood, we must explain what is meant by covering property. We mentioned already, that insurances for greater sums than the insured had really at stake, were contrary to law: but some latitude is allowed in that respect; for if the owner were to insure no more than the exact value of his property, he would lose the premium of insurance, and the abatement, if any was agreed on.

For example, if he has goods on board to the value of 100l. and insures the same at 5 per cent. to abate 2 per cent. in case of loss; then, if a total loss happen, he recovers 98l. from the

insurers, of which 5l. being applied to re-plate the premium, the nett sum saved is only 93l.: but, if the value on board be only 93l. and the sum insured 100l. he would be fully indemnified for the loss; and his property, in that case, is said to be covered.

To find how much should be insured to cover any sum, subtract the amount of the premium and abatement (if any) from 100l. As the remainder is to 100l. so is the value to the sum which covers it.

In case of a total loss, if the sum insured be not greater than that which covers the property, the insurers must pay it all. If greater, they pay what covers the property, and return the premium on the overplus.

Partial losses are regulated by this principle, that whereas the owner is not fully indemnified, in case of a total loss, unless he covers his property, therefore he should only be indemnified for a partial loss in the same proportion; and if it be not fully insured, he is considered as insurer himself for the part not covered, and must bear a suitable proportion of the loss. Therefore the value of the property is proved, and the sum required to cover it computed. If that sum be all insured, the underwriters pay the whole damage; if only part be insured, they pay their share, which is computed by the following rule: As the sum which covers the property is to the sum insured, so is the whole damage to the part for which the insurers are liable.—For example, if the value of the property be 360l. the sum insured 300l. the premium 8 per cent. and abatement 2 per cent.; then the sum which should be insured to cover the property is 400l.; and, if damage be sustained to the extent of 200l. the owners will recover 150l.

If a voyage is insured out and home, the premium outward must be considered as part of the value on the homeward property, and the sum necessary to cover it computed accordingly. For example, to insure 100l. out and home, at 5 per cent. each voyage, abatement 2 per cent. we compute thus:

93 : 100 : : L. 100 : L. 107 : 10 : 6, to be insured outward, premium on L. 107 : 10 : 6 outwards, at 5 per cent. L. 5 : 7 : 6 : 93 : 100 : : L. 105 : 7 : 6 : L. 113 : 6s. to be insured home; the premium on which is L. 5 : 13 : 6; and if the ship be lost on the homeward voyage,

Covered property L. 100 — —

II. INSURANCE against Fire. There are several offices in Britain for this purpose, of which the Sun Fire-office is the most considerable. Insurances are divided into common, hazardous, and doubly hazardous, according to the nature of the subject insured. When the sum insured is high, there is a higher premium per cent. demanded; and money, papers, jewels, pictures, and gun-powder, are not comprehended. If a subject be wrong described, in order that it may be insured at a lower premium, the policy is void. The benefit of a policy is transferred, by indorsement, to the representatives of the person in whose favour it was made; and it may be transferred to other houses when the insured changes his habitation. If insurance be made on the same subject in different offices, it must be specified, by indorsement, on the policy; and, in case of loss, the offices pay proportionally. The insurers pay all expences in attempting to extinguish fire, or save goods, though not successful. If the value of a subject be insured in part, and damage be sustained, the insurers pay the whole, if it does not exceed the sum insured.

III. INSURANCE of Debts. See BOTTOMRY.

IV. INSURANCE for Lives. In virtue of this, when the person dies, a sum of money becomes payable to the person on whose behalf the policy of insurance was granted. One of the principal insurance-offices of this kind is that of the Amicable Society for a Perpetual Assurance, kept in Serjeant's-inn, Fleet-street, London.

This society at Serjeant's-inn requires an annual payment of 5 l. from every member during life, payable quarterly. The whole annual income hence arising is equally divided among the nominees, or heirs, of such members as die every year; and this renders the dividends among the nominees, in different years, more or less, according to the number of members who have happened to die in those years. But this society engages that the dividends shall not be less than 150 l. to each claimant, though they may be more.—None are admitted whose ages are greater than 45, or less than 12; nor is there any difference of contribution allowed on account of difference of age.—This society has subsisted ever since 1706, and its credit and usefulness are well-established. Its plan, however, is liable to several objections. First, it is evident that regulating the dividends among the nominees by the number of members who die every year, is not equitable; because it makes the benefit which a member is to receive to depend, not on the value of his contribution, but on a contingency, that is, the number of members that shall happen to die the same year with him. Secondly, its requiring the same payments from all persons under 45, is also not equitable; for the payment of a person admitted at 12, ought not to be more than half the payment of a person admitted at 45. Thirdly, its plan is so narrow, as to confine its usefulness too much. It can be of no service to any person whose age exceeds 45. It is, likewise, by no means properly adapted to the circumstances of persons who want to make assurances on their lives for only one year, or a short term of years. For example: the true value of the assurance of 150 l. for five years, on the life of a person whose age is 39, may be found, by calculation, to be nearly three guineas *per ann.* supposing interest at 3 *per cent.* and the probabilities of the duration of human life as they are given in Dr. Halley's Table of Observations. But such an assurance could not be made in this society without an annual payment of 5 l. Neither is the plan of this society at all adapted to the circumstances of persons who want to make assurances on particular survivorships. For example: a person possessed of an estate or salary, which must be lost with his life, has a person dependent upon him, for whom he desires to secure a sum of money payable at his death. But he desires this only as a security against the danger of his dying first, and leaving a wife, or a parent, without support. In these circumstances he enters himself into this society; and, by an annual payment of 5 l. entitles his nominee at his death to 150 l. In a few years, perhaps, his nominee happens to die; and having then lost the advantages he had in view, he determines to forfeit his former payments, and to withdraw from the society. The right method, in this case, would have been to have taken from such a person the true value of the sum assured, "on the supposition of non payment, provided he should survive." In this way he would have chosen to contract with the society: and had he done this, he would have paid for the assurance (supposing interest at 3 *per cent.* his age 30, the age of his nominee 30, and the values of lives as given by M. de Moivre) 3 l. 8 s. in annual payments, to begin immediately, and to be continued during the joint duration of his own life, and the life of his nominee.

None of these objections are applicable to the plan of the society which meets at Black-briars bridge, and which has justly styled itself the *Equitable Society for Assurances on Lives and Survivorships*. The business transacted by this society is so

extensive, and it is governed so entirely by calculations founded on the best rules and observations, that it cannot but prove one of the greatest public benefits.

It was established in the year 1762, in consequence of proposals which had been made, and lectures recommending such a design, which had been read by Mr. Dodson, the author of the *Mathematical Repository*. It assures any sums or reversionary annuities, on any life or lives for any number of years, as well as for the whole continuance of the lives; and in any manner that may be best adapted to the views of the persons assured: that is, either by making the assured sums payable certainly at the failure of any given lives, or on condition of survivorship; and also, either by taking the price of the assurance in one present payment, or in annual payment, during any single or joint lives, or any terms less than the whole possible duration of the lives. Any persons, for instance, who depend on incomes which must be lost when they die, or who are only tenants for life in estates, may, if they want to borrow money, be enabled to give sufficient security by assuring such sums as they want to borrow in this society, and assigning the policy; in consequence of which, the lender will, during the term of the assurance, be guarded against all danger of losing his principal by the death of the borrower. In the same way, clergymen, counsellors, persons holding any places of profit, traders, and others, who have families, whose subsistence depends on the continuance of their lives, may here be enabled to make some provision for their families after their decease. All persons who enjoy annuities for the lives of others, may here secure themselves against the loss they would sustain, should they survive the persons on whose lives the annuities depend, by making assurances which should entitle them to any sums payable on condition their survivorship should take place. Any person entitled to an estate, annuity, legacy, or office, after another person, provided he survives, may here secure some equivalent for his family at his decease, provided he does not survive.—Husbands may, in this society, secure annuities for their wives, provided they should leave them widows. Parents, by assuring the lives of their children when infants, till they attain a given age, may secure for them, should they live to that age, such sums as may be necessary to put them out to apprenticeships, or to make capitals or fortunes for them, with which to set out in business, or to marry. Any persons apprehensive of being left without support in old age, when incapable of labour, may, in this society, purchase an annuity, to commence at any future year of his life, and to continue during the remainder of his life; and he may do this at a very small expence, if he is young, and willing to wait for the commencement of his annuity till he is 55 or 60 years of age.

In short, there are no kinds of assurances on lives and survivorships, which this society does not make. In doing this, it follows the rules which have been given by the best mathematical writers on the doctrine of *life annuities* and *reversions*, particularly Mr. Simpson: and, in order to gain such a profit as may render it a *permanent* benefit to the public, and enable it to bear the expences of management, it takes the advantage of making its calculations at so low an interest as 3 *per cent.* and from tables of the probabilities and values of lives in London, where (as in all great towns) the rate of human mortality is much greater than it is in common among mankind.

This society has lately made a particular inquiry into its own state, as to *profit* and *loss*, by all the business it has transacted from its first institution. This inquiry was made in three different methods, proposed to the directors by Dr. Price, the author of the *Treatise on Reversionary Payments*; and the result has been, that it appears, that a much smaller proportion of the persons assured have died than *should* have died, according to the tables for London, from which the calculations have been made, or even according to Dr. Halley's table for Breslaw; that, for this reason, the claims have been much less than they

should have been; and that the society has for many years been enjoying an income some thousands *per annum* greater than it wants, and a *surplus stock* of near L. 40,000 over and above what is necessary to enable it to make good all its engagements.

In these circumstances, the society finding itself well secured against future hazards, and being unwilling to take from the public an extravagant profit, have determined to reduce all the future payments for assurances *one-tenth*; and also to return to the persons now assured *one-tenth* of all the payments which they have made. And there is, it seems, reason to expect, that this will be only a preparation for farther reductions. Nor need the public, we are informed, be apprehensive of their going too far in making reductions; for, in consequence of the inquiry they have lately made, and of the order into which this inquiry has thrown their accounts, they will have it in their power to determine exactly from year to year what they are able to do, and always to keep under their view a clear state of their own circumstances.

From the preceding account of this society, it is manifest, that its business is such that none but skilful mathematicians are qualified to conduct it. The interest of the society therefore absolutely requires, that it should make the places of those who manage its business so advantageous as to induce the ablest mathematicians to accept them; and this will render it the more necessary for the society to take care, on any future vacancies, to pay no regard, in filling them up, to any other considerations than the ability and integrity of the candidates. The consequence of granting good pay will be a multitude of solicitations on every vacancy, from persons who, however unqualified, will hope for success from their connections, and the interest they are able to make; and should the society, in any future time, be led by such causes to trust its business in the hands of persons not possessed of sufficient ability as *calculators* and *mathematicians*, such mistakes may be committed as may prove in the highest degree detrimental. We have reason to know, that at present the society is in no danger of this kind; and one of the great public advantages attending it is, that it has established an *office*, where not only the business we have described is transacted with faithfulness and skill, but where also all who want solutions of any questions relating to life annuities and reversions may apply, and be sure of receiving just answers.

TABLE of the Rates of Assurance on Single Lives in the Society for Equitable Assurances near Black-Friars Bridge.

Sum assured L. 100.

Age	One Year			Seven years at an annual payment of			For the whole life, at an annual payment of		
	£.	s.	d.	£.	s.	d.	£.	s.	d.
10	1	9	6	1	10	7	2	2	10
15	1	11	0	1	12	7	2	6	6
20	1	13	11	1	16	0	2	12	10
25	1	17	7	2	0	2	3	0	6
30	2	2	6	2	6	0	3	8	11
35	2	8	7	2	14	2	3	17	9
40	2	19	2	3	5	1	4	7	11
45	3	11	0	3	18	6	5	0	0
50	4	4	8	4	11	2	5	12	11
55	5	0	9	5	11	7	6	9	3
60	5	19	1	6	16	10	7	17	7
65	7	0	11	8	13	0	10	3	9

These rates are 10 *per cent.* lower than the true values, according to the decrements of life in London, reckoning interest at 3 *per cent.*; but at the same time, for all ages under 50, they are near a *third* higher than all the true values, according to Dr. Halley's Table of the decrements of life at Breslaw, and Dr.

Price's Tables of the decrements of life at Northampton and Norwich.—As therefore this society has lately found, that the decrements of life among its members have hitherto been lower than even those given in these last Tables, it may be reasonably expected that they will in time reduce their rates of assurance to the true values by these Tables.

Re-INSURANCE is a second contract, made by an insurer, to transfer the risk he has engaged for to another. It is in general forbidden by 19 Geo. II. c. 37. but is permitted to the representatives of an insurer in case of his death, or to his assignees in case of his bankruptcy; and it must be mentioned in the policy that it is a re-insurance.

INTAGLIOS, precious stones, on which are engraved the heads of great men, inscriptions, and the like; such as we frequently see set in rings, seals, &c.

INTEGER, in arithmetic, a whole number, in contradistinction to a fraction.

INTEGRAL, or INTEGRANT, in philosophy, appellations given to parts of bodies which are of a similar nature with the whole: thus filings of iron have the same nature and properties as bars of iron. Bodies may be reduced into their integrant parts by triture or grinding, limation or filing, solution, amalgamation, &c. See GRINDING, &c.

INTEGUMENTS, in anatomy, denote the common coverings which invest the body; as the cuticula, cutis, &c. What are called the *common integuments*, are, the skin, with the fat and cellular membrane adhering to it. See ANATOMY. The term *Integument* is also extended to the particular membranes which invest certain parts of the body; as the coats or tunics of the eye.

INTELLECT, a term used among philosophers, to signify that faculty of the soul usually called the *understanding*. See LOGIC and METAPHYSICS.

INTENDANT, one who has the conduct, inspection, and management, of any thing. See SUPERINTENDANT. This in the time of the monarchy was a title very frequent among the French. They had *Intendants of the marine*, who were officers in the sea-ports, whose business it was to take care the ordinances and regulations relating to sea-affairs were observed: *Intendants of the finances*, who had the direction of the revenues: *Intendants of provinces*, who were appointed by the king to take care of the administration of justice, policy, and finances in the provinces: also *Intendants of buildings, of houses, &c.* The term is still retained in certain offices under the Republic.

INTENDMENT, in law, is the intention, design, or true meaning, of a person or thing, which frequently supplies what is not fully expressed; but though the intent of parties in deeds and contracts is much regarded by the law, yet it cannot take place against the rules of law.

INTENDMENT of Crimes; this, in case of treason, where the intention is proved by circumstances, is punishable in the same manner as if it was put in execution. So, if a person enter a house in the night-time, with an intent to commit burglary, it is felony; also, an assault, with an intent to commit a robbery on the highway, is made felony, and punished with transportation, 7 Geo. II. c. 21.

INTENT, in the civil law, signifies to begin, or commence, an action or process.

INTENTION, in medicine, that judgment or method of cure which a physician forms to himself from a due examination of the symptoms of a disease.

INTENTION, in physics, the increase of the power or energy of any quality; as heat, cold, &c. by which it stands opposed to *remission*, which signifies its decrease or diminution.

INTENTION, in metaphysics, denotes an exertion of the intellectual faculties with more than ordinary vigour; when the mind with earnestness fixes its view on any idea, considers it on all sides, and will not be called off by any solicitation.

INTERAMNA, in ancient geography, so called from its

situation between rivers, or in an island in the river Nar; a town of the Cisalpine Umbria. *Interamnates* the people; surnamed *Narles* by Pliny, to distinguish them from the people of other Interamnæ. Now *Terni*; a town in the Pope's territory in Umbria. E. lon. 13. 38. N. Lat. 42. 40.

INTERAMNA, a town and colony of the Volsci in Latium, on the confines of Samnium, at the confluence of the rivers Liris and Melpis; and for distinction sake called *Lirinas*. The town is now in ruins.

INTERAMNA, or *Interamnina Prætutianorum* (Ptolemy); a town in the territory of the Prætutiani, a part of the Picenum. Now *Teramo*, in the Abruzzo of Naples. E. lon. 15. N. lat. 42. 40.

INTERCALARY, an appellation given to the odd day inserted in leap-year; which was so called from *calo, calare*, "to proclaim," it having formerly been proclaimed by the priests with a loud voice.

INTERCAUIA, in ancient geography, a town of the Vaccæi in the Hither Spain. Here Scipio Æmilianus slew a champion of the barbarians in single combat; and was the first who mounted the wall in taking the town. It was situated to the south-east of Asturica; now said to be in ruins.

INTERCESSION (*intercessio*), was used in ancient Rome, for the act of a tribune of the people, or other magistrate, by which he inhibited the acts of other magistrates; or even, in case of the tribunes, the decrees of the senate. *Veto* was the solemn word used by the tribunes when they inhibited any decree of the senate or law proposed to the people. The general law of these intercessions was, that any magistrate might inhibit the acts of his equal or inferior; but the tribunes had the sole prerogative of controlling the acts of every other magistrate, yet could not be controlled themselves by any.

INTERCESSOR, from *inter* and *cedo* "I go between", a person who prays, expostulates, or intercedes, in behalf of another. In the Roman law, intercessor was the name of an officer, whom the governors of provinces appointed principally to raise taxes and other duties.

INTERCESSOR is also a term heretofore applied to such bishops as, during the vacancy of a see, administered the bishoprick till a successor to the deceased bishop had been elected. The third council of Carthage calls these *interueniours*.

INTERCOLUMNIATION, in architecture, denotes the space between two columns, which is always to be proportioned to the height and bulk of the columns.

INTERCOSTAL, in anatomy, an appellation given to such muscles, nerves, arteries, and veins, as lie between the ribs.

INTERDICT, an ecclesiastical censure, by which the church of Rome forbids the performance of divine service in a kingdom, province, town, &c. This censure has been frequently executed in France, Italy, and Germany; and in the year 1170, pope Alexander III. put all England under an interdict, forbidding the clergy to perform any part of divine service, except baptizing of infants, taking confessions, and giving absolution to dying penitents. But this censure being liable to the ill consequences of promoting libertinism and a neglect of religion, the succeeding popes have very seldom made use of it. There was also an interdict of persons, who were deprived of the benefit of attending on divine service. Particular persons were also anciently interdicted of fire and water, which signified a banishment for some particular offence: by their censure no person was allowed to receive them, or allow them fire or water; and being thus wholly deprived of the two necessary elements of life, they were doubtless under a kind of civil death.

INTEREST, is a sum reckoned for the loan or forbearance of another sum, or principal, lent for, or due at, a certain time, according to some certain rate or proportion; being estimated

usually at so much per cent. or by the 100. This forms a particular rule in Arithmetic. The highest legal interest now allowed in England, is after the rate of 5 per cent. per annum, or the 20th part of the principal for the space of a year, and so in proportion for other times, either greater or less. Except in the case of pawn-brokers, to whom it has lately been made legal to take a higher interest, for one of the worst and most destructive purposes that can be suffered in any state. Interest is either Simple or Compound.

Simple INTEREST, is that which is counted and allowed upon the principal only, for the whole time of forbearance. The sum of the Principal and Interest is called the Amount. As the interest of any sum, for any time, is directly proportional to the principal sum and time; therefore the interest of 1 pound for one year being multiplied by any proposed principal sum, and by the time of its forbearance, in years and parts, will be its Interest for that time. That is, if

- r = the rate of interest of $1l.$ per annum,
- p = any principal sum lent,
- t = the time it is lent for, and
- a = the amount, or sum of principal and interest;

then is prt = the interest of the sum p , for the time t , at the rate r ; and consequently $p + prt = p \times 1 + rt = a$, the amount of the same for that time. And from this general theorem, other theorems can easily be deduced for finding any of the quantities above mentioned; which collected all together, will be as follow:

1st, $a = p + prt$ the amount,

2d, $p = \frac{a}{1 + rt}$ the principal,

3d, $r = \frac{a - p}{pt}$ the rate,

4th, $t = \frac{a - p}{pr}$ the time.

For example, let it be required to find in what time any principal sum will double itself, at any rate of Simple Interest. In this case we must use the first theorem $a = p + prt$, in which the amount a must be $= 2p$ or double the principal, i. e.

$p + prt = 2p$; and hence $t = \frac{1}{r}$; where r being the interest of $1l.$ for one year, it follows that the time of doubling at Simple Interest, is equal to the quotient of any sum divided by its Interest for one year. So that, if the rate of Interest

be 5 per cent. then $\frac{100}{5} = 20$ is the time of doubling.

Or the 4th theorem immediately gives

$$t = \frac{a - p}{pr} = \frac{2p - p}{pr} = \frac{2 - 1}{r} = \frac{1}{r}$$

For more readily computing the interest on money, various Tables of numbers are calculated and formed; such as a Table of interest of $1l.$ for any number of years, and for any number of months, or weeks, or days, &c. and at various rates of Interest.

Another Table is the following, by which may be readily found the Interest of any sum of money, from 1 to a million of pounds, for any number of days, at any rate of Interest.

pound interest, viz. the ratio of the rate of interest, which is the amount of 1l. for 1 time of payment, and which here let be denoted by R, viz. $R = 1 + r$. Then, the particular amounts for the several times may be thus computed, viz. As 1 pound is to its amount for any time, so is any proposed principal sum to its amount for the same time; i. e.

- 1l. : R :: p : pR the 1st year's amount,
- 1l. : R :: pR : pR² the 2d year's amount,
- 1l. : R :: pR² : pR³ the 3d year's amount,
- and so on.

Therefore, in general, $pR^t = a$ is the amount for the t year, or t time of payment. From whence the following general theorems are deduced :

- 1st, $a = pR^t$ the amount,
- 2d, $p = \frac{a}{R^t}$ the principal,
- 3d, $R = \sqrt[t]{\frac{a}{p}}$ the ratio,
- 4th, $t = \frac{\log. \text{ of } a - \log. \text{ of } p}{\log. \text{ of } R}$ the time.

From which any one of the quantities may be found, when the rest are given.

For example, suppose it were required to find in how many years any principal sum will double itself, at any rate of interest. In this case we must employ the 4th theorem, where a will be = 2p, and then it

$$\text{is } t = \frac{\log. 2}{\log. R} = \frac{\log. 2p - \log. p}{\log. R} = \frac{\log. 2}{\log. R}$$

So, if the rate of interest be 5 per cent. per annum; then $R = 1 + .05 = 1.05$, and hence

$$t = \frac{\log. 2}{\log. 1.05} = \frac{.3010300}{.0211893} = 14.2067 \text{ nearly; that is, any}$$

sum doubles in $14\frac{1}{5}$ years nearly, at the rate of 5 per cent. per annum compound interest.

Hence, and from the like question in simple interest, above given, are deduced the times in which any sum doubles itself, at several rates of interest, both simple and compound: viz.

At	At Sim. Int. Years.	At Comp. Int. Years.
2	50	35.0028
2½	40	28.0701
3	33⅓	23.4498
3½	28⅔	20.1488
4	25	17.6730
4½	22⅔	15.7473
5	20	14.2067
6	16⅔	11.8957
7	14⅔	10.2448
8	12½	9.0065
9	11⅓	8.0432
10	10	7.2725

The following Table will facilitate the calculation of compound interest for any sum, and any number of years, at various rates of interest.

The Amount of 1l. in any Number of Years.

Yrs.	3	3½	4	4½	5	6
1	1.0300	1.0350	1.0400	1.0450	1.0500	1.0600
2	1.0609	1.0712	1.0816	1.0920	1.1025	1.1236
3	1.0927	1.1087	1.1249	1.1412	1.1576	1.1910
4	1.1255	1.1475	1.1699	1.1925	1.2155	1.2625
5	1.1593	1.1877	1.2167	1.2462	1.2763	1.3382
6	1.1941	1.2293	1.2653	1.3023	1.3401	1.4185
7	1.2299	1.2723	1.3159	1.3609	1.4071	1.5036
8	1.2668	1.3168	1.3686	1.4221	1.4775	1.5939
9	1.3048	1.3629	1.4233	1.4861	1.5513	1.6895
10	1.3439	1.4106	1.4802	1.5530	1.6289	1.7909
11	1.3842	1.4600	1.5395	1.6229	1.7103	1.8983
12	1.4258	1.5111	1.6010	1.6959	1.7959	2.0122
13	1.4685	1.5640	1.6651	1.7722	1.8856	2.1329
14	1.5126	1.6187	1.7317	1.8519	1.9799	2.2609
15	1.5580	1.6753	1.8009	1.9353	2.0789	2.3966
16	1.6047	1.7340	1.8730	2.0224	2.1829	2.5404
17	1.6528	1.7947	1.9479	2.1134	2.2920	2.6928
18	1.7024	1.8575	2.0258	2.2085	2.4066	2.8543
19	1.7535	1.9225	2.1068	2.3079	2.5270	3.0256
20	1.8061	1.9898	2.1911	2.4117	2.6533	3.2071

The use of this table, which contains all the powers R^t, to the 20th power, or the amounts of 1l. is chiefly to calculate the interest, or the amount, of any principal sum, for any time, not more than 20 years. For example, required to find to how much 523l. will amount in 13 years, at the rate of 5l. per cent. per annum compound interest.

In the table, on the line 15 and column 5 per cent. is the amount of 1l. viz. 2.0789, this multiplied by the principal

$$\begin{array}{r} 2.0789, \\ \times 523, \\ \hline \end{array}$$

gives the amount 1087.2647

or 1087l. 5s. 3¼d.

and therefore the interest is 564l. 5s. 3¼d.

See ANNUITIES; DISCOUNT; REVERSION; Smart's Tables of Interest; the Philos. Transf. vol. vi. p. 508; and ARITHMETIC.

INTERJECTION, in grammar, an indeclinable part of speech, signifying some passion or emotion of the mind. See GRAMMAR.

INTERIM, a name given to a formulary, or kind of confession of the articles of faith, obtruded upon the Protestants after Luther's death by the emperor Charles V. when he had defeated their forces; so called because it was only to take place in the interim (mean time) till a general council should have decided all points in dispute between the Protestants and Romanists. It retained most of the doctrines and ceremonies of the Romanists, excepting that of marriage, which was allowed to the clergy, and communion to the laity under both kinds. Most of the Protestants rejected it. There were two other interims; one of Leipsic, the other of Franconia.

INTERLOCUTORY Decree, in law. In a suit in equity, if any matter of fact be strongly controverted, the fact is usually directed to be tried at the bar of the court of king's bench, or at the assizes, upon a feigned issue. If a question of mere law arises in the course of a cause, it is the practice of the court of chancery to refer it to the opinion of the judges of the court of king's bench, upon a case stated for that purpose. In such cases interlocutory decrees or orders are made.

INTERLOCUTORY Judgments are such as are given in the middle of a cause, upon some plea, proceeding on default,

which is only intermediate, and does not finally determine or complete the suit. But the interlocutory judgments most usually spoken of, are those incomplete judgments, whereby the right of the plaintiff is established, but the *quantum* of damages sustained by him is not ascertained, which is the province of a jury. In such a case a writ of inquiry issues to the sheriff, who summons a jury, inquires of the damages, and returns to the court the inquisition so taken; whereupon the plaintiff's attorney taxes costs, and signs final judgment.

INTERLOCUTORY Order, that which decides not the cause, but only settles some intervening matter relating to the cause. As where an order is made in chancery, for the plaintiff to have an injunction, to quit possession till the hearing of the cause; this order, not being *final*, is called *interlocutory*.

INTERLOPERS, are properly those who, without due authority, hinder the trade of a company or corporation lawfully established, by dealing in the same way.

INTERLUDE, an entertainment exhibited on the theatre between the acts of a play, to amuse the spectators while the actors take breath and shift their dress, or to give time for changing the scenes and decorations. In the ancient tragedy, the chorus sang the interludes, to show the intervals between the acts. Interludes, among us, usually consist of songs, dances, feats of activity, concerts of music, &c. Aristotle and Horace give it for a rule, that the interludes should consist of songs built on the principal parts of the drama; but since the chorus has been laid down, dancers, buffoons, &c. ordinarily furnish the interludes.

INTERMENT, the act of interring, *i. e.* burying or laying a deceased person in the ground. Aristotle asserted, that it was more just to assist the dead than the living. Plato, in his Republic, does not forget, amongst other parts of justice, that which concerns the dead. Cicero establishes three kinds of justice: the first respects the gods, the second the manes or dead and the third men. These principles seem to be drawn from nature; and they appear at least to be necessary for the support of society, since at all times civilized nations have taken care to bury their dead, and to pay their last respects to them. See **BURIAL**.

We find in history several traces of the respect which the Indians, the Egyptians, and the Syrians entertained for the dead. The Syrians embalmed their bodies with myrrh, aloes, honey, salt, wax, bitumen, and resinous gums; they dried them also with the smoke of the fir and the pine tree. The Egyptians preserved theirs with the resin of the cedar, with aromatic spices, and with salt. These people often kept such mummies, or at least their effigies, in their houses; and at grand entertainments they were introduced, that by reciting the great actions of their ancestors they might be better excited to virtue. See **FUNERAL Rites**.

The Greeks, at first, had probably not the same veneration for the dead as the Egyptians. Empedocles, therefore, in the eighty-fourth Olympiad, restored to life Ponthia, a woman of Agrigentum, who was about to be interred. See *Diogenes Laertius de Vita et Moribus Philosophorum*, lib. 8. But this people, in proportion as they grew civilized, becoming more enlightened, perceived the necessity of establishing laws for the protection of the dead.

At Athens the law required that no person should be interred before the third day; and in the greater part of the cities of Greece a funeral did not take place till the sixth or seventh. When a man appeared to have breathed his last, his body was generally washed by his nearest relations, with warm water mixed with wine. They afterwards anointed it with oil; and covered it with a dress commonly made of fine linen, according to the custom of the Egyptians. This dress was white at Messina, Athens, and in the greater part of the

cities of Greece, where the dead body was crowned with flowers. At Sparta it was of a purple colour, and the body was surrounded with olive leaves. The body was afterwards laid upon a couch in the entry of the house, where it remained till the time of the funeral. At the magnificent obsequies with which Alexander honoured Hephæstion, the body was not burned until the tenth day.

The Romans, in the infancy of their empire, paid as little attention to their dead as the Greeks had done. Acilius Aviola having fallen into a lethargic fit, was supposed to be dead; he was therefore carried to the funeral pile; the fire was lighted up; and though he cried out he was still alive, he perished for want of speedy assistance. The Prætor Lania met with the same fate. Tubero, who had been Prætor, was saved from the funeral pile. Asclepiades a physician, who lived in the time of Pompey the Great, about one hundred and twenty years before the Christian æra, returning from his country-house, observed near the walls of Rome a grand convoy and a crowd of people, who were in mourning, assisting at a funeral, and showing every exterior sign of the deepest grief. Having asked what was the occasion of this intercourse, no one made any reply. He therefore approached the pretended dead body; and imagining that he perceived signs of life in it, he ordered the by-standers to take away the flambeaux, to extinguish the fire, and to pull down the funeral pile. A kind of murmur on this arose throughout the whole company. Some said that they ought to believe the physician, while others turned both him and his profession into ridicule. The relations, however, yielded at length to the remonstrances of Asclepiades; they consented to defer the obsequies for a little; and the consequence was, the restoration of the pretended dead person to life. It appears that these examples, and several others of the like nature, induced the Romans to delay funerals longer, and to enact laws to prevent precipitate interments.

At Rome, after allowing a sufficient time for mourning, the nearest relation generally closed the eyes of the deceased; and the body was bathed with warm water, either to render it fitter for being anointed with oil, or to reanimate the principle of life, which might remain suspended without manifesting itself. Proofs were afterwards made, to discover whether the person was really dead, which were often repeated during the time that the body remained exposed; for there were persons appointed to visit the dead, and to prove their situation. On the second day, after the body had been washed a second time, it was anointed with oil and balm. Luxury increased to such a pitch in the choice of foreign perfumes for this purpose, that under the consulship of Licinius Crassus and Julius Cæsar, the senate forbade any perfumes to be used except such as were the production of Italy. On the third day the body was clothed according to its dignity and condition. The robe called the prætesta was put upon magistrates, and a purple robe upon consuls: for conquerors, who had merited triumphal honours; this robe was of gold tissue. For other Romans it was white, and black for the lower classes of the people. These dresses were often prepared at a distance, by the mothers and wives of persons still in life. On the fourth day the body was placed on a couch, and exposed in the vestibule of the house, with the visage turned towards the entrance, and the feet near the door: in this situation it remained till the end of the week. Near the couch were lighted wax-tapers, a small box in which perfumes were burnt, and a vessel full of water for purification, with which those who approached the body besprinkled themselves. An old man, belonging to those who furnished every thing necessary for funerals, sat near the deceased, with some domestics clothed in black. On the eighth day the funeral rites were performed; but to prevent the body from corrupting before that time, salt, wax, the resinous gum of the cedar,

myrrh, honey, balm, gypsum, lime, asphalt, or bitumen of Judea, and several other substances, were employed. The body was carried to the pile with the face uncovered, unless wounds or the nature of the disease had rendered it loathsome and disgusting. In such a case a mask was used, made of a kind of plaster; which has given rise to the expression of *funera larvata*, used in some of the ancient authors. This was the last method of concealment which Nero made use of, after having caused Germanicus to be poisoned: for the effect of the poison had become very sensible by livid spots and the blackness of the body; but a shower of rain happening to fall, it washed the plaster entirely away, and thus the horrid crime of fratricide was discovered.

The Turks have, at all times, been accustomed to wash the bodies of their dead before interment; and as their ablutions are complete, and no part of the body escapes the attention of those who assist at such melancholy ceremonies, they can easily perceive whether one be really dead or alive, by examining, among other methods of proof, whether the *sphincter ani* has lost its power of contraction. If this muscle remains still contracted, they warm the body, and endeavour to recall it to life; otherwise, after having washed it with water and soap, they wipe it with linen cloths, wash it again with rose water and aromatic substances, cover it with a rich dress, put upon its head a cap ornamented with flowers, and extend it upon a carpet placed in the vestibule or hall at the entrance of the house.

In the primitive church the dead were washed and then anointed; the body was wrapped up in linen, or clothed in a dress of more or less value according to circumstances, and it was not interred until after being exposed and kept some days in the house. The custom of clothing the dead was usual in France only for princes and ecclesiastics.

In other countries, more or less care is taken to prevent sudden interments. At Geneva, there are people appointed to inspect all dead bodies. Their duty consists in examining whether the person be really dead, and whether one died naturally or by violence. In the north, as well as at Genoa, it is usual not to bury the dead till three days have expired. In Holland, people carry their precautions much farther, and delay the funerals longer. And in England bodies generally remain unburied three or four days.

Premature INTERMENT. Notwithstanding the customs above recited; still, in many places, and on many occasions in all places, too much precipitation attends this last office; or, if not precipitation, a neglect of due precautions in regard to the body. In general, indeed, the most improper treatment that can be imagined is adopted, and many a person made to descend into the grave before he has sighed his last breath. The histories related by Hildanus, by Camerarius, by Horstius, by Macrobius in his *Somnium Scipionis*, by Plato in his *Republic*, by Valerius Maximus, and by a great many modern authors, leave us no doubt respecting the dangers or misconduct of such precipitation. It must appear astonishing that the attention of mankind has been after all so little roused by an idea the most terrible that can be conceived on this side of eternity. According to present usage, as soon as the semblance of death appears, the chamber of the sick is deserted by friends, relatives, and physicians; and the apparently dead, though frequently living, body is committed to the management of an ignorant and unfeeling nurse, whose care extends no farther than laying the limbs straight, and securing her accustomed perquisites. The bed-clothes are immediately removed, and the body is exposed to the air. This, when cold, must extinguish any spark of life that may remain, and which, by a different treatment, might have been kindled into flame; or it may only continue to repress it, and the unhappy person afterwards revive amidst the horrors of the tomb.

The difference between the end of a weak life and the commencement of death, is so small, and the uncertainty of the signs of the latter is so well established both by ancient and modern authors who have turned their attention to that important object, that we can scarcely suppose undertakers capable of distinguishing an apparent from a real death. Animals which sleep during winter show no signs of life; in this case, circulation is only suspended: but, were it annihilated, the vital spirit does not so easily lose its action as the other fluids of the body; and the principle of life, which long survives the appearance of death, may re-animate a body in which the action of all the organs seems to be at an end. But how difficult is it to determine whether this principle may not be revived! It has been found impossible to recall to life some animals suffocated by mephitic vapours, though they appeared less affected than others who have revived. Coldness, heaviness of the body, a leaden livid colour, with a yellowness in the visage, are all very uncertain signs: Mr. Zimmerman observed them all upon the body of a criminal, who fainted through the dread of that punishment which he had merited. He was shaken, dragged about, and turned in the same manner as dead bodies are, without the least signs of resistance; and yet at the end of 24 hours he was recalled to life by means of volatile alkali.

A director of the coach-office at Dijon, named *Colinet*, was supposed to be dead, and the news of this event was spread throughout the whole city. One of his friends, who was desirous of seeing him at the moment when he was about to be buried, having looked at him for a considerable time, thought he perceived some remains of sensibility in the muscles of the face. He therefore made an attempt to bring him to life by spirituous liquors, in which he succeeded; and this director enjoyed afterwards for a long time that life which he owed to his friend. This remarkable circumstance was much like those of Empedocles and Asclepiades. These instances would perhaps be more frequent, were men of skill and abilities called in cases of sudden death, in which people of ordinary knowledge are often deceived by false appearances.

A man may fall into a syncope, and may remain in that condition three or even eight days. People in this situation have been known to come to life when deposited among the dead. A boy belonging to the hospital at Cassel appeared to have breathed his last: he was carried into the hall where the dead were exposed, and was wrapped up in a piece of canvas. Some time after, recovering from his lethargy, he recollected the place in which he had been deposited, and crawling towards the door knocked against it with his foot. This noise was luckily heard by the sentinel, who soon perceiving the motion of the canvas called for assistance. The youth was immediately conveyed to a warm bed, and soon perfectly recovered. Had his body been confined by close bandages or ligatures, he would not have been able, in all probability, to make himself heard: his unavailing efforts would have made him again fall into a syncope, and he would have been thus buried alive.

We must not be astonished that the servants of an hospital should take a syncope for a real death, since even the most enlightened people have fallen into errors of the same kind. Dr. John Schmid relates, that a young girl, seven years of age, after being afflicted for some weeks with a violent cough, was all of a sudden freed from this troublesome malady, and appeared to be in perfect health. But some days after, while playing with her companions, this child fell down in an instant as if struck by lightning. A death-like paleness was diffused over her face and arms; she had no apparent pulse, her temples were sunk, and she showed no signs of sensation when shaken or pinched. A physician, who was called, and who believed her to be dead, in compliance with the repeated and press-

ing request of her parents, attempted, though without any hopes, to recall her to life; and at length, after several vain efforts, he made the soles of her feet be smartly rubbed with a brush dipped in strong pickle. At the end of three quarters of an hour she was observed to sigh; she was then made to swallow some spirituous liquor; and she was soon after restored to life, much to the joy of her disconsolate parents.—A certain man having undertaken a journey, in order to see his brother, on his arrival at his house found him dead. This news affected him so much, that it brought on a most dreadful syncope, and he himself was supposed to be in the like situation. After the usual means had been employed to recall him to life, it was agreed that his body should be dissected, to discover the cause of so sudden a death; but the supposed dead person overhearing this proposal opened his eyes, started up, and immediately betook himself to his heels.—Cardinal Elpinola, prime minister to Philip II. was not so fortunate; for we read in the *Memoirs of Amelot de la Houssai*, that he put his hand to the knife with which he was opened in order to be embalmed. In short, almost every one knows that Vesalius, the father of anatomy, having been sent for to open a woman subject to hysterics, who was supposed to be dead, he perceived, on making the first incision, by her motion and cries, that she was still alive; that this circumstance rendered him so odious, that he was obliged to fly; and that he was so much affected by it, that he died soon after.—On this occasion, we cannot forbear to add an event more recent, but no less melancholy. The Abbé Prevost, so well known by his writings and the singularities of his life, was seized with a fit of the apoplexy, in the forest of Chantilly, on the 23d of October 1763. His body was carried to the nearest village, and the officers of justice were proceeding to open it, when a cry which he sent forth affrightened all the assistants, and convinced the surgeon that the Abbé was not dead; but it was too late to save him, as he had already received the mortal wound.

Even in old age, when life seems to have been gradually drawing to a close, the appearances of death are often fallacious. The following instance is recorded in the *London Chronicle*, vol. iv. p. 456. A lady in Cornwall, more than 80 years of age, who had been a considerable time declining, took to her bed, and in a few days seemingly expired in the morning. As she had often desired not to be buried till she had been two days dead, her request was to have been regularly complied with by her relations. All that saw her looked upon her as dead, and the report was current through the whole place; nay, a gentleman of the town actually wrote to his friend in the island of Scilly that she was deceased. But one of those who were paying the last kind office of humanity to her remains, perceived some warmth about the middle of the back; and acquainting her friends with it, they applied a mirror to her mouth, but, after repeated trials, could not observe it in the least stained; her under jaw was likewise fallen, as the common phrase is; and, in short, she had every appearance of a dead person. All this time she had not been stripped or dressed; but the windows were opened, as is usual in the chambers of the deceased. In the evening the heat seemed to increase, and at length she was perceived to breathe.

In short, not only the ordinary signs are very uncertain, but we may say the same of the stiffness of the limbs, which may be convulsive; of the dilatation of the pupil of the eye, which may proceed from the same cause; of putrefaction, which may equally attack some parts of a living body; and of several others. Haller, convinced of the uncertainty of all these signs, proposes a new one, which he considers as infallible. “If the person (says he) be still in life, the mouth will immediately shut of itself, because the contraction of the muscles of the jaw will awaken their irritability.” The jaw, however, may

be deprived of its irritability though a man may not be dead. Life is preserved a long time in the passage of the intestines. The sign pointed out by Dr. Fothergill appears to deserve more attention. “If the air blown into the mouth (says this physician) passes freely through all the alimentary channels, it affords a strong presumption that the irritability of the internal sphincters is destroyed, and consequently that life is at an end.” These signs, which deserve to be confirmed by new experiments, are doubtless not known to undertakers.

The difficulty of distinguishing a person apparently dead from one who is really so, has, in all countries where bodies have been interred too precipitately, rendered it necessary for the law to assist humanity. Of several regulations made on this subject, we shall quote only a few of the most recent; such as those of Arras in 1772; of Mantua in 1774; of the Grand Duke of Tuscany in 1775; of the Senechaussée of Sivrai, in Poitou, in 1777; and of the Parliament of Metz in the same year. To give an idea of the rest, it will be sufficient to relate only that of Tuscany. By this edict, the Grand Duke forbids the precipitate interment of persons who die suddenly. He orders the Magistrates of Health to be informed, that physicians and surgeons may examine the body; that they may use every endeavour to recall it to life, if possible, or to discover the cause of its death; and that they shall make a report of their procedure to a certain tribunal. On this occasion, the Magistrate of Health orders the dead not to be covered until the moment they are about to be buried, except so far as decency requires; observing always that the body be not closely confined, and that nothing may compress the jugular veins and the carotid arteries. He forbids people to be interred according to the ancient method; and requires that the arms and the hands should be left extended, and that they should not be folded or placed cross-wise upon the breast. He forbids, above all, to press the jaws one against the other; or to fill the mouth and nostrils with cotton, or other stuffing. Lastly, he recommends not to cover the visage with any kind of cloth until the body is deposited in its coffin.

We shall conclude this article by subjoining, from the publications of the Humane Society in London, a few of the cases in which this fallacious appearance of death is most likely to happen, together with the respective modes of treatment which he recommends.

In apoplexie and fainting fits, and in those arising from any violent agitation of mind, and also when opium or spirituous liquors have been taken in too great a quantity, there is reason to believe that the appearance of death has been frequently mistaken for the reality. In these cases, the means recommended by the Society should be persevered in for several hours; and bleeding, which in similar circumstances has sometimes proved pernicious, should be used with great caution. See the article *DROWNING*. In the two latter instances it will be highly expedient, with a view of counteracting the soporific effects of opium and spirits, to convey into the stomach, by a proper tube, a solution of tartar emetic, and by various other means to excite vomiting.

From the number of children carried off by convulsions, and the certainty arising from undoubted facts, that some who have in appearance died from that cause have been recovered; there is the greatest reason for concluding, that many, in consequence of this disease, have been prematurely numbered among the dead; and that the fond parent, by neglecting the means of recalling life, has often been the guiltless executioner of her own offspring. To prevent the commission of such dreadful mistakes, no child, whose life has been apparently extinguished by convulsions, should be consigned to the grave till the means of recovery above recommended in apoplexies, &c. have been tried; and, if possible, under the direction of some skilful prac-

Theor. 3. When the terms $a, b, c, d, \&c.$ are at unequal distances from each other; to find any intermediate one of these terms, the rest being given.

Let $p, q, r, s, \&c.$ be the several distances of those terms from each other; then let

$$B = \frac{b-a}{p}, C = \frac{B_1-B}{p+q}, D = \frac{C_1-C}{p+q+r}, E = \frac{D_1-D}{p+q+r+s}$$

$$B_1 = \frac{c-b}{q}, C_1 = \frac{B_2-B_1}{q+r}, D_1 = \frac{C_2-C_1}{q+r+s}$$

$$B_2 = \frac{d-c}{r}, C_2 = \frac{B_3-B_2}{r+s}$$

$$B_3 = \frac{e-d}{s}$$

&c. &c. &c.

Then the term x , whose distance from the beginning is x , will be

$$x = a + Bx + \frac{Cx \cdot x - p + Dx \cdot x - p \cdot x - p - q}{+ Ex \cdot x - p \cdot x - p - q \cdot x - p - q - r + \&c};$$

to be continued to as many terms as there are terms in the given series. By this series may be found the place of a comet, or the sun, or any other object at a given time; by knowing the places of the same for several other given times. Other methods of interpolation may be found in the *Philos. Trans.* number 362; or Stirling's Summation and Interpolation of Series.

INTERPOSITION, the situation of a body between two others, so as to hide them, or prevent their action. The eclipse of the sun is occasioned by an interposition of the moon between the sun and us; and that of the moon by the interposition of the earth between the sun and moon. See **ECLIPSE**.

INTERPRETER, a person who explains the thoughts, words, or writings, of some other, which before were unintelligible. The word *interpretes*, according to Isidore, is composed of the preposition *inter*, and *partes*, as signifying a person in the middle betwixt two parties, to make them mutually understand each others thoughts: others derive it from *inter*, and *præs*, i. e. *fidejussor*; q. d. a person who serves as security between two others who do not understand one another. There have been great debates about interpreting Scripture. The Romanists contend, that it belongs absolutely to the church; adding, that where she is silent, reason may be consulted; but where she speaks, reason is to be disregarded. The Protestants generally allow Reason the sovereign judge, or interpreter; though some among them have a strong regard to synods, and others to the authority of the primitive fathers. Lastly, others have recourse to the spirit within every person to interpret for them; which is what Bochart calls *ἀποδείξις τῆς πνευμαλῆος*.

INTERREGNUM, the time during which the throne is vacant in elective kingdoms; for in such as are hereditary, like ours, there is no such thing as an interregnum.

INTERREX, the magistrate who governs during an interregnum. This magistrate was established in old Rome, and was almost as ancient as the city itself: after the death of Romulus there was an interregnum of a year, during which the senators were each interrex in their turn, five days a-piece. After the establishment of consuls and a commonwealth, though there were no kings, yet the name and function of *interrex* was still preserved: for, when the magistrates were absent, or there was any irregularity in their election, or they had abdicated, so that the comitia could not be held; provided they were unwilling to create a dictator, they made an interrex, whose office and authority was to last five days; after which they made another. To the interrex was delegated all the regal and consular authority, and he performed all their func-

tions. He assembled the senate, held comitia or courts, and took care that the election of magistrates was according to rules. Indeed at first it was not the custom of the interrex to hold comitia, at least we have no instance of it in the Roman history. The patricians alone had the right of electing an interrex; but this office fell with the republic, when the emperors made themselves masters of every thing.

INTERROGATION, **EROTESIS**, a figure of rhetoric, in which the passion of the speaker introduces a thing by way of question, to make its truth more conspicuous. The interrogation is a kind of apostrophe which the speaker makes to himself; and it must be owned, that this figure is suited to express most passions and emotions of the mind; it serves also to press and bear down an adversary, and generally adds an uncommon briskness, action, force, and variety, to discourse.

INTERROGATION, in grammar, is a point which serves to distinguish such parts of a discourse where the author speaks as if he were asking questions. Its form is this (?).

INTERROGATORIES, in law, are particular questions demanded of witnesses brought in to be examined in a cause, especially in the court of chancery. And these interrogatories must be exhibited by the parties in suit on each side; which are either direct for the party that produces them, or counter, on behalf of the adverse party; and generally both plaintiff and defendant may exhibit direct, and counter, or cross interrogatories. They are to be pertinent, and only to the points necessary; and either drawn or perused by counsel, and to be signed by them.

INTERSCENDENT, in Algebra, is applied to quantities, when the exponents of their powers are radical quantities.

Thus $x^{\sqrt{2}}$, $x^{\sqrt{a}}$, &c. are interscendent qualities. See **FUNCTION**.

INTERSECTION, in mathematics, the cutting of one line, or plane, by another; or the point or line wherein two lines, or two planes, cut each other. The mutual intersection of two planes is a right line. The centre of a circle is in the intersection of two diameters. The central point of a regular or irregular figure of four sides, is the point of intersection of the two diagonals. The equinoxes happen when the sun is in the intersections of the equator and ecliptic.

INTERSPINALES. See **ANATOMY**, *Table of the Muscles*.

INTERSTELLAR, a word used by some authors to express those parts of the universe that are without and beyond the limits of our solar system. In the Interstellar regions, it is supposed there are several other systems of planets moving round the fixed stars, as the centres of their respective motions. And if it be true, as it is not improbable, that each fixed star is thus a sun to some habitable orbs, or earths, that move round it, the Interstellar world will be infinitely the greatest part of the universe.

INTERVAL, the distance or space between two extremes, either in time or place. The word comes from the Latin *intervallum*, which, according to Isidore, signifies the space *inter fossam & murum*, "between the ditch and the wall;" others note, that the stakes or piles, driven into the ground in the ancient Roman bulwarks, were called *valla*; and the interstices or vacancy between them *intervalla*.

INTERVAL, in music. The distance between any given sound and another, strictly speaking, is neither measured by any common standard of extension or duration; but either by immediate sensation, or by computing the difference between the numbers of vibrations produced by two or more sonorous bodies, in the act of sounding, during the same given time. As the vibrations are slower and fewer during the same instant, for example, the sound is proportionally lower or

graver; on the contrary, as during the same period the vibrations increase in number and velocity, the sounds are proportionably higher or more acute. An interval in music, therefore, is properly the difference between the number of vibrations produced by one sonorous body of a certain magnitude and texture, and of those produced by another of a different magnitude and texture in the same time.

Intervals are divided into consonant and dissonant. A consonant interval is that whose extremes, or whose highest and lowest sounds, when simultaneously heard, coalesce in the ear, and produce an agreeable sensation called by Lord Kames a *tertium quid*. A dissonant interval, on the contrary, is that whose extremes, simultaneously heard, far from coalescing in the ear, and producing one agreeable sensation, are each of them plainly distinguished from the other, produce a grating effect upon the sense, and repel each other with an irreconcilable hostility. In proportion as the vibrations of different sonorous bodies, or of the same sonorous body in different modes, more or less frequently coincide during the same given time, the chords are more or less perfect, and consequently the intervals more or less consonant. When these vibrations never coincide at all in the same given time, the discord is consummate, and consequently the interval absolutely dissonant.

Intervals are not only divided according to their natures, but also with respect to their degrees. In this view, they are either enharmonic, chromatic, or diatonic. Of these therefore in their order, from the least to the greatest.

An enharmonic interval is what they call the *eighth part of a tone*, or the difference between a major and minor semitone generally distinguished by the name of a *comma*. Commas, however, are of three different kinds, as their quantities are more or less; but since these differences cannot be ascertained without long and intricate computations, it is not necessary for us to attempt an investigation, whose pursuit is so unpleasant, and whose result attended with so little utility. It has by musicians been generally called the *eighth part of a tone*; but they ought to have considered, that a comma is by no means the object of auricular perception, and that its estimate can only be formed by calculation. For a more minute disquisition of this matter, our readers may consult the article *COMMA* in the *Musical Dictionary*, or as mentioned in the article *MUSIC* in this *Work*. A chromatic interval consists properly of a minor semitone, but may also admit the major. A diatonic interval consists of a semitone-major at least, but may consist of any number of tones within the octave. When an octave higher or lower is assumed, it is obvious that we enter into another scale which is either higher or lower, but still a repetition of the former degrees of sound.

Intervals again are either simple or compound. All the intervals within any one octave are simple; such as the second major or minor, the third, the fourth, the fifth, the sixth, the seventh, &c. Of these afterwards. All intervals whose extremes are contained in different octaves, such as the ninth, the tenth, the eleventh, the twelfth, the thirteenth, the fourteenth, the fifteenth, &c. may be termed *compound intervals*.

The semitone either exactly or nearly divides the tone into two equal parts. In the theory of harmonical computation three kinds of semitones are recognised, viz. the greatest, the intermediate, and the smallest semitone. But in practice, to which these explications are chiefly adapted, the semitone is only distinguished into major and minor. The semitone major is the difference between the third major and the fourth, as E F. Its ratio is as 15 to 16, and it forms the least of all diatonic intervals.

The semitone minor consists of the difference between the third major and minor: it may be marked in the same degree

by a sharp or a flat, and it only forms a chromatic interval; its ratio is as 24 to 25.

Though some distinction is made between these semitones by the manner of marking them, yet on the organ and harpsichord no distinction can be made; nor is there any thing more common for us than to say, that D sharp in rising is E flat in descending, and so through the whole diapason above or below: besides, the semitone is sometimes major and sometimes minor, sometimes diatonic and sometimes chromatic, according to the different modes in which we compose or practise; yet in practice those are called *semitones minor*, which are marked by sharps or flats, without changing the degree; and semitones major are those which form the interval of a second.

With respect to the three semitones recognised in theory, the greatest semitone is the difference between a tone major and a semitone minor; and its ratio is as 25 to 27. The intermediate semitone is the difference between a semitone major and a tone major; and its ratio is as 128 to 135. In a word, the small semitone consists of the difference between the greatest and the intermediate semitone; and its ratio is as 125 to 128.

Of all these intervals, there is only the semitone major, which is sometimes admitted as a second in harmony.

The interval of a tone, which characterises the diatonic species of composition, is either major or minor. The former consists of the difference between the fourth and fifth; and its ratio is as 8 to 9: and the latter, whose ratio is as 9 to 10, results from the difference between the third minor and the fourth.

Seconds are distinguished into four kinds; two of which are not in practice sufficiently momentous to be mentioned. The second major is synonymous with the intervals of a tone; but as that tone may be either major or minor, its ratio may be either as 8 to 9, or as 9 to 10.

The second minor consists of the distance from B to C, or from E F; and its ratio is as 15 to 16.

The third is so called, because it consists of 2 gradations, or 3 diatonic sounds, as from G to B ascending, or from A to C, inclusive of the extremes; of which the first is a third major, composed of two full tones, and its ratio as 4 to 5; the second, a third minor, consisting of a tone and a semitone major, and its ratio as 5 to 6.

The fourth has by some been reckoned an imperfect, but more justly by others a perfect, chord. It consists of three diatonic degrees, but takes its name from the four different sounds of which it is formed; or, in other words, the number by which it is denominated includes the extremes. It is composed of a tone major, a tone minor, and a semitone major, as from C to F ascending; its ratio as 3 to 4.

The fifth next to the octave is, perhaps, the most perfect interval, as least susceptible of alteration. The number from whence it assumes its name likewise includes its extremes. It consists of two tones major, one minor, and a semitone major, as from A to E ascending; its ratio is as 2 to 3.

The sixth is not found among the natural order of consonances, but only admitted by combination. It is not here necessary to mention its various distinctions and uses, as we only give an account of intervals in general.

The sixth major consists of four tones, and a semitone major; as from G to E ascending; its ratio is as 3 to 5. The sixth minor contains three tones and two semitones major, as from E to C ascending; its ratio is as 5 to 8.

The seventh, as a reduplication of the second, is a dissonance. When major, it consists diatonically of five tones, three major, and two minor; and a major semitone, as from C to B ascending; its ratio is as 8 to 15.

When minor, it consists of four tones, three major and one minor, and two major semitones, as from E to D ascending; its ratio is as 5 to 9.

The octave is the most perfect of all chords, and in many cases hardly to be distinguished by the ear from an unison; that is to say, from that coincidence of sound produced by two musical strings, whose matter, lengths, diameters, and tensions, are the same. As the vibrations of two strings in unison during any given time are precisely coincident; so, whilst the lowest extreme of the octave vibrates once, the highest vibrates twice; and consequently its ratio is as 1 to 2, as from c to C ascending. It consists of six full tones and two semitones major. Its name is derived from the Latin *octo*, "eight;" because that number likewise includes its extremes. It may likewise be divided into twelve semitones. It contains the whole diatonic scale; and every series above or below consists only of the same returning sounds. From whence the natures, distances and powers, of every interval greater than the octave, as the ninth, the tenth, the eleventh, the twelfth, the thirteenth, the fourteenth, the fifteenth, the triple octave, &c. may easily be computed.

During our past observations upon the term *interval*, we have either wholly neglected our faithful associate M. Rousseau, or only maintained a distant and momentary intercourse with him. We now purpose to pay him a more permanent and familiar visit; but as he is engaged in the dispute between the Pythagoreans and Aristoxenians, we think it more advantageous to decline the controversy, and to follow him, after having escaped the fray, like a gentleman and a scholar. Having put the partisans of Aristoxenus to silence, let us, with him, forsake the lists of combat, nor stain his triumph by insulting the falling champions.

"We divide (says he), as did the ancients, intervals into consonant and dissonant. The consonances are perfect or imperfect (see CONSONANCE); dissonances are either such by nature, or become such by accident. There are only two intervals naturally dissonant, viz. the second and seventh, including their octaves or replications; nay, still these two may be reduced to one alone, as the seventh is properly no more than a replication of the second; for B, the seventh above the lowest C, where we have generally begun the scale, is really an octave above B, the note immediately below that C; and consequently the interval between these lower sounds is no more than that of a second major, to which all dissonances may therefore be ultimately reduced, whether considered as major or minor; but even all the consonances may become dissonant by accident. See DISCORD.

"Besides, every interval is either simple or reduplicated. Simple intervals are such as the limits of a single octave comprehend. Every interval which surpasses this extent is reduplicated; that is to say, compounded of one or more octaves, and of the simple interval whose replication it is

"Simple intervals are likewise divided into direct and inverted. Take any simple interval whatever for a direct one; the quantity which, added to itself, is required to complete the octave, will be found an inverted interval; and the same observation holds reciprocally true of such as are inverted.

"There are only six kinds of simple intervals; of which three contain such quantities, as, added to the other three, are required to complete the octave: and of consequence likewise the one must be inversions of the other. If you take at first the smallest intervals, you will have, in the order of direct intervals, the second, the third, and fourth; for inverted, the seventh, the sixth, and fifth. Suppose these to be direct, the others will be inverted; every thing here is reciprocal.

"To find the name of any interval whatever, it is only necessary to add the denomination of unity to the degree which it contains. Thus, the interval of one degree shall give a second; of two, a third; of three, a fourth; of seven, an octave; of nine, a tenth, &c. But this is not sufficient to determine an interval with accuracy; for under the same name it may be either major or minor, true or false, diminished or redundant

"The consonances which are imperfect, and the two natural dissonances, may be major or minor; which, without changing their degree, occasions in the interval the difference of a semitone; so that if, from a minor interval, we still deduce a semitone, it becomes an interval diminished; if, by a semitone, we increase a major interval, it becomes an interval redundant.

"The perfect consonances are by their nature invariable. When their intervals are such as they ought to be, we call them *just, true*: and if we dilate or contract this interval by a semitone, the consonance is termed *false*, and becomes a dissonance; *redundant*, if the semitone be added; *diminished*, if it be abstracted. We improperly give the name of a *false fifth* to the fifth diminished; this is taking the genus for the species: the fifth redundant is every jot as false as the diminished, it is even more so in every respect."

In the Musical Dictionary, plate C, fig. 2, may be seen a table of all the simple intervals practicable in music, with their names, their degrees, their values, and their ratios.

Having ascertained the distinction between major and minor intervals, it is only necessary to add; that these may be natural or artificial. Of the natural we have already given some account, by ascertaining the distances and ratios of such as have been mentioned. Of the artificial we may observe, that they are such as change their position from what it naturally is in the diatonic scale, to what the conveniency of composition or transposition requires it to be. A note thus artificially heightened by a semitone, together with the character which expresses that elevation, is called a *sharp*; on the contrary, a note artificially depressed by a semitone, together with the character by which that depression is signified, is called a *flat*. The character which restores a note thus depressed or raised to its primary state, is called a *natural*. Major or minor intervals, as they prevail, characterise the major or minor mode. See MODE.

INTESTATE, in law, a person who dies without making a will.

An heir *ab intestato*, is a person who inherits an estate by some other right than that of will or testament.

Heretofore, those who died *intestate* were held infamous, and accursed; in regard, by the canons of several councils, every person was enjoined to bequeath a part of his estate (and Matthew Paris says it was at least to be a tenth part) to the church, for the safety of his soul; which a person who neglected to make a will, and to leave this legacy to the church, was judged to have abandoned. Several councils took on them to command the priests to solicit dying persons to be charitable to the church; and this they did so earnestly, that absolution and the viaticum were denied to those whom they could not prevail on; so that they made no difference between these *intestates* and self-murderers; and they were alike denied Christian burial. Du Cange adds, that all who died without absolution, without receiving the viaticum, and without leaving alms to the church (even though they died suddenly), had their effects seized, and confiscated to the use of the church, bishop, &c.

In the English law there are two kinds of *intestates*: the one *de facto*, which are those who make no will at all; the other *de jure*, called also *quasi intestati*, which are those who make a will, but such an one as is null and void, either from the executors refusing to act, or from some other cause: in which case they are judged to die as *intestate, quasi-intestati*.

And the 22 and 23 Car. II. c. 10. commonly called the statute of distribution, appoints a distribution of *intestates'* estates, after debts and funeral expences are paid, among the wife and children of the deceased; or, for want of such, among the next of kin, &c. and the act of parliament doth, immediately upon the death of the *intestate*, vest an interest in the persons entitled; so that if any one dies before the distribution, though within

the year, his share shall go to his executors and administrators; and not to the survivors or next of kin to the *intestate*. 1. Lill. Abr. 487. The brothers and sisters of the *intestate* shall have equal shares with the mother. 1 Jac. II. c. 17. By the same statute it is enacted, that one third part of the surplusage of the estate of any person dying *intestate*, shall be distributed to his wife, and the residue amongst his children by equal portions, or among such persons as legally represent his children, in case any of them be then dead, excepting such child or children (not being heir at law) who shall have any estate by the settlement of the *intestate*, or shall be advanced by the *intestate* in his lifetime, by portion or portions equal to the share which shall by such distribution be allotted to the other children; and in case their portions have not been equal, they shall be made so as nearly as possible out of the said surplusage. But the heir at law is to have an equal part in the distribution with the rest of the children, without any consideration of the value of the land which he hath by descent or otherwise from the *intestate*. In case there be no children or legal representatives, one moiety of the said estate shall be allotted to the wife of the *intestate*, and the residue distributed equally to every of the next kindred of the *intestate*, who are in equal degree, and those who legally represent them; provided that there be no representations admitted among collaterals, after brothers and sisters children: and if there be no wife, the said estate shall be wholly distributed in equal shares among the children; or, if there be no child, to the next of kindred in equal degree, and their legal representatives. But no such distribution of the goods of an *intestate* should be made till after one year be fully expired after his death; and those to whom distribution is made are required to give bonds, with sufficient sureties, to refund in case of debts.

INTESTINE Motion of the parts of fluids, that which is among its corpuscles or component parts. When the attracting corpuscles of any fluid are elastic, they must necessarily produce an intestine motion; and that, greater or less, according to the degrees of their elasticity and attractive force. For, two elastic particles, after meeting, will fly from each other with the same degree of velocity with which they met; abstracting from the resistance of the medium. But when, in leaping back from each other, they approach other particles, their velocity will be increased.

A most important discovery has been made by Count Rumford, relative to the intestine motion produced in fluids, according as their particles become specifically heavier or lighter by the acquisition or deprivation of heat. See an account of this discovery under the article **PROPAGATION of Heat**.

INTESTINA, in the *Linnean System*, an order of worms. See **ZOOLOGY**.

INTESTINES, INTESTINA, in *anatomy*, the guts or bowels; those hollow, membranous, cylindrical parts, extended from the right orifice of the stomach to the anus; by which the chyle is conveyed to the lacteals, and the excrements are voided. See **ANATOMY**.

INTONATION, in music, the action of sounding the notes in the scale with the voice, or any other given order of musical tones. Intonation may be either true or false, either too high or too low, either too sharp or too flat; and then this word *intonation*, attended with an epithet, must be understood concerning the manner of performing the notes.

In executing an air, to form the sounds, and preserve the intervals as they are marked with justness and accuracy, is no inconsiderable difficulty, and scarcely practicable, but by the assistance of one common idea, to which, as to their ultimate test, these sounds and intervals must be referred: these common ideas are those of the key, and the mode in which the performer is engaged; and from the word *tone*, which is sometimes used in a sense almost identical with that of the key, the word *into-*

nation may perhaps be derived. It may also be deduced from the word *diatonic*, as in that scale it is most frequently convenient; a scale which appears most convenient and most natural to the voice. We feel more difficulty in our intonation of such intervals as are greater or lesser than those of the diatonic order; because, in the first case, the glottis and vocal organs are modified by gradations too large; or too complex, in the second.

INTRADOS, the interior and lower side, or curve, of the arch of a bridge, &c. In contradistinction from the *extrados*, or exterior curve, or line on the upper side of the arch. See **ARCHITECTURE**.

INTRENCHMENT, in the military art, any work that fortifies a post against an enemy who attacks. It is generally taken for a ditch or trench with a parapet. Intrenchments are sometimes made of fascines with earth thrown over them, of gabions, hogsheds, or bags filled with earth, to cover the men from the enemy's fire.

INTRIGUE, an assemblage of events or circumstances, occurring in an affair, and perplexing the persons concerned in it. In this sense, it is used to signify the nodus or plot of a play or romance; or that point wherein the principal characters are most embarrassed through the artifice and opposition of certain persons, or the unfortunate falling out of certain accidents and circumstances.

In tragedy, comedy, or an epic poem, there are always two designs. The first and principal is that of the hero of the piece: the second contains the designs of all those who oppose him. These opposite causes produce opposite effects, to wit, the efforts of the hero for the execution of his design, and the efforts of those who thwart it. As those causes and designs are the beginning of the action, so these efforts are the middle, and there form a knot or difficulty which we call the *intrigue*, that makes the greatest part of the poem. It lasts as long as the mind of the reader or hearer is suspended about the event of those opposite efforts: the solution or catastrophe commences when the knot begins to unravel, and the difficulties and doubts begin to clear up.

The intrigue of the *Iliad* is two-fold. The first comprehends three days fighting in Achilles's absence, and consists on the one side in the resistance of Agamemnon and the Greeks, and on the other in the inexorable temper of Achilles. The death of Patroclus unravels this intrigue, and makes the beginning of a second. Achilles resolves to be revenged, but Hector opposes his design; and this forms the second intrigue, which is the last day's battle. In the *Æneid* there are also two intrigues. The first is taken up in the voyage and landing of Æneas in Italy; the second is his establishment there: the opposition he met with from Juno in both these undertakings, forms the intrigue.

As to the choice of the intrigue, and the manner of unravelling it, it is certain they ought both to spring naturally from the ground and subject of the poem. Bossu gives us three manners of forming the intrigue of a poem: the first is that already mentioned; and the second is taken from the fable and design of the poet; in the third the intrigue is so laid, as that the solution follows from it of course.

INTRINSIC, a term applied to the real and genuine values and properties, &c. of any thing, in opposition to their *extrinsic* or *apparent* values.

INTRODUCTION, in general, signifies any thing which tends to make another in some measure known before we have leisure to examine it thoroughly; and hence it is used on a great variety of occasions. Thus we speak of the introduction of one person to another; the introduction to a book, &c.— It is also used to signify the actual motion of any body out of one place into another, when that motion has been occasioned by some other body.

INTRODUCTION, in oratory. See **ORATORY**.

INTUITION, among logicians, the act whereby the mind perceives the agreement or disagreement of two ideas, immediately by themselves, without the intervention of any other; in which case the mind perceives the truth as the eye does the light only by being directed towards it. See **LOGIC**.

INTUITIVE EVIDENCE, is that which results from **INTUITION**. Dr. Campbell distinguishes different sorts of *intuitive* evidence; one resulting purely from intellection, or that faculty which others have called intuition; another kind arising from consciousness; and a third sort from that now-named faculty *Common Sense*, which this ingenious writer, as well as several others, contends to be a distinct original source of knowledge, whilst others refer its supposed office to the *intuitive* power of the understanding.

INVALID, a person wounded, maimed, or disabled for action by age. At Chelsea and Greenwich are magnificent **HOSPITALS** or colleges, built for the reception and accommodation of *invalids*, or soldiers and seamen worn out in the service. We have also twenty independent companies of invalids, dispersed in the several forts and garrisons. At Paris is a college of the same kind, called *les Invalides*, which is accounted one of the finest buildings in that city.

INVECTED, in heraldry, denotes a thing fluted or furrowed. See **HERALDRY**.

INVECTIVE, in rhetoric, differs from reproof, as the latter proceeds from a friend, and is intended for the good of the person reproofed; whereas the invective is the work of an enemy, and entirely designed to vex and give uneasiness to the person against whom it is directed.

INVEGES (**AUGUSTIN**), a learned Sicilian Jesuit, wrote in Italian an History of the city of Palermo, and other works, which are esteemed. He died in 1677, aged 82.

INVENTION, denotes the act of finding any thing new, or even the thing thus found. Thus we say, *the invention of gunpowder, of printing, &c.* The alcove is a modern invention owing to the Moors. The Doric, Ionic, and Corinthian orders are of Greek invention; the Tuscan and Composite of Latin invention. Janson ab Almelooven has written an Onomasticon of inventions; wherein are shown, in an alphabetical order, the names of the inventors, and the time, place, &c. where they are made. Panciroillus has a treatise of old inventions that are lost, and new ones that have been made; Polydore Virgil has also published eight books of the inventors of things. *De Inventoribus Rerum*.

INVENTION is also used for the finding of a thing hidden. The Romish church celebrates a feast on the 4th of May, under the title of *Invention of the Holy Cross*.

INVENTION is also used for subtilty of mind, or somewhat peculiar to a man's genius, which leads him to a discovery of things new; in which sense we say, *a man of invention*.

INVENTION, in painting, is the choice which the painter makes of the objects that are to enter the composition of his piece. See **PAINTING**.

INVENTION, in poetry, is applied to whatever the poet adds to the history of the subject he has chosen; as well as to the new turn he gives it. See **POETRY**.

INVENTION, in rhetoric, signifies the finding out and choosing of certain arguments which the orator is to use for the proving or illustrating his point, moving their passions, or conciliating the minds of his hearers. Invention, according to Cicero, is the principal part of oratory: he wrote four books *De Inventione*, whereof we have but two remaining. See **ORATORY**.

INVENTORY, in law, a catalogue or schedule, orderly made, of all a deceased person's goods and chattels, at the time of his death, with their value appraised by indifferent persons, which every executor or administrator is obliged to exhibit to the ordinary at such time as he shall appoint. By 21 Hen. VIII.

c. 5, executors and administrators are to deliver in upon oath to the ordinary, indented inventories, one part of which is to remain with the ordinary, and the other part with the executor or administrator; this is required for the benefit of the creditors and legatees, that the executor or administrator may not conceal any part of the personal estate from them. The statute ordains that the inventory shall be exhibited within three months after the person's decease; yet it may be done afterwards, for the ordinary may dispense with the time, and even with its being ever exhibited, as in cases where the creditors are paid, and the will is executed.

INVERARY, a royal borough of Scotland, in Argyleshire, seated on the N. W. side of Loch Fyne. In the neighbourhood of this place is a considerable iron work. It is 75 miles N.W. of Edinburgh, and 45 N.W. of Glasgow. W. lon. 5. o. N. lat. 56. 16.

INVERBERVIE, or **BERVIE**, a town of Kincardineshire or the Mearns, 13 miles N. E. from Montrose. It lies between two small hills, which terminate in high cliffs towards the sea; and though a royal borough, and the only one in the country, it is but a small place, the inhabitants of which are chiefly employed in making thread.

INVERKEITHING, a parliament-town of Scotland, in the county of Fife, situated on the northern shore of the Frith of Forth, in W. lon. 3. 15. N. lat. 56. 5. It was much favoured by William, who granted its first charter. He extended its liberties considerably, and in the time of David I. it became a royal residence. The Moubrays had large possessions here, which were forfeited in the reign of Robert II. The Franciscans had a convent in this town; and, according to Sir Robert Sibbald; the Dominicans had another. This town has a considerable trade in coal and other articles.

INVERLOCHY, an ancient castle in the neighbourhood of **FORT WILLIAM** in Invernesshire. It is adorned with large round towers; and, by the mode of building, seems to have been the work of the English in the time of Edward I. who laid large fines on the Scotch barons for the purpose of erecting new castles. The largest of these towers is called *Camin's*. But long prior to these ruins, Inverlochy, according to Iocce, had been a place of great note, a most opulent city, remarkable for the vast resort of French and Spaniards, probably on account of trade. It was also a seat of the kings of Scotland, for here Achaius in the year 790 signed (as is reported) the league offensive and defensive between himself and Charlemagne. In after-times it was utterly destroyed by the Danes, and never again restored.

In the neighbourhood of this place were fought two fierce battles, one between Donald Balloch brother to Alexander lord of the Isles, who with a great power invaded Lochaber in the year 1427: he was met by the earls of Mar and Cathness; the last was slain, and their forces totally defeated. Balloch returned to the isles with vast booty, the object of those plundering chieftains. Here also the Campbells under the marquis of Argyle, in February 1645, received from Montrose an overthrow fatal to numbers of that gallant name. Fifteen hundred fell in the action and in the pursuit, with the loss only of three to the royalists. Sir Thomas Ogilvie, the friend of Montrose, died of his wounds. His death suppressed all joy for the victory.

INVERNESS, a royal borough of Scotland, capital of a county of the same name, pleasantly situated on the S. bank of the river Ness, and overlooking the frith of Murray. It has a safe and convenient harbour, and a good deal of shipping. Several large buildings have been erected on the N. side of the town, in which a considerable manufactory of ropes and canvass is carried on. It is a populous and flourishing town, being the chief market to a wide tract of surrounding country. An academy is intended to be erected here on an extensive scale;

a liberal subscription having been entered into for that benevolent purpose. On an eminence above the town are the ruins of the old castle of Inverness, demolished by the rebels in 1746. Over the river Ness is a handsome bridge of seven arches. The salmon fishery in this river is very considerable, and is let to some fishmongers of London. Near this town, on the wide heath, called Culloden Muir, the duke of Cumberland gained a decisive victory over the rebels in 1746; and a little to the W. of this town is the remarkable vitrified fort called Craig Phadrick: the stones composing its walls appear to have been partly melted by fire. Inverness is 5 miles N. E. of Fort William, and 106 N. of Edinburgh. W. lon. 4. 5. N. lat. 57. 30.

INVERNESS-SHIRE, the most extensive county of Scotland, bounded on the N. by Ross-shire; on the E. by the counties of Nairne, Murray, and Aberdeen; on the S. by those of Perth and Argyle; and on the W. by the channel called the Minch. Its extent from N. to S. is above 50 miles, and from E. to W. about 80. The northern part is very mountainous and barren. The woody mountains are the haunts of stags and roes. The heath is possessed by black game and grouse; and the lofty summits of the hills by ptarmigans and alpine hares. This county has several considerable lakes; being divided, in a manner, into two equal parts, by Loch Ness, Loch Oich, Loch Lochy, and Loch Eil; all which might be united by a canal, that would form a communication between the two seas. Of most of the great lakes in this county, it is remarkable, that, notwithstanding the coldness of the climate, they are seldom or never known to freeze; much less are the arms of the sea, even in the most northern parts of Scotland, subject to be frozen in the hardest seasons; while the Texel, and many bays and great rivers in Holland and Germany, are covered with ice. The southern part of the shire is also very mountainous, and is supposed to be the most elevated ground in Scotland. The extensive plains which surround the lakes are in general fertile; and the high grounds feed many sheep and black cattle, the rearing and selling of which is the chief trade of the inhabitants. Limestone, iron ore, and some traces of different minerals have been found in this county, with beautiful rock-crystals of various tints; but no mines have been worked hitherto with much success. The principal river is the Spey; but there are many others of inferior note, as the Ness, Fyers, Glas, Lochy, &c. The common people in the high parts of the country, and on the western shore, speak Gaelic; but the people of fashion in Inverness, and its neighbourhood, use the English language, and pronounce it with propriety.

INVERSE, is applied to a manner of working the rule of three, or proportion, which seems to go backward, i. e. reverse or contrary to the order of the common and direct rule: so that, whereas, in the direct rule, more requires more, or less requires less; in the Inverse rule, on the contrary, more requires less, or less requires more. For instance, in the direct rule it is said, If 3 yards of cloth cost 20 shillings, how much will 6 yards cost? The answer is 40 shillings: where more yards require more money, and less yards require less money. But in the Inverse rule it is said, If 20 men perform a piece of work in 4 days, in how many days will 40 men perform as much? where the answer is 2 days; and here the more men require the less time, and the fewer men the more time.

INVERSE Method of Fluxions, is the method of finding fluents, from the fluxions being given; and is similar to what the foreign mathematicians call the Calculus Integralis.

INVERSE Method of Tangents, is the method of finding the curve belonging to a given tangent; as opposed to the direct method, or the finding the tangent to a given curve. As, to find a curve whose subtangent is a third proportional to $r-y$ and y , or whose subtangent is equal to the semiordinate, or whose subnormal is a constant quantity.—The solution of

this problem depends chiefly on the Inverse method of FLUXIONS.

INVERSE Proportion, or INVERSE Ratio, is that in which more requires less, or less requires more. As for instance, in the case of light, or heat from a luminous object, the light received is less at a greater distance, and greater at a less distance; so that here more, as to distance, gives less, as to light, and less distance gives more light. This is usually expressed by the term Inversely, or Reciprocally; as in the case above, where the light is Inversely, or Reciprocally, as the square of the distance; or in the Inverse or Reciprocal duplicate ratio of the distance.

INVERSION, *Invertendo*, or *by Inversion*, according to the 14th definition of Euclid, lib. 5. is Inverting the terms of a proportion. by changing the antecedents into consequents, and the consequents into antecedents. As in these, $a : b :: c : d$, then by Inversion $b : a :: d : c$.

INVERSION, in grammar, is where the words of a phrase are ranged in a manner not so natural as they might be. For instance: "Of all vices, the most abominable, and that which least becomes a man, is impurity." Here is an inversion; the natural order being this: Impurity is the most abominable of all vices, and that which least becomes a man.—An inversion is not always disagreeable, however, but sometimes has a very harmonious effect.

INVERTED, in music, is derived from the Latin preposition *in*, and *vertere* "to turn any thing a contrary way." The analogy of this term, and its use in music, will appear more obvious from the sequel.

It signifies a change in the order of the notes which form a chord, or in the parts which compose harmony: which happens by substituting in the bass those sounds which ought to have been in the upper part: an operation not only rendered practicable, but greatly facilitated, by the resemblance which one note has to another in different octaves; whence we derive the power of exchanging one octave for another with so much propriety and success, or by substituting in the extremes those which ought to have occupied the middle station; and *vice versa*.

It is certain, that in every chord there must be a fundamental and natural order, which is the same with that of its generation: but the circumstances of succession, taste, expression, the beauty of melody, and variety, the approximation of harmony, frequently oblige the composer to change that order by inverting the chords, and of consequence the disposition of the parts.

As three things may be arranged in six different orders, and four things in twenty-four; it would seem at first, that a perfect chord should be susceptible of six inversions, and a dissonant chord of twenty-four; since one is composed of four and the other of three sounds, and since inversion consists only in a transposition of octaves. But it must be observed, that in harmony all the different dispositions of acuter sounds are not reckoned as inversions, whilst the same sounds remain in the lower parts. Thus, these two orders of the perfect chord *ut mi sol*, or C E G, and *ut sol mi*, or C G E, are only taken for the same inversion, and only bear the same name: this reduces the whole of inversions of which a perfect chord is susceptible to three; that is to say, to as many inversions as the chord contains different sounds: for the replications of the same sound are here reckoned as nothing.

Every time, therefore, when the fundamental bass is heard in the lowest parts, or, if the fundamental bass be retrenched, every time when the natural order is preserved in the chords, the harmony is direct. As soon as that order is changed, or as soon as the fundamental sounds, without being in the lower parts, are heard in some of the others, the harmony is *inverted*. It is an inversion of the chord, when the fundamental sound

is transposed; it is likewise an inversion of the harmony, when the treble or any other part moves as the bass ought to have done.

Every where, where a direct chord can be well placed, its inversions will likewise be so with respect to the harmony; for it is still the same fundamental succession. Thus, at every note of the fundamental bass, it is in the power of the composer to arrange the chord at his pleasure, and of consequence every moment to produce different inversions; provided that he does not change the regular and fundamental succession; provided also, that the dissonances may always be prepared and resolved in the same parts where they are first heard, that the sensible note may always ascend, and that such false relations may be avoided as would be too harsh upon the ear in the same part. This is the key of these mysterious distinctions which composers have made between those chords where the treble is syncopated, and those in which the bass ought to be syncopated; as, for instance, between the ninth and the second: it is thus that in the first the chord is direct, and the dissonance in the treble; in the others, the chord is reversed, and the dissonance in the bass.

With respect to chords by supposition, greater precaution is necessary in inverting them. As the sound which they add to the bass is absolutely foreign to the harmony; it is often only tolerable there, on account of its vast distance from the other sounds, which renders the dissonance less harsh. But if these added sounds should happen to be transposed in the higher parts, as it sometimes does; if this transposition be not performed with much art, it may produce a very bad effect; and never can this be happily practised without taking away some other sound from the chord. See, at the article ACCORD in the Musical Dictionary, the cases when *inversion* may be practised, and the choice of such as are proper.

The perfect knowledge of *inversion* depends on art and study alone: the choice is a different matter; to this an ear and a taste are necessary; experience of the different effects is likewise indispensable; and though the choice of inversions be indifferent with respect to the foundation of the harmony, it is by no means such in regard of the effect and expression. It is certain, that the fundamental bass is formed to support the harmony, and to prevail beneath. Every time therefore when the order is changed and the harmony inverted, there ought to be good reasons for it: without which, the composer will fall into the vice of our more recent music, where the melody of the treble is often like what the bass should be, and the bass always like that of the treble, where every thing is confounded, reversed, disordered, without any other reason than to subvert the established order, and to spoil the harmony.

INVERURY, a small borough of Aberdeenshire, in Scotland, situated on the beautiful and fertile banks of the river Don, just above its confluence with the river called Urie Water. Inverury is 15 miles N. W. of Aberdeen.

INVESTIGATION, properly denotes the searching or finding out any thing by the tracks or prints of the feet; whence mathematicians, schoolmen, and grammarians, come to use the term in their respective researches.

INVESTING a PLACE, in the art of war, is when a general, having an intention to besiege it, detaches a body of horse to possess all the avenues; blocking up the garrison, and preventing supplies from getting into the place, till the army and artillery are got up to form the siege.

INVESTITURE, in law, a giving livery of seisin or possession. There was anciently a great variety of ceremonies used upon investitures; as at first they were made by a certain form of words, and afterwards by such things as had the greatest resemblance to the thing to be transferred: thus, where lands were intended to pass, a turf, &c. was delivered by the granter

to the grantee. In the church, it was customary for princes to make investiture of ecclesiastical benefices, by delivering to the person they had chosen a pastoral staff and a ring.

INULA, ELECAMPANE; a genus of the polygamia superflua order, belonging to the syngenesia class of plants; and in the natural method ranking under the 49th order, *Compositæ*. The receptacle is naked; the pappus simple; the antheræ, at the base, ending in two bristles. There are 22 species, of which the helinium, or common elecampane, is the most remarkable. It is a native of Britain; but is cultivated in gardens for the sake of the root, which is used in medicine. The root is perennial, thick, branching, and of a strong odour. The lower leaves are eight or nine inches long, and four broad in the middle. rough on their upper side, but downy on the under side. The stalks rise about four feet high, and divide toward the top into several smaller branches, garnished with oblong oval leaves indented on their edges, ending in acute points. Each branch is crowned with one large yellow radiated flower, succeeded by narrow four cornered seeds, covered with down. It may be propagated in autumn by seeds or offsets.

The root of elecampane, especially when dry, has an agreeable aromatic smell; its taste, on chewing, is glutinous, and as it were somewhat rancid; in a little time it discovers an aromatic bitterness, which by degrees becomes considerably acrid and pungent. The old practitioners in medicine ranked it in the class of alexipharmics; and principally recommended it for promoting expectoration in asthmas and coughs. Liberally taken, it is said to excite urine, and to loosen the belly. In some parts of Germany, large quantities of this root are candied, and used as a stomachic for strengthening the tone of the viscera. Proof spirit will extract its virtues in greater perfection than water. The former scarce elevates any thing in distillation: with the latter an essential oil arises, which concretes into white flakes. This possesses at first the flavour of the elecampane, but is very apt to lose it in keeping. Outwardly applied, a decoction of it is said to cure the itch. The root bruised and macerated in urine with balls of ashes and whortleberries, dyes a blue colour.

INUNDATÆ, the name of the 15th order in Linnæus's Fragments of a natural method; consisting of plants which grow in the water. See BOTANY, p. 50.

INUNDATION, a sudden overflowing of the dry land by the waters of the ocean, rivers, lakes, springs, or rains. In the Transactions of the Society for the Encouragement of Arts for the year 1796, p. 238, Mr. Bramley, of Leeds, gives the following account of a method of constructing banks to guard against the inundation of the sea. He says, "The procuring of new scenes, on which industry may act with profit, is so desirable an object, that I hope the Society's excuse for introducing an idea, which, should it answer, may be of considerable utility, and which is, the application of the system of puddling in embankments made near to the sea, and liable to be overflowed at spring tides. In such situations, water is to be found almost with certainty at a few feet under the surface; and the great bar to inclosure or embankment in such situations being the difficulty which occurs in giving sufficient density to the bank, and thereby enabling it to resist the spring tides, the following mode would, it is supposed (where a small portion of ooze is intermixed with the sand), be capable of binding the same so firmly, as to give it a density sufficient to resist the impulse of the tide. Having first laid out, ideally, the ground intended to be embanked, it will be necessary to fix pumps at one or both ends of, or more spaces in the line, capable of throwing up considerable quantities of water; and, in proportion to the work intended to be done, to have extra hands, rather than be in any respect deficient: the line should then be drawn with a convexity to the water, and the soil dug

over and puddled as a base, continuing the same mode for every five or six inches thickness of soil thrown on above the surface, and guarded by an external wall of loose earth or silt: the pumps at each end should be set to work, making a channel for the water to run centrally along the bank, and, as fast as it could proceed, to have parties stationed ready to puddle it nearly from side to side; which being brought to a proper consistence, another layer should be thrown thereon, and in a curving shape, narrowing upwards from the base: the same process in puddling should be then renewed, and alternate applications of fresh soil and puddling be proceeded on, until the bank is raised to the height sufficient to guard against the highest tides.

“Earth in this puddled state becomes so dense as to resist the impression of water, which can by no means penetrate it; and though the experiment has not to my knowledge been before thought of, or tried in such situation, yet I apprehend it will, by this means, acquire a compactness of substance, sufficient to withstand every common effort of the tides: after it is once completed, and by strewing a few hay-seeds on the curving sides, it would probably soon be covered with a complete greenward, which would be forwarded much by the moisture exhaling from the adjoining puddled earth; thus answering the double purpose, of making the internal earth cohesive, and promoting vegetation on the surface. The idea originated in reflecting on the solidity attained in the puddled banks of canals, &c. which mode might probably be thus applied to purposes of unbounded utility; and where under-drains are necessary to quit land-floods or streams, care might be taken, prior to forming the bank, to leave proper vacancies for their reception, after its completion. Should these hints be thought worthy of attention by the Society, I hope their public recommendation will induce a trial to prove the efficacy; and the hearing of attendant success will give a great pleasure to one who wishes to promote every object conducive to the progress of agriculture.”

INVOCATION, in theology, the act of adoring God, and especially of addressing him in prayer for his assistance and protection. See the articles **ADORATION** and **PRAYER**. The difference between the invocation of God and of the saints, as practised by the Papists, is thus explained in the catechism of the council of Trent: “We beg of God (says the catechism) to give us good things, and to deliver us from evil; but we pray to the saints, to intercede with God and obtain those things which we stand in need of. Hence we use different forms in praying to God and to the saints: to the former we say, *Hear us, have mercy on us*; to the latter we only say, *Pray for us*.” The council of Trent expressly teaches, that the saints who reign with Jesus Christ offer up their prayers to God for men; and condemns those who maintain the contrary doctrine. The Protestants reject and censure this practice, as contrary to scripture, deny the truth of the fact, and think it highly unreasonable to suppose that a limited finite being should be in a manner omni-present, and at one and the same time hear and attend to the prayers that are offered to him in England, China, and Peru; and from thence infer, that if the saints cannot hear their requests, it is inconsistent with common sense to address any kind of prayer to them.

INVOCATION, in poetry, an address at the beginning of a poem, wherein the poet calls for the assistance of some divinity, particularly of his muse, or the deity of poetry.

INVOICE, an account in writing of the particulars of merchandize, with their value, custom, charges, &c. transmitted by one merchant to another in a distant country.

INVOLUCRUM, among botanists, expresses that sort of cup which surrounds a number of flowers together, every one of which has beside this general cup its own particular perian-

thium. The involucre consists of a multitude of little leaves disposed in a radiated manner. See **CALYX**.

INVOLUTION, in algebra, the raising any quantity from its root to any height or power assigned. See **ALGEBRA**, p. 155.

IO, in fabulous history, daughter of Inachus, or according to others of Jafus or Pirene, was priestess of Juno at Argos. Jupiter became enamoured of her; but Juno, jealous of his intrigues, discovered the object of his affection, and surprised him in the company of Io. Jupiter changed his mistress into a beautiful heifer; and the goddess, who well knew the fraud, obtained from her husband the animal whose beauty she had condescended to commend. Juno commanded the hundred-eyed Argus to watch the heifer; but Jupiter, anxious for the situation of Io, sent Mercury to destroy Argus, and to restore her to liberty. Io, freed from the vigilance of Argus, was now persecuted by Juno, who sent one of the Furies to torment her. She wandered over the greatest part of the earth, and crossed over the sea, till at last she stopped on the banks of the Nile, still exposed to the unceasing torments of the Fury. Here she entreated Jupiter to restore her to her natural form; and when the god had changed her from a heifer into a woman, she brought forth Epaphus. Afterwards she married Telegonus king of Egypt, or Oiris according to others; and she treated her subjects with such mildness and humanity, that after death she received divine honours, and was worshipped under the name of *Isis*. According to Herodotus, Io was carried away by Phœnician merchants, who wished to make reprisals for Europa, who had been stolen from them by the Greeks.

JOAB, general of the army of king David, defeated the Syrians and the other enemies of David, and took the fort of Zion from the Jebusites, who, thinking it impregnable, committed it to the care of the lame and blind, whom they placed on the walls. He signalized himself in all David's wars, but was guilty of basely murdering Abner and Amasa. He procured a reconciliation between Absalom and David; and afterwards slew Absalom, contrary to the express orders of the king. He at length joined Adonijah's party; and was put to death by the order of Solomon, 1014 B. C.

JOACHIMITES, in church history, the disciples of Joachim a Cistercian monk, who was an abbot of Flora in Calabria, and a great pretender to inspiration. The Joachimites were particularly fond of certain ternaries: The Father, they said, operated from the beginning till the coming of the Son; the Son from that time to theirs, which was the year 1260; and from that time the Holy Spirit was to operate in his turn. They also divided every thing relating to men, to doctrine, and the manner of living, into three classes, according to the three persons in the Trinity. The first ternary was that of men; of whom the first class was that of married men, which had lasted during the whole period of the Father; the second was that of clerks, which had lasted during the time of the Son; and the last was that of the monks, in which there was to be an uncommon effusion of grace by the Holy Spirit. The second ternary was that of doctrine, viz. the Old Testament, the New, and the everlasting Gospel; the first they ascribed to the Father, the second to the Son, and the third to the Holy Spirit. A third ternary consisted in the manner of living: viz. under the Father men lived according to the flesh; under the Son, they lived according to the flesh and the spirit; and under the Holy Ghost, they were to live according to the spirit only.

JOAN (Pope), called by Platina *John VIII.* is said to have held the holy see between Leo IV. who died in 855, and Benedict III. who died in 858. Marianus Scotus says, she sat two years five months and four days. Numberless have been the controversies, fables, and conjectures, relating to this pope. It is said that a German girl, pretending to be a man, went to Athens, where she made great progress in the sciences; and

afterwards came to Rome in the same habit. As she had a quick genius, and spoke with a good grace in the public disputations and lectures, her great learning was admired, and every one loved her extremely; so that after the death of Leo she was chosen Pope, and performed all offices as such. Whilst she was in possession of this high dignity, she was got with child; and as she was going in a solemn procession to the Lateran church, she was delivered of that child, between the Coliseum and St. Clement's church, in a most public street, before a crowd of people, and died on the spot, in 857. By way of embellishing this story, may be added the precaution reported to have been afterward taken to avoid such another accident. After the election of a pope, he was placed on a chair with an open seat, called the *groping chair*, when a deacon came most devoutly behind and satisfied himself of the pontiff's sex by feeling. This precaution however, has been long deemed unnecessary, because the cardinals now always get bastards enough to establish their virility before they arrive at the pontificate.

JOACHIMS-THAL, that is to say, the valley of St. Joachim, a town and valley of Bohemia, in the circle of Elnobogen. A rich silver mine was discovered in it at the beginning of the 16th century.

JOAN *d'Arc*, or the Maid of Orleans, whose heroic behaviour in reanimating the expiring valour of the French nation, though by the most superstitious means (pretending to be inspired), deserved a better fate. She was burnt by the English as a sorceress in 1411, aged 24.

JOANNA (St.), one of the Comora-islands in the Indian ocean. See HINZUAN.

JOB, or *Book of Job*, a canonical book of the Old Testament, containing a narrative of a series of misfortunes which happened to a man whose name was *Job*, as a trial of his virtue and patience; together with the conferences he had with his cruel friends on the subject of his misfortunes, and the manner in which he was restored to ease and happiness. This book is filled with those noble, bold and figurative expressions which constitute the very soul of poetry.

Many of the Jewish rabbins pretend that this relation is altogether a fiction; others think it a simple narrative of a matter of fact, just as it happened: whilst a third sort of critics acknowledge, that the groundwork of the story is true, but that it is written in a poetical strain, and decorated with peculiar circumstances, to render the narration more profitable and entertaining.

The time is not set down in which Job lived. Some have thought that he was much ancients than Moses, because the law is never cited by Job or his friends, and because it is related that Job himself offered sacrifices. Some imagine that this book was written by himself; others say, that Job wrote it originally in Syriac or Arabic, and that Moses translated it into Hebrew: but the rabbins generally pronounce Moses to be the author of it; and many Christian writers are of the same opinion.

JOBB: R, a person who undertakes jobs, or small pieces of work. In some statutes, jobber is used for a person who buys and sells for others. See BROKER.

JOBBING, the business of a jobber. Thus the practice of trafficking in the public funds, or of buying and selling stock with a view to its rise or fall, is called *Stock Jobbing*. The term indeed is most commonly applied to the illegal practice of buying and selling stock *for time*, or of accounting for the differences in the rise or fall of any particular stock for a stipulated time, whether the buyer or seller be possessed of any such real stock or not. See STOCK BROKER.

JOBERT (LEWIS), a pious and learned Jesuit, born at Paris in 1647. He distinguished himself as a preacher; and besides several other tracts wrote a treatise entitled *La Science des Mé-*

dailles, which is in some esteem. He died in 1710; and the best edition of this work is that of Paris in 1739, 2 vols. 12mo.

JOCASTA, in fabulous history, a daughter of Menoecus, who married Laius king of Thebes, by whom she had Oedipus. She afterwards married her son Oedipus, without knowing who he was, and had by him Eteocles, Polynices, &c. When she discovered that she had married her own son, and been guilty of incest, she hanged herself in despair. She is called *Epicasta* by some mythologists.

JOCKEY, in the management of horses, the person who trims up, artfully conceals the defects of horses, and rides them about for sale.

JODE (PETER de), an engraver of some note, was a native of Antwerp. He received his first instructions in the art of engraving from Henry Goltzius; and afterwards went to Italy, in order to complete his studies from the works of the great masters. He engraved several plates in that country from different painters; and returned to Antwerp about the year 1601, where he resided till the time of his death, which happened A. D. 1634. His works are very numerous, and possess a considerable share of merit.

JODE (Peter de) the younger, was son to the former, and born in 1606. From his father he learned the art of engraving, and surpassed him in taste and the facility of handling the graver; though he can scarcely be said to have equalled him in correctness of drawing, especially when confined to the naked parts of the human figure. It does not appear that he went to Italy; but he accompanied his father to Paris, where they engraved conjointly a considerable number of plates for M. Bonenfant, and Le Sieur L'Imago. His most capital performances are from Rubens and Vandyck. Bâillon says of him, that in several of his engravings he has "equalled the best engravers, and in others he has sunk below himself." The time of his death is not known. He left a son, *Arnold*, who was also an engraver, but of very inferior merit.

JODELLE (STEPHEN), lord of Limodin, was born at Paris in 1532; and distinguished himself so greatly by his poetical talents that he was reckoned one of the Pleiades celebrated by Ronfard. He is said to be the first Frenchman who wrote plays in his own language according to the ancient form. He was remarkably ready at composition, writing without study or labour; and was well skilled in polite arts and genteel exercises. In his younger years he embraced the reformed religion, and wrote a satire on the mass in 100 Latin verses; yet all of a sudden returned to that mass again. He died in 1579, very poor.

JOEL, or *the Prophecy of Joel*, a canonical book of the Old Testament. Joel was the son of Pethuel, and the second of the twelve lesser prophets. The style of this prophet is figurative, strong, and expressive. He upbraids the Israelites for their idolatry, and foretels the calamities they should suffer as the punishment of that sin: but he endeavours to support them with the comfort that their miseries should have an end upon their reformation and repentance. Some writers, inferring the order of time in which the minor prophets lived from the order in which they are placed in the Hebrew copies, conclude that Joel prophesied before Amos, who was contemporary with Uzziah, king of Judah. Archbishop Usher makes this inference from Joel's foretelling that drought, chap. i. which Amos mentions as having happened, chap. iv. 7, 8, 9. If we consider the main design of Joel's prophecy, we shall be apt to conclude, that it was uttered after the captivity of the ten tribes; for he directs his discourse only to Judah, and speaks distinctly of the sacrifices and oblations that were daily made in the temple.

JOGHIS, a sect of heathen religious in the East Indies, who

never marry, nor hold any thing in private property; but live on alms, and practise strange severities on themselves. They are subject to a general, who sends them from one country to another to preach. They are, properly, a kind of penitent pilgrims; and are supposed to be a branch of the ancient Gymnosophists. They frequent, principally, such places as are consecrated by the devotion of the people, and pretend to live several days together without eating or drinking. After having gone through a course of discipline for a certain time, they look on themselves as impeccable, and privileged to do any thing; upon which they give a loose to their passions, and run into all manner of debauchery.

JOGUES, or YOOGS, certain ages, æras, or periods of extraordinary length, in the chronology of the Hindoos. They are four in number; of which the following is an account, extracted from Halhed's Preface to the Code of Gentoo Laws, p. xxxvi.

1. The *Suttee Jogue* (or age of purity) is said to have lasted three million two hundred thousand years; and they hold that the life of man was extended in that age to one hundred thousand years; and that his stature was twenty-one cubits.

2. The *Tirtah Jogue* (in which one-third of mankind was corrupted) they suppose to have consisted of two million four hundred thousand years, and that men lived to the age of ten thousand years.

3. The *Dwapaar Jogue* (in which half of the human race became depraved) endured one million six hundred thousand years, and the life of man was then reduced to a thousand years.

4. The *Collee Jogue* (in which all mankind are corrupted, or rather lessened, for that is the true meaning of *Collee*) is the present æra, which they suppose ordained to subsist four hundred thousand years, of which near five thousand are already past; and the life of man in that period is limited to one hundred years.

Concerning the Indian chronology, we have already had occasion to say something under the article HINDOOS. We shall here, however, subjoin Dr. Robertson's observations on the above periods, from the Notes to his *Historical Disquisition concerning India*.

"If (says he) we suppose the computation of time in the Indian chronology to be made by solar or even by lunar years, nothing can be more extravagant in itself, or more repugnant to our mode of calculating the duration of the world, founded on sacred and infallible authority. From one circumstance, however, which merits attention, we may conclude, that the information which we have hitherto received concerning the chronology of the Hindoos is very incorrect. We have, as far as I know, only five original accounts of the different Jogues or æras of the Hindoos. The first is given by M. Roger, who received it from the Brahmins on the Coromandel coast. According to it, the *Suttee Jogue* is a period of one million seven hundred and twenty-eight thousand years; the *Tirtah Jogue* is one million two hundred and ninety-six thousand years; the *Dwapaar Jogue* is eight hundred and sixty-four thousand. The duration of the *Collee Jogue* he does not specify. (*Porte Ouverte*, p. 179.) The next is that of M. Bernier, who received it from the Brahmins of Benares. According to him, the duration of the *Suttee Jogue* was two million five hundred thousand years; that of the *Tirtah Jogue* one million two hundred thousand years; that of the *Dwapaar Jogue* is eight hundred and sixty-four thousand years. Concerning the period of the *Collee Jogue*, he likewise is silent. (*Voyages*, tom. ii. p. 160.) The third is that of Colonel Dow; according to which the *Suttee Jogue* is a period of fourteen million of years, the *Tirtah Jogue* one million eighty thousand, the *Dwapaar Jogue* seventy-two thousand, and the *Collee Jogue* thirty-six

thousand years. (*Hist. of Hindost.* vol. 1. p. 2.) The fourth account is that of M. Le Gentil, who received it from the Brahmins of the Coromandel coast; and as his information was acquired in the same part of India, and derived from the same source with that of M. Roger, it agrees with his in every particular. (*Mem. de l'Academ. des Sciences pour 1772*, tom. ii. part i. p. 176.) The fifth is the account of Mr. Halhed, which has been already given. From this discrepancy, not only of the total numbers, but of many of the articles in the different accounts, it is manifest that our information concerning Indian chronology is hitherto as uncertain as the whole system of it is wild and fabulous. To me it appears highly probable, that when we understand more thoroughly the principles upon which the factitious æras or Jogues of the Hindoos have been formed, we may be more able to reconcile their chronology to the true mode of computing time, founded on the authority of the Old Testament; and may likewise find reason to conclude, that the account given by their astronomers of the situation of the heavenly bodies at the beginning of the *Collee Jogue*, is not established by actual observation, but the result of a retrospective calculation."

JOHN (St.), the BAPTIST, the fore-runner of Jesus Christ, was the son of Zacharias and Elizabeth. He retired into a desert, where he lived on locusts and wild honey; and about the year 29 began to preach repentance, and to declare the coming of the Messiah. He baptized his disciples, and the following year Christ himself was baptized by him in the river Jordan. Some time after, having reprov'd Herod Antipas, who had a criminal correspondence with Herodias his brother Philip's wife, he was cast into prison, where he was beheaded. His head was brought to Herodias; who, according to St. Jerome, pierced his tongue with the bodkin she used to fasten up her hair, to revenge herself after his death for the freedom of his reproofs.

JOHN (St.), the apostle, or the evangelist, was the brother of St. James the Great, and the son of Zebedee. He quitted the business of fishing to follow Jesus, and was his beloved disciple. He was witness to the actions and miracles of his Master; was present at his transfiguration on mount Tabor; and was with him in the garden of Olives. He was the only apostle who followed him to the cross; and to him Jesus left the care of his mother. He was also the first apostle who knew him again after his resurrection. He preached the faith in Asia; and principally resided at Ephesus, where he maintained the mother of our Lord. He is said to have founded the churches of Smyrna, Pergamus, Thyatira, Sardis, Philadelphia, and Laodicea. He is also said to have preached the gospel amongst the Parthians, and to have addressed his first epistle to that people. It is related; that, when at Rome, the emperor Domitian caused him to be thrown into a cauldron of boiling oil, when he came out unhurt; on which he was banished to the isle of Patmos, where he wrote his Apocalypse. After the death of Domitian, he returned to Ephesus, where he composed his Gospel, about the year 96; and died there, in the reign of Trajan, about the year 100, aged 94.

Gospel of St. JOHN, a canonical book of the New Testament, containing a recital of the life, actions, doctrine, and death, of our Saviour Jesus Christ, written by St. John the apostle and evangelist. St. John wrote his Gospel at Ephesus, after his return from the isle of Patmos, at the desire of the Christians of Asia. St. Jerome says, he would not undertake it, but on condition that they should appoint a public fast to implore the assistance of God; and that, the fast being ended, St. John, filled with the Holy Ghost, broke out into these words, "In the beginning was the Word," &c. The ancients assign two reasons for this undertaking: The first is, because, in the other three Gospels, there was wanting the history of the beginning

of Jesus Christ's preaching, till the imprisonment of John the Baptist, which therefore he applied himself particularly to relate. The second reason was, in order to remove the errors of the Cerinthians, Ebionites, and other sects. But Mr. Lampe and Dr. Lardner have urged several reasons to show that St. John did not write against Cerinthus or any other heretics in his Gospel.

Revelation of St. JOHN. See APOCALYPSE.

JOHN of Salisbury, bishop of Chartres in France, was born at Salisbury in Wiltshire, in the beginning of the 12th century. Where he imbibed the rudiments of his education, is unknown; but we learn that in the year 1136, being then a youth, he was sent to Paris, where he studied under several eminent professors, and acquired considerable fame for his application and proficiency in rhetoric, poetry, divinity, and particularly in the learned languages. Thence he travelled to Italy; and, during his residence at Rome, was in high favour with pope Eugenio III. and his successor Adrian IV. After his return to England he became the intimate friend and companion of the famous Thomas BECKET, archbishop of Canterbury, whom he attended in his exile, and is said to have been present when that haughty prelate was murdered in his cathedral. What preferment he had in the church during this time, does not appear; but in 1176 he was promoted by king Henry II. to the bishopric of Chartres in France, where he died in 1182. This John of Salisbury was really a phænomenon. He was one of the first restorers of the Greek and Latin languages in Europe; a classical scholar, a philosopher, a learned divine, and an elegant Latin poet. He wrote several books; the principal of which are, his life of St. Thomas of Canterbury, a collection of letters, and Polycraticon.

Pope JOHN XXII. a native of Cahors, before called *James d'Essè*, was well skilled in the civil and canon law; and was elected pope after the death of Clement V. on the 7th of August 1316. He published the constitutions called *Clementines*, which were made by his predecessor; and drew up the other constitutions called *Extravagantes*. Lewis of Bavaria being elected emperor, John XXII. opposed him in favour of his competitor; which made much noise, and was attended with fatal consequences. That prince, in 1329, caused the antipope Peter de Corbiero, a Cordelier, to be elected, who took the name of Nicholas V. and was supported by Michael de Cesenne, general of his order; but that antipope was the following year taken and carried to Avignon, where he begged pardon of the pope with a rope about his neck, and died in prison two or three years after. Under this pope arose the famous question among the Cordeliers, called *the bread of the Cordeliers*; which was, Whether those monks had the property of the things given them, at the time they were making use of them? for example, Whether the bread belonged to them when they were eating it, or to the pope, or to the Roman church? This frivolous question gave great employment to the pope; as well as those which turned upon the colour, form, and stuff, of their habits, whether they ought to be white, grey, or black; whether the cowl ought to be pointed or round, large or small; whether their robes ought to be full, short, or long; of cloth, or of serge, &c. The disputes on all these minute trifles were carried so far between the Minor Brothers, that some of them were burned upon the occasion. He died at Avignon in 1334, aged 90.

JOHN of Gaunt, duke of Lancaster, a renowned general, father of Henry IV. king of England, died in 1438.

JOHN Sobieski of Poland, one of the greatest warriors in the 17th century, was, in 1665, made grand-marshal of the crown; and, in 1667, grand-general of the kingdom. His victories obtained over the Tartars and the Turks procured him the crown, to which he was elected in 1674. He was an encourager

of arts and sciences, and the protector of learned men. He died in 1696, aged 72.

St. JOHN'S Day, the name of two Christian festivals; one observed on June 24th, kept in commemoration of the wonderful circumstances attending the birth of John the Baptist; and the other on December 27th, in honour of St. John the Evangelist.

St. JOHN'S Wort. See HYPERICUM.

St. JOHN'S, an island of the East-Indies, and one of the Philippines, east of Mindanayo, from which it is separated by a narrow strait. E. lon. 125. 25. N. lat. 7. 0.

St. JOHN'S, an island of North-America, in the bay of St. Lawrence, having New-Scotland on the south and west, and Cape Breton on the east. The British got possession of it when Louisbourg was surrendered to them, on July 26, 1758.

JOHNSON or *JONSON* (*BEN*), one of the most considerable dramatic poets of the last age, whether from the number or merit of his productions. He was born at Westminster in 1574, and was educated at the public school there under the great Camden. He was descended from a Scottish family; and his father, who lost his estate under queen Mary, dying before our poet was born, and his mother marrying a bricklayer for her second husband, Ben was taken from school to work at his father-in-law's trade. Not being captivated with this employment, he went into the Low Countries, and distinguished himself in a military capacity. On his return to England, he entered himself at St. John's college, Cambridge; and having killed a person in a duel, was condemned, and narrowly escaped execution. After this he turned actor; and Shakespeare is said to have first introduced him to the world, by recommending a play of his to the stage, after it had been rejected. His Alchymist gained him such reputation, that in 1619 he was, at the death of Mr. Daniel, made poet-laureat to king James I. and master of arts at Oxford. As we do not find Jonson's æconomical virtues any where recorded, it is the less to be wondered at, that after this we find him petitioning king Charles, on his accession, to enlarge his father's allowance of 100 merks into pounds; and quickly after we learn, that he was very poor and sick, lodging in an obscure alley; on which occasion it was that Charles, being prevailed on in his favour, sent him ten guineas; which Ben receiving, said, "His majesty has sent me ten guineas, because I am poor and live in an alley; go and tell him, that his soul lives in an alley." He died in August 1637, aged 63 years, and was buried in Westminster-Abbey.—The most complete edition of his works was printed in 1756, in 7 vols. 8vo.

JOHNSON (*Samuel*), an English divine, remarkable for his learning, and steadiness in suffering for the principles of the Revolution in 1688. He was born in 1649; and, entering into orders, obtained in 1670 the rectory of Corringham in the hundreds of Essex, worth no more than 80 l. a year; which was the only church-preferment he ever had. In 1685, for having printed and dispersed *An humble and hearty address to all the Protestants in the present army*, he was fined 500 merks, degraded from the priesthood, stood twice in the pillory, and was whipped from Newgate to Tyburn. It happened luckily, that, in the degradation, they omitted to strip him of his cassock; which circumstance, slight as it may appear, rendered his degradation imperfect, and afterwards preserved his living to him. On the Revolution, the parliament resolved the proceedings against him to be null and illegal; and recommended him to the king, who offered him the rich deanery of Durham: but this he refused, as inadequate to his services and sufferings, which he thought to merit a bishopric. The truth was, he was passionate, self opinionated, and turbulent: and though, through Dr. Tillotson's means, he obtained a pension of 300 l. a-year, with other gratifications, he remained discontented;

pouring forth all his uneasiness against a standing army and the great favours shown to the Dutch. He died in 1703, and his works were afterwards collected in one volume folio.

JOHNSON (Dr. Samuel), who has been styled the brightest ornament of the 18th century, was born in the city of Litchfield in Staffordshire on the 18th of September N. S. 1709. His father Michael was a bookseller; and must have had some reputation in the city, as he more than once bore the office of chief magistrate. By what casuistical reasoning he reconciled his conscience to the oaths required to be taken by all who occupy such stations, cannot now be known; but it is certain that he was zealously attached to the exiled family, and instilled the same principles into the youthful mind of his son. So much was he in earnest in this work, and at so early a period did he commence it, that when Dr. Sacheverel, in his memorable tour through England, came to Litchfield, Mr. Johnson carried his son, not then quite three years old, to the cathedral, and placed him on his shoulders, that he might see as well as hear the far-famed preacher.

But political prejudices were not the only bad things which young Sam inherited from his father: he derived from the same source a morbid melancholy, which, though it neither depressed his imagination nor clouded his perspicacity, filled him with dreadful apprehensions of insanity, and rendered him wretched through life. From his nurse he contracted the *scrophula* or king's evil, which made its appearance at a very early period, disfigured a face naturally well-formed, and deprived him of the sight of one of his eyes.

When arrived at a proper age for grammatical instruction, he was placed in the free school of Litchfield, of which one Mr. Hunter was then master; a man whom his illustrious pupil thought "very severe, and wrong-headedly severe," because he would beat a boy for not answering questions which he could not expect to be asked. He was, however, a skilful teacher; and Johnson, when he stood in the very front of learning, was sensible how much he owed to him; for, upon being asked how he had acquired so accurate a knowledge of the Latin tongue, he replied, "My master beat me very well; without that, Sir, I should have done nothing."

At the age of 15 Johnson was removed from Litchfield to the school of Stourbridge in Worcestershire, at which he remained little more than a year, and then returned home, where he staid two years without any settled plan of life or any regular course of study. He read, however, a great deal in a desultory manner, as chance threw books in his way, and as inclination directed him through them; so that, when in his 19th year he was entered a commoner of Pembroke college, Oxford, his mind was stored with a variety of such knowledge as is not often acquired in universities, where boys seldom read any books but what are put into their hands by their tutors. He had given very early proofs of his poetical genius both in his school exercises and in other occasional compositions: but what is perhaps more remarkable, as it shows that he must have thought much on a subject on which other boys of that age seldom think at all, he had before he was 14 entertained doubts of the truth of revelation. From the melancholy of his temper these would naturally prey upon his spirits, and give him great uneasiness: but they were happily removed by a proper course of reading; for "his studies, being honest, ended in conviction. He found that religion is true, and what he had learned, he ever afterward endeavoured to teach."

Concerning his residence in the university, and the means by which he was there supported, his two principal biographers contradict each other; so that these are points of which we cannot write with certainty. According to Sir John Hawkins, the time of his continuance at Oxford is divisible into two periods: Mr. Boswell represents it as only one period, with the

usual interval of a long vacation. Sir John says, that he was supported at college by Mr. Andrew Corbet in quality of assistant in the studies of his son: Mr. Boswell assures us, that though he was promised pecuniary aid by Mr. Corbet, that promise was not in any degree fulfilled. We should be inclined to adopt the knight's account of this transaction, were it not palpably inconsistent with itself. He says, that the two young men were entered in Pembroke on the *same day*; that Corbet continued in the college two years; and yet that Johnson was driven home in little more than *one year*, because by the *removal* of Corbet he was deprived of his pension. A story, of which one part contradicts the other, cannot wholly be true. Sir John adds, that "meeting with another source, the bounty, as it is supposed, of some one or more of the members of the cathedral of Litchfield, he returned to college, and made up the whole of his residence in the university about three years." Mr. Boswell has told us nothing, but that Johnson, though his father was unable to support him, continued three years in college, and was then driven from it by extreme poverty.

These gentlemen differ likewise in their accounts of Johnson's tutors. Sir John Hawkins says that he had two, Mr. Jordan and Dr. Adams. Mr. Boswell affirms that Dr. Adams *could not* be his tutor, *because* Jordan did not quit the college till 1731; the year in the autumn of which Johnson himself was compelled to leave Oxford. Yet the same author represents Dr. Adams as saying, "I was Johnson's *nominal* tutor, but he was above my mark;" a speech of which it is not easy to discover the meaning, if it was not Johnson's duty to attend Adams's lectures. In most colleges we believe there are two tutors in different departments of education; and therefore it is not improbable that Jordan and Adams may have been tutors to Johnson at the same time, the one in languages, the other in science. Jordan was a man of such mean abilities, that, though his pupil loved him for the goodness of his heart, he would often risk the payment of a small fine rather than attend his lectures; nor was he studious to conceal the reason of his absence. Upon occasion of one such imposition, he said, "Sir, you have scondced me two-pence for non-attendance at a lecture not worth a penny." For some transgression or absence his tutor imposed upon him as a Christmas exercise the task of translating into Latin verse Pope's *Messiah*; which being shown to the author of the original, was read and returned with this encomium, "The writer of this poem will leave it a question for posterity, whether his or mine be the original." The particular course of his reading while in college and during the vacation which he passed at home, cannot be traced. That at this period he read much, we have his own evidence in what he afterwards told the king; but his mode of study was never regular, and at all times he thought more than he read. He informed Mr. Boswell, that what he read *solidly* at Oxford was Greek, and that the study of which he was most fond was metaphysics.

It was in the year 1731 that Johnson left the university without a degree; and as his father, who died in the month of December of that year, had suffered great misfortunes in trade, he was driven out a commoner of nature, and excluded from the regular modes of profit and prosperity. Having therefore not only a profession but the means of subsistence to seek, he accepted, in the month of March 1732, an invitation to the office of under-master of a free school at Market Bosworth in Leicestershire: but not knowing, as he said, whether it was more disagreeable for him to teach or for the boys to learn the grammar-rules, and being likewise disgusted at the treatment which he received from the patron of the school, he relinquished in a few months a situation which he ever afterwards recollected with horror. Being thus again without any fixed employment, and with very little money in his pocket, he translated Lobo's Voyage to Abyssinia, for the trifling sum, it is

said, of five guineas, which he received from a bookseller in Birmingham. This was the first attempt which it is certain he made to procure pecuniary assistance by means of his pen; and it must have held forth very little encouragement to his commencing author by profession.

In 1735, being then in his 26th year, he married Mrs. Porter, the widow of a mercer in Birmingham; whose age was almost double his; whose external form, according to Garrick and others, had never been captivating; and whose fortune amounted to hardly 800l. That she had a superiority of understanding and talents is extremely probable, both because she certainly inspired him with a more than ordinary passion, and because she was herself so delighted with the charms of his conversation as to overlook his external disadvantages, which were many and great. He now set up a private academy; for which purpose he hired a large house well situated near his native city: but his name having then nothing of that celebrity which afterwards commanded the attention and respect of mankind, this undertaking did not succeed. The only pupils who are known to have been placed under his care, were the celebrated David Garrick, his brother George Garrick, and a young gentleman of fortune whose name was Offely. He kept his academy only a year and a half; and it was during that time that he constructed the plan and wrote a great part of his tragedy of Irene.

The respectable character of his parents and his own merit had secured him a kind reception in the best families at Litchfield; and he was particularly distinguished by Mr. Walmsley, register of the ecclesiastical court, a man of great worth and of very extensive and various erudition. That gentleman, upon hearing part of Irene read, thought so highly of Johnson's abilities as a dramatic writer, that he advised him by all means to finish the tragedy and produce it on the stage. To men of genius the stage holds forth temptations almost irresistible. The profits arising from a tragedy, including the representation and printing of it, and the connections which it sometimes enables the author to form, were in Johnson's imagination inestimable. Flattered, it may be supposed, with these hopes, he set out some time in the year 1737 with his pupil David Garrick for London, leaving Mrs. Johnson to take care of the house and the wreck of her fortune. The two adventurers carried with them from Mr. Walmsley an earnest recommendation to the reverend Mr. Colson, then master of an academy, and afterwards Lucasian professor of mathematics in the university of Cambridge; but from that gentleman it does not appear that Johnson found either protection or encouragement.

How he spent his time upon his first going to London is not particularly known. His tragedy was refused by the managers of that day; and for some years the Gentleman's Magazine seems to have been his principal resource for employment and support. To enumerate his various communications to that far-famed miscellany, would extend this article beyond the limits which we can afford. Suffice it to say, that his connection with Cave the proprietor became very close; that he wrote prefaces, essays, reviews of books, and poems; and that he was occasionally employed in correcting the papers written by other correspondents. When complaints of the nation against the administration of Sir Robert Walpole became loud, and a motion was made, February 13th, 1740-1, to remove him from his majesty's councils for ever, Johnson was pitched upon by Cave to write what was in the Magazine entitled *Debates in the Senate of Lilliput*, but was understood to be the speeches of the most eminent members in both houses of parliament. These orations, which induced *Voltaire* to compare British with ancient eloquence, were hastily sketched by Johnson while he was not yet 32 years old, while he was little acquainted with life, while he was struggling not for distinction but for existence. Perhaps

in none of his writings has he given a more conspicuous proof of a mind prompt and vigorous almost beyond conception: for they were composed from scanty notes taken by illiterate persons employed to attend in both houses; and sometimes he had nothing communicated to him but the names of the several speakers, and the part which they took in the debate.

His separate publications which at this time attracted the greatest notice were, "*London*, a Poem in imitation of Juvenal's third Satire;" "*Marmor Norfolkense*, or an Essay on an ancient prophetic Inscription in Monkish Rhyme, lately discovered near Lynne in Norfolk;" and "*A complete Vindication of the Licensers of the Stage from the malicious and scandalous aspersions of Mr. Brook author of Gustavus Vasa.*" The poem which was published in 1738 by Doddsley, is universally known and admired as the most spirited instance in the English language of ancient sentiments adapted to modern topics. Pope, who then filled the poetical throne without a rival, being informed that the author's name was *Johnson*, and that he was an obscure person, replied, "he will soon be *déterré*." The other two pamphlets, which were published in 1739, are filled with keen satire on the government: and though Sir John Hawkins has thought fit to declare that they display neither learning nor wit, Pope was of a different opinion; for, in a note of his preserved by Mr. Boswell, he says, that "the whole of the Norfolk prophecy is very humorous."

Mrs. Johnson, who went to London soon after her husband, now lived sometimes in one place and sometimes in another, sometimes in the city and sometimes at Greenwich: but Johnson himself was oftener to be found at St. John's Gate, where the Gentleman's Magazine was published, than in his own lodgings. It was there that he became acquainted with *Savage*, with whom he was induced, probably by the similarity of their circumstances, to contract a very close friendship; and such were their extreme necessities, that they have often wandered whole nights in the street for want of money to procure them a lodging. In one of these nocturnal rambles, when their distress was almost incredible, so far were they from being depressed by their situation, that, in high spirits and brimful of patriotism, they traversed St. James's Square for several hours, inveighed against the minister; and, as Johnson said in ridicule of himself, his companion, and all such patriots, "resolved that *they* would stand by their country!" In 1744 he published the life of his unfortunate companion; a work which, had he never written any thing else, would have placed him very high in the rank of authors. His narrative is remarkably smooth and well disposed, his observations are just, and his reflections disclose the inmost recesses of the human heart.

In 1749, when Drury-lane theatre was opened under the management of Garrick, Johnson wrote a prologue for the occasion; which for just dramatic criticism on the whole range of the English stage, as well as for poetical excellence, is confessedly unrivalled. But this year is, in his life, distinguished as the epoch when his arduous and important work, the Dictionary of the English Language, was announced to the world by the publication of its plan or prospectus, addressed to the earl of Chesterfield. From that nobleman Johnson was certainly led to expect patronage and encouragement; and it seems to be equally certain that his lordship expected, when the book should be published, to be honoured with the dedication. The expectations of both were disappointed. Lord Chesterfield, after seeing the lexicographer once or twice, suffered him to be repulsed from his door: but afterwards thinking to conciliate him when the work was upon the eve of publication, he wrote two papers in "*The World*," warmly recommending it to the public. This artifice was seen through; and Johnson, in very polite language, rejected his Lordship's advances, letting him know, that he was unwilling the public should consider him as owing to a patron

that which Providence had enabled him to do for himself. This great and laborious work its author expected to complete in three years: but he was certainly employed upon it seven; for we know that it was begun in 1747, and the last sheet was sent to the press in the end of the year 1754. When we consider the nature of the undertaking, it is indeed astonishing that it was finished so soon, since it was written, as he says, "with little assistance of the learned, and without any patronage of the great; not in the soft obscurities of retirement, or under the shelter of academic bowers, but amidst inconvenience and distraction, in sickness and in sorrow." The sorrow, to which he here alludes, is probably that which he felt for the loss of his wife, who died on the 17th of March O. S. 1752, and whom he continued to lament as long as he lived.

The Dictionary did not occupy his whole time: for while he was pushing it forward, he fitted his tragedy for the stage; wrote the lives of several eminent men for the Gentleman's Magazine; published an Imitation of the 10th Satire of Juvenal, entitled "The Vanity of human Wishes;" and began and finished "The Rambler." This last work is so well known, that it is hardly necessary to say that it was a periodical paper, published twice a-week, from the 20th of March 1750 to the 14th of March 1752 inclusive: but to give our readers some notion of the vigour and promptitude of the author's mind, it may not be improper to observe, that, notwithstanding the severity of his other labours, all the assistance which he received does not amount to five papers; and that many of the most masterly of those unequalled essays were written on the spur of the occasion, and never seen entire by the author till they returned to him from the press.

Soon after the Rambler was concluded, Dr. Hawkesworth projected "The Adventurer" upon a similar plan; and by the assistance of friends he was enabled to carry it on with almost equal merit. For a short time, indeed, it was the most popular work of the two; and the papers with the signature T, which are confessedly the most splendid in the whole collection, are now known to have been communicated by Johnson, who received for each the sum of two guineas. This was double the price for which he sold sermons to such clergymen as either would not or could not compose their own discourses; and of sermon-writing he seems to have made a kind of trade.

Though he had exhausted, during the time that he was employed on the Dictionary, more than the sum for which the booksellers had bargained for the copy; yet by means of the Rambler, Adventurer, sermons, and other productions of his pen, he now found himself in greater affluence than he had ever been before; and as the powers of his mind, distended by long and severe exercise, required relaxation to restore them to their proper tone, he appears to have done little or nothing from the closing of the Adventurer till the year 1756, when he submitted to the office of reviewer in the Literary Magazine. Of his reviews by far the most valuable is that of Soame Jenyns's "Free Inquiry into the Nature and Origin of Evil." Never were wit and metaphysical acuteness more closely united than in that criticism, which exposes the weakness and holds up to contempt the reasonings of those vain mortals, who presumptuously attempt to grasp the scale of existence, and to form plans of conduct for the Creator of the universe. But the furnishing of magazines, reviews, and even newspapers, with literary intelligence, and authors of books with dedications and prefaces, was considered as an employment unworthy of Johnson. It was therefore proposed by the booksellers that he should give a new edition of the dramas of Shakespeare; a work which he had projected many years before, and of which he had published a specimen which was commended by Warburton. When one of his friends expressed a hope that this employment would furnish him with amusement and add to his fame, he replied,

"I look upon it as I did upon the Dictionary; it is all work; and my inducement to it is not love or desire of fame, but the want of money, which is the only motive to writing that I know of." He issued proposals, however, of considerable length; in which he showed that he knew perfectly what a variety of research such an undertaking required: but his indolence prevented him from pursuing it with diligence, and it was not published till many years afterwards.

On the 15th of April 1758 he began a new periodical paper entitled "The Idler," which came out every Saturday in a weekly newspaper, called "The Universal Chronicle, or Weekly Gazette," published by *Newbery*. Of these Essays, which were continued till the 5th of April 1760, many were written as hastily as an ordinary letter; and one in particular composed at Oxford was begun only half an hour before the departure of the post which carried it to London. About this time he had the offer of a living, of which he might have rendered himself capable by entering into orders. It was a rectory in a pleasant country, of such yearly value as would have been an object to one in much better circumstances; but sensible, as it is supposed, of the asperity of his temper, he declined it, saying, "I have not the requisites for the office, and I cannot in my conscience shear the flock which I am unable to feed."

In the month of January 1750 his mother died at the great age of 90; an event which deeply affected him, and gave birth to the 41st Idler, in which he laments, that "the life which made his own life pleasant was at an end, and that the gate of death was shut upon his prospects." Soon afterwards he wrote his "Rasselas Prince of Abyssinia;" that with the profits he might defray the expence of his mother's funeral, and pay some debts which she had left. He told a friend, that he received for the copy 100l. and 25l. more when it came to a second edition; that he wrote it in the evenings of one week, sent it to the press in portions as it was written, and had never since read it over.

Hitherto, notwithstanding his various publications, he was poor, and obliged to provide by his labour for the wants of the day that was passing over him; but having been early in 1762 represented to the king as a very learned and good man without any certain provision, his majesty was pleased to grant him a pension, which Lord Bute, then first minister, assured him "was not given for any thing which he *was to do*, but for what he *had already done*." A fixed annuity of three hundred pounds a year, if it diminished his distress, increased his indolence; for, as he constantly avowed that he had no other motive for writing than to gain money, as he had now what was abundantly sufficient for all his purposes, as he delighted in conversation, and was visited and admired by the witty, the elegant, and the learned, very little of his time was passed in solitary study. Solitude was indeed his aversion; and that he might avoid it as much as possible, Sir Joshua Reynolds and he, in 1764, instituted a club, which existed long without a name, but was afterwards known by the title of the *Literary Club*. It consisted of some of the most enlightened men of the age, who met at the Turk's Head in Gerard-street, Soho, one evening in every week at seven, and till a late hour enjoyed "the feast of reason and the flow of soul."

In 1765, when Johnson was more than usually oppressed with constitutional melancholy, he was fortunately introduced into the family of Mr. Thrale, one of the most eminent brewers in England, and member of parliament for the borough of Southwark: and it is but justice to acknowledge, that to the assistance which Mr. and Mrs. Thrale gave him, to the shelter which their house afforded him for 16 or 17 years, and to the pains which they took to soothe or repress his uneasy fancies, the public is probably indebted for some of the most masterly as

well as most popular works which he ever produced. At length, in the October of this year, he gave to the world his edition of Shakespeare, which is chiefly valuable for the preface, where the excellencies and defects of that immortal bard are displayed with such judgment, as must please every man whose taste is not regulated by the standard of fashion or national prejudice. In 1767 he was honoured by a private conversation with the king in the library at the queen's house: and two years afterwards, upon the establishment of the royal academy of painting, sculpture, &c. he was nominated professor of ancient literature; an office merely honorary, and conferred on him, as is supposed, at the recommendation of his friend the president.

In the variety of subjects on which he had hitherto exercised his pen, he had forborne, since the administration of Sir Robert Walpole, to meddle with the disputes of contending factions; but having seen with indignation the methods which, in the business of Mr. Wilkes, were taken to work upon the populace, he published in 1770 a pamphlet entitled "The False Alarm;" in which he asserts, and labours to prove by a variety of arguments founded on precedents, that the expulsion of a member of the house of commons is equivalent to exclusion, and that no such calamity as the subversion of the constitution was to be feared from an act warranted by usage, which is the law of parliament. Whatever may be thought of the principles maintained in this publication, it unquestionably contains much wit and much argument, expressed in the author's best style of composition; and yet it is known to have been written between eight o'clock on Wednesday night and twelve o'clock on the Thursday night, when it was read to Mr. Thrale upon his coming from the house of commons. In 1771 he published another political pamphlet, entitled, "Thoughts on the late transactions respecting Falkland's Islands;" in which he attacked *Junius*: and he ever afterwards delighted himself with the thought of having destroyed that able writer, whom he certainly surpassed in nervous language and pointed ridicule.

In 1773 he visited with Mr. Boswell some of the most considerable of the Hebrides or Western Islands of Scotland, and published an account of his journey in a volume which abounds in extensive philosophical views of society, ingenious sentiments, and lively description, but which offended many persons by the violent attack which it made on the authenticity of the poems attributed to Ossian. For the degree of offence that was taken, the book can hardly be thought to contain a sufficient reason; if the antiquity of these poems be yet doubted, it is owing more to the conduct of their editor than to the violence of Johnson. In 1774, the parliament being dissolved, he addressed to the electors of Great Britain a pamphlet, entitled "The Patriot;" of which the design was to guard them from imposition, and teach them to distinguish true from false patriotism. In 1775, he published "Taxation no tyranny; in answer to the resolutions and address of the American Congress." In this performance his admirer, Mr. Boswell, cannot, he says, perceive that ability of argument or that felicity of expression for which on other occasions Johnson was so eminent. This is a singular criticism. To the assumed principle upon which the reasoning of the pamphlet rests many have objected, and perhaps their objections are well founded; but if it be admitted that "the supreme power of every community has the right of requiring from all its subjects such contributions as are necessary to the public safety or public prosperity," it will be found a very difficult task to break the chain of arguments by which it is proved that the British parliament had a right to tax the Americans. As to the *expression* of the pamphlet, the reader, who adopts the maxim recorded in the "Journal of a tour to the Hebrides," that a controvertist "ought not to strike soft in battle," must acknowledge that it is uncommonly happy, and that the whole

performance is one of the most brilliant as well as most correct pieces of composition that ever fell from the pen of its author. These essays drew upon him numerous attacks, all of which he heartily despised; for though it has been supposed that "A letter addressed to Dr. Samuel Johnson, occasioned by his political publications," gave him great uneasiness, the contrary is manifest, from his having, after the appearance of that letter, collected them into a volume with the title of "Political Tracts by the author of the Rambler." In 1765 Trinity College, Dublin, had created him LL.D. by *diploma*, and he now received the same honour from the university of Oxford; an honour with which, though he did not boast of it, he was highly gratified. In 1777 he was induced, by a case of a very extraordinary nature, to exercise that humanity which in him was obedient to every call. Dr. William Dodd, a clergyman under sentence of death for the crime of forgery, found means to interest Johnson in his behalf, and procured from him two of the most energetic compositions of the kind ever seen; the one a petition from himself to the king, the other a like address from his wife to the queen. These petitions failed of success.

The principal booksellers in London having determined to publish a body of English poetry, Johnson was prevailed upon to write the lives of the poets, and give a character of the works of each. This task he undertook with alacrity, and executed it in such a manner as must convince every competent reader, that as a biographer and a critic no nation can produce his equal. The work was published in ten small volumes, of which the first four came abroad in 1778, and the others in 1781. While the world in general was filled with admiration of the stupendous powers of that man, who at the age of seventy-two, and labouring under a complication of diseases, could produce a work which displays so much genius and so much learning; there were narrow circles in which prejudice and resentment were fostered, and whence attacks of different sorts issued against him. These gave him not the smallest disturbance. When told of the feeble, though shrill, outcry that had been raised, he said—"Sir, I considered myself as entrusted with a certain portion of truth. I have given my opinion sincerely; let them show where they think me wrong."

He had hardly begun to reap the laurels gained by this performance, when death deprived him of Mr. Thrale, in whose house he had enjoyed the most comfortable hours of his life; but it abated not in Johnson that care for the interests of those whom his friend had left behind him, which he thought himself bound to cherish, both in duty as one of the executors of his will, and from the nobler principle of gratitude. On this account, his visits to Streatham, Mr. Thrale's villa, were for some time after his death regularly made on Monday and protracted till Saturday, as they had been during his life; but they soon became less and less frequent, and he studiously avoided the mention of the place or the family. Mrs. Thrale, now Piozzi, says indeed, that "it grew extremely perplexing and difficult to live in the house with him when the master of it was no more; because his dislikes grew capricious, and he could scarce bear to have any body come to the house whom it was absolutely necessary for her to see." The person whom she thought it most necessary for her to see may perhaps be guessed at without any superior share of sagacity; and if these were the visits which Johnson could not bear, we are so far from thinking his dislikes capricious, though they may have been perplexing, that, if he had acted otherwise, we should have blamed him for want of gratitude to the friend whose "face for fifteen years had never been turned upon him but with respect or benignity."

About the middle of June 1783, his constitution sustained a feverish shock than it had ever before felt, by a stroke of the palsy; so sudden and so violent, that it awakened him out of a sound sleep, and rendered him for a short time speechless.

As usual, his recourse under this affliction was to piety, which in him was constant, sincere, and fervent. He tried to repeat the Lord's prayer first in English, then in Latin, and afterwards in Greek; but succeeded only in the last attempt; immediately after which he was again deprived of the power of articulation. From this alarming attack he recovered with wonderful quickness, but it left behind it some presages of an hydropic affection; and he was soon afterwards seized with a spasmodic asthma of such violence that he was confined to the house in great pain, while his dropsy increased notwithstanding all the efforts of the most eminent physicians in London and Edinburgh. He had, however, such an interval of ease as enabled him in the summer of 1784 to visit his friends at Oxford, Litchfield, and Ashbourne in Derbyshire. The Romish religion being introduced one day as the topic of conversation when he was at the house of Dr. Adams, Johnson said, "If you join the papists externally, they will not interrogate you strictly as to your belief in their tenets. No reasoning papist believes every article of their faith. There is one side on which a good man might be persuaded to embrace it. A good man of a timorous disposition, in great doubt of his acceptance with God, and pretty credulous, might be glad of a church where there are so many helps to go to heaven. I would be a papist if I could. I have fear enough; but an obstinate rationality prevents me. I shall never be a papist unless on the near approach of death, of which I have very great terror."

His constant dread of death was indeed so great, that it astonished all who had access to know the piety of his mind and the virtues of his life. Attempts have been made to account for it in various ways; but doubtless that is the true account which is given in the *Olla Podrida*, by an elegant and pious writer, who now adorns a high station in the church of England. "That he should not be conscious of the abilities with which Providence had blessed him, was impossible. He felt his own powers; he felt what he was capable of having performed; and he saw how little, comparatively speaking, he had performed. Hence his apprehension on the near prospect of the account to be made, viewed through the medium of constitutional and morbid melancholy, which often excluded from his sight the bright beams of divine mercy." This, however, was the case only while death was approaching from some distance. From the time he was certain it was near, all his fears were calmed. He died on the 13th of Dec. 1784, and in St. Paul's Cathedral a statue has lately been erected to his memory.

A just character of this great man would carry us far beyond our limits; we must therefore be somewhat concise in the following sketch. His stature was tall, his limbs were large, his strength was more than common, and his activity in early life had been greater than such a form gave reason to expect: but he was subject to an infirmity of the convulsive kind, resembling the distemper called St. Vitus's dance; and he had the seeds of so many diseases sown in his constitution, that a short time before his death he declared that he hardly remembered to have passed one day wholly free from pain. He possessed very extraordinary powers of understanding; which were much cultivated by reading, and still more by meditation and reflection. His memory was remarkably retentive, his imagination uncommonly vigorous, and his judgment keen and penetrating. He read with great rapidity, retained with wonderful exactness what he so easily collected, and possessed the power of reducing to order and system the scattered hints on any subject which he had gathered from different books. It would not perhaps be safe to claim for him the highest place, among his contemporaries, in any single department of literature; but, to use one of his own expressions, he brought more *mind* to every subject, and had a greater variety of knowledge *ready* for all occasions, than any other man that could be easily named. Though prone to

superstition, he was in all other respects so remarkably incredulous, that Hogarth said, while Johnson firmly believed the bible, he seemed determined to believe nothing but the bible. Of the importance of religion he had a strong sense, and his zeal for its interests were always awake, so that profaneness of every kind was abashed in his presence. The same energy which was displayed in his literary productions, was exhibited also in his conversation, which was various, striking, and instructive: like the sage in *Rasselas*, he spoke, and attention watched his lips; he reasoned, and conviction closed his periods: when he pleased, he could be the greatest sophist that ever contended in the lists of declamation; and perhaps no man ever equalled him in nervous and pointed repartees. His veracity, from the most trivial to the most solemn occasions, was strict even to severity: he scorned to embellish a story with fictitious circumstances; for what is not a representation of reality, he used to say, is not worthy of our attention. As his purse and his house were ever open to the indigent, so was his heart tender to those who wanted relief, and his soul was susceptible of gratitude and every kind impression. He had a roughness in his manner which subdued the saucy and terrified the meek: but it was *only* in his *manner*; for no man was more loved than Johnson was by those who knew him; and his works will be read with veneration for their author as long as the language in which they are written shall be understood.

JOHNSONIA, *callicarpa*, in botany, a genus of the *tetrandria monogynia* class. Its characters are these: the flower has an empalement of one leaf, cut at the brim into four short segments: it has one tubulous petal, divided into four parts at the brim, and four slender stamina, which are longer than the petal. In the centre is situated a roundish germen, which afterwards becomes a smooth globular berry, inclosing four hard oblong seeds. Miller reckons only one species, a native of South Carolina; but Linnæus enumerates two. The leaves of the American plant were used by Dr. Dale in dropical cases with some degree of advantage.

JOIGNY, a town of France, in Champagne, and in the diocese of Sens, with a very handsome castle. It consists of three parishes, and is pleasantly situated on the river Yonne, in E. lon. 3. 25. N. lat. 47. 56.

JOINERY, the art of working in wood, or of fitting various pieces of timber together. It is called by the French *menuiserie*, "small work," to distinguish it from carpentry, which is employed about large and less curious works.

JOINT, in general, denotes the juncture of two or more things. The joints of the human body are called by anatomists *articulations*. See ANATOMY, p. 168. The suppleness to which the joints may be brought by long practice from the time of infancy, is very surprising. Every common posture-master shows us a great deal of this; but one of the most wonderful instances we ever had of it, was in a person of the name of *Clark*, and famous for it in London, where he was commonly known by the name of *Clark the posture-master*. This man had found the way, by long practice, to distort many of the bones, of which nobody before had ever thought it possible to alter the position. He had such an absolute command of his muscles and joints, that he could almost disjoint his whole body; so that he once imposed on the famous Mullens by his distortions, in such a manner, that he refused to undertake his cure: but, to the amazement of the physician, no sooner had he given over his patient, than he saw him restore himself to the figure and condition of a proper man, with no distortion about him.

JOINTURE, in law, generally signifies a settlement of lands and tenements, made on a woman in consideration of marriage.

JOINVILLE (JOHN SIRE de), an eminent French statesman of the 13th century, who was senechal or high-steward of Champagne, and one of the principal lords in the court of

Lewis IX. He attended that monarch in all his expeditions; and had so much confidence placed in him, that all matters of justice in the palace were referred to his decision, and the king undertook nothing of consequence without consulting him. He wrote the history of St. Lewis in French, which is a very curious and interesting piece; and died about the year 1318. The best edition of this work is that of Du Cange, in folio, with learned remarks.

JOINVILLE, an ancient and considerable town of France, in Champagne, with the title of a principality, and a large magnificent castle. It is situated on the river Marne, in E. lon. 5. 10. N. lat. 48. 20.

JOISTS, or **JOYSTS**, in architecture, those pieces of timber framed into the girders and summers, on which the boards of the floor are laid. See **ARCHITECTURE**.

IOLAIA, a festival at Thebes, the same as that called **Heracleia**. It was instituted in honour of Hercules and his friend Iolas, who assisted him in conquering the Hydra. It continued during several days, on the first of which were offered solemn sacrifices. The next day horse-races and athletic exercises were exhibited. The following day was set apart for wrestling; the victors were crowned with garlands of myrtle generally used at funeral solemnities. They were sometimes rewarded with tripods of brass. The place where the exercises were exhibited was called Iolaion; where there were to be seen the monument of Amphitryon and the cenotaph of Iolas, who was buried in Sardinia. These monuments were strewed with garlands and flowers on the day of the festival.

IOLAS or **IOLAUS**, in fabulous history, a son of Iphiclus king of Thesaly, who assisted Hercules in conquering the Hydra, and burnt with a hot iron the place where the heads had been cut off, to prevent the growth of others. He was restored to his youth and vigour by Hebe, at the request of his friend Hercules. Some time afterwards Iolas assisted the **HERACLIDÆ** against Eurytheus, and killed the tyrant with his own hand. According to Plutarch, Iolas had a monument in Bœotia and Phocis, where lovers used to go and bind themselves by the most solemn oaths of fidelity, considering the place as sacred to love and friendship. According to Diodorus and Pausanias, Iolas died and was buried in Sardinia, where he had gone to make a settlement at the head of the sons of Hercules by the 50 daughters of Thespius.

JOLI, or **JOLY**, (**CLAUDIUS**), a worthy parish-priest, and an excellent scholar, descended from a family eminent for learning and piety; was born at Paris in 1607. He applied himself first to the law, and pleaded for some time at the bar: but inclining afterwards to the church, he entered into orders, and in 1631 obtained a canonry in the cathedral church of Notre Dame at Paris; the duties of which office he discharged with an exactness beyond all example as long as he lived. Discovering at the same time occasionally a capacity for state-affairs, the duke de Longueville, the French plenipotentiary for negotiating a general peace, took Joly with him to Munster, where he proved a good assistant. On his return, he resumed his former employments with his usual zeal. In 1671 he was made precentor in his church; and several times official of Paris, without his seeking; always behaving, as an ecclesiastical magistrate, with perfect integrity, and testifying a sincere love for justice. He died in 1700, and left many works; in which, as in as many mirrors, his true character fully appears.

JOLI (Guy), king's counsellor to the Chatelet, and syndic of the revenues of the Hotel de Ville at Paris, attached himself for a long time to cardinal de Retz in the capacity of secretary. Beside other tracts, he wrote *Memoirs* from 1648 to 1665, including those of Cardinal de Retz; a translation of which into English was published in 1755.

JOLLOXOCHITL, or **FLOWER OF THE HEART**, in ho-

tany; a large beautiful flower growing in Mexico; where it is not less esteemed for its beauty than for its odour, which is so powerful, that a single flower is sufficient to fill a whole house with the most pleasing fragrance. It has many petals, which are glutinous, externally white, internally reddish or yellowish, and disposed in such a manner, that when the flower is open and its petals are expanded, it has the appearance of a star; but when shut it resembles in some measure a heart, from whence its name arose. The tree which bears it is tolerably large, and its leaves are long and rough. See pl. 25.

ION, in fabulous history, a son of Xuthus and Creusa daughter of Erechtheus, who married Helice, the daughter of Selinus king of Ægiæle. He succeeded to the throne of his father-in-law; and built a city, which he called *Helice* on account of his wife. His subjects from him received the name of *Ionians*, and the country that of *Ionia*. See **IONIA**.

ION, a tragic poet of Chios, who flourished about the 82d Olympiad. His tragedies were represented at Athens, where they met with universal applause. He is mentioned and greatly recommended by Aristophanes and Athenæus, &c.

IONA. See **ICOLMILL**.

JONAH, or *Prophecy of JONAH*, a canonical book of the Old Testament; in which it is related, that Jonah (about 771 B. C.) was ordered to go and prophesy the destruction of the Ninevites, on account of their wickedness. But the prophet, instead of obeying the divine command, embarked for Tarshish; when, a tempest arising, the mariners threw him into the sea: he was swallowed by a great fish; and, after being three days and nights in his belly, was cast upon the land. Hereupon being sensible of his past danger and surprising deliverance, he betook himself to the journey and embassy to which he was appointed; and arriving at Nineveh the metropolis of Assyria, he, according to his commission, boldly laid open their sins and miscarriages, and proclaimed their sudden overthrow: upon which the whole city, by prayer and fasting, and a speedy repentance, happily averted the divine vengeance, and escaped the threatened ruin. Jonah upon this, fearing to pass for a false prophet, retired to a hill at some distance from the city; where God, by a miracle, condescended to show him the unreasonableness of his discontent.

JONAS (**JUSTUS**), a Protestant divine, born at North Haufen, in Thuringia, in 1493. He was one of Luther's most zealous disciples. He contracted a strict friendship with Melancthon; became principal of the college of Wittenburg, and afterwards dean of the university of that city. He wrote a treatise in favour of the marriage of priests, and other works; and died in 1555.

JONAS (**ARNGRIMUS**), a learned Icelandèr, acquired great reputation by his skill in the sciences, and particularly in astronomy. He was the coadjutor to Gundeban de Thorlac, bishop of Holar, in Iceland. He refused that bishopric, after the death of Gundeban; and died in 1649. He wrote several works; the principal of which are, *Idea vera Mægisbratús*, and his history and description of Iceland.

JONATHAN, the son of Saul, celebrated in sacred history for his valour, and for his friendship for David against the interest of his own house. Slain in battle 1055 B. C.

JONATHAN Maccabæus, brother of Judas, a renowned general of the Jews. He forced Bacchides the Syrian general, who made war with the Jews, to accept a peace; conquered Demetrius Soter, and afterwards Apollonius, that prince's general; but, being ensnared by Tryphon, was put to death 144 B. C.

JONES (**INIGO**), a celebrated English architect, was the son of a cloth-worker of London, and was born in 1572. He was at first put apprentice to a joiner; but early distinguished himself by his inclination to drawing or designing, and was par-

particularly taken notice of for his skill in landscape-painting. This afterwards recommended him to the favour of William earl of Pembroke, who sent him abroad with a handsome allowance in order to perfect himself in that branch. He was no sooner at Rome, than he found himself in his proper sphere: he felt that nature had not formed him to decorate cabinets, but to design palaces. He dropt the pencil, and conceived Whitehall. In the state of Venice he saw the works of Palladio, and learned how beautifully taste may be exerted on a less theatre than the capital of an empire. How his abilities distinguished themselves in a spot where they certainly had no opportunity to act, we are not told, though it would not be the least curious part of his history; certain it is, that, on the strength of his reputation at Venice, Christian IV. invited him to Denmark, and appointed him his architect; but on what buildings he was employed in that country, we are yet to learn. James I. found him at Copenhagen, and queen Ann took him in the quality of her architect to Scotland. He served prince Henry in the same capacity, and the place of surveyor-general of the works was granted to him in reversion. On the death of that prince, with whom at least all his lamented qualities did not die, Jones travelled once more into Italy, and, assisted by ripeness of judgment, perfected his taste. To the interval between these voyages Mr. Walpole is inclined to assign those buildings of Inigo, which are less pure, and border too much upon the bastard style, which one may call *king James's Gothic*. Inigo's designs of that period are not Gothic, but have a little-ness of parts, and a weight of ornaments, with which the revival of the Grecian taste was encumbered, and which he shook off in his grander designs. The surveyor's place fell, and he returned to England; and, as if architecture was not all he had learned at Rome, with an air of Roman disinterestedness he gave up the profits of his office, which he found extremely in debt; and prevailed upon the comptroller and pay-master to imitate his example, till the whole arrears were cleared.

In 1620 he was employed in a manner very unworthy of his genius: king James set him upon discovering, that is, guessing, who were the founders of Stonehenge. His ideas were all Romanized; consequently, his partiality to his favourite people, which ought rather to have prevented him from charging them with that mass of barbarous clumsiness, made him conclude it a Roman temple.

In the same year Jones was appointed one of the commissioners for the repair of St. Paul's; but which was not commenced till the year 1633, when Laud, then bishop of London, laid the first stone, and Inigo the fourth. In the restoration of that cathedral, he made two capital faults. He first renewed the sides with very bad Gothic; and then added a Roman portico, magnificent and beautiful indeed, but which had no affinity with the ancient parts that remained, and made his own Gothic appear ten times heavier. He committed the same error at Winchester, thrusting a screen in the Roman or Grecian taste into the middle of that cathedral. Jones indeed was by no means successful when he attempted Gothic. The chapel of Lincoln's Inn has none of the characteristics of that architecture. The cloyster beneath seems oppressed by the weight of the building above.

The authors of the Life of Jones place the erecting of the Banqueting-house in the reign of king Charles; but it appears, from the accounts of Nicholas Stone, that it was begun in 1619, and finished in two years—a small part of the pile designed for the palace of our kings; but so complete in itself, that it stands a model of the most pure and beautiful taste. Several plates of the intended palace at Whitehall have been given; but Mr. Walpole thinks, from no finished design. The four great sheets are evidently made up from general hints; nor could such a source of invention and taste as the mind of

Inigo ever produce so much sameness. The whole fabric, however, was so glorious an idea, that one forgets for a moment (says Mr. Walpole), in the regret for its not being executed, the confirmation of our liberties, obtained by a melancholy scene that passed before the windows of that very Banqueting-house.

In 1623 he was employed at Somersethouse, where a chapel was to be fitted up for the Infanta, the intended bride of the prince. The chapel is still in being. The front to the river, part only of what was designed, and the water-gate, were erected afterwards on the designs of Inigo, as was the gate at York-stairs.

On the accession of Charles, Jones was continued in his posts under both king and queen. His fee as surveyor was 8s. 4d. a day, with an allowance of 46l. a-year for house-rent, besides a clerk, and incidental expences. What greater rewards he had are not upon record.

During the prosperous state of the king's affairs, the pleasures of the court were carried on with much taste and magnificence. Poetry, painting, music, and architecture, were all called in to make them rational amusements. Mr. Walpole is of opinion, that the celebrated festivals of Louis XIV. were copied from the shows exhibited at Whitehall, in his time the most polite court in Europe. Ben Jonson was the laureat; Inigo Jones the inventor of the decorations; Lanieri and Ferrabosco composed the symphonies; the king, the queen, and the young nobility danced in the interludes. We have accounts of many of those entertainments, called *masques*; they had been introduced by Anne of Denmark. Lord Burlington had a folio of the designs for these solemnities, by Inigo's own hand, consisting of habits, masks, scenes, &c. The harmony of these masks was a little interrupted by a war that broke out between the composers, Inigo and Ben; in which, whoever was the aggressor, the turbulent temper of Jonson took care to be most in the wrong.

The works of Inigo Jones are not scarce; Surgeon's hall is one of his best works. One of the most admired is the Arcade of Covent-garden, and the Church: "two structures (says Mr. Walpole), of which I want taste to see the beauties. In the arcade there is nothing remarkable; the pilasters are asarrant and homely stripes as any plasterer would make. The barn-roof over the portico of the church strikes my eyes with as little idea of dignity and beauty, as it could do if it covered nothing but a barn. It must be owned, that the defect is not in the architect, but in the order.—Who ever saw a beautiful Tuscan building? Would the Romans have chosen that order for a temple?" The expence of building that church was 4500l.

Ambresbury in Wiltshire was designed by Jones, but executed by his scholar Webb. Jones was one of the first that observed the same diminution of pilasters as in pillars. Lindsey-house in Lincoln's-lin Fields, which he built, owes its chief grace to this singularity. In 1618 a special commission was issued to the lord chancellor, the earls of Worcester, Pembroke, Arundel, and others, to plant and reduce to uniformity Lincoln's-lin Fields, as it should be drawn by way of map, or ground-plot, by Inigo Jones, surveyor-general of the works. That square is laid out with a regard to so trifling a singularity, as to be of the exact dimensions of one of the pyramids: this would have been admired in those ages when the Keep at Kennelworth Castle was erected in the form of an horse-fetter, and the Escorial in the shape of St. Laurence's gridiron.

Colehill in Berkshire, the seat of Sir Matthew Pleydell, built in 1650, and Cobham-hall in Kent, were Jones's. He was employed to rebuild Castle Ashby, and finished one front: but the civil war interrupted his progress there and at Stoke-park in Northamptonshire. Shaftsbury-house, now the General Dispensary, on the east side of Aldersgate-street, is a beautiful

front. The Grange, the seat of the lord chancellor Henley, in Hampshire, is entirely of this master. It is not a large house, but by far one of the best proofs of his taste. The hall, which opens to a small vestibule with a cupola, and the stair-case adjoining, are beautiful models of the purest and most classic antiquity. The gate of Peaufort-garden at Chelsea, designed by Jones, was purchased by lord Burlington, and transported to Chiswick. He drew a plan for a palace at Newmarket; but not that wretched hovel that stands there at present. One of the most beautiful of his works is the Queen's house at Greenwich. The first idea of the hospital is said to have been taken by his scholar Webb, from his papers.

Inigo tasted early the misfortunes of his master. He was not only a favourite, but a Roman Catholic: in 1646 he paid 545 l. for his delinquency and sequestration. Whether it was before or after this fine, it is uncertain, that he and Stone the mason buried their joint stock in Scotland-yard; but an order being published to encourage the informers of such concealments, and four persons being privy to the spot where the money was hid, it was taken up, and reburied in Lambeth-marsh. Grief, misfortunes, and age, put an end to his life at Somerset-house, July 21, 1651. Several of his designs have been published by Mr. Kent, Mr. Colin Campbell, and Mr. Isaac Ware. He left in MS. some curious notes on Palladio's architecture, which are inserted in an edition of Palladio published in 1714.

IONIA, a country of Asia minor, bounded on the north by Æolia, on the west by the Ægean and Icarian seas, on the south by Caria, and on the east by Lydia and part of Caria. It was founded by colonies from Greece, and particularly Attica, by the Ionians or subjects of Ion. Ionia was divided into 12 small states, which formed a celebrated confederacy often mentioned by the ancients. These 12 states were Priene, Miletus, Colophon, Clazomenæ, Ephesus, Lebedos, Teos, Phocæa, Erythræ, Smyrna, and the capitals of Samos and Chios. The inhabitants of Ionia built a temple which they called *Pan Ionium* from the concourse of people that flocked there from every part of Ionia. After they had enjoyed for some time their freedom and independence, they were made tributary to the power of Lydia by Cræsus. The Athenians assisted them to shake off the slavery of the Asiatic monarchs; but they soon forgot their duty and relation to their mother-country, and joined Xerxes when he invaded Greece. They were delivered from the Persian yoke by Alexander, and restored to their original independence. They were reduced by the Romans under the dictator Sylla. Ionia has been always celebrated for the salubrity of the climate, the fruitfulness of the soil, and the genius of its inhabitants.

IONIC ORDER. See ARCHITECTURE.

IONIC *Dialect*, in grammar, a manner of speaking peculiar to the people of Ionia.

IONIC *Sect* was the first of the ancient sects of philosophers; the others were the Italic and Eleatic. The founder of this sect was Thales, who, being a native of Miletus in Ionia, occasioned his followers to assume the appellation of *Ionian*: Thales was succeeded by Anaximander, and he by Anaximenes, both of Miletus; Anaxagoras Clazomenius succeeded them, and removed his school from Asia to Athens, where Socrates was his scholar. It was the distinguishing tenet of this sect, that water was the principle of all natural things.

IONIUM MARE, a part of the Mediterranean Sea, at the bottom of the Adriatic. It lies between Sicily and Greece. That part of the Ægean sea which lies on the coasts of Ionia in Asia, is called the *Sea of Ionia*, and not the *Ionian Sea*. According to some authors, the Ionian sea receives its name from Io, who swam across there after she had been metamorphosed into a heifer.

JONK, or JONGUE, in naval affairs, is a kind of small ship, very common in the East Indies. These vessels are about the

bigness of our fly-boats; and differ in the form of their building, according to the different methods of naval architecture used by the nations to which they belong. Their sails are frequently made of mats, and their anchors are made of wood.

JONSON (BEN), see JOHNSON.

JONSTON (JOHN), a learned Polish naturalist and physician, born in 1603. He travelled all over Europe, and procured esteem every where by his knowledge; afterward he bought the estate of Ziebendorf, in the duchy of Lignitz in Silesia, where he spent the remainder of his days. He wrote a natural history of birds, fish, quadrupeds, insects, serpents, and dragons, in folio; a piece upon the Hebrew and Greek festivals, a thaumatography, and some poems. He died in 1675.

JOPPA, a sea-port town in Palestine, lying south of Cæsarea; and anciently the only port to Jerusalem, whence all the materials sent from Tyre towards the building of Solomon's temple were brought hither and landed (2 Chr. ii. 16.). It is said to have been built by Japhet, and from him to have taken its name *Japho*, afterwards moulded into *Joppa*; and the very heathen geographers speak of it as built before the Flood. It is now called *Jaffa*, somewhat nearer to its first appellation, and is but in a poor and mean condition.

JOR, the Hebrew for a river, which, joined with Dan, concurs to form the term *Jordan*. See DAN.

JORDANO (LUCA), an eminent Italian painter, was born at Naples in 1632. He became very early a disciple of Joseph Ribera; but going afterwards to Rome he attached himself to the manner of Pietro da Cortona, whom he assisted in his great works. Some of his pictures being seen by Charles II. king of Spain, he engaged him in painting the Escorial; in which task he acquitted himself as a great painter. The king showed him a picture of Bassani, expressing his concern that he had not a companion: Luca painted one to exactly in Bassani's manner, that it was taken for a performance of that master; and for this service he was knighted, and gratified with several honourable and valuable employments. The great works he executed in Spain, gave him still greater reputation when he returned to Naples; so that, though he was a very quick workman, he could not supply the eager demands of the citizens. No one, not even Tintoret, ever painted so much as Jordano; and his generosity carried him so far as to present altar-pieces to churches that were not able to purchase them. His labours were rewarded with great riches; which he left to his family, when he died, in 1705.

JORDANS (JAMES), one of the most eminent painters of the Flemish school, was born at Antwerp in 1593. He learned the principles of his art from Adam Van Ort, whose daughter he married; which connection hindered him from gratifying his inclination of visiting Italy. He improved most under Rubens; for whom he worked, and from whom he drew his best principles: his taste directed him to large pieces; and his manner was strong, true, and sweet. A great number of altar-pieces painted by him are preserved in the churches in the Netherlands, which maintain the reputation of this artist. He died in 1678.

JORTIN (JOHN), a very learned and ingenious English clergyman, was born in Huntingdonshire about the year 1701. Having some private fortune of his own, and being of a peculiar disposition that could not solicit promotion, he remained long without preferment. In 1738, lord Winchester gave him the living of Eastwell in Kent; but the place not agreeing with his health, he soon resigned it. Archbishop Herring, who had a great value for him, about the year 1751 presented him to the living of St. Dunstan's in the East; and bishop Osbaldiston in 1762 gave him that of Kensington, with a prebend in St. Paul's cathedral, and made him archdeacon of London. His temper, as well as his aspect, was rather morose and saturnine; but in company that he liked, he was at all times facetious, yet still

with a mixture of *sal censura superiorum*. His sermons were sensible and argumentative; and would have made more impression on his hearers, had he been more attentive to the advantages flowing from a good delivery: but he appeared to greater advantage as a writer. His remarks on ecclesiastical history, his six dissertations, his life of Erasmus, and his sermons, were extremely well received by the public, and have undergone several editions. He died in the year 1770.

JOSEPH, the son of Jacob; memorable for his chastity, and the honours conferred on him at the court of Egypt, &c. He died in 1635 B. C. aged 110.

JOSEPHUS, the celebrated historian of the Jews, was of noble birth, by his father Mattathias descended from the high-priests, and by his mother of the blood-royal of the Maccabees: he was born A. D. 37, under Caligula, and lived under Domitian. At 16 years of age he betook himself to the sect of the Essenes, and then to the Pharisees; and having been successful in a journey to Rome, upon his return to Judæa he was made captain-general of the Galilæans. Being taken prisoner by Vespasian, he foretold his coming to the empire, and his own deliverance by his means. He accompanied Titus at the siege of Jerusalem, and wrote his "Wars of the Jews," which Titus ordered to be put in the public library. He afterwards lived at Rome, where he enjoyed the privileges of a Roman citizen, and where the emperors loaded him with favours, and granted him large pensions. Besides the above work, he wrote, 1. Twenty books of Jewish antiquities, which he finished under Domitian. 2. Two books against Apion. 3. An elegant discourse on the martyrdom of the Maccabees. 4. His own life. These works are excellently written in Greek.

JOSHUA, the renowned general of the Jews, who conducted them through the wilderness, &c. died in 1424 B. C. aged 110.

JOSHUA, a canonical book of the Old Testament, containing a history of the wars and transactions of the person whose name it bears. This book may be divided into three parts: the first of which is a history of the conquest of the land of Canaan; the second, which begins at the 12th chapter, is a description of that country, and the division of it among the tribes; and the third, comprised in the two last chapters, contains the renewal of the covenant he caused the Israelites to make, and the death of their victorious leader and governor. The whole comprehends a term of 17, or, according to others, of 27 years.

JOSIAH, king of Judah; the destroyer of idolatry, and the restorer of the true worship, an excellent magistrate, and a valiant general, was slain in battle, 609 B. C.

JOTAPATA, in ancient geography, a town of the Lower Galilee, distant 40 stadia from Gabara; a very strong place, situated on a rock, walled round, and encompassed on all hands with mountains, so as not to be seen but by those who came very near. It was with great difficulty taken by Vespasian, being defended by Josephus, who commanded in it; when taken, it was ordered to be razed.

JOUBERT (LAWRENCE), counsellor and physician to the king of France, chancellor and judge of the university of Montpellier, was born at Valance in Dauphiny in 1530. He became the disciple of Rondelet at Montpellier; and at his death succeeded to the regius professorship of that university, where he had given abundant proofs of his merit, and strengthened his reputation by the lectures he read in that capacity, as well as by the works he published. Henry III, who passionately wished to have children, sent for him to Paris, in hopes by his assistance to render his marriage fruitful; but he was disappointed, without any loss of repute to Joubert. Much offence was indeed taken at a piece he published under the title

of *Vulgar Errors*, in which he treated of virginity and generation more plainly than had ever before been done in the French language. But, though he had promised something more on the same subject, he was so piqued at the clamour raised against it, that the public saw no more of six parts promised, than the first, and part of the second, though they were greatly called for. He died in 1582; and his son Isaac translated some of his Latin paradoxes into French.

JOVIAN, the Roman emperor, elected by the army, after the death of Julian the apostate, in 363. He at first refused, saying he would not command idolatrous soldiers; but, upon an assurance that they would embrace Christianity, he accepted the throne, and immediately shut all the Pagan temples, and forbade their sacrifices. But he did not long enjoy the dignity to which his merit had raised him; being suffocated in his bed by the fumes of a fire that had been made to dry the chamber, in 364, the 33d of his age, and the eighth month of his reign.

JOVIUS (PAUL), in Italian *Giovio*, a celebrated historian, was born at Como in Italy in the year 1483. As his father died in his infancy, he was educated by his eldest brother Benedict Jovius, under whom he became well skilled in classical learning; and then went to Rome, for the sake of enjoying the benefit of the Vatican library. He there wrote his first piece, *De piscibus Romanis*, which he dedicated to cardinal Lewis of Bourbon. He received a pension of 500 crowns for many years from Francis I. king of France, whose favour he secured by his flatteries. But, in the following reign, having disgusted the constable Montmorency, his name was struck out of the list of pensioners. Jovius did not suffer his spirits to sink under his misfortune: he had obtained a high reputation in the learned world by his writings; and having always showed great respect to the house of Medicis, on whose praises he had expatiated in his works, he applied to Clement VII. and obtained the bishoprick of Nocera. His principal piece is his history, which is that of his own time throughout the world, beginning with 1494, and extending to the year 1544. This was the chief business of his life. For he formed the plan of it in the year 1515; and continued upon it till his death, which happened at Florence in 1552. It is printed in three volumes folio. He is allowed to have been a man of wit as well as learning: he was master of a bright and polished style, and has many curious observations: but being a venal writer, his histories are not much credited.

JOURNAL, a day-book, register, or account of what passes daily. See DIARY. In merchants' accounts, it denotes a book into which every particular article is posted out of the waste-book, and made debtor. This is to be very clearly worded, and fairly engrossed. See BOOK-KEEPING.

JOURNAL, in navigation, a sort of diary, or daily register of the ship's course, winds, and weather; together with a general account of whatever is material to be remarked in the period of a sea-voyage. In all sea journals, the day, or what is called the 24 hours, terminates at noon, because the errors of the dead-reckoning are at that period generally corrected by a solar observation. The daily compact usually contains the state of the weather; the variation, increase, or diminution of the wind; and the suitable shifting, reducing, or enlarging the quantity of sail extended; as also the most material incidents of the voyage, and the condition of the ship and her crew; together with the discovery of other ships or fleets, lands, shoals, breakers, soundings, &c.

JOURNAL is also a name common for weekly essays, newspapers, &c. as the Gray's-Inn journal, the Westminster journal, &c.

JOURNAL is also used for the titles of several books which come out at stated times, and give abstracts, accounts, &c. of the books that are published, and the new improvements daily.

made in arts and sciences; as the *Journal des Sçavans*, *Journal de l'Physique*, &c.

JOUVENET (JOHN), a celebrated French painter, was born at Rouen in 1644; where his father, who was a painter, bred him up to the same profession: but his greatest improvement was confessedly derived from the instructions of Nicholas Poussin, and studying the works of that master. He acquired so good a knowledge of design, as qualified him for employment in several grand works in the palaces at Paris and Trianon; in many of the churches and convents; and in the hospital of invalids, where he painted the twelve apostles, each figure being 14 feet high. He was esteemed to have a ready invention, to be correct in his designs, and to have a taste for grandeur in his compositions: it is observed of this artist, that, being deprived of the use of his right hand by a paralytic disorder, he nevertheless continued to paint with his left. He died in the year 1717.

JOY, in ethics, is that passion which is produced by love, regarding its object as present, either immediately or in prospect, in reality or imagination. This passion has been said to increase the PERSPIRATION and urine of human bodies.

IPECACUANHA, in the materia medica, a West-Indian root, of which there are principally two kinds, distinguished by their colour, and brought from different places; but both possessing the same virtues, though in a different degree. The one is ash coloured or grey, and brought from Peru; the other is brown, and is brought from the Brasils: and these are indifferently sent into Europe under the general name of *ipecacuanha*. These two sorts have been by some supposed to be the roots of two different plants: but, according to others, this is a mistake; the only difference being, that one grows in a different place, and in a richer and moister soil, and is better supplied with juices than the other. The plant they belong to is a species of *PSYCHOTRIA*.

The ash-coloured ipecacuan is a small wrinkled root, bent and contorted into a great variety of figures, brought over in short pieces full of wrinkles, and deep circular fissures, quite down to a small white woody fibre that runs in the middle of each piece: the cortical part is compact, brittle, looks smooth and resinous upon breaking: it has very little smell; the taste is bitterish and subacid, covering the tongue as it were with a kind of mucilage. The brown sort is small, and somewhat more wrinkled than the foregoing; of a brown or blackish colour without, and white within. The first sort, the ash-coloured or grey ipecacuan, is that usually preferred for medicinal use. The brown has been sometimes observed, even in a small dose, to produce violent effects. A third sort, called the *white* from its colour, has also been distinguished. It is woody, has no wrinkles, and no perceptible bitterness in taste. This, though taken in a large dose, has scarcely any effect at all. It is supposed to belong to a species of *VIOLA*. Mr. Geoffroy calls this sort *bastard ipecacuan*, and complains that it is an imposition upon the public. Geoffroy, Neumann, Dale, and Sir Hans Sloane, inform us, that the roots of a kind of apocynum (dogs-bane) are too frequently brought over instead of it; and instances are given of ill consequences following from the use of it. But if the marks above laid down, particularly the ash colour, brittleness, deep wrinkles, and bitterish taste, be carefully attended to, all mistakes of this kind may be prevented.

Ipecacuan was first brought into Europe about the middle of last century, and an account of it published about the same time by Pifo; but it did not come into general use till about the year 1786, when Helvetius, under the patronage of Louis XIV. introduced it into practice. This root is one of the mildest and safest emetics with which we are acquainted; and has this peculiar advantage, that if it should not operate by

vomit, it passes off by the other emunctories. It was first introduced among us with the character of an almost infallible remedy in dysenteries, and other inveterate fluxes, as menorrhagia and leucorrhœa, and also in disorders proceeding from obstructions of long standing: nor has it lost much of its reputation by time. In dysenteries, it almost always produces happy effects, and often performs a cure in a very short space of time. In other fluxes of the belly, in beginning dysenteries, and such as are of a malignant kind, or where the patient breathes a tainted air, it has not been found equally successful: in these cases it is necessary to continue the use of this medicine for several days, and to join with it opiates, diaphoretics, and the like. This root, given in substance, is as effectual, if not more so, than any of the preparations of it: the pure resin acts as a strong irritating emetic, but is of little service in dysenteries; while an extract prepared with water is almost of equal service in these cases with the root itself, though it has little effect as an emetic. Geoffroy concludes from hence, that the chief virtue of ipecacuan in dysenteries depends upon its gummy substance, which lining the intestines with a soft mucilage, when their own mucus has been abraded, occasions their exulcerations to heal, and defends them from the acrimony of the juices: and that the resinous part, in which the emetic quality resides, is required where the morbid matter is lodged in the glands of the stomach and intestines. But if the virtues of this root were entirely owing to its mucilaginous or gummy part, pure gum, or mucilages, might be employed to equal advantage. Water, assisted by a boiling heat, takes up from all vegetables a considerable portion of resinous along with the gummy matter: if the ipecacuan remaining after the action of water be digested with pure spirit, it will not yield half so much resin as at first; so that the aqueous extract differs from the crude root only in degree, being proportionably less resinous, and having less effect, both as an emetic, and in the cure of dysenteries. The virtues of ipecacuan, in this disorder, depend upon its promoting perspiration, the freedom of which is here of the utmost importance, and an increase of which, even in healthful persons, is generally observed to suppress the evacuation by stool. In dysenteries, the skin is for the most part dry and tense, and perspiration obstructed: the common diaphoretics pass off without effect through the intestinal canal: but ipecacuan, if the patient after a puke or two be covered up warm, brings on a plentiful sweat. After the removal of the dysentery, it is necessary to continue the use of the medicine for some time longer, in order to prevent a relapse; for this purpose, a few grains divided into several doses, so as not to occasion any sensible evacuation, may be exhibited every day: by this means the cure is effectually established. And indeed small doses, given even from the beginning, have been often found to have better effects in the cure of this disease than larger ones. Geoffroy informs us from his own experience, that he has observed ten grains of the powder to act as effectually as a scruple or two; and therefore confines the dose betwixt six and ten grains: it has lately been found, that even smaller doses prove sufficiently emetic. The only officinal preparation of this root is a tincture made in wine, which accordingly has now the appellation of *vinum ipecacuanbæ* both in the London and Edinburgh pharmacopœias.

Many ingenious experiments have been made on the subject of ipecacuan by Dr. Irving, for which he obtained the prize medal of the Harveian Society at Edinburgh for 1784. He has ascertained, that while this root contains a gummy resinous matter, yet that the gummy exists in a much greater proportion than the resinous part; that the gummy part is much more powerfully emetic than the resinous; that although the cortical part of the root be more active than the ligneous,

yet that even the pure ligneous part possesses a considerable emetic power; and that the whole of the root possesses considerable influence, both as an antiseptic and astringent. To determine whether the emetic power of ipecacuan was of a volatile or fixed nature, Dr. Irving subjected it to distillation. The water obtained by distillation was found to have very little influence; but the decoction which remained in the still, not only operated violently as an emetic, but produced rigours, cold sweats, and other alarming symptoms. By long continued boiling, the activity of the root itself is almost totally destroyed; but Dr. Irving found, that the emetic property of ipecacuan was most effectually counteracted by means of the acetous acid, inasmuch that thirty grains of the powder taken in two ounces of vinegar produced only some loose stools.

Ipecacuan, particularly in the state of powder, is now advantageously employed in almost every disease in which full vomiting is indicated; and when combined with opium under the form of the pulvis sudorificus, it furnishes us with the most useful and active sweating medicine which we possess. It is also often given with advantage in very small doses, so as neither to operate by vomiting, purging, nor sweating.

The full dose of the powder is a scruple or half a dram, and double that in form of watery infusion. The full dose is recommended in the paroxysm of spasmodic asthma, and a dose of three or four grains every morning in habitual asthmatic indisposition. A dose of $\frac{1}{3}$ or $\frac{1}{2}$ grain rubbed with sugar, and given every four hours or oftener, is recommended in uterine hemorrhagy, cough, pleurisy, hæmoptœ, &c. and has often been found highly serviceable.

IPHIGENIA, a daughter of Agamemnon and Clytemnestra. When the Greeks going to the Trojan war were detained by contrary winds at Aulis, they were informed by one of the soothsayers, that to appease the gods they must sacrifice Iphigenia, Agamemnon's daughter, to Diana. The father, who had provoked the goddess by killing her favourite stag, heard this with the greatest horror and indignation; and rather than shed the blood of his daughter, he commanded one of his heralds, as chief of the Grecian forces, to order all the assembly to depart each to his respective home. Ulysses and the other generals interfered, and Agamemnon consented to immolate his daughter for the common cause of Greece. As Iphigenia was tenderly loved by her mother, the Greeks sent for her on pretence of giving her in marriage to Achilles. Clytemnestra gladly permitted her departure, and Iphigenia came to Aulis. Here she saw the bloody preparations for the sacrifice. She implored the forgiveness and protection of her father; but tears and entreaties were unavailing. Calchas took the knife in his hand; and as he was going to strike the fatal blow, Iphigenia suddenly disappeared, and a goat of uncommon size and beauty was found in her place for the sacrifice. This supernatural change animated the Greeks, the wind suddenly became favourable, and the combined fleet set sail from Aulis.

IPICRATIS, general of the Athenians, had that command conferred upon him at 20 years of age, and became famous for the exactness of his military discipline. He made war on the Thracians; restored Scythæ, who was an ally of the Athenians; attacked the Lacedæmonians; and, on many other occasions, gave signal proofs of his conduct and courage. Many ingenious repartees have been mentioned of this general: a man of good family with no other merit than his nobility, reproaching him one day for the meanness of his birth, he replied, "I shall be the first of my race, and thou the last of thine." He died 480 B. C.

IPOMEA, QUAMOILIT, or *Scarlet Convulvulus*; a genus of the rotogymna order, belonging to the pentandria class of plants; and in the natural method ranking under the 29th order, *Companaceæ*. The corolla is funnel-shaped; the stigma

round-headed; the capsule trilocular. There are several species; but not more than one (the *coccinea*) cultivated in our gardens. This hath long, slender, twining stalks, rising upon support six or seven feet high. The leaves are heart-shaped, pointed, and angulated at the base; and from the sides of the stalks and branches arise many slender foot-stalks, each supporting several large and beautiful funnel-shaped and scarlet flowers. There is a variety with orange-coloured flowers. Both of them are annual, rising from seed in spring, flowering in July and August, ripening their seeds in September and October, and totally perishing in a short time after. They are tender, and must be brought up in a hot-bed till the latter end of May or beginning of June, when they may be planted out to adorn the borders, or some may be planted in pots to move occasionally to adorn any particular place; but in either case there must be sticks for them to twine upon.

IPSWICH, a borough of Suffolk, with markets on Wednesday, Friday and Saturday. It is seated on the river Orwell, near the place where the fresh and salt water meet. It is a place of great antiquity, and was once surrounded by a wall, traces of which are yet to be seen. It is divided into four wards, containing 12 parish churches, with a Presbyterian, an Independent, and a Quaker's meeting-house; and has a handsome guild-hall, two hospitals, a free-school, with a good library, several alms-houses, and a custom-house with a good quay. It is governed by two bailiffs, a recorder, 12 portmen (from whom two bailiffs are chosen), a town-clerk, 2 chamberlains, 2 coroners, and 24 common-council-men. It is populous and well inhabited, though irregularly built; but it has declined from its former consequence. Its manufactures of broad-cloth and canvas are at an end; and its present commerce chiefly depends upon the malting and exportation of corn. It has a considerable coasting trade and a small share of foreign commerce, and has lately sent ships to Greenland. Vessels of large burden are obliged to stop at some distance below the town. It is noted for being the birth-place of Cardinal Wolfey; is 20 miles N. E. of Colchester, and 69 N. E. of London. E. lon. 1. 16. N. lat. 52. 8.

IRASCIBLE, in the old philosophy, a term applied to an appetite or a part of the soul where anger and the other passions, which animate us against things difficult or odious, were supposed to reside. Of the eleven kinds of passions attributed to the soul, philosophers ascribe five to the irascible appetite; viz. wrath, boldness, fear, hope, and despair: the other six are charged on the concupiscible appetite, viz. pleasure, pain, desire, aversion, love, and hatred. Plato divided the soul into three parts; the reasonable, irascible, and concupiscible parts. The two last, according to that philosopher, are the corporeal and mortal parts of the soul, which give rise to our passions. Plato fixes the seat of the irascible appetite in the heart; and of the concupiscible in the liver; as the two sources of blood and spirits, which alone affect the mind.

IRELAND, one of the British islands lying to the W. of that of Great Britain. It is bounded on the E. by St. George's Channel and the Irish sea, which separate it from England and Wales; on the N. E. by a channel about 20 miles broad, which separates it from Scotland; and on every other side by the ocean. It lies between W. lon. 5. 25. and 10. 40. and between N. lat. 51. 15. and 55. 15. being about 278 miles in length, and 155 in breadth. It is divided into four large provinces; namely, Ulster to the N. Leinster to the E. Munster to the south, and Connaught to the W.; and these are subdivided into counties. The air is mild and temperate, being cooler in summer, and warmer in winter, than in England: though it is not so clear and pure, nor so proper for ripening corn and fruits. It is more humid than in England; for which reason strangers at first are very liable to colds, &c. but this

quality is pretty much mended, and will be more so when the bogs and morasses are drained. In general, it is a fruitful, level country, well watered with lakes and rivers; and the soil, in most parts, is very good and fertile: even in those places where the bogs and morasses have been drained, there is good meadow ground. It produces corn, hemp, and flax, in great plenty; and there are so many cattle, that their beef and butter are exported into foreign parts; and not only the English but other ships frequently come to be victualled here. The principal riches and commodities of Ireland are, cattle, hides, wool, tallow, suet, butter, cheese, wood, salt, honey, wax, furs, hemp, and, more especially, fine linen cloth, which they have brought to great perfection, and their trade in it is vastly increased. This country is exceedingly well situated for foreign trade, on account of their many secure and commodious harbours. Their laws differ but little from those of England; and the established religion is the same. The members of parliament usually sat for life, unless upon the demise of the king of Great Britain; but in 1768 their parliaments were made octennial. Formerly, this kingdom was entirely subordinate to that of Great Britain, whose parliament could make laws to bind the people of Ireland; and an appeal might be made from their courts of justice to the house of lords in England: but, in 1782, it was declared, that although Ireland was an imperial crown, inseparably annexed to that of Britain (on which connection the interest and happiness of both nations essentially depended), yet the kingdom of Ireland was distinct, with a parliament of its own, and that no body of men were competent to make laws for Ireland, except the king, lords, and commons thereof. And, some time after, this declaration being thought insufficient, the British legislature, in the most solemn manner, by an express act of parliament for that purpose, relinquished all claim of right to interfere with the judgment of the Irish courts, or to make laws to bind Ireland in time to come. The lord lieutenant of Ireland, as well as the council, are appointed from time to time by the king. There is usually a body of 16,000 men kept in pay on the Irish establishment. They are not quartered in public houses, but lodge in barracks built for that purpose. There are a great number of Roman catholics in this country, whose religion is tolerated, and to whom, in 1793, the liberal spirit of the Irish legislature granted many important concessions. There are likewise many protestant dissenters, particularly in the N. of Ireland. Dublin is the only university in the kingdom; and that consists of one college, in which there are about 600 students. The common people were so poor, and it was so hard for them to get a livelihood, that they frequently went into other countries to seek their fortunes; and, particularly, great numbers went over to the plantations in America. That part of the inhabitants called the Wild Irish, were formerly as savage as the native Americans; and, like them, lived in huts, making a fire in the middle of them: but it is to be hoped that all the rude and barbarous customs, by which they have been hitherto distinguished from more civilized people, as well as every other trace of wretchedness and degradation, will vanish in time, since the emancipation of the country has removed the ancient restrictions on their commerce and manufactures, and left them to the pursuits of industry and enterprise, on the same footing as the happiest subjects of the British empire. Ireland contains 32 counties, four archbishoprics, and 18 bishoprics. Its principal rivers are the Shannon, Boyne, Liffey, &c. Dublin is the capital.

IRENÆUS (St.), a bishop of Lyons, was born in Greece about the year 120. He was the disciple of Pappias and St. Polycarp, by whom, it is said, he was sent into Gaul in 157. He stopped at Lyons, where he performed the office of a priest; and in 178 was sent to Rome, where he disputed with Valentinus, and his two disciples Florinus and Blastus. At his re-

turn to Lyons, he succeeded Photinus, bishop of that city; and suffered martyrdom in 202, under the reign of Severus. He wrote many works in Greek, of which there only remains a barbarous Latin version of his five books against heretics, some Greek fragments in different authors, and pope Victor's letter mentioned by Eusebius. The best editions of his works are those of Erasmus, in 1526; of Grabe, in 1702; and of Father Massuet, in 1710. St. Irenæus's style is close, clear, and strong, but plain and simple. Dodwell has composed six curious dissertations on the works of St. Irenæus. He ought not to be confounded with St. Irenæus the deacon, who in 255 suffered martyrdom in Tuscany, under the reign of Aurelian; nor with St. Irenæus bishop of Sirmich, who suffered martyrdom on the 25th of March 304, during the persecution of Dioclesian and Maximianus.

IRENE, empress of the East, celebrated for her valour, wit, and beauty; but detestable for her cruelty, having sacrificed her own son to the ambition of reigning alone. She died in 803.

IRENE, in botany; a genus of the pentandria order, belonging to the diœcia class of plants; and in the natural method ranking under the 54th order, *Miscellanea*. The male calyx is diphyllous, the corolla pentapetalous; and there are five nectaria. The female calyx is diphyllous, the corolla pentapetalous; there are two sessile stigmata, and a capsule with fleshy seeds.

IRIS, in physiology, the rainbow. The word is Greek, *ἰρις*, supposed by some to be derived from *ἔρω* "I speak, I tell;" as being a meteor that is supposed to foretell, or rather to declare, rain. See RAINBOW.

Lunar IRIS, or Moon-rainbow. See Lunar RAINBOW.

IRIS, in anatomy, a striped variegated circle round the pupil of the eye, formed of a duplicature of the uvea. See ANATOMY, p. 210.

IRIS is also applied to those changeable colours which sometimes appear in the glasses of telescopes, microscopes, &c. so called from their similitude to a rainbow. The same appellation is also given to that coloured spectrum, which a triangular prismatic glass will project on a wall when placed at a due angle in the sun-beams.

IRIS, the *Flower de Luce*, or Flag-flower, &c. in botany; a genus of the monogynia order, belonging to the triandria class of plants; and in the natural method ranking under the sixth order, *Ensatæ*. The corolla is divided into six parts; the petals alternately reflexed: the stigmata resembling petals.

There are 44 species, all herbaceous, flowering perennials, both of the fibrous, tuberous, and bulbous rooted kind, producing thick annual stalks from 3 or 4 inches to a yard high, terminated by large hexapetalous flowers, having three of the petals reflexed quite back, and three erect; most of which are very ornamental, appearing in May, June, and July. All the species are easily propagated by offsets from the roots, which should be planted in September, October, or November, though almost any time from September to March will do. They may also be raised from seed, which is the best method for procuring varieties. It is to be sown in autumn, soon after it ripens, in a bed or border of common earth, and raked in. The plants will rise in the spring, and are to be transplanted next autumn.

The roots of the Florentine white iris, when dry, are supposed to have a slight pectoral virtue. They have an agreeable smell, resembling that of violets; and hence are used in perfumes, and in flavouring of liquors. When recent, they have a bitter, acrid, nauseous taste; and when taken into the body, prove strongly cathartic; on which account they have been recommended in dropsies, in the dose of three or four scruples. The juice of the species called *bastard acorus*, or *yellow flag-flower*, is also very acrid, and hath been found to produce

plentiful evacuations from the bowels when other means had failed. For this purpose, it may be given in doses of 80 drops every hour or two; but the degree of its acrimony is so uncertain, that it can hardly ever come into general use. Goats eat the leaves when fresh; but cows, horses, and swine, refuse them. Cows will eat them when dry. The roots are used in the island of Jura for dyeing black. The roots or bulbs of a species growing at the Cape are roasted in the ashes, and used as food by the natives: they are called *oenkjes*, and have nearly the same taste with potatoes. The Hottentots, with more reflection than generally falls to the share of savages, use the word *oenkjes* in the same sense in which Virgil used that of *aristæ*, that is, for reckoning of time; always beginning the new year whenever the *oenkjes* push out of the ground, and marking their age and other events by the number of times in which in a certain period this vegetable has made its appearance.—The Siberians, it is said, cure the venereal disease by a decoction of the root of the *Iris Siberica*, which acts by purging and vomiting. They keep the patient eight days in a stove, and place him in a bed of the leaves of the *arabum lappa*, or common burdock, which they frequently change till the cure is effected.

IRIS-Stone. See *MOON-Stone*.

IRON, one of the imperfect metals, but the hardest and most useful as well as the most plentiful of them all, is of a livid whitish colour inclining to grey, and internally composed to appearance of small facets; susceptible of a fine polish, and capable of having its hardness more increased or diminished by certain chemical processes than any other metal.

It is very generally diffused throughout the globe, being frequently found mixed with sand, clay, chalk, and being likewise the colouring matter of a great number of stones and earth. It is found also in the ashes of vegetables, and in the blood of animals, in such abundance, that some authors have attributed both the colours of vegetables, and of the vital fluid itself, to the iron contained in them. In consequence of this abundance the iron ores are extremely numerous.

1. Native iron, formerly thought not to have an existence any where, is now certainly known to have been met with in several places. It is however by no means common, but occurs sometimes in iron mines. Margraaff found a fibrous kind of it at Eibenstock in Saxony, and Dr. Pallas found a mass in Siberia weighing 1600 pounds. Mr. Adanson likewise informs us, that native iron is common about Senegal; but some naturalists are of opinion that these pieces which have been taken for native iron, are in reality artificial, and have been accidentally buried in the earth. The large piece mentioned by Dr. Pallas is of that species called *red short*, which is malleable when cold, but brittle when red hot.—A mass of a similar nature is said to have been lately found in South America.

This American mass of iron was discovered by some Indians, in the district of Santiago del Elero, in the midst of a wide extended plain. It projected about a foot above the ground, and almost the whole of its upper surface was visible; and the news of its being found in a country where there are no mountains, nor even the smallest stone within a circumference of 100 leagues, could not but be very surprising. Though the journey was attended with great danger on account of the want of water, and abundance of wild beasts in these deserts, some private persons, in hopes of gain, undertook to visit this mass; and, having accomplished their journey, sent a specimen of the metal to Lima and Madrid, where it was found to be very pure soft iron.

As it was reported that this mass was only the extremity of an immense vein of the metal, a commission was given to Don Michael Rubio de Celis to examine the spot; and the following is an abstract of his account:

“The place is called *Oumpa*, in lat. 27. 23. S. and the

mass was found almost buried in pure clay and ashes. Externally it had the appearance of very compact iron; but internally was full of cavities, as if the whole had been formerly in a liquid state. I was confirmed in this idea (says our author), by observing, on the surface of it, the impression of human feet and hands of a large size, as well as of the feet of large birds, which are common in this country. Though these impressions seem very perfect, yet I am persuaded that they are either a *lusus naturæ*, or that impressions of this kind were previously upon the ground, and that the liquid mass of iron falling upon it received them. It resembled nothing so much as a mass of dough; which having been stamped with impressions of hands and feet, and marked with a finger, had afterwards been converted into iron.

“On digging round the mass, the under surface was found covered with a coat of scoriæ from four to six inches thick, undoubtedly occasioned by the moisture of the earth, because the upper surface was clean. No appearance of generation was observed in the earth below or round it to a great distance. About two leagues to the eastward is a brackish mineral spring, the only one to be met with in all the country. Here there was a very gentle ascent of between four and six feet in height, running from north to south; all the rest being as perfect a level as can be imagined. The earth in every part about this spring, as well as near the mass, is very light, loose, and greatly resembling ashes even in colour. The grass of the adjacent parts is very short, small, and extremely unpalatable to cattle; but that at a distance is long, and extremely grateful to them: from all which circumstances it is probable that this mass was produced by a volcanic explosion. Its weight might be estimated at about 300 quintals. It is likewise an undoubted fact, that in these forests there exists a mass of pure iron in the shape of a tree with its branches. At a little depth in the earth are found stones of quartz of a beautiful red colour, which the honey-gatherers, the only persons who frequent this country, make use of as flints to light their fires. They had formerly carried some of them away on account of their peculiar beauty, being spotted and studded as it were with gold. One of these, weighing about an ounce, was ground by the governor of the district, who extracted from it a drachm of gold.”

The native iron, said to have been found about Senegal, has a cubical form; and out of this the black inhabitants make different kinds of vessels for their own use. Some masses have been found in a polyhedral granulated form, and of a bright yellow colour; but which, on being polished, show the proper colour of the metal. Mr. Bergman informs us, that the great mass of native metal found in Siberia resembles forged iron in its composition, a centenary, or 63 grains, yielding 49 cubic inches of inflammable air; and from many experiments it appears, that ductile iron yields from 48 to 51 cubic inches of the same kind of air. Dr. Matthew Guthrie informs us, that “the pores of this iron were filled with a yellow vitreous matter, of such hardness as to cut glass.” The cells are lined with a kind of varnish contiguous to the glassy substance within.

2. The *calciform ores* are either composed of the blackish, blackish-brown, or red calx of the metal; the former being in some measure magnetic, in consequence of the phlogiston it contains; the latter showing nothing of this property until it be roasted.

The name of *calciform* may be applied to all the ores of this metal, excepting the native iron already mentioned, and the native Prussian blues, of which we shall afterwards treat. All of them are mixed with different minerals, and generally take their colour from that of the calx of iron which is prevalent in them. Mr. Kirwan enumerates a great many different species.

3. *Steel ore*, *Stachlerz*, the *ferrum chalybeatum Linnæi*, and

minera ferri nigra of Cronstedt. This is of a dark colour, solid, and compact, but with difficulty striking fire with steel; reducible to a black powder, obedient to the magnet, and somewhat malleable when red hot; affording from 60 to 80 per cent. of good iron. It is met with in Sweden, the Isle of Elbe, and North America. The *ferrum tessulare* and *minera ferri crystallizata* of Wallerius belongs to this species, but is somewhat less magnetic. Our author denominates it crystallized iron ore in an octohedral or cubic form.

4. The magnet, according to Fourcroy, is a muddy iron ore, which, however, some authors suppose to be very near the metallic state. Mr. Kirwan says it differs but little from the foregoing, only that it has less lustre. There are two kinds, the fine and the coarse grained, of which the latter lose their power the soonest. When heated red hot, it smells of sulphur. Our author thinks it may contain nickel, as this semi-metal is found to possess a magnetic property when purified to a certain degree.

5. The brown calx of iron combined with plumbago, *black eisen glimmer*, *schwarz eisen balen* or *eisenman*, consists of black shining scales more or less magnetic, affording, according to Mr. Rinman, 26 per cent. of iron, the rest being plumbago.

6. The brown calx of iron united with the white calx of manganese and mild calcareous earth in various proportions. These constitute the white ores of iron, on which Mr. Bergman has given a dissertation. "They have received (says he) divers denominations from the singular heat with which they are accompanied. Their texture is almost the same with that of the calcareous stone, yet it is rarely found compact, and composed of impalpable particles. It is sometimes squamous, sometimes granulated with small distinct particles, some of them shining, but in general spathous. This description, however, is not meant for their complete and perfect state; for the figure of their parts is more or less destroyed by spontaneous calcination; nay, the whole mass is at length resolved into a powder: sometimes it is found stalactitic, fistulous and ramous, cellular, or even germinating like moss. Sometimes, though very seldom, they have sufficient hardness to strike fire with steel; but though, when found mixed with flint and newly dug up, they are of this kind, yet they soon lose the property we speak of. When perfect, they generally resemble the calcareous stone, unless when exposed for some time to the air, by which the union of their parts is gradually diminished. Their colour is white, but the surface which comes into contact with the air grows gradually brown, or even blackish; yet as long as the iron which is converted into an ochre remains in them, they have a ferruginous hue; but though the surface is thus changed, the internal parts remain the same, and, on being filed or broken, exhibit the natural colour. This change is effected by the air, not upon the iron, as is commonly believed, but on the white calx of manganese which is dephlogistiated by the atmosphere.

"The specific gravity of the ore, when perfect, varies between 3,640 and 3,810, and is diminished according to the degree of calcination. The ore whose particles are quite separated is from 2.5 to 2.9; but that which is not perfectly corroded is from 3.3 to 3.6. It is rarely attracted by the magnet, whether perfect or calcined, though the metallic part sometimes amounts to nearly one half the weight.

"The white ores of iron are found, though in very small quantity, in Sweden. The *Suart-begger*, or *Black Mountain*, in Dalecarlia, has its name from its surface, which is grown black by calcination. It is high, and naked on the summit, which is crossed by a broad calcareous vein with shining particles of spar, and a white ore of iron, together with a galena, pseudo-galena, black ore of iron, pyrites, selchoerl, and garnet intermixed. In the old mines at Halleboro, or the eastern mines, the rock itself

appears to consist of a white ore of iron; but in other places it is either found in small quantity, or very poor in metal. Many mountains about Smialkald in Germany contain these ores. In one called *Stahlbegger*, a broad vein occurs almost horizontal, and from 25 to 30 fathoms thick. It consists of an irregular spar, in which are dispersed quartz and pieces of the ore, which are found of a better quality in proportion as they are more deeply seated. The uppermost side, which is pendent, consists of a sandy stone from 9 to 20 fathoms high; but the lower is margaceous, and is found more indurated towards the lower parts; and at the very lowest is extended by a blue mica: the sides scarcely cohere to the vein. The whole mountain in Naussavia consists of a yellowish ore of iron, certain veins of which are accompanied with copper, and others with hematites. The hill of *Arzberg*, situated at Eisenartz in Upper Sina, is 600 fathoms in circuit, 900 in diameter, and 450 in height. According to some accounts the ore is irregularly accumulated and concreted, consisting of masses of quartz charged with argillaceous earth and white ore of iron; but, according to others, the ore is found there not only in heaps, but in various veins."

This ore, when analysed, gave 38 parts of the brown calx of iron, 24 of the white calx of manganese, and 50 of mild calcareous earth. Another from West Silvathreg yielded 22 of the brown calx of iron, 28 of the white calx of manganese, and 50 of mild calcareous earth. The aerial acid is used, and is united not only to the earth, but also to the metallic calx. The above proportions of the crude materials in the ore of Eisenartz would yield, according to Mr. Kirwan, 38 parts of calcareous earth, 38 of iron in its metallic state, and 24 of manganese. Many others are poorer, and some to such a degree as scarcely to deserve the name of an ore. They abound also in France and Spain, and are found sometimes in heaps, sometimes also forming veins, strata, or even whole mountains. Mr. Bergman never found them contain any organized bodies: a mark (says he) by which the most ancient productions of the earth have been distinguished. When this iron ore bears a stalactitic appearance, and is very white, it is called *flos ferri*, and *eisen bluth*. An hundred parts of it yield 65 of calcareous earth, and 35 of calx of iron; which, according to Rinman, produce 27 of iron in its metallic state.

7. *Magnetic sand*. Of this kind is the black sand of Virginia, whose specific gravity is about 4.600, and contains half its weight of metal.

From an account inserted in the Philosophical Transactions for 1763, we are informed, that there are very large quantities of this sand-iron ore in Virginia; perhaps as large as of any other kinds of iron ore. It is so pure, that it requires a mixture of bog ore, or of slags from other smeltings, to reduce it to a metallic form. The iron and steel produced from it were above 60 per cent. or from 50 to 85; the quality of both extremely good; and two small bars were sent as a sample to the museum of the Royal Society of London. Large strata of black sand-iron ore are found in Portugal, even at a considerable distance from the sea-shore, or from any running waters. A very great part of this black sand is attracted by the magnet. There is also found, particularly in France, a black, heavy, unmagnetic sand, of the siliceous kind, which is said to contain iron and zinc in great quantity. Mr. Kirwan, p. 143. of his Mineralogy, speaks of a siliceous sand consolidated by semiphlogistiated calx of iron, which does not crumble into sand when powdered. It is generally of a black or brown colour; but grows reddish or yellowish, and moulders by exposure to the air. It does not effervesce with acids, unless it contains testaceous particles, which is frequently the case; it is even frequently covered with shells. He adds, that the agglutinating power of solutions of iron has been shown by a stony concretion of this sort that had been long buried in the sea, and is men-

tioned in a paper of Mr. Edward King in the Philosophical Transactions for 1779. Mr. Kirwan, however, has found that dephlogisticated calces of iron, and particularly its solutions in mineral acids, have no binding power.

8. Red calx of iron indurated and combined with a small quantity of clay, frequently with manganese.—Fourcroy calls this a muddy iron-ore, which seems to be formed in the manner of stalactites, and derives its name from its colour, which is commonly red, or the colour of blood, though not without variations. Mr. Kirwan says, that “it is generally of a red, yellow, purple, or brown colour, of a metallic lustre, and very hard, though seldom capable of giving fire with steel.” Fourcroy tells us, that it is usually composed of layers which cover each other, and are themselves formed of convergent needles, the external part being covered with tubercles; and that it is not only distinguished by the colour, but by the form, as the hæmatites botrytes, in the form of bunches of grapes. Mr. Kirwan tells us, that its structure is either solid, granular, scaly or fibrous; that it occurs in shapeless masses, in a stalactitical form; or, according to Gmelin, crystallized in regular forms, though M. de Lisle denies this. In some places it forms whole mountains, and affords from 40 to 80 *per cent.* of iron. Mr. Gerhard extracted alum from it, which affords a proof of its containing clay; and Mr. Hialm found it also to contain manganese. In its natural state it is not affected by the magnet; but by torrefaction it becomes black and magnetic.

9. Hæmatitical, red, yellow, and brown ochres. These are, by Mr. Kirwan, entitled “hæmatites in a loose form, mixed with a notable proportion of argyl” (clay). They are distinguished, he says, from clays, by containing a larger proportion of martial particles. To this species belong the ores which become brown by calcination, and likewise magnetic. They are sometimes mixed with clay or calcareous earths; in which case these ores effervesce with acids. The hæmatites, or blood stones, have their names, not on account of their external colours, but because, when reduced to powder, they produce a red or blood colour. The yellow hæmatites, however, only produce the same colour by pulverisation. They are productive of very good iron, and are found in great abundance in the province of Galiza in Spain. The inhabitants of Compostella, the capital, make a good commerce of these hæmatites of the hardest kind for the burnishing gold leaves, and various other metals. A dark blue kind, somewhat similar to black-lead, is principally employed for these purposes. They are found in many parts of Europe, sometimes forming whole mountains. The most extraordinary ores of this kind, both on account of their forms and of their various and brilliant colours, are found in the island of Elba near the coast of Tuscany. The crystallized ores are here the most beautiful and the most common, though not to be met with any where else. They exhibit various gradations of the finest colours, as red, violet, blue, green, yellow, brown, and black; insomuch that, according to Coudrai’s expression, they look like so many clusters of emeralds, sapphires, diamonds, rubies, and topazes. E. Peni and Mongez affirm, that these ores are mineralized only by the aerial acid; though Coudrai is of opinion, that they contain sulphur also. Besides these beautiful crystallized ores, this island contains also many others; being indeed little other than a group of iron-mountains. The ores in general produce the very best kind of iron.

10. *Emery, Smyris*, is a grey or reddish iron-ore found in great quantity on the islands of Jersey and Guernsey. It is extremely hard, yielding in this respect to no substance except the diamond itself. It is also very refractory, and for these reasons is not used for the sake of the metal it contains, nor indeed is it well known what proportion is contained in it. “The best sort” (says Mr. Kirwan) is of a dark-grey colour, but becomes

brown, and in great measure magnetic, by calcination: other sorts are of a rusty reddish-white or yellowish colour. Its specific gravity is from 3.000 to 4.000. It is used in polishing glass and metals: for which purpose it must first be ground down and levigated in mills.

11. The *argillaceous ores*. These comprehend the ochres, and more particularly those mentioned by Fourcroy under the name of *bog-ores* of iron, which are commonly met with deposited in beds, and seemingly deposited by waters. Mr. Fourcroy informs us, that this kind of ore is very often in the form of spherical bodies either regular or irregular. Organic matters, such as wood, leaves, bark, shells, &c. are not unfrequently found in the state of bog ores. This kind of transition seems to indicate an analogy betwixt iron and organic substances. In the wood of Boulogne near Auteuil there is a mine of bog-ore of iron, in which vegetable substances become mineralized almost immediately under our eyes.

Mr. Kirwan distinguishes two principal varieties of these; one found on mountains, and such as are met with in swampy grounds or low lands overflowed with water; both of them very heavy, and some absorbing water like clays.

The Highland argillaceous ochres are either yellow, red, brown, or greyish, indurated and friable, or loose and powdery, or in grains; they are composed chiefly of the red or yellow calx of iron, or of a grey iron-ore called *Torsten*, in a loose form mixed with clay. Hence they often contain manganese or siderite, and in France are said to be mixed with a calx of zinc. They do not obey the magnet before calcination, and rarely after it. They effervesce with acids only in consequence of being mixed with calcareous earths; they are soluble with difficulty in the acids, but the most soluble are the best. The iron produced from them is of very different quality, according to the nature of the ore from which it is produced. To this species belong the hornstone overloaded with iron, and a white iron ore mentioned by Kirwan found in Kent. It is mixed with clay or marl, and is scarcely soluble in acids. It affords 47 *per cent.* of brittle iron.

The swampy argillaceous ores, according to Mr. Kirwan, are found in irregular lumps of a brown or brownish-black, and sometimes in round balls, porous or solid, or in flat round pieces, or in grains, and sometimes in slender triangular prisms parallel to each other, and very brittle. It is mixed with clay and extractive, and becomes magnetic by calcination; during which operation it gives out a quantity of aerated volatile alkali, and loses one fourth of its weight. The crude ore affords about 36 *per cent.* of metal, and 50 *per cent.* after calcination. The iron produced from it, at least in Sweden, is that called *coldshort*. According to Mr. Hialm, some sorts of this ore contain 28 *per cent.* of manganese.

12. *Red calcareous iron-ore* is found loose in many parts of England, effervesces strongly with acids, and is used as a paint under the name of red ochre.

13. *Martial calamine*. Though calamine is properly an ore of zinc, it sometimes contains such a large proportion of iron as to make it worth while to extract the iron. The ore consists of a mixture of quartz and clay, with the calces of iron and zinc. It is of a moderate hardness, and a yellow, red, or brown colour.

14. *Martial pyrites*. This has its name from its property of giving fire with steel. It is commonly in small red masses, sometimes regularly formed, and usually cubical, spherical, or dodecahedral, though their form varies considerably. Some are brown on the outside, others of the colour of iron, some yellowish, and resembling the ores of copper, even on their surface; but all of them are yellow, and as it were coppery within, and for the most part composed of needles, or pyramids of several sides, whose summits converge to a common centre. The pyrites are commonly dispersed, and particularly in copper mines in the neighbourhood of iron mines, and in clays and

coal mines, the upper stratum of the latter being almost always pyritous. They are all easily decomposed, and yield green vitriol, as is explained under the article CHEMISTRY.

15. *Iron mineralized by arsenic.* This combination takes place either by the combination of arsenic alone with the metal, or in conjunction with sulphur. The former is called in Germany *mispickel*, and *speiss* by the Bohemians; is of a bright white colour, sometimes, though rarely, variegated like a pigeon's neck, and is not easily altered by exposure to the air. It is not magnetic either before or after calcination; it is soluble in acids, and affords arsenic by distillation in the proportion of 30 or 40 *per cent.* and sometimes contains a small proportion of copper and silver. It is frequently found in indurated clay, quartz, spar, schoerl, &c. and mixed with other metallic ores. When this metal contains less than $\frac{1}{10}$ th of arsenic, it is magnetic, according to Scheffer; whence, if the calcination be pushed to a sufficient length, the ore must remain magnetic.

That species of ore which consists of iron mineralized by *sulphur and arsenic together*, contains the white, grey or bluish grey pyrites or marcasite. It is found either in solid compact masses of a moderate size, or in grains, and gives fire with steel. When burnt it affords a blue flame and the smell of arsenic, with orpiment or realgar, instead of pure arsenic by distillation in close vessels. It is not magnetic either before or after calcination, and contains much more arsenic than sulphur.

16. *Native Prussian blue* consists of clay mixed with iron, and coloured with some unknown tingeing substance, generally found in swampy grounds or bogs. It is at first white, but when exposed to the air becomes either of a light or deep blue. By heat it turns greenish, and emits a slight flame, becoming afterward red and magnetic. It is soluble both in alkalies and acids; but the alkaline solution is precipitated by acids, and the acid solution by alkalies. The precipitate at first is greenish, and gradually assumes a white hue, but regains its blue colour on being mixed with vegetable astringents. Mr. Woulfe found this kind of ore in Scotland on the surface of the earth. The greatest part of marshy grounds containing turf, likewise have some of this.

17. The *terre verte*, or green earth, of Verona and Normandy, is used as a pigment, and contains iron in some unknown state, mixed with clay, and sometimes with chalk and pyrites; alum and selenite being likewise accidentally mixed with it. It is soluble with difficulty in acids, is not magnetic before calcination, and becomes of a coffee colour by heat.

18. Mr. Fourcroy informs us, that "it has been discovered some years ago, that iron is often united naturally with the phosphoric acid. The muddy or bog ores are sometimes of this nature: a portion of this compound remaining in the iron gives it the property of being brittle when cold. Iron in this state was called *siderite* by Bergman, and it has since been called *water-iron*."

There are several other kinds of iron ore enumerated by mineralogists; but those already mentioned are the most remarkable.

The following observations on iron in its different states, with an account of the methods of manufacturing it, &c. are extracted from Magellan's Notes on Cronstedt's Mineralogy.

1. Iron is employed in three different states, each having its peculiar properties, by which they are each more particularly applicable to various purposes. The first is *cast iron*, the second is *wrought* or *malleable iron*, and the third is called *steel*.

According to Bergman, cast iron, which may be called *unripe* or *raw-iron*, contains the smallest share of phlogiston. The malleable iron contains the greatest quantity; and the steel a middling share between both, neither so much as the malleable,

nor so little as the cast-iron. This last is called also *pig-iron*, and *yellin* in England.

2. The richest ores of iron are the compact and ponderous, of a brownish, reddish-brown, or red colour. Some of these ores, in colour and appearance, do not ill resemble iron itself; as the grey ores of Derbyshire, and the bluish of the Forest of Dean in Gloucestershire. Most of the Swedish ores are likewise of this kind. Others are blackish, brown, red, yellowish, or rusty-coloured: these are the most common in England and Germany. There is one very singular species of a stratified texture, and of a pale yellowish or greyish colour, oftentimes white, and in some degree pellucid; which, although in its crude state it promises nothing metallic, nevertheless, on being moderately calcined, discovers, by the deep colour it assumes, that it abounds in iron. Cramer informs us, that it gives out by fusion from 30 to 60 *per cent.* But some richer ores yield no less than 70 and 80 on the hundred.

3. Different kinds of iron ore are found adhering in some mines to the tops of caverns in form of icicles or stræ, sometimes irregularly clustered together, sometimes hanging down like the brittles of a brush; from whence the name of *brush-iron-ore*. Other particular forms of the iron stone have occasioned a variety of fanciful names, that are met with in some of the metallurgic writers.

4. The iron of Great Britain is made from three different kinds of ores: 1. From the iron-ore called the *Lancashire ore*, from the county where it is found in greatest abundance. This ore is very heavy, of a fibrous or lamellated texture; it is of a dark purple, approaching to a shining black; and when reduced to powder, it becomes of a deep red: it lies in veins like the ores of other metals. 2. The bog-ore, which resembles a deep yellow ochry clay, and seems to be the deposition of some ferruginaceous rivulets, whose currents had formerly been over the surface of those flat marshy plains. It lies in beds of irregular thickness, commonly from 12 to 20 inches, and very various in their breadths from side to side, never being of great dimensions. 3. The iron-stones, however, have no regular appearance, and do not in the least resemble a metal in their external surface. They lie often in beds of great extent, like other stony matters, and are sometimes stratified with seams of pit-coal, forming alternate layers.

5. The ores of iron are commonly calcined previous to the fusion, even the harder ones, though they should contain nothing sulphureous or arsenical, in order to calcine the hard adhering matrices, and render the masses soft enough to be easily broken into fragments of a convenient size for melting. After the mineral is duly prepared, it must be smelted in furnaces of large capacities, from 16 to 25 feet high, and from 10 to 14 wide: the most approved shape nearly resembles that of a hen's egg, with the largest end undermost, below which is a square cavity to contain the melted metal, and at the top a very short vent about 20 inches in diameter. The inner wall is built of fire-stone, which endures very strong heat with little risk of melting, and all the joints are cemented with mortar composed of sand and clay. This is surrounded with more building, which deviates more and more from a circular form, and becomes a square building of about 20 feet at the base, and gradually converges to the top.

6. Near the bottom is an aperture, for the insertion of the pipe of a large bellows, worked by water or by other machines that may produce a strong current of air. Some very powerful ones, as those in the iron works at Colebrook dale and at Carron, consist of two or more iron cylinders, upwards of two feet wide, whose pistons are alternately moved by a small fire-engine or by a water-wheel: but Mr. Wilkinson very ingeniously adapted to his own a large vaulted receiver surrounded by water, which produces a very regular and uniform

blast. Two or more holes are also left ready to be occasionally opened at the bottom of the furnace, to permit at a proper time the scoria and the metal to flow out, as the process may require. Charcoal, or coke with lighted brushwood, is first thrown in; and when the inside of the furnace has acquired a strong ignition, the ore is thrown in by small quantities at a time, with more of the fuel; and commonly a portion of limestone is thrown also as a flux. The ore gradually subsides into the hottest part of the furnace, where it becomes fused, and the metallic parts being revived by the coal, pass through the scoria, and fall to the lower part or bottom of the furnace, where a passage is open for taking off the scum or dross. The metal now in strong fusion is let out by a tap-hole into furrows made on a bed of sand: the large mass, which sets in the main furrow, is called by the workmen a *flow*, and the lesser ones *pigs* of iron. Chimney-backs, stoves, garden rollers, &c. are formed of this rough metal, taken out of the receiver with ladles, and cast into moulds made of fine sand."

It is proper to observe, that the excessive and long continued ignition kept up in these furnaces gradually wastes the materials of which they are composed, rendering their sides thinner until at last they become unable to sustain the weight of the melted metal; so that it has sometimes been known to burst out suddenly in a violent and most destructive stream. At certain intervals, therefore, the fire ought to be allowed to go out, whatever may be the expence of rekindling it, and the furnace examined and repaired.

7. The quantity of fuel, the additions, and the heat, must be regulated, in order to obtain iron of good quality; and this quality must likewise in the first product be necessarily different, according to the nature of the parts that compose the ore.

8. Two or three tons, *viz.* 4000 or 6000 pounds weight of iron, are now run off in 24 hours, at some large furnaces, after the application of the large bellows; whilst scarcely an hundred weight could be obtained in a day before that application, because a large quantity of the metal was left in the dross: hence in some places the slags of different ores, left by old operators in former times, are now remelted to advantage along with fresh ore; and on account of the richness of these old slags of different ores, some people have been misled into the opinion, that the metal was regenerated in them.

9. Peat and turf has been found to answer tolerably well, mixed with charcoal, for the smelting of iron ores; but an attempt to use it on a large scale has at last been found not to answer the expectations that had been conceived from the first trials. Pit-coal, if applied to the same purpose, renders the iron hard and brittle; but this inconvenience is prevented, by previously coking the coal, and employing it in the state of true coke. Cramer, in his *Art of Assaying*, p. 347, says, that pit-coals, kennel-coals, and Scotch-coals, which burn to a white ash like wood, and abound more in bitumen, may be used in the first fluxion of the iron from its ore; and if the iron proves not so malleable as required, this property may be given to it by melting the metal a second time with wood.

10. The best cast-iron, or raw iron, as much freed from heterogeneous matters as the usual process of smelting can effect it, is not at all malleable, and so hard as perfectly to withstand the file.

11. In general the impure cast-iron, as run from the ore, is melted down a second time in another furnace, intermixed with charcoal. A strong blast of air being impelled on the surface of the metal, its fusion is remarkably promoted; the iron thickens into a mass called a *loop*, which is conveyed under a large hammer raised by the motion of a water-wheel. The iron is there beaten into a thick square form, is then heated again until almost ready to melt, and is forged: by a few repetitions

of this process, it becomes completely malleable, and is at length formed into bars for sale.

12. Iron in this state of malleability is much softer than before, and of a fibrous texture. But if it is still crude and brittle after the above process, it shows that there have remained heterogeneous matters, being hidden in its interstices, which must be expelled: for this purpose the iron must be stratified with charcoal-dust within a proper furnace, heaped up in good quantity in strata; then the fire must be blown pretty strongly, so as to bring it to a fusion, which is to be helped by the addition of fusible scorias or of sand. The fire must not be much greater than necessary to make all these melt as equally as possible: to obtain this end, the melted mass must be agitated here and there with poking rods of wrought iron, in order to make every part feel alike the action of the fire and air; and the increasing scorias taken out once or twice.

13. In the mean time, a great many sparkles will be thrown out from the iron, which diminish the more as the iron comes nearer to the desired degree of purity, but they never cease entirely. The burning coals being then removed, and the scoria conveyed out of the fire through a channel made for that purpose, the iron, by lessening the violence of the fire, grows solid, and must be taken out red hot, and tried by striking it with a hammer. If it proves crude still, let the melting be repeated; and when it is at last sufficiently purified, it is to be hammered, and extended various ways, by making it red-hot many times over: this done, it will no longer be brittle, even when cold, as Cramer asserts.

14. Cast-iron has of late been brought into the malleable state by passing it through rollers instead of forging it. Indeed this seems to be a real improvement in the process, as well in point of dispatch, as in its not requiring that skill and dexterity which forgemen only acquire by long practice. If the purposes of commerce should require more iron to be made, it will be easy to fabricate and erect rolling machines, though it might be impracticable to procure expert forgemen in a short time.

15. This method was discovered by Henry Cort of Gosport, who obtained an exclusive privilege granted by the king's patent. See *Repertory of Arts*, vol. iii. p. 289. By this process the raw or cast-iron is freed from the impurities, which are not discharged in the common methods of rendering this metal malleable; for iron is in itself a simple homogeneous metal; and all iron must become equally good, if it be purified from the heterogeneous and unmetallic particles that are any ways mixed with it.

16. The ordinary method of converting cast-iron into malleable, is, as we have seen, by employing great quantities of charcoal, which furnishes phlogiston, and remetalizes the particles, which are unmetalized and mixed with the heterogeneous matters contained in the fused mass: but in Cort's method there is no need of charcoal, instead of which only sea-coal is employed; because the object is not to remetalize, but only to expel what is unmetallic, instead of endeavouring to restore the calcined parts with charcoal at a great expence, and still leaving the business undone. In this method the iron is only heated and wrought simply by the heat of the flame, instead of being mixed with the burning fuel and ashes, which are not easily disengaged afterwards from the metal. The squeezing it between the rollers, forces out the melted slags from the metallic pores, and brings its metallic fibres into a perfect solidity and close contact, so that they are obliged to cohere much more perfectly to each other than by the interrupted and partial action of the hammer. By the operation of being long stirred, the sulphureous particles are more disposed to be disengaged, and are burned away in the form of blue sparks; the metal then begins to curdle, and to lose its fusibility, like solder

when it just begins to settle; the metallic particles meeting and coalescing together, much as in the churning of milk, where the cream is separated by the union formed between the fibrous particles of the cheese. The curdles formed into a connected mass become what is called *loops*. The process is as follows:

17. Five or six hundred weight of raw cast-iron (and even of cold-short iron) is brought into a low fusion, on a kind of hearth or low furnace, in which it lies to the depth of about 6 inches. One or two workmen continually stir this fused mass with long iron pokers for about 4 or 5 hours. The heat is then lowered: the men fashion the iron into narrow pieces of about $3\frac{1}{2}$ feet long, and 3 inches square, with long knives or chisels made for that purpose. They are then heated to the welding degree, and hammered to expel and scatter the unmetallic dross. These slabs are then formed to a wedge-point at one end, in order to adapt them to be received between the rollers: they are malleable already, but they contain still some dross.

18. They are then heated again to the hottest welding heat in the air-furnace, and immediately passed through large iron-rollers, turned by a water-wheel, or by horses. If the end presented to the rollers should slip instead of entering, a boy, who stands ready, throws some sand upon the iron, and it goes in easily. Much foreign and heterogeneous matter is squeezed out by the rollers; and the iron comes out in a purer malleable state. The same heat will serve to pass the iron through two sets of rollers, which are grooved so as to fashion it into nail-rods or other forms according to the required purposes.

19. Various and repeated severe trials have been made in the royal dock-yards of England, in the presence of persons of knowledge and rank, to prove the strength, malleability, and softness or toughness of this new iron; and it has proved to be equal, and even sometimes superior, to the best Swedish iron. But it is not easy to conceive by what singular fatality so great an improvement in manufacturing this most useful metal has not yet been generally adopted by the iron-masters.

20. Steel is iron in an intermediate state between cast-iron and malleable iron, which is soft and tough. The iron run from some German ores is found to be a good steel when forged only to a certain point.

But the best steel is usually made by cementation from the best forged iron, with matters chiefly of the inflammable kind. Two parts of pounded charcoal and one of wood ashes is esteemed a good cement. The charcoal dust may be made of bones, horns, leather, and hairs of animals, or of any of these ingredients, after they are burned in a close vessel till they are black: these being pulverised, and mixed with wood ashes, must be well mixed together. The iron should be of pure metal, not over thick, and quite free from heterogeneous matters: their flexibility, both when hot and when cold, is a very good sign thereof. A deep crucible, two or three inches higher than the bars, is to receive part of the cement, well pressed at the bottom, the height of $1\frac{1}{2}$ inch; and the bars are to be placed perpendicularly, about one inch distant from the sides of the vessel and from each other. All the interstices are to be filled with the same cement, and the whole covered to the top with it; then a tile is applied to cover the vessel, stopping the joints with thin lute.

21. The crucible is then to be put in the furnace, and a strong fire is to be made, that it be kept moderately red-hot for six or ten hours together; at the end of which time the bars will be found converted into steel. If the cementation be continued too long, the steel will become excessively brittle, incapable of being welded, and apt to crack and fly in forging. On the contrary, steel cemented with absorbent earths is reduced to the state of forged iron.

22. Steel is further purified for making the nicest kinds of

instruments, such as lancets, pen-knives, razors, and various pieces for the best kind of watches, time-keepers, or chronometers, and astronomical regulators. This purification of steel consists in melting it again with a strong but regular fire in a crucible, the better to free it from the heterogeneous parts, and little flaws that may be contained in it. It is then called *cast-steel* when fused into bars: which name, however, does not imply that the pieces, for instance the cast-steel razors, have been really cast in their present shape; for they must be forged from the bar after it is cast. The fusion must have been perfect, so that the metallic parts be rendered uniform. The metal diminishes a little by this process; for a bar of common steel 36 inches long will afterwards produce another only of 35, if properly fused and purified.

23. The cast-steel will not bear more than a red heat; otherwise it runs away, like sand, under the hammer, if the heat is pushed to the welding degree. Dr. Watson says, that this manufacture of cast-steel was introduced at Sheffield only about 40 years ago by one Waller. This man was still living about the year 1765; he dwelt at St. Bartholomew's close, and was a galloon wire-drawer by trade. The difficulty of procuring small cylinders of good steel to flatten the wire for lace-work in his business, whose defect proceeded from the bad texture of the steel, set his imagination on the enquiry after a method of purifying the metal to a greater perfection: and he thought that a new fusion of it was the most likely to accomplish his views. After some trials, he at last succeeded; but it was soon known to others, who got the advantages for themselves; so which ill fate the real inventor very bitterly complained till the end of his life. His own name was even forgotten, as one Huntsman practised this art to such an extent, that cast-steel was known under his sole name afterwards.

24. But before this discovery made by Waller in England, this kind of steel was made already in Germany, as Watson asserts; and from thence some small quantities were brought to England at a considerable price. Since that time this branch of business is carried on advantageously at Sheffield; for the manufacturers there collect a great abundance of broken tools, and old bits of steel, at a penny a pound, which, after fusion and purification, sell for 10 or 12 times as much.

25. It is a valuable property of iron, after it is reduced into the state of steel, that, though it is sufficiently soft when hot, or when gradually cooled, to be formed without difficulty into various tools and utensils; yet it may be afterwards rendered more or less hard, even to an extreme degree, by simply plunging it, when red hot, into cold water. This is called *tempering*. The hardness produced is greater in proportion as the steel is hotter and the water colder. Hence arises the superiority of this metal for making mechanic instruments or tools, by which all other metals, and even itself, are filed, drilled, and cut. The various degrees of hardness given to iron, depend on the quantity of ignition it possesses at the moment of being tempered, which is manifested by the succession of colours, exhibited on the surface of the metal, in the progress of its receiving the increasing heat. They are the yellowish-white, yellow, gold-colour, purple, violet, and deep-blue; after which, the complete ignition takes place. They proceed from a kind of scorification on the surface of the heated metal.

26. A bar of clean white steel may be made to assume all the above colours at once, by placing one end in the fire, and keeping the other end out, which is supposed of a proper length to remain cold.

27. These colours serve as signs to direct the artist in tempering this metal. For though ignited steel, suddenly quenched in very cold water, proves excessively hard and brittle; yet it may be reduced to the required degree of temper by heating it till it exhibits a known colour. This is the method employed

in this process by the artists. As soon as the piece of steel is completely ignited, they plunge it in very cold water; and as soon as it loses its fiery appearance, they take it out, rub it quickly with a file, or on a plate covered with sand, that it may have a white surface. The heat, which is still within the metal, soon begins to produce the succession of colours. If a hard temper is desired, as soon as the yellow tinge appears, the piece is dipped again, and stirred about in the cold water. If the purple appears before the dipping it, the temper will be fit for tools employed in working upon metals; if dipped while blue, it will be proper for springs, and for other instruments fit to cut all sorts of soft substances; but if the last pale colour be waited for, the steel will not be hard at all.

28. It deserves notice, that a piece of iron is rendered considerably warm by hammering, so as even to become red-hot. But after the iron has been completely hammered once, it is asserted that it cannot be rendered again red-hot by the same operation, because no further compression can then be made. Hard steel is the only metal that, being struck slantwise with the sharp edge of a flint, or of another hard stone, produces sparks of fire.

29. Iron is often manufactured so as to be 150 times, and even above 630 times, more valuable than gold. On weighing some common watch pendulum-springs, such as are sold at half a crown by the London artists for common work, ten of them weighed but one single grain. Hence one pound avoirdupois (= 7000 gr.) contains ten times as many of these springs; which, at half a crown a-piece, amount to 8750l. sterling. The troy ounce of gold sells at 4l. sterling, and the pound (= 5760 gr.) at 48l. sterling, which gives 58,33 (or 58l. 6s. 7d.) for each pound avoirdupois of gold: and of course $\frac{8750}{5760} = 150$. But the pendulum-springs of the best kind of watches sell at half a guinea each; and at this rate the abovementioned value must be increased in the ratio of 1 to 4.2; viz. of half a crown to half a guinea: which will amount to 36,750l. sterling; and this sum divided by the value of the pound of gold gives above 630 to the quotient.

We may not improperly introduce in this place an extract from the specification of Mr. Purnell's patent, granted in the year 1787, for a method of preparing, shingling, and welding iron, with pit-coal from the ore, by the help of a machine, which is said to produce better iron, more in quantity, with less waste both of metal and fuel, than can be effected by any other method. After some preliminary remarks, Mr. Purnell proceeds thus:

"I use the common air or reverberatory furnace, in manner as is practised at the common iron-founderies; in which the metal must be brought into the most equable and perfect state of fusion, by being agitated here and there in the fire, so that every part may receive such effect from it, that not the smallest particle may remain unmelted, or in an unfused state: and, after that is completed, the heat must be abated by slow degrees, (still keeping it stirred and separated) so that, as it cools gradually, it may be taken from the furnace in lumps, loops, or pieces, of about the weight of fourteen pounds, more or less, (as it may happen, or as the power of the rollers hereinafter described may best overcome) on shovels made light, with their edges turned up, and rather dished in the middle, the better to prevent the hot metal falling off, whilst conveying from the furnace-mouth to a cast iron plate, placed on the floor, between the furnace-mouth and rollers, on which it must be laid down to receive a few blows from a common sledge-hammer, by a labourer placed ready for that purpose, to bring it into somewhat of the shape of a wedge; when it must, with all possible dispatch, be taken up by a man, who must attend before the rollers, with a shovel, like to that before described, or other such

tool or instrument, and conveyed to an iron plate, placed nearly in a direct line with the centre of a pair of iron rollers sixteen inches long by fifteen in diameter, or of such other dimensions as the force of the machinery used may render necessary, to be worked by steam, fire, or water; on which plate it is laid, and a blow or blows must be instantly given it by the edge of the said shovel, or other such tool, against the thickest edge or side, the better to force it to enter betwixt the rollers (always observing that the thin edge of the lump or loop be presented to pass first); and whilst this first lump or loop is passing betwixt the rollers, and falling into a cistern through which a continual stream of water is made to pass, another such lump or loop must be prepared and brought forward in regular succession, until the whole charge of one furnace be rolled; which, in quantity, may be from three to five hundred weight, more or less, and which may be made to pass between the said iron rollers in about fifteen minutes; which, in the common method used, would take up much longer time, and be attended with a greater expence. But, should a still greater dispatch in the rollers be required, a much larger quantity may be made to pass between a pair of rollers in the same given time, by working them abreast, or parallel to each other, and letting the lumps or loops fall between the rollers whilst in motion, aided by a slight blow from a light sledge-hammer, or even generally by their own weight. In which latter case, the dispatch will be equal to the expedition with which the metal can be made to pass to the rollers, either by means of the shovels, as before described, or by iron troughs and rakes, to convey it from the furnace to the rollers. The furnaces to be placed in the most convenient situation to the rollers, that the hot metal may have but a short distance to be conveyed to them from the furnaces, that it may pass between them in a proper state of heat, so that the rollers, by their superior force, and uniform pressure on all the parts of the hot crude metal, may squeeze, force out, and separate from the true metallic part, the greatest possible quantity of cinder, or obnoxious unmetallic earth; and which it does in a much superior degree to any tilting forge, or other hammer and anvil, be their weight or force what it may."

Under the article ELECTRICITY, we have taken notice of a curious experiment of burning iron in dephlogisticated air; of which an account is also given under AEROLOGY, where the experiments of Dr. Priestley are related. In the last number of the Chemical Annals we find the subject particularly treated of by M. Lavoisier. "The beautiful experiment of Mr. Ingenhoufz (says he) is now well known. A piece of very fine iron wire is turned into a spiral form; one end of it is fixed in a bottle cork; to the other a piece of agaric is fastened: when this has been done, a bottle is filled with vital air, the agaric is lighted, and it is then, along with the iron wire, quickly introduced into the bottle, which is stopped with the cork. As soon as the agaric is plunged into the vital air, it begins to burn with a dazzling light; the inflammation is communicated to the iron, which also burns, throwing off bright sparks that fall to the bottom of the bottle in round globules. These globules become black as they cool, and preserve some remains of their metallic lustre. The iron thus burnt is more brittle than glass itself; it powders easily; is attractable by the magnet, but less so than before the operation."

M. Lavoisier, in order to observe more fully the changes which happened to the metal on this occasion, repeated the experiment upon a scale considerably larger. He immersed chips of iron turned into a spiral form into a vessel filled with pure air which contained about 12 quarts; fixing to the end of each chip a small bit of agaric, and a particle of phosphorus weighing scarce $\frac{1}{16}$ th of a grain. Having set fire to the phosphorus and agaric, the iron is wholly consumed to the very last

particle with a bright white light resembling stars in rockets. The heat in this combustion melts the iron, which falls down in globules of different sizes. In the first instant of the combustion there is a slight dilatation of the air; but this is succeeded by a very rapid diminution; and when the quantity of iron is sufficient, and the air very pure, almost the whole gas is absorbed. Our author recommends only small quantities of iron to be burnt at a time; because the heat produced by its combustion is so great, that the glass is apt to fly. A dram, or a dram and an half, is sufficient for a jar holding four gallons, which ought to be very strong in order to resist the weight of the mercury with which it is to be filled. The increase of weight in the iron, by being burnt in this manner, is, according to our author, about 35 per cent. It is then in a state of ethiops, and may be powdered in a mortar. When the air in which the combustion has been performed is very pure, there is no great difference betwixt that in which the iron has been burnt and the original quantity, excepting only a small mixture of fixed air from the little portion of charcoal contained in the iron.

In this work also we find some observations on the solubility of iron in pure water from Crell's Annals for the year 1788. It has generally been supposed that pure water is incapable of dissolving or holding iron in solution: but the fact seems now to be established by the following experiment: A pound of fresh distilled water was poured upon two ounces of iron-filings into a narrow-necked glass retort; the vessel was then put in a sand heat, and the liquid evaporated to one-half; after which the mouth was slightly stopped with a cork, and the matter left to digest in a gentle heat. On opening the vessel it was found that the water had become styptic, and had a ferruginous taste; whence it appeared that part of the metal was dissolved. Phlogisticated alkali had no effect upon this solution until a few drops of pure distilled acetic acid were added, when a little prussian blue fell to the bottom. Soon after making this experiment, our author met with a natural mineral water which contained iron in solution, though it would not precipitate any thing until a few drops of acid were added. This solubility of iron in pure water has been also taken notice of by M. Landriani and M. Monnet.

Iron is easily calcinable by fire, and is soluble in all the acids, even that of fixed air. By exposure to the atmosphere it is attacked by the pure part of the surrounding fluid, which thus becomes converted into fixed air, the metal in the mean time being changed into a yellowish-brown powder called *rust*. Common iron is much more subject to rust than steel; and this facility of calcination renders it a matter of great importance to discover some effectual method of preventing it from taking place. Various compositions have been recommended, but none have been found more effectual than common oil. As the use of this, however, must be on many occasions troublesome and disagreeable, a still more commodious method has been fallen upon. It is known that the metal, after having undergone that kind of calcination in which it combines with the base of dephlogisticated air, or begins to combine with it, is not subject to rust. By giving it a coating of this kind, therefore, it is effectually preserved from any action of the air; and this is done by heating it till it assumes a blue colour, which indicates a partial calcination on the outside: and thus utensils are made capable of being preserved from rust for a long time; though even these, when exposed wet, or even a long time to the atmosphere, will be covered with rust, and decay like others. For the chemical properties of iron, see CHEMISTRY; for its electrical and magnetical ones, see ELECTRICITY and MAGNETISM.

IRON-Bridge.—Among the great variety of purposes to which iron has been applied, is that of the construction of bridges;

an art of late years brought to an extraordinary degree of perfection.

The bridge at Colebrook-dale has been long considered as a most curious structure; but the following account of similar inventions, as they are described in the Repertory of Arts, will shew how very considerable have been the subsequent improvements in the construction of iron bridges.

Mr. Burdon's elegant bridge across the Wear at Sunderland, is a monument of fine taste, ingenuity, and public spirit. We shall here describe the principles of his invention from the specification of the patent granted to him for "a certain mode or manner of making, uniting, and applying, cast-iron blocks to be substituted in lieu of keystones, in the construction of arches."

"I the said Rowland Burdon do hereby declare, that my invention consists in applying iron, or other metallic compositions, to the purpose of constructing arches, upon the same principle as stone is now employed, by a subdivision into blocks, easily portable, answering to the keystones of a common arch, which, being brought to bear on each other, gives them all the firmness of the solid stone arch; whilst, by the great vacuities in the blocks, and their respective distances in their lateral position, the arch becomes infinitely lighter than that of stone; and, by the tenacity of the metal, the parts are so intimately connected, that the accurate calculation of the extrados and intrados, so necessary in stone arches of magnitude, is rendered of much less consequence. Fig. 1. pl. 21. represents a block of cast iron, 5 feet in depth from A to A, and four inches in thickness, having three arms B, B, B, and making a part of a circle, or ellipsis: the middle arm is 2 feet in length from B to C, and the other two are in proportion. On each side of the arms are grooves ($\frac{3}{4}$ of an inch deep, and 3 inches broad.) for the purpose of receiving malleable or bar iron; and in each arm are two bolt-holes. D, fig. 2. represents two of these blocks placed together, and the joints confined to their respective positions by the bar-iron on each side of the arms, as at E, E, E; which, with other similar blocks, so united and bearing upon each other, become a rib. Fig. 3. and F, F, fig. 2. are hollow tubes, 6 feet long, and 4 inches in diameter, having shoulders at each end, with holes answering to those of the blocks. G is a block of another rib, connected with the former by the tubes F, F, placed horizontally. Through the holes in the shoulders and arms of the block and bar-iron are bolts (fastened with cotters or forelocks), as at H, H, H, H. The blocks being united with each other in ribs, and the ribs connected, and supported laterally, by the tubes, as above described, the whole becomes one mass, having the property of key-stones cramped together. The blocks and tubes above specified are those intended to be used in the construction of the arch of the bridge, now erecting by me, across the river Wear, at Wearmouth, near Sunderland, in the county of Durham. The arch is a segment of a circle, whose chord or span is 236 feet; its versed sine or height 34 feet; and its breadth 32 feet, consisting of six ribs: but the sizes of the blocks, tubes, and other parts, with the number of ribs and arms in the blocks, must be suited to the dimensions, form, and use, of the arch."

We now proceed to transcribe Mr. Burdon's account of the bridge at Sunderland, the first wherein that principle has been adopted.

"From the increasing population and trade of Sunderland and the two Wearmouths, the ancient ferry, which was almost in the centre of the harbour, was become very insufficient, and unsafe; insomuch that frequent instances occurred of the loss of lives, independent of the constant delay and disappointment occasioned to all descriptions of people.

"Under these circumstances, Mr. Burdon, who had previously procured a turnpike-road from Stockton to Sunderland,

was early in expressing his wishes for the accommodation of a bridge across the Wear, as near Sunderland as possible. Being returned to parliament by the county of Durham, in the year 1790, he began to move in the business during the ensuing year, and an act of parliament for a bridge was, with some difficulty, obtained in 1792. At first a stone bridge was proposed, of 200 feet span, and 80 feet to the crown of the arch; but, the plan, with the estimate, being referred to persons of skill, the extent of expence appeared beyond all reasonable bounds; and, upon searching for foundations, none were to be found within the limits of the space covered by the tide, which flowed between rocky shores distant from each other in the narrowest part about 240 feet. Another difficulty also arose from the situation being so near the mouth of the river, and perpetually occupied by the craft of the coal, lime, and other trades, which could not admit even a momentary interruption. From the attempts at constructing bridges of iron by the Colebrook-dale Company, and also by Thomas Paine, Mr. Burdon, though he disapproved of their principles, conceived the idea of making use of that metal; adhering however to the ancient construction of bridges, by the subdivision of the parts of the arch in the manner of key-stones, and taking advantage of the ductility and tenacity of iron, to produce an arch of that metal, at least fifteen times lighter than a corresponding arch of stone, and capable of being put together upon an ordinary scaffold, instead of an accurate centre, in an infinitely less space of time.

“ After having caused an experimental rib to be cast, and set up, by Messrs Walkers of Rotherham, under the direction of Mr. Thomas Willon, Mr. Burdon brought forward a proposal to the town of Sunderland and the county, of constructing a bridge, on his principles, over the Wear, between the Wear-mouths, immediately adjoining to Sunderland and its harbour. His proposition was adopted; and the foundation-stone was laid on the north side, on September 24, 1793. To the superintendance of the execution of the work Mr. Thomas Willon of Sunderland was appointed, through whose indefatigable zeal the bridge was rendered passable, and opened for the accommodation of the public, in the presence of a vast concourse of people, on August 9, 1796. The arch is a segment of a large circle; its span is 236 feet; the height from low water to the spring of the arch is about 60 feet; and the versed sine 34; producing so flat an arch, that ships of 200 or 300 tons may pass under it, with equal facility, within fifty feet on either side of its centre; having 94 feet clear at low water, and abundant depth in the mid-stream. The bridge consists of 6 ribs, at 5 feet distance from each other: the spandrels are composed of cast-iron circles. The 6 ribs were put together over the river in the short space of 10 days. The superstructure is of timber, planked over to support the carriage-road, which is composed of marle, limestone, and gravel, with a cement of tar and chalk immediately upon the planks, to preserve them. The whole width of the bridge is 32 feet; and on each side is a footway of substantial flags, having an iron palisade, with lamp-posts of timber at intervals. The weight of the arch is calculated, to exceed 900 tons, of which 260 tons are iron. Of 28 parts of the iron, 23 are cast, and 5 are wrought iron.

“ The expence of constructing the bridge will amount to above 26,000*l.* of which 4000*l.* was subscribed by different gentlemen, and the remainder by Mr. Burdon. The tolls, which are the same as those of the ancient ferry, are subjected by the act to pay 5 *per cent.* on the capital, if equal thereto; and all accumulations beyond that are to go to discharge the capital.”

The success of this undertaking will no doubt induce others to construct public bridges on similar principles and with similar materials.

IRON-Moulds, and spots of ink in linen, may be taken out by

dipping the stained part in water, sprinkling it with a little of the powdered salt of wood-forrel or of lemons, then rubbing it on a pewter plate laid over a basin of hot-water; and lastly washing the spot out with warm water.

IRON-Sick, in the sea language, is said of a ship or boat, when her bolts or nails are so eaten with rust, and so worn away, that they occasion hollows in the planks, whereby the vessel is rendered leaky.

IRON-Wood, in botany. See the article SIDERXYLUM.

IRON-Work, in botany. See the article SIDERITIS.

IRONY, in rhetoric, is when a person speaks contrary to his thoughts, in order to add force to his discourse; whence Quintilian calls it *diversiloquium*. Thus, when a notorious villain is scornfully complimented with the titles of a very honest and excellent person; the character of the person commended, and the air of contempt that appears in the speaker, and the exorbitancy of the commendations, sufficiently discover the dissimulation of irony. Ironical exhortation is a very agreeable kind of trope; which, after having set the inconveniences of a thing in the clearest light, concludes with a feigned encouragement to pursue it. Such is that of Horace, when, having beautifully described the noise and tumults of Rome, he adds ironically—
“ *Go now, and study tuneful verse at Rome!*”

IROQUOIS, the name of five nations in North America, in alliance with the British colonies. They are bounded by Canada on the north, by the American States of New York and Pennsylvania on the east and south, and by the lake Ontario on the west.

IRRADIATION, the act of emitting subtile effluvia, like the rays of the sun, every way. See EFFLUVIA.

IRREGULAR, something that deviates from the common forms or rules: thus we say, an irregular fortification, an irregular building, an irregular figure, &c. In grammar, this term denotes such inflections of words as vary from the general rules; thus we say, irregular nouns, irregular verbs, &c. The distinction of irregular nouns, according to Mr. Ruddiman, is into three kinds, viz. variable, defective, and abundant; and that of irregular verbs into anomalous, defective, and abundant.

IRRIGATION, the improvement of land by watering it artificially. We draw the following valuable remarks on a subject of so much importance to agriculture, from the General View of the Agriculture of the County of Stafford; drawn up, for the Consideration of the Board of Agriculture, by William Pitt, Esq. of Pendeford, near Wolverhampton.

“ Irrigation, or the improvement of land by watering, is, or may be, a very important and extensive part of agriculture; and though the advantages to be derived from it are generally admitted and well known in this county, at least by all intelligent farmers, yet it is by no means in general carried to the extent of which it is capable; many streams being suffered to glide quietly down their own channel, which might easily be drawn over the adjoining lands, to their great improvement. This omission is in part owing to neglect; in part to the jealousy of millers, and other persons interested in the streams; and, in some degree, to the best methods of extending this application of water not being generally and sufficiently understood. The industry of many individuals is, however, very properly and successfully exerted in this very commendable species of improvement.

“ Respecting a system for irrigation, no general one can apply to particular cases: different modes of spreading the water must be adopted, according to different circumstances of situation, and form of surface. In all cases where a stream naturally falls down a valley, and the sides of such valley consist of easy and regular declivities, the best way undoubtedly is to draw a sufficient quantity of water nearly upon a level, along a main carrier; such water to be let out of the said main car-

rier, at pleasure, by sluices constructed in different places in the sides thereof, into floating gutters; such floating gutters being cut on a level along the sides of the declivities, one below another. These floating gutters will collect the water from the spaces of land above them, and, if well constructed, deliver it very regularly upon the spaces below each of them respectively. The watering in this case will require very little attendance, except that of opening and closing the sluices in rotation, so as to irrigate different parts of such lands successively. The gutters too will require an annual cleansing, or scouring-out, otherwise they will choke and grow up with grass.

“The particular mode of action, or operation, by which land is benefited by watering, has not perhaps hitherto been satisfactorily explained; yet it is an established and well known fact, that all waters (except such as are highly putrid) produce a good effect upon land, in some degree proportioned to their rapidity or briskness of motion. Thus, common water, suffered to stagnate upon, or dribble in small quantities over land, will encourage the growth only of rushes, seg-grass (*carex*), and other coarse aquatics, and weaken, if not destroy, the finest and most valuable grasses. The same water, driven over the same land with a brisk motion, and the surface left to dry at intervals, and exposed to the sun and atmosphere, will have a directly contrary effect; the valuable grasses will flourish, and the aquatics be weakened or destroyed. Hence it should seem, that the good effects of watering are in part produced by mechanical operation, by moistening and tendering the surface; which circumstance, combined at intervals with the effects of the sun and atmosphere, brings into action the latent principles of vegetation in plants; which principles would have lain dormant, under the influence of chilling or stagnant water; or would have been locked up by the matting of turf on the surface, had not such turf been softened, and made easily penetrable, by moistening its surface. The coarse aquatics, being hardier, vegetate in a less degree of heat; they seem intended by nature to fill up those vacancies which are yet unprepared for the production of the more valuable tribes, upon this principle in her vegetable œconomy, that a bad plant is better than none; yet, upon the proper application of human industry, they always decline, and give way to those of superior value.

“Every one knows the necessity there is (previous to improvements by irrigation) of discharging the stagnant water from, or from near, the surface of all lands intended to be so improved, by hollow drains or otherwise.

“As the benefit to be derived from irrigation depends so much upon the watering being effected with a brisk motion, and not continued for too long a time, the great desideratum in this species of improvement seems to be the introduction of reservoirs, constructed so as to contain large quantities of flood water; which water, so collected, may be successively, and at pleasure, distributed upon any land below its surface, and continued with such velocity, and for such length of time, as may be thought proper.

“This idea, as applicable to agriculture, is, I believe, novel, and may be treated as visionary; but I am so thoroughly convinced of the great advantages to be derived from it, that I will venture a prediction of its being, in some future time, practised to a great extent. The practice will be much facilitated by the construction of dams being so well and so commonly understood, in consequence of the number of navigable canals which have been, and are still executing. A reservoir of a few acres, and of two yards average depth, may be constructed at from ten to twenty pounds *per acre*, according to circumstances of situation. Such a reservoir as a fishery (under proper management) would be equal or superior in value to an equal breadth of land, and the surface water, to a certain depth, might be drawn down, for the purpose of irrigation, at pleasure.

“Upon this subject of water, the following extensive idea is thrown out by Mr. Jessop, an ingenious gentleman, high in his profession as an engineer; which is, that nine parts in ten of the waters of the kingdom at present run away in waste, great parts of which might be usefully employed; nay farther (putting expence out of the question), that every stream in the kingdom may be made to run equally through the whole year. This position, however extraordinary, is easily demonstrable; for, if upon any given stream one or more reservoirs be made, capable of containing its flood water, and through the dam or dams be laid a pipe or pipes, whose apertures will just discharge the average produce, the business is done. And though there may be no probability of this business being ever brought to so great a nicety, yet hence some idea may be formed of the prodigious extent to which improvements by water may be carried.

“With this subject, and that of forming reservoirs for the purposes of agriculture, is connected another of great importance in domestic and commercial œconomy; namely, the having an extensive command of the application of water, to all mechanical purposes wherein such application will answer better than for irrigation of land, and thus, as it were, arresting every drop of water that falls from the heavens, and rendering it, in the most extensive way, subservient not only to the immediate subsistence of man and beast, and the improvement of land, but even having the residue solely at command, for the purpose of shortening manual labour: such a system would certainly be an important addition to the powers required in many of our mechanical operations, and of great importance in a manufacturing country.”

The following are Mr. Jessop's observations on the use of reservoirs for flood-waters:

“The rapid improvements (says he) which have for some years past been made in the agriculture and commerce of this country, and the happy effects derived therefrom, naturally excite a desire to investigate every means by which they may be continued and increased.

“Among the many causes which have combined to promote our prosperity, the facility of intercourse by inland navigation is a great and leading feature. All unite in admitting this as a general position; but many, from private motives, or mistaken opinions, have too often prevailed in preventing the execution of useful projects, which, if they could have been effected, would have greatly contributed to the national benefit derived from those already established.

“Among the obstacles that stand forward, none are more conspicuous, or more generally urged, than the want of water in dry seasons. It usually happens, that where canals are most wanted, manufactories, or agriculture, have already taken possession of the ground, and occupied the streams of water; it is plainly to be foreseen, therefore, that, unless some means are devised to reconcile this competition, those desirable improvements must be crippled in their growth, and stop long before the age of maturity.

“It can hardly have escaped any one's observation, that streams of water used for the purpose of working mills, or the more valuable purpose of watering meadows (in the few instances where this has been practised), while they have a scanty supply in summer, generally discharge in winter such superabundance as frequently to do material injury.

“There are, in some parts of this island, exceptions to this general position. Where the soil is porous, and the *substrata* so open as to absorb the rains as they fall, there are no floods: the pores and fissures of the earth form reservoirs or regulators to the streams; they preserve the winter waters, and so equalize the discharge, that there is but little difference between their winter and summer state; but in clay or other similar soils so little is absorbed, and so much suddenly glides off from the sur-

face, that the extremes of scarcity and exuberance are the necessary consequences.

“ It is now well understood, that all natural springs derive their supply from the waters of the atmosphere, and they may fairly be considered as the discharges of natural reservoirs; it is immaterial whether those reservoirs may be composed of large cavities, or minute fissures.

“ Leaving expence out of the question, it is possible to conceive (however extravagant the idea may appear) that the waters of all rivers might, by art, be nearly equalized throughout the year; but it will be sufficient to prove that this is practicable if applied to small rivulets or brooks, particularly where nature holds forth a temptation, by furnishing deep ravines, or capacious hollows on the surface of the ground, capable, at a moderate expence, of being made to contain large quantities of water.

“ We are taught, from the simple instinct of animals, the provident lesson of storing up the superabundant supplies of one season for the wants of another. Necessity has compelled mankind in many countries to follow this example: in hot climates the inhabitants could hardly exist, without storing up the waters of winter for their use in summer. At Alicant the king of Spain has made a reservoir, the water of which, for the uses of summer agriculture, brings him in a revenue of 2000*l. per annum.*

“ There are instances, in this country, where canals are in want of water in summer; while the brooks that supply them discharge floods in winter, in one day, sufficient for the supply of the whole year.

“ Those who entertain doubts of the practicability of making reservoirs sufficient for the supply of canals, state their objections under three heads: the expence; the want of sufficiency of water; and the uncertainty of making such reservoirs capable of retaining it.

“ When the necessary magnitude is ascertained, the expence is a subject of plain calculation; and it is easy to determine whether the project, to which it is to be applied, will bear the expence. There have been several instances, where the expences of repelling an opposition from mill-owners to a bill in parliament, would have been more than enough to have made sufficient reservoirs.

“ Whether they can be filled with water may be known before they are undertaken, by an enquiry and measurement of the discharge in winter.

“ The waste of water from a reservoir is in two ways: by exhalation and by leakage. The first, in a dry summer, would consume about nine inches in depth from the surface: making the head nine inches higher than otherwise necessary would compensate for this. The leakage would be in few cases (where it would be prudent to attempt the scheme at all), even upon small streams, more than equal to the summer supply; and whether the water be discharged by leakage, or by a pipe or artificial discharger, if they shall both discharge into the same channel, it is not very material. In clay, or other soils where rushes grow, there will be no sensible leakage; in soils more open, the pores of the soil would be an extension of the reservoir; and, in cases where it might be necessary to discharge constantly from the reservoir a quantity equal to the summer stream, it would for a time supply that discharge.

“ Even in extreme cases of leaky soils, if there were any sudden floods, the reservoir would at least prevent their sudden discharge. but, where the soil and strata are so close as to absorb little, and cause sudden floods (and it is to these cases that reservoirs are peculiarly applicable), there is little reason to apprehend leakage.

“ The writer of this has lately had an opportunity of experiencing the effect of a small reservoir, not yet completed, as a

regulator to a stream. It covers at present about twenty acres, and is made on a small brook, which, in dry seasons, does not furnish more water than would run through an aperture of an inch in diameter, but is subject to floods, which can hardly be discharged by a pipe of three feet in diameter.

“ There is fixed under the head of it an iron pipe of six inches bore, which during the last winter has almost constantly been open; and discharged a quantity no otherwise unequal than from the difference of pressure by the rising and falling of the water in the reservoir, at the different intervals of rainy and fair weather; and, when the reservoir shall be enlarged, on the one hand, the meadows below will never be overflowed, and, on the other hand, the reservoir will furnish, in the dry part of the summer, *at least twenty times* the quantity of water daily that the brook would otherwise afford.

“ There is now depending in parliament a bill for making a navigable canal through the vale of Belvoir to the town of Grant-ham, where the soil is almost wholly a firm tenacious clay, and will not require above half the water to supply it which is necessary for canals in other instances.

“ That country is subject to an extreme scarcity of water in summer, and to a great superabundance in winter; and every circumstance is favourable to the intention of supplying the canal by artificial reservoirs. It is therefore earnestly hoped, that those who might be induced by their doubts to repel the intention (under the idea that, because no canal hath hitherto been totally supplied by reservoirs, therefore it must be impracticable), will give some credit to those who, on well-grounded information, have advised the measure, and that they will suffer it to be effected.

“ It is also hoped, that the execution of a canal upon this system may tend to promote the extension and continuance of those improvements in commerce and agriculture, on which so greatly depends the prosperity of this county; and which, in many instances, have been already checked, by neglecting to employ the assistance of art in remedying the defects, or rather in using or improving the bounties of Nature.”

Mr. Pitt concludes his remarks in the following words:

“ Farther, respecting the particular subject of applying water to the improvement of land (says he), though this practice is by no means carried to the extent of which it is capable, and large quantities of flood waters are lost (which, in the tenacious clay-soils that abound over a considerable part of this country, can be retained in no other way than by artificial reservoirs), yet considerable exertions are made in this business by many persons, and omitted by few who have the means of doing it; almost every occupier, who has a stream through his meadows, bestowing considerable attention to it in floods. Amongst others, my neighbour Mr. Miller, of Dunstall near Wolverhampton, has upwards of one hundred and eighty acres of land capable of irrigation; and when water abounds, it is applied to this purpose in various ways. Upon his farms are two mill-ponds, and the mills kept in use in his own hands. The jealousy of the millers below, upon the same stream, prevents his applying it to this purpose at any time except when there is plenty of water; on which occasion he often rakes up the mud of his mill-ponds, by small narrows dragged in them to and fro by ropes, and the mud is by this means sent in the water over the land; which water is drawn, in floating gutters, to every part of the land the level will admit; and the consequence is an early and plentiful hay-harvest, often after spring-grazing. There are few instances, in this county, of land formed artificially for the purpose of receiving water by irrigation, by being laid in broad ridges; and the few I have seen would certainly induce any attentive person to reject the method. The soil is seldom left equally upon the land; and the length of time lost, before a good turf can be restored, is a great objection to the

practice; and, as the water may, in almost all cases, be as well applied upon an even surface variously disposed, as land often is by nature, I think such mode of application is to be preferred to breaking the turf, and giving it a new form. Upon the estate of Lord Bagot, adjoining Tedbrook, I observed a considerable tract of formerly morassy land, after draining and being made sound, prepared for irrigation in a very ingenious way: without altering the natural disposition of the turf, the business was effectually done, and meant to be gradually and progressively extended down the valley. At Stoke, near Stone, about fifty acres of meadow-land are watered in a very superior style, from the Trent, and from land floods, by Messrs. Jenkinson. Here the main gutters or carriers are constructed with some fall down the land; and from them are cut sideways a proper number of floating gutters, upon an exact level. Below each of these floating gutters, in the main carriers, are fixed wooden trunks laid in a puddle, with a sliding paddle to each; by means of which the water is either kept back along the floating gutters, and so forced upon and over the land, or drawn down the main gutters, and off the land at pleasure: the gutters are generally constructed deep enough to drain the land, when not used for floating. These meadows have been much improved by this practice, which commenced about seven or eight years ago; before which, I was informed, they were of little value: but at present, after spring-grazing, they produce a full crop of hay, and are improving every year."

IRRITABILITY, in anatomy and medicine, a term first invented by Glisson, and adopted by Dr. Haller, to denote an essential property of all animal bodies; and which, he says, exists independently of and in contradistinction to sensibility. This ingenious author calls that part of the human body *irritable*, which becomes shorter upon being touched; *very irritable*, if it contracts upon a slight touch; and the contrary, if by a violent touch it contracts but little. He calls that a sensible part of the human body, which upon being touched transmits the impression of it to the soul: and in brutes, he calls those parts sensible, the irritation of which occasions evident signs of pain and disquiet in the animal. On the contrary, he calls that insensible, which, being burnt, torn, pricked, or cut till it is quite destroyed, occasions no sign of pain or convulsion, nor any sort of change in the situation of the body. From the result of many cruel experiments he concludes, that the epidermis is insensible; that the skin is sensible in a greater degree than any other part of the body; that the fat and cellular membrane are insensible; and the muscular flesh sensible, the sensibility of which he ascribes rather to the nerves than to the flesh itself. The tendons, he says, having no nerves distributed to them, are insensible. The ligaments and capsulæ of the articulations are also concluded to be insensible; whence Dr. Haller infers, that the sharp pains of the gout are not seated in the capsulæ of the joint, but in the skin, and in the nerves which creep upon its external surface. The bones are all insensible, says Dr. Haller, except the teeth; and likewise the marrow. Under his experiments the periosteum and pericranium, the dura and pia mater, appeared insensible; and he infers, that the sensibility of the nerves is owing to the medulla, and not to the membranes. The arteries and veins are held susceptible of little or no sensation, except the carotid, the lingual, temporal, pharyngeal, labial, thyroïdal, and the aorta near the heart; the sensibility of which is ascribed to the nerves that accompany them. Sensibility is allowed to the internal membranes of the stomach, intestines, bladder, ureters, vagina, and womb, on account of their being of the same nature with the skin: the heart is also admitted to be sensible: but the lungs, liver, spleen, and kidneys, are possessed of a very imperfect, if any, sensation. The glands, having few nerves, are endowed with only an obtuse sensation. Some sensibility is allowed to the tunica choroides and

the iris, though in a less degree than the retina; but none to the cornea. Dr. Haller concludes, in general, that the nerves alone are sensible of themselves; and that, in proportion to the number of nerves apparently distributed to particular parts, such parts possess a greater or less degree of sensibility.

Irritability, he says, is so different from sensibility, that the most irritable parts are not at all sensible, and *vice versa*. He alleges facts to prove this position, and also to demonstrate, that irritability does not depend upon the nerves, which are not irritable, but upon the original formation of the parts which are susceptible of it. Irritability, he says, is not proportioned to sensibility; in proof of which, he observes that the intestines, though rather less sensible than the stomach, are more irritable; and that the heart is very irritable, though it has but a small degree of sensation.

Irritability, according to Dr. Haller, is the distinguishing characteristic between the muscular and cellular fibres; whence he determines the ligaments, periosteum, meninges of the brain, and all the membranes composed of the cellular substance, to be void of irritability. The tendons are unirritable; and though he does not absolutely deny irritability to the arteries, yet his experiments on the aorta produced no contraction. The veins and excretory ducts are in a small degree irritable, and the gall bladder, the ductus choledochus, the ureters and urethra, are only affected by a very acrid corrosive; but the lacteal vessels are considerably irritable. The glands and mucous sinuses, the uterus in quadrupeds, the human matrix, and the genitals, are all irritable; as are also the muscles, particularly the diaphragm. The œsophagus, stomach, and intestines, are irritable: but of all the animal organs the heart is endued with the greatest irritability. In general, there is nothing irritable in the animal body but the muscular fibres; and the vital parts are the most irritable. This power of motion, arising from irritations, is supposed to be different from all other properties of bodies, and probably resides in the glutinous mucus of the muscular fibres, altogether independent of the influence of the soul. The irritability of the muscles is said to be destroyed by drying of the fibres, congealing of the fat, and more especially by the use of opium in living animals. The physiological system, of which an abstract has been now given, has been adopted and confirmed by Casell and Zimmermann, and also by Dr. Brocklesby, who suggests, that irritability, as distinguished from sensibility, may depend upon a series of nerves different from such as serve either for voluntary motion or sensation. This doctrine, however, has been controverted by M. le Cat, and particularly by Dr. Whytt in his *Physiological Essays*.

IRROGATIO, a law term amongst the Romans, signifying the instrument in which were put down the punishments which the law provided against such offences as any person was accused of by a magistrate before the people. These punishments were first proclaimed *viva voce* by the accuser, and this was called *Inquisitio*. The same, being immediately after expressed in writing, took the name of *Rogatio*, in respect of the people, who were to be consulted or asked about it; and was called *Irogatio* in respect of the criminal, as it imported the mulct or punishment assigned him by the accuser.

IRROMANGO, or **ERRAMONGO**, one of the New Hebrides islands, is about 24 or 25 leagues in circuit; the middle of it lies in E. lon. 169. 19. S. lat. 18. 54. The inhabitants are of the middle size, and have a good shape and tolerable features. Their colour is very dark; and they paint their faces, some with black and others with red pigment: their hair is curly and crisp, and somewhat woolly. Few women were seen, and those very ugly: they wore a petticoat made of the leaves of some plant. The men were quite naked, excepting a belt tied about the waist, and a piece of cloth, or a leaf, used for a wrapper. No canoes were seen in any part of the island. They

live in houses covered with thatch; and their plantations are laid out by line, and fenced round. An unlucky scuffle between the British sailors and these people, in which four of the latter were desperately wounded, prevented captain Cook from being able to give any particular information concerning the produce, &c. of this island.

IRONAM, one of the Hebrides, in the S. Pacific Ocean, near Tanna. E. lon. 170. 26. S. lat. 19. 31.

IRGIS, a large river of Asia, in Siberia, which rises among the hills of the country of the Kalmucks, and, running north-east, falls into the Oby. It abounds with fish, particularly sturgeon, and delicate salmon.

IRTYSH, a large river in Asia, in Siberia, which running from the S. to N. E. falls into the Oby, near Tobolsk. The N. W. shore is low pasture-ground; on the other side are a prodigious number of black bears, wolves, and red and grey foxes, beside the best grey squirrels in all Siberia. This river abounds with fish.

IRVINE, a sea-port and parliament town of Scotland, in the bailiwick of Cunningham; seated at the mouth of a river of the same name on the frith of Clyde, in W. lon. 2. 55. N. lat. 55. 36. This port had formerly several buffes in the herring-fishery. At present that branch is given up; but the inhabitants still employ a number of brigs in the coal-trade to Ireland. Irvine had a viscount's title, now extinct.

IRVINE, or **IRWIN**, a river of Scotland, in Ayrshire, which, descending from the mountains on the E. passes by Derval, Newmills, Galston, and Riccarton, and falls into the frith of Clyde, close by the town of Irvine.

IRWELL, a river of Lancashire, which rises above Bolton, flows thence to Manchester, and falls into the Mersey below Flixton.

ISAAC, the Jewish patriarch, and example of filial obedience, died 1716 B. C. aged 180.

ISABELLA, FORT, a fortress of the Austrian Netherlands, seated on the W. side of the river Scheldt, opposite Antwerp. E. lon. 4. 26. N. lat. 51. 13. There is another fort of the same name, two miles S. W. of Sluys, in Dutch Flanders.

ISABELLA, ST. an island of the S. Sea, and the largest of the Isles of Solomon. It was discovered by the Spaniards in 1568.

ISADAGAS, a town of Africa, in the kingdom of Morocco, and province of Escura. The inhabitants are good-natured and civil to strangers, for they will not let them pay any thing for their entertainment. It is seated in a country abounding in cattle; and the honey is very white, and in great esteem.

ISÆUS, a Greck orator, born at Colchis, in Syria, was the disciple of Lysias, and the master of Demosthenes; and taught eloquence at Athens, about 344 years B. C. Sixty-four orations are attributed to him; but he composed no more than 50, of which only 10 are now remaining. He took Lysias for his model, and so well imitated his style and elegance, that we might easily confound the one with the other, were it not for the figures which Isæus first introduced into frequent use. He was also the first who applied eloquence to politics, in which he was followed by his disciple Demosthenes. He ought not to be confounded with Isæus, another celebrated orator, who lived at Rome in the time of Pliny the younger, about the year 97.

ISAIAH, or *the Prophecy of ISAIAH*, a canonical book of the Old Testament. Isaiah is the first of the four greater prophets; the other three being Jeremiah, Ezekiel, and Daniel. This prophet was of royal blood, his father Amos being brother to Azariah king of Judah. The five first chapters of his prophecy relate to the reign of Uzziah; the vision in the sixth chapter happened in the time of Jotham: the next chapters, to the fifteenth, include his prophecies under the reign of Ahaz; and those that were made under the reigns of Hezekiah and

Manasseh, are related in the next chapters to the end. Isaiah foretold the deliverance of the Jews from their captivity in Babylon by Cyrus, one hundred years before it came to pass. But the most remarkable of his predictions are those concerning the Messiah, which describe not only his descent, but all the remarkable circumstances of his life and death. The style of this prophet is noble, nervous, sublime, and florid, which he acquired by converse with men of the greatest abilities and elocution: Grotius calls him the Demosthenes of the Hebrews. However, the profoundness of his thoughts, the loftiness of his expressions, and the extent of his prophecy, render him one of the most difficult of all the prophets; and the commentaries that have been hitherto written on his prophecy fall short of a full explication of it. Bishop Lowth's new translation, &c. published in 1778, throws considerable light on the composition and meaning of *Isaiab*.

ISATIS, WOAD; a genus of the siliquosa order, belonging to the tetradynamia class of plants; and in the natural method ranking under the 39th order, the *Siliquosa*. The siliqua is lanceolated, unilocular, monospermous, bivalved, and deciduous; the valves navicular or canoe-shaped. There are four species; but the only one worthy of notice is the tinctoria, or common woad, which is cultivated in several parts of Britain for the purposes of dyeing; being used as a foundation for many of the dark colours. See *COLOUR-Making*, *DYEING*, and *WOAD*.

The plant is biennial; the lower leaves are of an oblong oval figure, and pretty thick consistence, ending in obtuse roundish points; they are entire on their edges, and of a lucid green. The stalks rise four feet high, dividing into several branches, garnished with arrow-shaped leaves sitting close to the stalks; the branches are terminated by small yellow flowers, in very close clusters, which are composed of four small petals, placed in form of a cross, which are succeeded by pods shaped like a bird's tongue, which, when ripe, turn black, and open with two valves, having one cell, in which is situated a single seed.

This sort is sown upon fresh land which is in good heart, for which the cultivators of woad pay a large rent. They generally choose to have their lands situated near great towns, where there is plenty of dressing: but they never stay long on the same spot; for the best ground will not admit of being sown with woad more than twice; and if it is oftener repeated, the crop seldom pays the charges of culture, &c. Those who cultivate this commodity have gangs of people who have been bred to the employment; so that whole families travel about from place to place wherever their principal fixes on land for the purpose. As the goodness of woad consists in the size and fatness or thickness of the leaves, the only method to obtain this, is by sowing the seed upon ground at a proper season, and allowing the plants proper room to grow; as also to keep them clean from weeds, which, if permitted to grow, will rob the plants of their nourishment. After having made choice of a proper spot of land, which should not be too light and sandy, nor over stiff and moist, but rather a gentle hazel loam, whose parts will easily separate, the next is to plough this up just before winter, laying it in narrow high ridges, that the frost may penetrate through the ridges to mellow and soften the clods; then in the spring plough it again crosswise, laying it again in narrow ridges. After it has lain for some time in this manner, and the weeds begin to grow, it should be well harrowed to destroy them: this should be repeated twice while the weeds are young; and, if there are any roots of large perennial weeds, they must be harrowed out, and carried off the ground. In June the ground should be a third time ploughed, when the furrows should be narrow, and the ground stirred as deep as the plough will go, that the parts may be as well separated as possible; and when the weeds appear again, the ground should

be well harrowed to destroy them. Toward the end of July, or the beginning of August, it should be ploughed the last time, when the land should be laid smooth; and when there is a prospect of showers, the ground must be harrowed to receive the seeds, which should be sown in rows with the drill plough, or in broad-cast after the common method; but it will be proper to steep the seeds one night in water before they are sown, which will prepare them for vegetation: if the seeds are sown in drills, they will be covered with an instrument fixed to the plough for that purpose, but those which are sown broad cast in the common way must be well harrowed in. If the seeds are good, and the season favourable, the plants will appear in a fortnight, and in a month or five weeks will be fit to hoe; for the sooner this is performed when the plants are distinguishable, the better they will thrive, and the weeds being then young will be soon destroyed. The method of hoeing these plants is the same as for turnips; with this difference only, that these plants need not be thinned so much; for at the first hoeing, if they are separated to the distance of four inches, and at the last to six inches, it will be space enough for the growth of the plants; and if this is carefully performed, and in dry weather, most of the weeds will be destroyed: but as some of them may escape in this operation, and young weeds will rise, so the ground should be a second time hoed in the beginning of October, always choosing a dry time for this work: at this second operation, the plants should be singled out to the distance they are to remain. After this, if carefully performed, the ground will be clean from weeds till the spring, when young weeds will come up: therefore about the middle of March will be a good time to hoe the ground again; for, while the weeds are young, it may be performed in less than half the time it would require if the weeds were permitted to grow large, and the sun and wind will much sooner kill them: this hoeing will also stir the surface of the ground, and greatly promote the growth of the plants: if this is performed in dry weather, the ground will be clean till the first crop of woad is gathered, after which it must be again well cleaned: if this is carefully repeated after the gathering each crop, the land will always lie clean, and the plants will thrive the better. The expence of the first hoeing will be about six shillings *per* acre, and for the after-hoings half that price will be sufficient, provided they are performed when the weeds are young; for, if they are suffered to grow large, it will require more labour, nor can it be so well performed.

If the land, in which this seed is sown, should have been in culture before for other crops, so not in good heart, it will require dressing before it is sown; in which case rotten stable-dung is preferable to any other: but this should not be laid on till the last ploughing, just before the seeds are sown, and not spread till the land is ploughed, that the sun may not exhale the goodness of it, which in summer is soon lost when spread on the ground. The quantity should not be less than 20 loads to each acre, which will keep the ground in heart till the crop of woad is spent.

The time for gathering of the crop is according to the season: but it should be performed as soon as the leaves are fully grown, while they are perfectly green: for, when they begin to change pale, great part of their goodness is over; for the quantity will be less, and the quality greatly diminished.

If the land is good, and the crop well husbanded, it will produce three or four gatherings; but the two first are the best. These are commonly mixed together in the manufacturing of it: but the after-crops are always kept separate; for, if these are mixed with the other, the whole will be of little value. The two first crops will sell from 25 l. to 30 l. a ton; but the latter will not bring more than 7 l. or 8 l. and sometimes not so much. An acre of land will produce a ton of woad, and in good seasons near a ton and an half.

When the planters intend to save the seeds, they cut three crops of the leaves, and then let the plants stand till the next year for seed; but if only one crop is cut, and that only of the outer leaves, letting all the middle leaves stand to nourish the stalks, the plants will grow stronger, and produce a much greater quantity of seeds.

These seeds are often kept two years, but it is always best to sow new seeds when they can be obtained. The seeds ripen in August; and when the pods turn to a dark colour, the seeds should be gathered. It is best done by reaping the stalks in the same manner as wheat, spreading the stalks in rows upon the ground: and in four or five days the seeds will be fit to thrash out, provided the weather is dry; for, if it lies long, the pods will open and let out the seeds.

There are some of the woad-planters who feed down the leaves in winter with sheep; which is a very bad method; for all plants which are to remain for a future crop should never be eaten by cattle, for that greatly weakens the plants; therefore those who eat down their wheat in winter with sheep are equally blameable.

ISATIS, in zoology, a synonyme of the *canis lagopus*. See CANIS.

ISAURA, or ISAVRUS, in ancient geography, a strong city at mount Taurus, in Isauria, twice demolished; first by Perdiccas, or rather by the inhabitants, who, through despair, destroyed themselves by fire, rather than fall into the hands of the enemy; again by Servilius, who thence took the surname *Lauricus*. Strabo says there were two Isauras, the old and the new, but so near that other writers took them but for one.

ISAURIA, a country touching Pamphylia and Cilicia on the north, rugged and mountainous, situated almost in mount Taurus, and taking its name from Isaura; according to some, extending to the Mediterranean by a narrow slip. Stephanus, Ptolemy, and Zosimus, make no mention of places on the sea; though Pliny does, as also Strabo; but doubtful, whether they are places in Isauria Proper, or in Pamphylia, or in Cilicia.

ISAURICA, a part of Lycaonia, bordering on mount Taurus.

ISCA DUMNIORUM, in ancient geography; a town in Britain. Now Exeter, capital of Devonshire. Called *Cacr-Ijk* in British. (Camden.)

ISCA SILURUM, in ancient geography the station of the Legio II. Augusta, in Britain. Now *Carlton*, a town of Monmouthshire, on the Uike.

ISCHALIS, or ISCALIS, in ancient geography; a town of the Belgæ in Britain. Now *Ilchester* in Somersetshire, on the river Ill.

ISCHÆMUM, in botany; a genus of the monœcia order, belonging to the polygamia class of plants; and in the natural method ranking under the 4th order, *Gramina*. The calyx of the hermaphrodite is a biflorous glume; the corolla bivalved; there are three stamina, two styles, and one seed. The calyx and corolla of the male, as in the former, with three stamina.

ISCHIUM, in anatomy, one of the bones of the pelvis. See ANATOMY, p. 166.

ISCHIA, an island of Italy, in the kingdom of Naples, about 15 miles in circumference, lying on the coast of the Terra di Lavoro, from which it is three miles distant. It is full of agreeable valleys, which produce excellent fruits. It hath also mountains on which grow vines of an excellent kind: likewise fountains, rivulets, and fine gardens.

ISCHIA, a town of Italy, and capital of an island of the same name, with a bishop's see and a strong fort. Both the city and fortrefs stand upon a rock, which is joined to the island by a strong bridge: the rock is about seven furlongs in circumference. The city is like a pyramid of houses piled upon one another, which makes a very singular and striking appearance. At the

end of the bridge next the city are iron gates, which open into a subterraneous passage, through which they enter the city. They are always guarded by soldiers who are natives of the island. E. lon. 13. 55. N. lat. 40. 50.

ISCHURIA, *ισχυρία*, formed from *ισχω* "I stop," and *ουρι* "urine," in phylis, a disease consisting in an entire suppression of urine. See **SURGERY**. It is occasioned by any thing which may obstruct the urinary passages, as sand, stone, mucus, &c. It may also arise from a loss of power in the nerves which pass to the kidneys or bladder, as we see it does in a palsy of the parts below the diaphragm. The too great distension of the bladder may also produce the same effect; for it sometimes happens, that persons who have retained their urine a long time find a great deal of difficulty in discharging it.

ISELASTICS, a kind of games, or combats, celebrated in Greece, and Asia, in the time of the Roman emperors. The victor at these games had very considerable privileges conferred on him, after the example of Augustus and the Athenians, who did the like to conquerors at the Olympic, Pythian, and Isthmian games. They were crowned on the spot immediately after their victory, had pensions allowed them, were furnished with provisions at the public cost, and were carried in triumph to their country.

ISELSTEIN, a small town of the United Provinces, seated on the river Issel, four miles from Utrecht.

ISENACH, a town of Germany, in the circle of Upper Saxony, from whence one of the Saxon princes takes the title of *duke*. There are iron mines in the neighbourhood. E. lon. 9. 17. N. lat. 51. 0.

ISENBURG, a large town of Germany, capital of a county of the same name, with a handsome castle, seated on the river Seine, in E. lon. 7. 14. N. lat. 50. 28. The county belongs to the elector of Treves.

ISENGHEIN, a town of the Austrian Netherlands, with the title of a *principality*, seated on the river Mandera, in E. lon. 3. 18. N. lat. 50. 44.

ISER, a considerable river of Germany, which rises on the confines of Tirol and Bavaria, and, having passed by Munich and Landshut, falls into the Danube between Straubing and Passau.

ISERE, a department of France, which includes part of the late province of Dauphiny. It is so named from a river which rises on the confines of Savoy, and falls into the Rhone, above Valence. Grenoble is the episcopal city of this department.

ISENARTS, or **EISENARTS**, a considerable town of Germany, in Stiria; famous for its iron mines, 30 miles N. W. of Gratz. E. lon. 15. 4. N. lat. 47. 25.

ISERNIA, a town of Italy, in the kingdom of Naples, and in the county of Molise, with a bishop's see. It is seated at the foot of the Appenines, in E. lon. 14. 20.

ISIA, *Ἰσηία*, feasts and sacrifices anciently solemnized in honour of the goddess Isis. The Isia were full of the most abominable impurities; and for that reason, those who were initiated into them were obliged to take an oath of secrecy. They were held for nine days successively, but grew so scandalous, that the senate abolished them at Rome under the consulate of Piso and Gabinius. They were re-established by Augustus; and the emperor Commodus himself assisted at them, appearing among the priests of that goddess with his head shaven, and carrying the Anubis.

ISIAC TABLE is one of the most considerable monuments of antiquity, discovered at Rome in 1525, and supposed by the various figures in bas-relief upon it to represent the feasts of Isis, and other Egyptian deities. There have been various opinions as to the antiquity of this monument: some have supposed that it was engraved long before the time when the Egyptians worshipped the figures of men and women. Others, among

whom is bishop Warburton, apprehend, that it was made at Rome by persons attached to the worship of Isis. Dr. Warburton considers it as one of the most modern of the Egyptian monuments, on account of the great mixture of hieroglyphic characters which it bears.

ISIACI, priests of the goddess Isis. Dioecorides tells us, that they bore a branch of sea-wormwood in their hands instead of olive. They sung the praises of the goddess twice a-day, viz. at the rising of the sun, when they opened her temple; after which they begged alms the rest of the day, and, returning at night, repeated their orisons, and shut up the temple. Such was the life and office of the *Isiaci*: they never covered their feet with any thing but the thin bark of the plant papyrus, which occasioned Prudentius and others to say they went bare-footed. They wore no garments but linen, because Isis was the first who taught mankind the culture of this commodity.

ISIDORUS, called **DAMIATENSIS**, or **PELUSIOTA**, from his living in a solitude near that city, was one of the most famous of all St. Chryostom's disciples, and flourished in the time of the general council held in 421. We have 2012 of his epistles in five books. They are short, but well written, in Greek. The best edition is that of Paris, in Greek and Latin, printed in 1638, in folio.

ISIGNI, a town of France, in the department of Calvados and late province of Normandy, with a small harbour. It is 15 miles W. of Bayeux, and well known on account of its salt-works, its cider, and its butter. W. lon. 0. 59. N. lat. 49. 20.

ISINGLASS. See **ICHTHYOCOLLA**.

ISIS, a celebrated deity of the Egyptians, daughter of Saturn and Rhea, according to Diodorus of Sicily. Some suppose her to be the same as Io, who was changed into a cow, and restored to her human form in Egypt, where she taught agriculture, and governed the people with mildness and equity; for which reasons she received divine honours after death. According to some traditions mentioned by Plutarch, Isis married her brother Osiris, and was pregnant by him even before she had left her mother's womb. These two ancient deities, as some authors observe, comprehended all nature and all the gods of the heathens. Isis was the Venus of Cyprus, the Minerva of Athens, the Cybele of the Phrygians, the Ceres of Eleusis, the Proserpine of Sicily, the Diana of Crete, the Bellona of the Romans, &c. Osiris and Isis reigned conjointly in Egypt; but the rebellion of Typhon, the brother of Osiris, proved fatal to this sovereign. The ox and the cow were the symbols of Osiris and Isis; because these deities, while on earth, had diligently applied themselves in cultivating the earth. As Isis was supposed to be the moon, as Osiris the sun, she was represented as holding a globe in her hand, with a vessel full of ears of corn. The Egyptians believed that the yearly and regular inundations of the Nile proceeded from the abundant tears which Isis shed for the loss of Osiris, whom Typhon had basely murdered. The word *Isis*, according to some, signifies "ancient," and on that account the inscriptions on the statues of the goddess were often in these words: "I am all that has been, that shall be, and none among mortals has hitherto taken off my veil." The worship of Isis was universal in Egypt; the priests were obliged to observe perpetual chastity, their head was closely shaved, and they always walked barefooted, and clothed themselves in linen garments. They never ate onions, they abstained from salt with their meat, and were forbidden to eat the flesh of sheep and of hogs. During the night they were employed in continual devotion near the statue of the goddess. Cleopatra, the beautiful queen of Egypt, was wont to dress herself like this goddess, and affected to be called a second Isis.

ISIS, or *Thames*, a river that has its rise in Gloucestershire, and flows through only a small part of Wiltshire. It enters

this county near its source, and begins to be navigable for boats at Cricklade; but after running in a serpentine manner about four miles, it leaves Gloucestershire at a village called *Castle Eaton*.

ISLAM; the true faith, according to the Mahometans. See MAHOMETANISM.

ISLAND, a tract of dry land encompassed with water; in which sense it stands contradistinguished from CONTINENT, or TERRA FIRMA. Several naturalists are of opinion, that the islands were formed at the deluge; others think, that there have been new islands formed by the casting up of vast heaps of clay, mud, sand, &c.; others think that they have been separated from the continent by violent storms, inundations, and earthquakes. These last have observed, that the East Indies, which abound in islands more than any other part of the world, are likewise more annoyed with earthquakes, tempests, lightnings, volcanoes, &c. than any other part. Others again conclude, that islands are as ancient as the world, and that there were some at the beginning; and, among other arguments, support their opinion from Gen. x. 5. and other passages of Scripture.

Varenus thinks that there have been islands produced each of these ways. St. Helena, Ascension, and other steep rocky islands, he supposes to have become so by the sea's overflowing their neighbouring champagnes: but by the heaping up huge quantities of sand, and other terrestrial matter, he thinks the islands of Zealand, Japan, &c. were formed. Sumatra and Ceylon, and most of the East India islands, he thinks, were rent off from the main land; and concludes, that the islands of the Archipelago were formed in the same way, imagining it probable that Deucalion's flood might contribute towards it. The ancients had a notion that Delos, and a few other islands, rose from the bottom of the sea; which, how fabulous soever it may appear, agrees with later observations. Seneca takes notice, that the island Therasia rose thus out of the Ægean sea in his time, of which the mariners were eye-witnesses.

It is indeed very probable, that many islands have existed not only from the deluge, but from the creation of the world; and we have undoubted proofs of the formation of islands in all the different ways above mentioned. Another way, however, in which islands are frequently formed in the South Sea, is by the coralline insects. On this subject the following curious dissertation by Alexander Dalrymple, Esq. appeared in the Philosophical Transactions for 1767.

"These islands are generally long and narrow: they are formed by a narrow bar of land, inclosing the sea within it; generally, perhaps always, with some ingress at least to the tide; commonly with an opening capable of receiving a canoe, and frequently sufficient to admit even larger vessels.

"The origin of these islands will explain their nature. What led me first to this deduction was an observation of Abdul Roobin, a Sooloo pilot, that all the islands lying off the north-east coast of Borneo had shoals to the eastward of them.

"These islands being covered to the westward by Borneo, the winds from that quarter do not attack them with violence. But the north-east winds, tumbling in the billows from a wide ocean, heap up the coral with which those seas are filled. This, obvious after storms, is perhaps at all other times imperceptibly effected.

"The coral banks, raised in the same manner, become dry. These banks are found of all depths, at all distances from shore, entirely unconnected with the land, and detached from each other; although it often happens that they are divided by a narrow gut without bottom.

"Coral banks also grow, by a quick progression, towards

the surface; but the winds, heaping up the coral from deeper water, chiefly accelerate the formation of these into shoals and islands. They become gradually shallower; and, when once the sea meets with resistance, the coral is quickly thrown up by the force of the waves breaking against the bank; and hence it is, that, in the open sea, there is scarce an instance of a coral-bank having so little water that a large ship cannot pass over, but it is also so shallow that a boat would ground on it.

"I have seen these coral banks in all the stages; some in deep water, others with few rocks appearing above the surface; some just formed into islands, without the least appearance of vegetation; and others from such as have a few weeds on the highest part, to those which are covered with large timber, with a bottomless sea at a pistol-shot distance.

"The loose coral, rolled inward by the billows in large pieces, will ground; and the reflux being unable to carry them away, they become a bar to coagulate the sand, always found intermixed with coral; which sand, being easiest raised, will be lodged at the top. When the sand-bank is raised by violent storms beyond the reach of common waves, it becomes a resting-place to vagrant birds, whom the search of prey draws thither. The dung, feathers, &c. increase the soil, and prepare it for the reception of accidental roots, branches and seed, cast up by the waves, or brought thither by birds. Thus islands are formed: the leaves and rotten branches, intermixing with the sand, form in time a light black mould, of which in general these islands consist; more sandy as less woody; and, when full of large trees, with a greater proportion of mould.

"Cocoa-nuts, continuing long in the sea without losing their vegetative powers, are commonly to be found in such islands; particularly as they are adapted to all soils, whether sandy, rich, or rocky.

"The violence of the waves within the tropics must generally be directed to two points, according to the monsoons.

"Hence the islands formed from coral-banks must be long and narrow, and lie nearly in a meridional direction. For, even supposing the banks to be round, as they seldom are when large, the sea meeting most resistance in the middle, must heave up the matter in greater quantities there than towards the extremities: and, by the same rule, the ends will generally be open, or at least lowest. They will also commonly have soundings there, as the remains of the bank, not accumulated, will be under water.

"Where the coral-banks are not exposed to the common monsoon, they will alter their direction; and be either round, extending the parallel, or be of irregular forms, according to accidental circumstances.

"The interior parts of these islands being sea, sometimes form harbours capable of receiving vessels of some burthen, and, I believe, always abound greatly with fish; and, such as I have seen, with turtle-grass and other sea-plants, particularly one species, called by the Sooloos *gammye*, which grows in little globules, and is somewhat pungent, as well as acid, to the taste.

"It need not be repeated, that the ends of those islands only are the places to expect soundings; and they commonly have a shallow spit running out from each point.

"Abdul Roobin's observation points out another circumstance, which may be useful to navigators; by consideration of the winds to which any islands are most exposed, to form a probable conjecture which side has deepest water; and from a view which side has the shoals, an idea may be formed which winds rage with most violence."

Islands from their situation enjoy many great advantages, the principal of which are these. In the first place, many benefits are derived to the inhabitants of an island from its unity. The very largest country on a continent is still but a

part, which implies dependence, and is necessarily attended with a train of imperfections; from all of which, by the unerring and unalterable laws of nature, the people who live in an island are or may be entirely free. All countries on the continent are exposed to continual dangers, against which their inhabitants must be perpetually upon their guard. This renders a large military force requisite. It involves them in continual negotiations, leagues, and alliances; all of which, however, cannot exempt them from frequent wars, or the miseries that attend them, and which have commonly bad effects on their internal policy. In the next place, the climate is generally mild and salubrious from the vapours of the surrounding sea, which according to the latitude abates the violence of heat, and moderates the rigour of cold, both which are sensibly and constantly less than on continents under the same elevation of the pole. We have a remarkable instance of this in the islands called anciently *Stœvades*, in the modern Latin *Insulæ Arcarum*, by us the islands of *Hieres*. They are three in number, lying in 43° north latitude, before the port of Toulon. In them the fruits of France and Italy arrive at the highest perfection, and all the medical herbs of Italy, Greece, and Egypt, grow wild. Yet the climate is wonderfully temperate and pleasant in all seasons. There is also commonly a greater variety, and always a greater fertility, in the soil, occasioned chiefly by the warmth of the circumambient air, frequent showers, and, in consequence of both, being continually impregnated with vegetable salts. Another considerable advantage arises from its accessibility on every side, by which it is open to receive supplies from other countries, and has the conveniency of exporting its commodities and manufactures to all markets, and, in comparison of the continent, at all seasons. The opposite sides of an island may in regard to commerce be considered as two countries; each has its ports, its proper commodities, its proper correspondencies; in consequence of which, it promotes the cultivation, and procures vent for the manufactures, of a large district behind it; while the intermediate midland space finds a profit in that inland trade, which these two districts supply. The winds contrary on one side are favourable on the other; and the sea, the common road to both coasts, is continually ploughed by vessels outward and homeward bound, which keeps up that active and enterprising spirit which characterizes islanders. An island has at once the most extensive and the most effectual frontier, and this on all sides, subsisting for ever, without repairs, and without expence; and, which is still more, derives from this very frontier a great part of the subsistence of its inhabitants, and a valuable article in its commerce, from its fisheries. It is commonly said the sea is a mine, but in truth it is better; its treasures are more lasting and more certain, procured by labour solely, and fit for use or for sale as soon as procured, quickly consumed, and thereby the source of continual employment to a stout, hardy, laborious race of men, who likewise find employment for numbers, and are in various respects otherwise beneficial members of the community. The defence of this natural barrier, which, as we have said, costs nothing, but on the contrary yields much, is not only permanent, but in every respect more to be relied on than any that could be raised by the skill and industry of men at the greatest expence. All these blessings and benefits are insured by the lesson that nature dictates, some would say the law which she prescribes, to the inhabitants of every island, to place all their hopes in the assiduous cultivation of their own country, to bend all their endeavours to raising and extending their commerce, and to put their trust in Providence, and in the safeguard which she directs; men accustomed to robust and hardy exercises, and in what necessarily arises from their way of life, a naval force. The first inhabitants come

in vessels, are for a time dependent on the country from whence they came, arrive at independence by enlarging their correspondence: and thus commerce is natural and essential to the people of an island; which is the reason that they thrive so long as they possess it, and gradually decline in the same proportion in which that decays.

ISLANDS of Ice. See ICE-Island.

Floating-ISLANDS. Histories are full of accounts of floating islands; but the greater part of them are either false or exaggerated. What we generally see of this kind is no more than the concretion of the lighter and more viscous matter floating on the surface of the water in cakes; and, with the roots of the plants, forming congeries of different sizes, which, not being fixed to the shore in any part, are blown about by the winds, and float on the surface. These are generally found in lakes, where they are confined from being carried too far; and, in process of time, some of them acquire a very considerable size. Seneca tells us of many of these floating islands in Italy; and some later writers have described not a few of them in other places. But, however true these accounts might have been at the time when they were written, very few proofs of their authenticity are now to be found; the floating islands having either disappeared again, or been fixed to the sides in such a manner as to make a part of the shore. Pliny tells us of a great island which at one time swam about in the lake Cutilia in the country of Reatinum, which was discovered to the old Romans by a miracle; and Pomponius tells us, that in Lydia there were several islands so loose in their foundations, that every little accident shook and removed them.

Bay of ISLANDS, a bay of New Zealand, at the N. extremity of the most northern of the two islands that go under that name. In 1772, M. Dufresne Marion, with two French sloops under his command, put into this bay in great distress, and, with 28 of his crew, was surprised and murdered by the natives.

ISLAND (or Iceland) Crystal. See ISLAND-CRYSTAL.

ISLAY, or ILA, an island of Scotland, one of the Hebrides, to the S. W. of Jura. Its greatest length is 25 miles; its breadth 18. The principal village is Bowmore, which is in a manner a new town, and has a convenient harbour. The face of the country is hilly. Several mines are wrought to great advantage; and the lead-ore is very rich and productive. Here likewise are copper, emery, native quicksilver, and black lead; with immense stores of limestone, marl, coral, and shell-sand, for manure. Much corn and flax is raised here, and a great number of cattle exported. In this, and some of the neighbouring islands, multitudes of adders infest the heath. On the N. W. side of the island is the cave of Sanegmore, which is a grotto, divided into a number of far-winding passages, sometimes opening into fine expanses; again closing, for a long space, into galleries, and forming a curious subterraneous labyrinth. There are also many other caverns, the haunts of numerous wild pigeons, that lodge and breed in them. The goats that feed among the rocks are so wild, that they are obliged to be shot like deer. Some vestiges of antiquity are on this island; particularly, the remains of a circular dry stone building, on the hill of Lofset, near the sound of Ilay. This hill contains fine iron ore and emery.

ISLE-ADAM, a town of France, in the department of Seine and Oise and late province of the Isle of France, with a handsome castle, seated on the river Oise, three miles from Beaumont, and 20 from Paris. E. lon. 2. 13. N. lat. 49. 7.

ISLE of Beeves, an island of N. America, in the gulf of Mexico, and bay of Campeachy, about 17 miles in length, and eight in breadth. It is fertile in several places, and abounds in cattle and excellent fruits.

ISLE-de-Dieu, a small island of France, 14 miles from the coast of Poitou. W. lon. 2. 15. N. lat. 46. 45.

ISLE-de-France. See FRANCE, *Isle of*.

ISLE-Jourdain, a town of France, in the department of Gers, and late province of Armagnac, in an island of the little river Save, eight miles N. of Lombez. E. lon. 1. 2. N. lat. 43. 40.

ISLE-Rouffe, a town of Corsica, on the sea-coast, 36 miles S. W. of Bastia.

ISLE and Vilaine, a department of France, containing part of the late province of Bretagne. Rennes is the capital.

ISLEBIANS, in ecclesiastical history, a name given to those who adopted the sentiments of a Lutheran divine of Saxony, called John Agricola, a disciple and companion of Luther, a native of Iseb, whence the name; who, interpreting literally some of the precepts of St. Paul with regard to the Jewish law, declaimed against the law and the necessity of good works. See **ANTINOMIANS**.

ISLEWORTH, a large village in Middlesex, 9 miles W. of London, seated on the river Thames. In this parish is Sion House, the magnificent seat of the duke of Northumberland, and several handsome villas. The S. side of Hounslow is also in this parish. W. lon. 0. 14. N. lat. 51. 29.

ISLINGTON, a village of Middlesex, on the north side of London, to which it is almost contiguous. It appears to be of Saxon origin; and in the Conqueror's time was written *Isledon*, or *Isendon*. The church is one of the prebends of St. Paul's; to the dean and chapter of which a certain precinct here belongs, for the probate of wills, and granting administrations. The church was a Gothic structure, erected in 1503, and stood till 1751, when the inhabitants applied to parliament for leave to rebuild it, and soon after erected the present structure, which is a very substantial brick edifice, though it does not want an air of lightness. Its houses are above 4000, including the Upper and Lower Holloways, three sides of Newington-Green, and part of Kingsland, on the road to Ware. The White Conduit-house in this place, so called from a white stone conduit that stands before the entrance, has handsome gardens with good walks, and two large rooms one above the other for the entertainment of company at tea, &c. In the S. W. part of this village is that noble reservoir, improperly called New-River Head; though they are only two basons, which receive that river from Hertfordshire, and from whence the water is thrown by an engine into the company's pipes for the supply of London. In the red-moat on the north side of these basons, called Six-Acre-Field from the contents of it, which is the third field beyond the White-Conduit, there appears to have been a fortress in former days, inclosed with a rampart and ditch, which is supposed to have been a Roman camp made use of by Suetonius Paulinus after his retreat, which Tacitus mentions, from London, before he sallied thence, and routed the Britons under their queen Boadicea; and that which is vulgarly, but erroneously, called Jack Straw's castle, in a square place in the S. W. angle of the field, is supposed to have been the seat of the Roman general's pretorium or tent. In this parish are two charity-schools; one founded in 1613 by Dame Alice Owen, for educating 30 children. This foundation, together with that of a row of alms-houses, are under the care of the brewers' company. Here is an hospital with its chapel, and a work-house for the poor. There is a spring of chalybeate water, in a very pleasant garden, which for some years was honoured by the constant attendance of the princess Amelia, and many persons of quality, who drank the waters. To this place, which is called New Tunbridge Wells, many people resort, particularly during the summer, the price of drinking the waters being 10s. 6d. for the season. Near this place is a house

of entertainment called Sadler's Wells, where, during the summer season, people are amused with balance-masters, walking on the wire, ropè-dancing, tumbling, and pantomime entertainments.

ISLIP, a town of Oxfordshire, 56 miles from London, is noted for the birth and baptism of Edward the Confessor. By the late inland navigation, it has communication with the rivers Mersey, Dee, Ribble, Ouse, Trent, Darwent, Severn, Humber, Thames, Avon, &c. which navigation, including its windings, extends above 500 miles, in the counties of Lincoln, Nottingham, York, Lancaster, Westmoreland, Chelster, Stafford, Warwick, Leicester, Oxford, Worcester, &c. It has a good market for sheep, and some remains of an ancient palace, said to have been king Ethelred's. Here is a charity-school. The chapel wherein Edward was baptized stood at a small distance north from the church, and is still called the king's chapel. It was entirely defaced during Cromwell's usurpation, and converted to the meanest uses of a farm-yard; at present it has a roof of thatch. It is built of stone 15 yards long and 7 broad, and retains traces of the arches of an oblong window at the east end. This manor was given by Edward the Confessor to Westminster abbey, to which it still belongs.

ISMAELITES, the descendants of Ismael; dwelling from Havila to the wilderness of Sur, towards Egypt, and thus overspreading Arabia Petraea; and therefore Josephus calls Ismael the founder of the Arabs.

ISMAIL, a strong town of Turkey in Europe, in Bessarabia. It was taken by storm, by the Russians, on the 22d of December 1790; and it is said, that the long siege, and the capture, did not cost them less than 10,000 men. The most shocking part of the transaction is, that the garrison (whose bravery merited, and would have received from a generous foe, the highest honours) were massacred in cold blood by the mercilefs Russians, to the amount, by their own account, of 30,000 men: and the place was abandoned to the fury of the brutal soldiery. Ismail is seated on the N. side of the Danube, 140 miles S. by W. of Bender. E. lon. 29. 30. N. lat. 45. 11.

ISMARUS, in ancient geography, a town of the Cicones in Thrace, giving name to a lake. In Virgil it is called *Ismara*. Servius supposes it to be a mountain of Thrace; on which mountain Orpheus dwelt.

ISNARDIA, in botany; a genus of the monogynia order, belonging to the tetrandria class of plants; and in the natural method ranking under the 17th order, *Calycanthemæ*. There is no corolla; the calyx is quadrifid; the capsule quadrilocular, and girt with the calyx.

ISNIC, a town of Turkey in Asia, and in Natolia, with a Greek archbishop's see. It is the ancient Nice, famous for the first general council held here in 325. There is now nothing remaining of its ancient splendour but an aqueduct. The Jews inhabit the greatest part of it; and it is seated in a country fertile in corn and excellent wine. E. lon. 30. 9. N. lat. 47. 15.

ISNY, an imperial town of Germany, in Swabia, and in Algow; seated on the river Isny, in E. lon. 9. 10. N. lat. 47. 33.

ISOCHRONAL is applied to such vibrations of a pendulum as are performed in the same space of time; as all the vibrations or swings of the same pendulum are, whether the arches it describes are shorter or longer.

ISOCHRONAL-Line, that in which a heavy body is supposed to descend without any acceleration.

ISOCRATES, one of the greatest orators of Greece, was born at Athens 436 B. C. He was the son of Theodorus, who had enriched himself by making musical instruments, and gave his son a liberal education. Isocrates was the disciple of Prodicus, Gorgias, and other great orators. He endeavoured

at first to declaim in public, but without success; he therefore contented himself with instructing his scholars, and making private orations. He always showed great love for his country; and being informed of the loss of the battle of Cheronæa, he abstained four days from eating, and died, aged 98. There are still extant 21 of his discourses or orations, which are excellent performances, and have been translated from the Greek into Latin by Wolfius. Isocrates particularly excelled in the justness of his thoughts, and the elegance of his expressions. There are also nine letters attributed to him.

ISOETES, in botany; a genus of the natural order of flics, belonging to the cryptogamia class of plants. The anthers of the male flower are within the base of the frons or leaf. The capsule of the female flower is bilocular, and within the base of the leaf.

ISOLA, a town of Italy, in the kingdom of Naples, and in the Farther Calabria, with a bishop's see. It is a sea-port town, and is seated 15 miles south-east of St. Severina. E. lon. 7. 33. N. lat. 39. 1.

ISOPERIMETRICAL FIGURES, in geometry, are such as have equal perimeters or circumferences.

ISOPYRUM, in botany; a genus of the polygynia order, belonging to the polyandria class of plants; and in the natural method ranking under the 26th order, *Multifloræ*. There is no calyx, but five petals; the nectaria trifid and tubular; the capsules recurved and polyspermous.

ISOSCELES TRIANGLE, in geometry, one that has two equal sides.

ISPAHAN, or, as the Persians pronounce it, *Spauhawn*, the capital of Persia, is situated in the province of Irac, Agemi, or Persia Proper, upon the ruins, as generally supposed, of the ancient Hecatompylos, or, as others think, of the Aspa of Ptolemy. Most of the eastern astronomers and geographers place it in N. lat. 32. 25. E. lon. 86. 40. It stands in a very extensive plain, surrounded by mountains; and has eight districts belonging to it, that contain about 400 towns and villages. The fertility of the soil, the mildness of the seasons, and the fine temperature of the air, all conspire to render Ispahan one of the most charming and delightful cities in the world. It is unanimously agreed, that the present city is of no great antiquity; and the two parts into which it is divided preserve the names of two contiguous towns, from the junction of which it was formed. The inhabitants of these, notwithstanding their neighbourhood, bear an inveterate antipathy to each other; which they discover on all public occasions. Spauhawn owes the glory it now possesses to the great Shah Abas; who, after the conquest of the kingdoms of Lar and Ormus, charmed with the situation of this place, made it the capital of his empire, between the years 1620 and 1628. The mountains, with which this city is surrounded, defend it alike from the sultry heats of summer and the piercing winds of the winter season; and the plain on which it stands is watered by several rivers, which contribute alike to its ornament and use. Of these rivers, the Zenderoud, after being joined by the Mahmood, passes by Spauhawn; where it has three fine bridges over it, and is as broad as the Seine at Paris. The waters of these united streams are sweet, pleasant, and wholesome, almost beyond comparison; as, indeed, are all the springs found in the gardens belonging to the houses of Spauhawn. The extent of Spauhawn is very great; not less, perhaps, than 20 miles within the walls, which are of earth, poorly built, and so covered with houses, and shaded with gardens, that in many places it is difficult to discover them. The Persians are wont to say, *Spauhawn nisfigibon*, i. e. Spauhawn is half the world. Sir John Chardin says, that, though some reckoned 11,000,000 inhabitants in it, he did not himself look upon it as more populous than London. At a distance, the city is not easily dis-

tinguished; for many of the streets being adorned with plantains, and every house having its garden, the whole looks like a wood. The streets in general are neither broad nor convenient; there being three great evils which attend them: the first is, that being built on common sewers, these are frequently broke up, which is very dangerous, considering that most people are on horseback; the second is, that there are many wells or pits in them, which are not less dangerous; the third arises from the people's emptying all their ordure from the tops of their houses: this last, indeed, is in some measure qualified by the dryness of the air, and by its being quickly removed by the peasants, who carry it away to dung their grounds. Some reckon eight, and others ten gates, besides posterns; but all agree that there is no difficulty of entering at any hour of the day or night. The three principal suburbs annexed to it are, Abas-Abad, built by Shah Abas, and belonging to the people of Tauris; Julfa, inhabited by a colony of Armenians, called by some *New Julfa*, to distinguish it from the ancient city of that name, situated in Armenia, upon the Araxes, whence the original inhabitants of New Julfa were brought; and Ghebr-Abad, or, as the Arabs pronounce it, Kebr Abad, the street of the magians, occupied entirely by the professors of magism, or the religion of the ancient Persians. The river Zenderoud separates the city of Ispahan and Abas-Abad from Julfa and Ghebr-Abad. This city has suffered greatly since the commencement of the dreadful rebellion in 1721; the whole kingdom from that period, till a few years ago, having been almost a continued scene of blood, ravages, and confusion. A celebrated modern traveller, who was on the spot, tells us, that the inhabitants of Julfa, not many years before the above revolution happened, amounted to 30,000 souls; had 13 churches, and above 100 priests; and paid the Persian court 200 tomans yearly for the free exercise of their religion: that some of the streets were broad and handsome, and planted with trees, with canals and fountains in the middle; others narrow and crooked, and arched a-top; others again, though extremely narrow, as well as turning and winding many ways, were of an incredible length, and resembled so many labyrinths: that, at a small distance from the town, there were public walks adorned with plane-trees on either hand, ways paved with stones, fountains, and cisterns: that there were above 100 caravanferas for the use of merchants and travellers, many of which were built by the kings and prime nobility of Persia: that, as little rain fell there, the streets were frequently full of dust, which rendered the city disagreeable during a considerable part of the summer; that the citizens, however, to make this inconvenience more tolerable, used to water them when the weather was warmer than usual: that there was a castle in the eastern part of the town, which the citizens looked upon as impregnable, in which the public money, and most of the military stores, were said to be kept: that, notwithstanding the baths and caravanferas were almost innumerable, there was not one public hospital: that most of the public buildings were rather neat than magnificent, though the great meydan or market place, the royal palace (which is three quarters of a league in circumference), and the alley denominated *Toker-lag* adjoining to it, made a very grand appearance: that the former contained the royal mosque; the building denominated *kayserieb*, where all sorts of foreign commodities were exposed to sale; and the mint, styled by the Persians *ferraa kkonch*, where the current money of the kingdom was coined: that, besides the native Persians, there were then in Ispahan above 10,000 Indians all supported by trade; 20,000 Georgians, Circassians, and Tartars of Daghestan or Leisgees, with a considerable number of English, Dutch, Portuguese, and a few French; that the Capuchins, discalceated or bare-footed Carmelites, Jesuits Dominicans, and Austin-friars, had likewise their convents

here, though they were unable to make any converts; and that there were above 100 mosques and public colleges. But since the fatal period above mentioned, the suburb of Julfa was almost totally abandoned by the Armenians. The government of Ispahan, 23 leagues long and as many broad, comprehending several districts, most of them formerly well peopled, appeared not many years ago little better than a desert; most of the inhabitants of that fertile and delightful tract being fled and dispersed. Multitudes of them had taken a precarious refuge in the mountains of Loristan, lying between Ispahan and Susser; their lands were left untilled, and their houses mouldered into ruins. In short, all the distresses of an unsuccessful war, or the invasion of a barbarous enemy, could not have plunged the people of Ispahan into greater misery than the victories of their tyrannical king Nadir Shah, who seemed more solicitous to humble his own subjects than his enemies.

ISPIDA, in ornithology. See ALCEDO.

ISRAEL, the name which the angel gave Jacob, after having wrestled with him all night at Mahanaim or Peniel (Gen. xxxii. 1, 2, and 28, 29, 30. and Hosea xii. 3.) It signifies *the conqueror of God, or a prince of God*; or, according to many of the ancients, *a man who sees God*. By the name of Israel is sometimes understood the person of Jacob; sometimes the whole people of Israel, or the whole race of Jacob; and sometimes the kingdom of Israel, or of the ten tribes, distinct from the kingdom of Judah.

ISRAELITES, the descendants of Israel; who were at first called *Hebrews*, by reason of Abraham, who came from the other side of the Euphrates; and afterwards *Israelites*, from Israel the father of the twelve patriarchs; and lastly *Jews*, particularly after their return from the captivity of Babylon, because the tribe of Judah was then much stronger and more numerous than the other tribes, and foreigners had scarce any knowledge of this tribe.

ISSACHAR, one of the divisions of Palestine by tribes; lying to the south of Zabulon, so as by a narrow slip to reach the Jordan, between Zabulon and Manasseh, Josh. xix. But whether it reached to the sea, is a question; some holding that it did: an assertion not easy to be proved, as Joshua makes no mention of the sea in this tribe, nor does Josephus extend it farther than to mount Carmel; and in Josh. xvii. 10. Asher is said to touch Manasseh on the north, which could not be if Issachar extended to the sea.

ISSEL, or YSSEL, a river of the United Provinces, which rises in Westphalia, runs N. by Doesburg, afterward by Zutphen, Deventer, and Campen, and soon falls into the Zuider-Zee, by two mouths.

ISSEL, or YSSEL, THE LITTLE, another river of the United Provinces, which waters Ysselstein, Montfort. and Gouda; and falls into the Maese, a mile and a half above Rotterdam.

ISSEQUIBO, a flourishing settlement of the Dutch in S. America, contiguous to that of Demarary, and about three leagues W. of the town of Surinam. It was taken by the English in 1781, but restored by the treaty of peace in 1783.

ISSOIRE, an ancient town of France, in the department of Puy de Dome and late province of Auvergne. At Vernet, near this town, are found amethysts, of as beautiful a colour as those of the East, but not so hard. Issoire is seated on the river Couze, near the Allier, 13 miles S. of Clermont. E. lon. 3. 15. N. lat. 45. 34.

ISSOUDUN, a handsome town of France, in the department of Indre and late province of Berry, with a castle. Its trade is in wood, cattle, cloth, hats, and stockings. It is seated on the river Theols, partly on a plain, and partly on an eminence, 17 miles S. W. of Bourges, and 155 S. of Paris. S. lon. 2. 6. N. lat. 46. 47.

ISSUE, in common law, has various applications; being

sometimes taken for the children begotten between a man and his wife—sometimes, for profits growing from amercements or fines—sometimes, for profits of lands and tenements—but more frequently for the point or matter depending in suit, whereupon the parties join, and put their cause to the trial of the jury. In all these occasions, issue has but one signification, which is, an effect of a cause preceding; as the children are the effect of the marriage between the parents; the profits growing to the king or lord, from the punishment of any man's offence, are the effect of his transgression; the point referred to the trial of twelve men, is the effect of pleading, or process. See PLEA and Issue.

ISSUES, in surgery, are little ulcers made designedly by the surgeon in various parts of the body, and kept open by the patient, for the preservation and recovery of his health.

ISSUS, now AJAZO, a town of Cilicia in Natolia, with a harbour on the Levant Sea, a little to the north of Scanderoon. E. lon. 36. 25. N. lat. 36. 56. Near this place, in a difficult pass between the mountains and the sea, Alexander the Great fought his second battle with Darius. One great cause of the defeat which the Persians received here was the bad conduct of their monarch, who led his numerous forces into a narrow place, where they had not room to act.

ISTHMA, or ISTHMIAN Games; one of the four solemn games which were celebrated every fifth year in Greece. They had the name from the Isthmus of Corinth, where they were celebrated. In their first institution, according to Pausanias, they consisted only of funeral rites and ceremonies in honour of Melicertes: but Theseus afterwards, as Plutarch informs us, in emulation of Hercules, who had appointed games at Olympia in honour of Jupiter, dedicated those to Neptune, his reputed father, who was regarded as the particular protector of the isthmus and commerce of Corinth. The same trials of skill were exhibited here as at the other three sacred games; and particularly those of music and poetry. These games, in which the victors were only rewarded with garlands of pine-leaves, were celebrated with great magnificence and splendor as long as paganism continued to be the established religion of Greece; nor were they omitted even when Corinth was sacked and burnt by Mummius the Roman general; at which time the care of them was transferred to the Sicyonians, but was restored again to the Corinthians when their city was rebuilt.

ISTHMUS, a narrow neck, or slip of ground, which joins two continents; or joins a peninsula to the terra firma, and separates two seas. See PENINSULA. The most celebrated isthmuses are, that of Panama or Darien, which joins North and South America; that of Suez, which connects Asia and Africa; that of Corinth, or Peloponnesus, in the Morea; that of Crim-Tartary, otherwise called *Taurica Chersonesus*; that of the peninsula Romania, and Eriisso, or the isthmus of the Thracian Chersonesus, twelve furlongs broad, being that which Xerxes undertook to cut through. The ancients had several designs of cutting the isthmus of Corinth, which is a rocky hillock about ten miles over; but they were all in vain, the invention of sluices being not then known. There have been attempts too for cutting the isthmus of Suez, to make a communication between the Red and Mediterranean Sea: but these also failed; and in one of them, a king of Egypt is said to have lost 120,000 men.

ISTRIA, a peninsula of Italy, in the territory of Venice, lying in the north part of the Adriatic sea. It is bounded by Carniola on the north: and on the south, east, and west, by the sea. The air is unwholesome, especially near the coast; but the soil produces plenty of wine, oil, and pastures; there are also quarries of fine marble. One part of it belongs to the Venetians, and the other to the house of Austria. Cabo d'Istria is the capital town.

ITALIAN, the language spoken in Italy. See the article LANGUAGE. This tongue is derived principally from the Latin;

and of all the languages formed from the Latin, there is none which carries with it more visible marks of its origin than the Italian. It is accounted one of the most perfect among the modern tongues. It is complained, indeed, that it has too many diminutives and superlatives, or rather augmentatives; but without any great reason: for, if those words convey nothing farther to the mind than the just ideas of things, they are no more faulty than our pleonasm and hyperboles.

The language corresponds to the genius of the people, who are slow and thoughtful: accordingly, their language runs heavily, though smoothly; and many of their words are lengthened out to a great degree. They have a great taste for music, and, to gratify their passion this way, have altered abundance of their primitive words; leaving out consonants, taking in vowels, softening and lengthening out their terminations, for the sake of the cadence. Hence the language is rendered extremely musical, succeeds better than any other in operas and some parts of poetry: but it fails in strength and nervousness; and a great part of its words, borrowed from the Latin, become so far disguised, that they are not easily known again.

The multitude of sovereign states into which Italy is divided, has given rise to a great number of different dialects in that language; which, however, are all good in the place where they are used. The Tuscan is usually preferred to the other dialects, and the Roman pronunciation to that of the other cities; whence the Italian proverb, *Lingua Toscana in bocca Romana*. The Italian is generally pretty well understood throughout Europe; and is frequently spoken in Germany, Poland, and Hungary. At Constantinople, in Greece, and in the ports of the Levant, the Italian is used as commonly as the language of the country: indeed in those places it is not spoken so pure as in Tuscany, but it is corrupted with many of the proper words and idioms of the place; whence it takes a new name, and is called *Frank Italian*.

ITALIC CHARACTER, in printing. See LETTER.

ITALICA, in ancient geography, a town of Bætica in Spain, built by Scipio Africanus, after finishing the Spanish war, for the reception of the wounded soldiers. At first it was a municipium; afterwards a colony: which was a matter of wonder to the emperor Adrian, the privileges of a municipium being beyond those of a colony (Gellius). Famous for being the birth-place of the emperors Trajan and Adrian, and of the poet Silius Italicus. Now *Sevilla Vieja*, scarce four miles from Seville; a small village of Andalusia on the Guadalquivir.—*Corfinium* in Italy was thus also called.

ITALY, one of the finest countries of Europe, lying between 7° and 19° E. lon. and 38° and 46° of N. lat. On the North, N. W. and N. E. it is bounded by France, Switzerland, the country of the Grisons, and Germany; on the E. by the gulph of Venice; and on the S. and W. by the Mediterranean; its figure bearing some resemblance to that of a boot. Its length, from Aousta, at the foot of the Alps, in Savoy, to the utmost verge of Calabria, in the kingdom of Naples, is about 600 miles; but its breadth is very unequal, in some places near 400 miles, in others not above 25 or 30. It is the most celebrated country in Europe, having been formerly the seat of the Roman empire, and, afterward, of that astonishing universal usurpation, the spiritual dominion of the Pope. Italy is divided into a great number of states, which differ much in extent and importance. Between the confines of France and Switzerland, on the W. and N. are the continental dominions of the king of Sardinia, namely, Piedmont, Savoy, Montferrat, part of the Milanese, and Oneglia. To the N. E. are the territories of Venice, which are enumerated under that article. South of these, are the Italian dominions of the Emperor, namely, part of the Milanese, and the Mantuan. South of these, are Modena, Mirandola and Reggio, belonging to the duke of Modena. West of these, are the duchies of Parma, Placentia,

and Guastalla, whose sovereign is of the house of Bourbon. South of Parma lies the republic of Genoa, and S. E. of this that of Lucca. Hence extends, along the coast of the Mediterranean, the grand duchy of Tuscany, whose sovereign is brother to the present emperor of Germany. The Ecclesiastical State, or territory of the Pope, lies principally to the E. and S. E. of Tuscany, between the gulph of Venice and the Mediterranean; and the remainder of Italy, which occupies the whole southern extremity, is the kingdom of Naples, with its dependent islands, of which Sicily is the principal. The air of Italy is very different, according to the different situations of the countries it contains. In those on the N. side of the Apennines, it is more temperate; but on the S. it is very warm. The air of the Campagna of Rome, and of the Ferrarese, is said to be unwholesome; which is owing to the lands not being duly cultivated, nor the marshes drained. That of the other parts is generally pure, dry, and healthy. In summer the heat is very great in the kingdom of Naples, and would be almost intolerable, if it were not mitigated by the sea-breezes. The principal rivers are the Po, Tiber, Arno, Adige, and Var; and there are several fine lakes, as the Maggiore, Lugano, Como, Garda, Perugia, Bracciano, and Celano. As there are a number of rivers in Italy, besides those mentioned above, the soil, in general, is very fertile. It produces a great variety of wines, and the best oil in Europe; excellent silk in abundance; corn of all sorts, but not in such plenty as in other countries; oranges, lemons, citrons, pomegranates, almonds, raisins, sugar, innumerable mulberry trees, figs, peaches, nectarines, apricots, pears, apples, filberds, chestnuts, &c. Most of these fruits were first imported by the Romans from Asia Minor, Greece, Africa, and Syria, and were not the natural products of the soil. The tender plants are sheltered, in winter, on the N. side of the Apennines; but on the S. side they have no need of that precaution. This country also yields good pasture, and abounds with cattle, sheep, goats, buffaloes, wild boars, mules and horses. The forests are well stored with game; and the mountains have not only mines of iron, lead, alum, sulphur, marble of all sorts, alabaster, jasper, porphyry, &c. but also gold and silver; with a great variety of aromatic herbs, trees, shrubs, and evergreens, as thyme, lavender, laurel, wild olive trees, tamarinds, junipers, oaks, and pines. Wine, oil, perfumes, fruits, and silks, are the principal articles of exportation; and great sums of money are expended by travellers in the purchase of pictures, curiosities, relics, antiquities, &c. The Italians are generally well-proportioned; but of their complexion they cannot boast. With respect to dress, they follow the fashions of the countries on which they border, or to which they are subject; namely, those of France, Spain, and Germany. As to their genius and taste in architecture, painting, carving, and music, they are thought to excel greatly the other nations of Europe; but their music, perhaps, is too soft and effeminate to merit all the praises bestowed upon it; and their houses, in respect to convenience, are far inferior to those of England. No country has produced better politicians, historians, poets, painters, and sculptors; that is, since the revival of the arts and sciences, exclusive of those of ancient times. The Italians are very affable, courteous, ingenious, sober, and ready-witted; but extremely jealous, vindictive, lascivious, ceremonious, and superstitious. In respect to jealousy, indeed, we are told, that a very extraordinary change has taken place, and that the Italians are now not less indulgent and complaisant to their wives, than the most polite husbands even in France. In their temper they seem to be a good medium between the French and Spaniards; neither so gay and volatile as the one, nor so grave and solemn as the other. Boiled snails, served up with oil and pepper, or fried in oil and the hinder parts of frogs, they reckon dainty dishes. Kites, jackdaws, hawks, and magpies, are also eaten, not only by the common people, but by the better sort.

Wine, cooled by ice or snow, is drunk here both in summer and winter. The women affect yellow hair, as did formerly the Roman ladies and courtezans: they also use paints and washes, both for their hands and face. The established religion of the country is the Roman Catholic. Their language is a corruption of the Latin, and is said to be spoken in its greatest purity at Florence. It is, indeed, denominated *La Lingua Toscana*.

ITCH, a cutaneous disease, appearing in small watery pustules on the skin; commonly of a mild nature, though sometimes attended with blotches and ulceration of the skin. The slightest application of sulphur mixed with a little cream, is sufficient for the cure; provided the patient wear the shirt he first dresses in for a week or more. A new crop of eruptions very commonly takes place, but a repetition of the sulphur is not necessary on that account; for the whole business is accomplished by a single application of the sulphur ointment. Mercury, applied either in the form of ointment or lotion, cures the itch; as does also the powder of white hellebore root, and some other stimulating remedies, mixed with any unctuous substance.

ITCH-Infest. See **ACARUS**. In speaking of the manner of finding these insects in the itch, Fabricius observes, that the failure of many who have sought for them has been owing to their having expected to meet with them in the larger vesicles that contain a yellowish fluid like pus; in these, however, he tells us, he has never found them, but in those pustules only which are recent, and contain only a watery fluid. We must, therefore, he observes, not expect to find them in the same proportionate number in patients who for many months have been afflicted with the disease, as in those in whom its appearance is recent, and where it is confined to the fingers and wrists. The cause of this difference with respect to the pustules, he conjectures, may be owing to the death of the insect after it has deposited its eggs.

A small transparent vesicle being found, a very minute white point, distinct from the surrounding fluid, may be discovered, and very often even without the assistance of a glass; this is the insect, which may be easily taken out on the point of a needle or a penknife, and when placed on a green cloth may be seen much more distinctly, and observed to move.

The author remarks, that even before such a transparent vesicle is formed, we may often discover traces of the insect on the fingers or hands, in a reddish streak or furrow, which is occasioned by the acarus; and he adds, that it is even more usual to find it in these furrows than in the pustules themselves. He tells us, that a friend of his at Hanover (who had the itch in a slight degree, and to whose accurate enquiries with an excellent microscope he acknowledges himself much indebted) found several insects in such furrows. Two of the longest of the furrows were about an inch in extent. They seemed to be thoroughly dry, but exhibited here and there very minute shining and transparent spots. These spots, however, were not at all elevated above the surface of the skin; and although several of them were opened and examined, no insect was found in them. These furrows he has observed only on the hands and fingers, having in vain sought for them on the legs and other parts of the body, in his children, who had the itch in a high degree.

ITEA, in botany; a genus of the monogynia order, belonging to the pentandria class of plants; and in the natural method ranking with those of which the order is doubtful. The petals are long, and inserted into the calyx; the capsule unilocular and bivalved. There is but one species, a native of North America. It grows by the sides of rivers, and in other parts where the ground is moist. It rises to the height of eight or ten feet, sending out many branches garnished with spear-shaped leaves, placed alternately and slightly sawed on their edges, of a light green colour. At the extremity of the branches are produced fine spikes of white flowers three or four

inches long, standing erect. When these shrubs are in vigour, they will be entirely covered with flowers, so that they make a beautiful appearance during the flowering season, which is July. They are propagated by layers, and are not injured by the cold of this climate; but are apt to die in summer, if they are planted on a dry gravelly soil. The shoots should be laid down in autumn, and will be rooted in one year.

ITHACA, in ancient geography, an island in the Ionian sea, on the coast of Epirus; the country of Ulysses, near Dulichium, with a town and port situated at the foot of mount Neius. According to Pliny it is about 25 miles in compass; according to Artemidorus only 10; and is now found to be only eight miles round. It is now uninhabited, and called *Jabaco*.

ITINERARY, **ITINERARIUM**; a journal or an account of the distances of places. The most remarkable is that which goes under the names of *Antoninus* and *Æthicus*; or, as Barthius found in his copy, *Antoninus Æthicus*; a Christian writer, posterior to the times of Constantine. Another called *Hierosolymitanum*, from Bourdeaux to Jerusalem, and from Heraclea through Aulona and Rome to Milan, under Constantine. *Itinerarium* denotes a day's march.

ITIUS, **PORTUS**, in ancient geography, the *crux geographorum*, such being the difficulty of ascertaining its position. It would be endless to recite the several opinions concerning it, with the several reasons advanced in support of them. Three ports are mentioned by Cæsar; two without any particular name, *viz.* the Higher and the Lower, with respect to the *Portus Itius*. Calais, Boulogne, St. Omer, and Whitland, have each in their turn had their several advocates. Cæsar gives two distinctive characters or marks which seem to agree equally to Boulogne and Whitland, namely, the shortness of the passage, and the situation between two other ports; therefore nothing can with certainty be determined about the situation of the *Portus Itius*.

ITTIGIUS (**THOMAS**), a learned professor of divinity at Leipzig, and son of John Ittigius, professor of physic in the same university. He first published a Treatise upon Burning Mountains; after which he became a minister, and exercised that function in various churches there. He furnished several papers in the Leipzig Acts, besides publishing some historical works and dissertations. He died in 1710.

ITYS, in fabulous history, a son of Tereus king of Thrace, by Procne daughter of Pandion king of Athens. He was killed by his mother when he was about six years old, and served up before his father. He was changed into a pheasant, his mother into a swallow, and his father into an owl.

ITZECUINTEPOTZOTLI, or **HUNCH BACKED DOG**, a Mexican quadruped similar to a dog, (See pl. 22.) as large as a Maltesian dog, the skin of which is varied with white, tawny, and black. Its head is small in proportion to its body, and appears to be joined directly to it on account of the shortness and greatness of its neck; its eyes are pleasing, its ears loose, its nose has a considerable prominence in the middle, and its tail is so small that it hardly reaches half way down its leg; but the characteristic of it is a great hunch which it bears from its neck to its rump. The place where this quadruped most abounds is the kingdom of Michuacan, where it is called *Ahora*.

ITZEHOA, an ancient and handsome town of Germany, in the circle of Lower Saxony, and duchy of Holstein. It belongs to the king of Denmark, and is seated on the river Stoer, in E. lon. 9. 25. N. lat. 54. 8.

IVA, in botany; a genus of the pentandria order, belonging to the monœcia class of plants; and in the natural method ranking under the 49th order, *Compositæ*. The male calyx is common and triphyllous; the florets of the disc monopetalous and quinquefid; the receptacle divided by small hairs. There is no female calyx nor corolla; but five florets in the radius; two long styles; and one naked and obtuse seed.

British Statute Miles 69 to a Degree
to 20 to 60 to 100 to 120

IVAHAH is the name of one of the canoes or boats used by the islanders of the South Sea for short excursions to sea: it is wall-sided and flat-bottomed. These boats are of different sizes, their length being from 72 feet to 10: but their breadth is by no means in proportion; for those of ten feet are about a foot wide, and those of more than 70 are scarcely two. The fighting-ivahah is the longest, with its head and stern considerably raised above the body in a semicircular form: the stern is sometimes 17 or 18 feet high. When they go to sea, they are fastened together side by side, at the distance of about three feet, by strong poles of wood laid across and lashed to the gun-wales. On these, in the fore-part, a stage or platform is raised, about 10 or 12 feet long, somewhat wider than the boats, and supported by pillars about six feet high: on this stage are ranged the fighting men, whose missile weapons are slings and spears; and below the stage the rowers sit. The fishing ivahahs are from 40 feet long to 10; those of 25 feet and upwards occasionally carry sail. The travelling ivahah is always double, and furnished with a small neat house about five or six feet broad, and six or seven feet long.

JUAN DE LA FRONTERA, (St.) a town of S. America, in Chili, in the province of Chiquito, near the lake Guanacho. The territory of this town is inhabited by 20,000 native Americans, who are tributary to Spain. It contains mines of gold, and a kind of almonds that are very delicate. It is seated at the foot of the Andes, 98 miles N. E. of St. Jago. W. lon. 68. 55. S. lat. 33. 25.

JUAN DE PUERTO RICO, (St.) an island of the West Indies, 57 miles E. of Hispaniola. By the English it is called *Porto Rico*, but improperly, as the Spanish word for a port is *Puerto*. It is 100 miles in length, and 50 in breadth. It belongs to the Spaniards, and is full of very high mountains, and extremely fertile valleys, interspersed with woods, and well watered by springs and rivulets. It produces sugar, rum, ginger, corn, and fruits, partly proper to the climate, and partly introduced from Spain. Besides, there are so many cattle, that they often kill them for the sake of the skins alone. Here are a great number of uncommon trees, and there is a little gold in the N. part of the island. It is commonly said, that the air is healthy, and yet, in the reign of queen Elizabeth, the earl of Cumberland, when he had taken this island, lost most of his men by sickness, and, on that account, was forced to abandon it. It is subject to storms and hurricanes, like the rest of these islands. The capital is of the same name. W. lon. 67. 4. N. lat. 18. 17.

JUAN DE PUERTO RICO, (St.) the capital of the island of the same name, with a good harbour, defended by several forts, and a bishop's see. It is seated on the north coast of the island, 200 miles from St. Domingo. W. lon. 69. 1. N. lat. 18. 29.

JUAN Fernandez, an island in the great South Sea, in S. lat. 33. 40. and W. lon. 78. 30. from London. It was formerly a place of resort for the buccaneers who annoyed the western coast of the Spanish continent. They were led to resort hither from the multitude of goats which it nourished; to deprive their enemies of which advantage, the Spaniards transported a considerable number of dogs, which, increasing greatly, have almost extirpated the goats, who now only find security among the steep mountains in the northern parts, which are inaccessible to their pursuers. There are instances of two men living, at different times, alone on this island for many years; the one a Musquito Indian; the other Alexander Selkirk, a Scotchman, who was, after five years, taken on board an English ship, which touched here in about 1710, and brought back to Europe. From the history of this recluse, Daniel de Foe is said to have conceived the idea of writing the *Adventures of Robinson Crusoe*. This island was very propitious to the remains of Commodore Anson's squadron in 1741, after having been buffeted with tempests, and debilitated by an inveterate

rate scurvy, during a three months passage round Cape Horn: they continued here three months; during which time the dying crews, who on their arrival could scarcely with one united effort heave the anchor, were restored to perfect health. Captain Carteret, in the *Swallow*, in 1767, having met with many difficulties and impediments in his passage into the South Sea, by the Straits of Magellan, attempted to make this island in order to recruit the health of his men; but he found it fortified by the Spaniards, and therefore chose rather to proceed to the island of Masafuero. But M. de Bougainville that same year is said to have touched here for refreshments, although in the narrative of the voyage the fact is cautiously suppressed. This island is not quite 15 miles long, and about six broad; its only safe harbour is on the north side. It is said to have plenty of excellent water, and to abound with a great variety of excellent vegetables highly antiscorbutic; besides which, Commodore Anson sowed a variety of garden-seeds, and planted the stones of plums, apricots and peaches, which he was many years afterwards informed had thriven greatly; and now doubtless furnish a very valuable addition to the natural productions of this spot. Vast shoals of fish of various kinds frequent this coast, particularly cod of a prodigious size; and it is said in not less abundance than on the banks of Newfoundland. There are but few birds here, and those few are of species well known and common.

JUAN DE ULHUA, (St.) an island of N. America, lying in the gulf of Mexico, near Vera Cruz, in New Spain. It was discovered in 1518, by Grijelva. W. lon. 97. 25. N. lat. 19. 12.

JUAN Blanco. See **PLATINA**.

JUBA, a king of Numidia and Mauritania. He had succeeded his father Hiempsal, and he favoured the cause of Pompey against Julius Cæsar. He defeated Curio, whom Cæsar had sent to Africa, and after the battle of Pharsalia he joined his forces to those of Scipio. He was conquered in a battle at Thapsus, and totally abandoned by his subjects. He killed himself with Petreius, who had shared his good fortune and his adversity, in the year of Rome 707. His kingdom became a Roman province, of which Sallust was the first governor.

JUBA II. son of the former, was led among the captives to Rome to adorn the triumph of Cæsar. His captivity was the source of the greatest honours; and his application to study procured him more glory than he would have obtained from the inheritance of a kingdom. He gained the hearts of the Romans by the courteousness of his manners; and Augustus rewarded his fidelity by giving him in marriage Cleopatra the daughter of Anthony, and conferring upon him the title of *king*, and making him master of all the territories which his father once possessed, in the year of Rome 723. His popularity was so great, that the Mauritians rewarded his benevolence by making him one of their gods. The Athenians raised him a statue, and the Æthiopians worshipped him as a deity. Juba wrote an history of Rome in Greek, which is often quoted and commended by the ancients. Of it only few fragments remain. He also wrote on the history of Arabia, and the antiquities of Assyria, chiefly collected from Berofus. Besides these he composed some treatises upon the drama, Roman antiquities, the nature of animals, painting, grammar, &c. now lost.

JUBILEE, among the Jews, denotes every fiftieth year; being that following the revolution of seven weeks of years; at which time all the slaves were made free, and all lands reverted to their ancient owners. The jubilees were not regarded after the Babylonish captivity.—The word, according to some authors, comes from the Hebrew, *jobel*, which signifies *fifty*: but this must be a mistake, for the Hebrew *jobel* does not signify fifty; neither do its letters, taken as cyphers, or according to their numerical power, make that number; being 10, 6, 2,

and 30, that is 48.—Others say, that *jobel* signifies a *ram*, and that the jubilee was thus called, because proclaimed with a ram's horn, in memory of the ram that appeared to Abraham in the thicket. Masius chooses to derive the word from *jubal*, the first inventor of musical instruments, which, for that reason, were called by his name; whence the words *jobel* and *jubilee* came to signify the year of deliverance and remission, because proclaimed with the sound of one of those instruments, which at first was no more than the horn of a ram. Others derive *jobel* from *יָבֵל*, *al*, in hiphil *הִבֵּיל*, *hobil*, which signifies to recall or return; because this year restored all slaves to their liberty, &c. The institution of this festival is in Lev. xxv. 8. 17.

The learned are divided about the year of jubilee; some maintaining that it was every forty-ninth, and others that it was every fiftieth year. The ground of the former opinion is chiefly this, that, the forty-ninth year being of course a sabbatical year, if the jubilee had been kept on the fiftieth, the land must have had two sabbaths, or have lain fallow two years, which, without a miracle, would have produced a dearth. On the other hand, it is alleged, that the Scripture expressly declares for the fiftieth year, Lev. xxv. 10, 11. And besides, if the jubilee and sabbatical year had been the same, there would have been no need of a prohibition to sow, reap, &c. because this kind of labour was prohibited by the law of the sabbatical year, Lev. xxv. 4, 5. The authors of the Universal History, book i. chap. 7. note R, endeavour to reconcile these opinions, by observing, that as the jubilee began in the first month of the civil year, which was the seventh of the ecclesiastical, it might be said to be either the forty-ninth or the fiftieth, according as one or other of these computations was followed. The political design of the law of the jubilee was to prevent the too great oppressions of the poor, as well as their being liable to perpetual slavery. By this means a kind of equality was preserved through all the families of Israel, and the distinction of tribes was also preserved, that they might be able, when there was occasion, on the jubilee year, to prove their right to the inheritance of their ancestors. It served also, like the Olympiads of the Greeks, and the Lustra of the Romans, for the readier computation of time. The jubilee has also been supposed to be typical of the gospel state and dispensation, described by Isaiah lxi. ver. 1, 2. in reference to this period, as the "acceptable year of the Lord."

JUBILEE, in a more modern sense, denotes a grand church solemnity or ceremony, celebrated at Rome, wherein the pope grants a plenary indulgence to all sinners; at least to as many as visit the churches of St. Peter and St. Paul at Rome.

The jubilee was first established by Boniface VII. in 1300, in favour of those who should go *ad limina apostolorum*; and it was only to return every hundred years. But the first celebration brought in such store of wealth to Rome, that the Germans called this the *golden year*; which occasioned Clement VI. in 1343, to reduce the period of the jubilee to fifty years. Urban VI. in 1389, appointed it to be held every thirty-five years, that being the age of our Saviour; and Paul II. and Sixtus IV. in 1475, brought it down to every twenty-five, that every person might have the benefit of it once in his life. Boniface IX. granted the privilege of holding jubilees to several princes and monasteries: for instance, to the monks of Canterbury, who had a jubilee every fifty years; when people flocked from all parts to visit the tomb of Thomas a Becket. Jubilees are now become more frequent, and the pope grants them as often as the church or himself have occasion for them. There is usually one at the inauguration of a new pope. To be entitled to the privileges of the jubilee, the bull enjoins fastings, alms, and prayers. It gives the priests a full power to absolve in all cases, even those otherwise reserved to the pope;

to make commutations of vows, &c. in which it differs from a *plenary indulgence*. During the time of jubilee, all other indulgences are suspended.

One of our kings, viz. Edward III. caused his birth-day to be observed in manner of a jubilee, when he became fifty years of age, in 1362, but never before or after. This he did by releasing prisoners, pardoning all offences except treason, making good laws, and granting many privileges to the people.

There are particular jubilees in certain cities, when several of their feasts fall on the same day: at Puy en Velay, for instance, when the feast of the Annunciation happens on Good-Friday; and at Lyons, when the feast of St. John Baptist concurs with the feast of Corpus Christi. In 1640, the Jesuits celebrated a solemn jubilee at Rome, that being the centenary or hundredth year from their institution; and the same ceremony was observed in all their houses throughout the world.

JUCATAN, or **YUCATAN**, a large province of North-America in New Spain, which is a peninsula. It is over against the island of Cuba, and contains a large quantity of timber proper for building ships; as also sugar, cassia, and Indian corn. The original inhabitants are few, they having been very ill used by the Spaniards. Merida is the capital town. It is a flat level country, and is very unhealthy; which may be owing to the frequent inundations.

JUDAH, the fourth son of Jacob, and father of the chief of the tribes of the Jews distinguished by his name, and honoured by giving birth to the Messiah, died 1636 B. C.

JUDAH Hakkadosh, or the Saint, a rabbi celebrated for his learning and riches, lived in the time of the Emperor Antoninus, and was the friend and preceptor of that prince. Leo of Modena, a rabbi of Venice, tells us, that rabbi Judah, who was very rich, collected about 26 years after the destruction of the temple, in a book which he called the *Misnia*, the constitutions and traditions of the Jewish magistrates who preceded him. But as this book was short and obscure, two Babylonish rabbis, Rabbina and Ase, collected all the interpretations, disputes, and additions, that had been made until their time upon the *Misnia*, and formed the book called the *Babylonish Talmud*, or *Gemara*; which is preferable to the Jerusalem Talmud, composed some years before by rabbi Jochanan of Jerusalem. The *Misnia* is the text of the Talmud; of which we have a good edition in Hebrew and Latin by Surenhusius, with notes, in 3 vols. folio. It were to be wished the same had been done to the *Gemara*.

The Kingdom of **JUDAH** was of small extent compared with that of the kingdom of Israel; consisting only of two tribes, Benjamin and Judah: its east boundary, the Jordan; the Mediterranean its west, in common with the Danites, if we except some places recovered by the Philistines, and others taken by the kings of Israel; on the south, its limits seem to have been contracted under Hadad of the royal progeny of Edom. 1 Kings xi. 14.

Tribe of JUDAH, one of the 12 divisions of Palestine by tribes (Josh. xv.), having Idumea on the south, from the extremity of the Lacus Asphaltites, also the Wilderness of Zin, Cadibarnea, and the brook or river of Egypt; on the east, the said lake; on the west, the Mediterranean; and on the north, the mouth of the said lake; where it receives the Jordan, Bethfemes, Thimna, quite to Ekron on the sea.

JUDAISM, the religious doctrines and rites of the Jews. See **JEW**.

JUDAS MACCABEUS, a celebrated general of the Jews, renowned for his many victories over his enemies, at last slain in battle 261 B. C. His exploits are recorded by Josephus in his *History of the Jews*.

JUDAS-Tree. See **CERCIS**.

JUDIE (St.), brother of St. James the younger, and son of Joseph (Mat. xiii. 55). He preached in Mesopotamia, Ara-

bia, Syria, Idumea; and died in Berytus for the confession of Christ. He wrote that epistle which goes under his name, and after the death of most of the apostles. He was cruelly put to death for reproving the superstition of the Magi.

JUDE, or *the General Epistle of Jude*, a canonical book of the New Testament, written against the heretics, who, by their disorderly lives and impious doctrines, corrupted the faith and good morals of the Christians. St. Jude draws them in lively colours, as men given up to their passions, full of vanity, conducting themselves by worldly wisdom, and not by the spirit of God.

JUDEA, in ancient geography, taken largely, either denotes all Palestine, or the greater part of it; and thus it is generally taken in the Roman history: Ptolemy, Rutilinus, Jerome, Origen, and Eusebius, take it for the whole of Palestine. Here we consider it as the third part of it on this side the Jordan, and that the southern part is distinct from Samaria and Galilee; under which notion it is often taken, not only in Josephus, but also in the New Testament. It contained four tribes: Judah, Benjamin, Dan, and Simeon, together with Philistia and Idumea; so as to be comprised between Samaria on the north, Arabia Petræa on the south, and to be bounded by the Mediterranean on the west, and by the Lacus Asphaltites, with part of the Jordan, on the east. Josephus divides it into 11 toparchies; Pliny into 10; by which it has a greater extent than that just mentioned. See **PALESTINE**.

JUDENBURG, a handsome and considerable town of Germany, in the circle of Austria, capital of Upper Stiria, with a handsome castle. The public buildings, with the square, are magnificent. It is seated on the river Muehr, 45 miles W. by N. of Gratz, and 100 S. W. of Vienna. E. lon. 14. 26. N. lat. 47. 10.

JUDEX (**MATTHEW**), one of the principal writers of the Centuries of Magdeburg, was born at Tippetwolde, in Misnia, in 1528. He taught theology with great reputation; but met with many disquiets in the exercise of his ministry from party-feuds. He wrote several works, and died in 1604.

JUDGE, a chief magistrate of the law, appointed to hear causes, to explain the laws, and to pass sentence. It is of the utmost consequence to the liberty of the subject that Judges should be independent, as is the case in England. In some countries in which this wholesome regulation has not been adopted, as in Hungary, and various other countries governed by absolute princes, the course of justice is exceedingly corrupted, and the decisions of the Judges influenced by the most shameless bribery.

JUDGES, in Jewish antiquity, certain supreme magistrates who governed the Israelites from the time of Joshua till the reign of Saul. These Judges resembled the Athenian archons or Roman dictators. The dignity of Judge was for life, but not always in uninterrupted succession. God himself, by some express declaration of his will, regularly appointed the judges: but the Israelites did not always wait for his appointment, but sometimes chose themselves a judge in times of danger. The power of the judges extended to affairs of peace and war. They were protectors of the laws, defenders of religion, avengers of all crimes; but they could make no laws, nor impose any new burthens upon the people. They lived without pomp or retinue, unless their own fortunes enabled them to do it; for the revenues of their office consisted in voluntary presents from the people. They continued from the death of Joshua till the beginning of the reign of Saul, being a space of about 339 years.

JUDGES, for ordinary affairs, civil and religious, were appointed by Moses in every city to terminate differences: in affairs of greater consequence, the differences were referred to the priests of Aaron's family, and the judge of the people or

prince at that time established. Moses likewise set up two courts in all the cities, one consisting of priests and Levites, to determine points concerning the law and religion; the other consisting of heads of families, to decide in civil matters.

Book of JUDGES, a canonical book of the Old Testament, so called from its relating the state of the Israelites under the administration of many illustrious persons who were called *judges*, from being both the civil and military governors of the people, and who were raised up by God upon special occasions, after the death of Joshua, till the time of their making a king. In the time of this peculiar polity, there were several remarkable occurrences, which are recorded in this book. It acquaints us with the gross impiety of a new generation which sprung up after the death of Joshua; and gives us a short view of the dispensations of heaven towards this people, sometimes relieving and delivering them, and at others severely chastising them by the hands of their enemies.

Select JUDGES, *Judices selecti*, in antiquity, were persons summoned by the prætor to give their verdict in criminal matters in the Roman courts, as juries do in ours. No person could be regularly admitted into this number till he was 25 years of age. The *Sortitio Judicum*, or impanelling the jury, was the office of the *Judex Questionis*, and was performed after both parties were come into court; for each had a right to reject or challenge whom they pleased, others being substituted in their room. The number of the *Judices selecti* varied, according to the nature of the charge. When the proper number appeared, they were sworn, took their places in the *subsellia*, and heard the trial.

JUDGMENT, among logicians, a faculty, or rather act of the human soul, whereby it compares its ideas, and perceives their agreement or disagreement. See **METAPHYSICS**, and **LOGIC**.

JUDGMENT, in law, is the sentence pronounced by the court upon the matter contained in the record. Judgments are of four sorts. First, where the facts are confessed by the parties, and the law determined by the court; as in case of judgment upon *demurrer*: secondly, where the law is admitted by the parties, and the facts disputed; as in the case of judgment on *verdict*: thirdly, where both the fact and the law arising thereon are admitted by the defendant; which is the case of judgments by *confession* or *default*: or, lastly, where the plaintiff is convinced that either fact, or law, or both, are insufficient to support his action, and therefore abandons or withdraws his prosecution; which is the case in judgments upon a *non suit* or *retrahit*.

The judgment, though pronounced or awarded by the judges, is not their determination or sentence, but the determination and sentence of the *law*. It is the conclusion that naturally and regularly follows from the premises of law and fact, which stands thus: Against him who hath rode over my corn, I may recover damages by law; but A hath rode over my corn; therefore I shall recover damages against A. If the major proposition be denied, this is a demurrer in law: if the minor, it is then an issue of fact: but if both be confessed or determined to be right, the conclusion or judgment of the court cannot but follow; which judgment or conclusion depends not therefore on the arbitrary caprice of the judge, but on the settled and invariable principles of justice. The judgment, in short, is the remedy prescribed by law for the redress of injuries; and the suit or action is the vehicle or means of administering it. What that remedy may be, it is indeed the result of deliberation and study to point out; and therefore the *style* of the judgment is not that it is decreed or resolved by the court, for then the judgment might appear to be their own; but, "it is considered," *consideratum est per curiam*, that the plaintiff do recover his damages, his debt, his possession, and the like: which implies that the judgment is none of their own; but the

act of law, pronounced and declared by the court, after due deliberation and inquiry. See *Blackst. Comment.* iii. 356.

JUDGMENT, in criminal cases, is the next stage of prosecution, after TRIAL and CONVICTION are past, in such crimes and misdemeanours as are either too high or too low to be included within the benefit of clergy. For when, upon a capital charge, the JURY have brought in their VERDICT guilty, in the presence of the prisoner; he is either immediately, or at a convenient time soon after, asked by the court, if he has any thing to offer why judgment should not be awarded against him. And in case the defendant be found guilty of a misdemeanour (the trial of which may, and does usually, happen in his absence, after he has once appeared), a *capias* is awarded and issued, to bring him in to receive his judgment; and if he absconds, he may be prosecuted even to outlawry. But whenever he appears in person, upon either a capital or inferior conviction, he may at this period, as well as at his arraignment, offer any exceptions to the indictment, in *arrest* or stay of judgment: as for want of sufficient certainty in setting forth either the person, the time, the place, or the offence. And if the objections be valid, the whole proceedings shall be set aside; but the party may be indicted again. Judge Blackstone observes, 1. That none of the statutes of *jeofails*, for amendment of errors, extend to indictments or proceedings in criminal cases; and therefore a defective indictment is not aided by a verdict, as defective pleadings in civil cases are. 2. That, in favour of life, great strictness has at all times been observed, in every point of an indictment. Sir Matthew Hale indeed complains, "that this strictness is grown to be a blemish and inconvenience in the law, and the administration thereof: for that more offenders escape by the over easy ear given to exceptions in indictments, than by their own innocence; and many times gross murders, burglaries, robberies, and other heinous and crying offences, remain unpunished by these unseemly niceties: to the reproach of the law, to the shame of the government, to the encouragement of villainy, and to the dishonour of God." And yet, notwithstanding this laudable zeal, no man was more tender of life than this truly excellent judge.

A pardon also may be pleaded in arrest of judgment: and it has the same advantage when pleaded here as when pleaded upon ARRAIGNMENT; viz. the saving the ATTAINDER, and, of course, the CORRUPTION of blood: which nothing can restore but parliament; when a pardon is not pleaded till after sentence. And certainly, upon all accounts, when a man hath obtained a pardon, he is in the right to plead it as soon as possible. See PARDON.

Praying the benefit of clergy may also be ranked among the motions in arrest of judgment. See *Benefit of Clergy*.

If all these resources fail, the court must pronounce that judgment which the law hath annexed to the crime. Of these some are capital, which extend to the life of the offender, and consist generally in being hanged by the neck till dead; though in very atrocious crimes other circumstances of terror, pain, or disgrace, are superadded: as, in treasons of all kinds, being drawn or dragged to the place of execution; in high treason affecting the king's person or government, embowelling alive, beheading, and quartering; and in murder, a public dissection. And in case of any treason committed by a female, the judgment's, to be burned alive. But the humanity of the English nation has authorised, by a tacit consent, an almost general mitigation of such parts of these judgments as favour of torture or cruelty: a sledge or hurdle being usually allowed to such traitors as are condemned to be drawn; and there being very few instances (and those accidental or by negligence) of any persons being embowelled or burned, till previously deprived of sensation by strangling. Some punishments consist in exile or banishment, by abjuration of the realm, or transportation to

New South Wales: others, in loss of liberty, by perpetual or temporary imprisonment. Some extend to confiscation, by forfeiture of lands, or moveables, or both, or of the profits of lands for life: others induce a disability of holding offices or employments, of being heirs, executors, and the like. Some, though rarely, occasion a mutilation or dismembering, by cutting off the hand or ears: others fix a lasting stigma on the offender, by slitting the nostrils or branding in the hand or face. Some are merely pecuniary, by stated or discretionary fines: and, lastly, there are others that consist principally in their ignominy, though most of them are mixed with some degree of corporeal pain; and these are inflicted chiefly for such crimes as either arise from indigence, or render even opulence disgraceful: such as whipping, hard labour in the house of correction, the pillory, the stocks, and the ducking-stool.

Disgusting as this catalogue may seem, it will afford pleasure to a British reader, and do honour to the British laws, to compare it with that shocking apparatus of death and torment to be met with in the criminal codes of almost every other nation in Europe. And it is moreover one of the glories of our law, that the nature, though not always the quantity or degree, of punishment is ascertained for every offence; and that it is not left in the breast of any judge, nor even of a jury, to alter that judgment which the law has beforehand ordained for every subject alike, without respect of persons. For, if judgments were to be the private opinions of the judge men would then be slaves to their magistrates; and would live in society without knowing exactly the conditions and obligations which it lays them under. And, besides, as this prevents oppression on the one hand; so, on the other, it fills all hopes of impunity or mitigation, with which an offender might flatter himself if his punishment depended on the humour or discretion of the court. Whereas, where an established penalty is annexed to crimes, the criminal may read their certain consequence in that law, which ought to be the unvaried rule, as it is the inflexible judge, of his actions.

JUDGMENT of God. See *JUDICIUM Dei*.

JUDICATURE, the quality or profession of those who administer justice. This term is also used to signify the extent of the jurisdiction of the judge, and the court wherein he sits to render justice.

JUDICIA CENTUMVIRALIA, in Roman antiquity, were trials before the *Centumviri*, to whom the *prætor* committed the decision of certain matters of inferior nature, like our justices of peace at the quarter sessions. During the *judicia centumviralia*, a spear was stuck up in the forum to signify that the court was sitting.

JUDICIUM CALUMNIE was an action brought against the plaintiff for false accusation. The punishment, upon conviction, was *inustio frontis*, or branding in the forehead. See *INUSTIO*.

JUDICIUM Dei, *Judgment of God*, was a term anciently applied to all extraordinary trials of secret crimes; as those by arms, and single combat, and the ordeals, or those by fire, or red-hot plough-shares; by plunging the arm in boiling water, or the whole body in cold water; in hopes God would work a miracle, rather than suffer truth and innocence to perish. *Si super defendere non possit, judicio Dei, scilicet aqua vel ferro, fiet de eo justitia.*—These customs were a long time kept up even among Christians; and they are still in use in some nations. See *BATTEL*, *ORDEAL*, &c.—Trials of this sort were usually held in churches in presence of the bishops, priests, and secular judges; after three days' fasting, confession, communion, and many adjurations and ceremonies described at large by Du Cange.

JUDICIUM Parium denotes a trial by a man's equals, i. e. of peers by peers, and of commoners by commoners. In *magis*

charta it is more than once insisted on as the principal bulwark of our liberties, but especially by chap. 29. that no freeman shall be hurt in either his person or property, *nisi per legale iudicium parium suorum vel per legem terræ*. And this was ever esteemed in all countries a privilege of the highest and most beneficial nature.

JUDICIUM Falsi was an action which lay against the judges for corruption or unjust proceedings.

JUDICIUM Prævaricationis was an action brought against the prosecutor, after the criminal was acquitted, for suppressing the evidence of or extenuating his guilt, rather than urging it home, and bringing it to light.

JUDOIGNE, a town of Austrian Brabant, near which the duke of Marlborough gained that signal victory, in 1706, called the battle of Ramillies. It is seated on the river Gete, 13 miles S. E. of Louvain, and 16 N. of Namur. E. lon. 5. 2. N. lat. 50. 45.

IVEACH, the name of two baronies of Ireland, in the county of Down, and province of Ulster. They are distinguished into Upper and Lower Iveach, and the former is by much the largest barony in that county. The name of *Iveach*, or *Hy Iveach*, is said to be taken from *Achaisius*, in Irish called *Eachach*, grandfather to king *Coalbpaig*, as much as to say "the territory of Eachach;" for *hy*, in the Irish language, is a common adjective, denoting not only the heads and founders of families, but also the territories possessed by them. Iveach (including both baronies) was otherwise called the *Magenifes country*, and in queen Elizabeth's time was governed by Sir Hugh Magennis, esteemed to have been one of the most polite of all the natives in those parts. Through part of this barony runs a chain of mountains considerably high, known by the name of *Iveach mountains*.

IUERNUS, in ancient geography, a town in the south-west of Ireland. Now *Dunkeram*, (Camden); called *Donckyne* by the natives, situated on the river Maire, in the province of Munster.

IUERNUS, or *Iernus*; Ptolemy; a river in the south-west of Ireland. Now called the *Maire* or *Kenmare*, running from east to west, in the province of Munster.

IVES, or **YVES** (St.), a celebrated bishop of Chartres, born in the territory of Beauvais in the 11th century. His merit procured his election to the see of Chartres in 1092, or 1093, under the pontificate of Urban II. who had deposed Geoffroy his predecessor for sundry accusations against him. Ives particularly signalized himself by his zeal against Philip I. who had put away his wife Bertha of Holland, and had taken Bertrade of Montford, wife of Fouques count of Anjou. Afterward he devoted himself wholly to the functions of his ministry; made several religious foundations; and died in 1115. Pope Pius V. permitted the monks of the congregation of Lateran to celebrate the festival of St. Ives on the 20th of May. We have a collection of decrees of his compiling. *Excerptiones ecclesiasticarum regularum*, a *Chronicon*, and 22 sermons; all very valuable pieces, which were collected and published in one volume folio in 1647, by John Baptiste Souciet, canon of Chartres.

IVES (St.), a sea-port town of Cornwall, in England, seated on a bay of the same name; which, being unsafe, is chiefly frequented by fishermen for the taking of pilchards. By this trade, however, and that of Cornish slates, it has thriven greatly, and 20 or 30 sail of ships belong to its harbour. It is a corporation, governed by a mayor, 12 capital and 24 inferior burgesses, with a recorder, town clerk, &c. and it sends two members to parliament. Here is a handsome spacious church, which is often buffeted by the waves of the sea; but the mother church is at Unilalant. There is a grammar

school here, which was founded by Charles I. It has two markets in the week, and an annual fair.

IVES (St.), is also the name of a town in Huntingdonshire, 64 miles from London. It has a fine stone bridge over the Ouse, had in the ninth century a mint, and was noted for its medicinal waters. Great part of it was burnt down some years ago, but it was rebuilt. Here is a very good market on Monday for fatted cattle brought from the north; and there are two fairs in the year. Here Oliver Cromwell rented a farm before he was chosen burgess for Cambridge.

JUGERUM, in Roman antiquity, a square of 120 Roman feet; its proportion to the English acre being as 10,000 to 16,097.

JUGLANS, in botany; a genus of the monœcia order, belonging to the polyandria class of plants; and in the natural method ranking under the 50th order, *Amentaceæ*. The male calyx is monophyllous, and squamiform; the corolla divided into six parts; there are 18 filaments: the female calyx is quadrifid, superior; the corolla quadripartite; there are two styles, and the fruit a plum with a furrowed kernel. There are five species, the most remarkable of which is the regia or common walnut. This rises 50 feet high or more, with a large upright trunk, branching into a very large spreading head, with large pinnated leaves, of two or three pair of oval, smooth, somewhat ferrated lobes, terminated by an odd one; and monœcious flowers, succeeded by clusters of large green fruit, inclosing furrowed nuts of different shapes and sizes in the varieties, ripening in September and October. Other two species, called the *nigra* and *alba*, or black and white Virginian walnut, are also cultivated in this country, though they are less proper for fruit, having very small kernels.

All the sorts are propagated by planting their nuts, which will grow in any common soil. The nuts being procured in the proper season, in their outer covers or husks if possible, they should be preserved in dry sand until February, and then planted. After two years growth in the seed bed, they are to be taken out, and planted in the nursery, where they must remain till grown five or six feet high, when they must be transplanted where they are finally to remain; but if intended for timber as well as fruit-trees, they ought to be finally transplanted when they have attained the height of three or four feet.

The fruit is used at two different stages of growth; when green to pickle, and when ripe to eat raw. As a pickle, the nuts may be used when about half or three fourths grown, before the outer coat or shell becomes hard; such nuts should be chosen as are most free from specks, and for this purpose they must be gathered by hand. Walnuts are ready for pickling in July and August. They are full ripe in September and October; and are then commonly beat down with long poles, especially on large trees; for, as the walnuts grow mostly at the extremities of the branches, it would be troublesome and tedious to gather them by hand. As soon as gathered, lay them in heaps a few days to heat and sweat, to cause their outer husks, which adhere closely, to separate from the shell of the nuts; then clean them from the rubbish, and deposit them in some dry room for use, covering them over close with dry straw half a foot thick, and they will keep three or four months. They are always readily sold at market, especially in London; where, at their first coming in, they are sold with the husks on, by the sack or bushel; but afterwards are brought clean, and sold both by measure and by the thousand. The wood of the walnut-tree is also very valuable; not indeed where strength is necessary, it being of a very brittle nature; but the cabinet-makers and joiners esteem it highly for several sorts of household furniture and other light works; for, being beautifully veined, it takes a fine polish, and the more knotty it is, the more it is valued for par-

ticular purposes. Walnut-trees are also well adapted for planting round the borders of orchards, where, by their large spreading heads, they will also guard the lesser fruit-trees from boisterous winds. The kernels of the nuts are similar in quality to almonds; but are not like them used in medicine.

The *Juglans alba* mentioned above, which is the North American hickory or walnut-tree, and also several other varieties, yield from their barks, rinds, and nuts, a yellow colour when boiled in water with alum. The tincture power of these is of the same nature as that of the *quercitron* bark, and may be adapted to the use of callico printers, dyers, paper stainers, &c. The hickory bark, however, supplies about one fourth less of colour than the quercitron, and is less suitable for mixing directly with the different mordants, and printing or pencilling on linens or cottons.

JUGON, a town of France, in the department of the North Coast, and late province of Brittany, seated on the little river Arqueon, 12 miles from the English Channel.

JUGORA, a considerable province of Muscovy, depending on the government of Archangel. It has the title of a duchy; and is inhabited by a kind of Tartars, who are very savage, and much of the same disposition with the Samoiedes.

JUGULAR, among anatomists, is applied to certain blood-vessels on each side of the neck. See ANATOMY.

JUGULARES, in the Linnæan system, is the name of an order or division of fish, the general character of which is, that they have ventral fins before the pectoral fins. See ZOOLOGY.

JUGUM, an humiliating mode of punishment inflicted by the victorious Romans upon their vanquished enemies. It was thus. They set up two spears, and laying a third across, in the form of a gallows, they ordered those who had surrendered themselves to pass under this ignominious erection, without arms or belts. None suffered the disgrace of passing *sub jugo* but such as had been obliged to surrender.

JUGURTHA, the illegitimate son of Mastabal the brother of Micipsa. Micipsa and Mastabal were the sons of Masinissa, king of Numidia. Micipsa, who had inherited his father's kingdom, educated his nephew with his two sons Adherbal and Hiempsal; but as he saw that the former was of an aspiring disposition, he sent him with a body of troops to the assistance of Scipio, who was besieging Numantia, hoping to lose a youth whose ambition seemed to threaten the tranquillity of his children. His hopes were frustrated; Jugurtha showed himself brave and active, and he endeared himself to the Roman general. Micipsa appointed him successor to his kingdom with his two sons; but the kindness of the father proved fatal to the children. Jugurtha destroyed Hiempsal, and stripped Adherbal of his possessions, and obliged him to fly to Rome for safety. The Romans listened to the well-grounded complaints of Adherbal; but Jugurtha's gold prevailed among the senators, and the suppliant monarch, forsaken in his distress, perished by the snare of his enemy. Cæcilius Metellus was at last sent against Jugurtha; and his firmness and success soon reduced the crafty Numidian, obliging him to fly among his savage neighbours for support. Marius and Sylla succeeded Metellus, and fought with equal success. Jugurtha was at last betrayed by his father-in-law Bocchus, from whom he claimed assistance; and he was delivered into the hands of Sylla 106 years before the Christian era. He was exposed to the view of the Roman people, and dragged in chains to adorn the triumph of Marius. He was afterwards put in a prison, where he died six days after of hunger.

IVICA, the capital of an island of the same name, in the Medite ranean, with a good harbour. E. lon. 1. 25. N. lat. 38. 25.

IVICA, an island of the Mediterranean, 56 miles S. W. of

Majorca. It is about 60 miles in circumference. It is mountainous, but fertile in corn, wine, and fruits; and it is remarkable for the great quantity of salt made here.

JUICE denotes the sap of vegetables, or the liquors of animals. See ANATOMY, BLOOD, PLANTS, SAP, &c. The juices of several plants are expressed to obtain their essential salts, and for several medicinal purposes, with intention either to be used without further preparation, or to be made into syrups and extracts. The general method of extracting these juices is, by pounding the plant in a marble mortar, and then by putting it into a press. Thus is obtained a muddy and green liquor, which generally requires to be clarified, as we shall soon observe. The juices of all plants are not extracted with equal ease. Some plants, even when fresh, contain so little juice, that water must be added while they are pounded, otherwise scarcely any juice would be obtained by expression. Other plants, which contain a considerable quantity of juice, furnish by expression but a small quantity of it, because they contain also much mucilage, which renders the juice so viscid that it cannot flow. Water must also be added to these plants to obtain their juice. The juices thus obtained from vegetables by a mechanical method, are not, properly speaking, one of their principles, but rather a collection of all the proximate principles of plants which are soluble in water; such as the saponaceous extractive matter, the mucilage, the odoriferous principle, all the saline and saccharine substances; all which are dissolved in the water of the vegetation of the plants. Besides these matters, the juice contains some part of the resinous substance, and of the green colouring matter, which in almost all vegetables is of a resinous nature. These two latter substances, not being soluble in water, are only interposed between the parts of the other principles which are dissolved in the juice, and consequently disturb its transparency. They nevertheless adhere together in a certain degree, and so strongly in most juices, that they cannot be separated by filtration alone. When therefore these juices are to be clarified, some previous preparations must be used by which the filtration may be facilitated. Juices which are acid, and not very mucilaginous, are spontaneously clarified by rest and gentle heat. The juices of most antiscorbutic plants abounding in saline volatile principles, may be disposed to filtration merely by immersion in boiling water; and as they may be contained in close bottles, while they are thus heated in a water bath, their saline volatile part, in which their medicinal qualities chiefly consist, may thus be preserved. Fermentation is also an effectual method of clarifying juices which are susceptible of it; for all liquors which have fermented, clarify spontaneously after fermentation. But this method is not used to clarify all juices, because many of them are susceptible of only an imperfect fermentation, and because the qualities of most of them are injured by that process. The method of clarification most generally used, and indispensably necessary for those juices which contain much mucilage, is boiling with the white of an egg. This matter, which has the property of coagulating in boiling water, and of uniting with mucilage, does accordingly, when added to the juice of plants, unite with and coagulate their mucilage, and separates it from the juice in form of scum, together with the greatest part of the resinous and earthy matters which disturb its transparency. And as any of these resinous matters which may remain in the liquor after this boiling with the whites of eggs, are no longer retained by the mucilage, they may easily be separated by filtration. See FILTRATION.

The juices, especially before they are clarified, contain almost all the same principles as the plant itself; because in the operation by which they are extracted, no decomposition happens; but every thing remains, as to its nature, in the same state as in the plant. The principles contained in the juice are

only separated from the grosser oily, earthy, and resinous parts which compose the solid matter that remains under the press. These juices, when well prepared, have therefore the same medicinal qualities as the plants from which they are obtained. They must evidently differ from each other as to the nature and proportions of the principles with which they are impregnated, as much as the plants from which they are extracted differ from each other in those respects.

Most vegetable juices coagulate when they are exposed to the air, whether they are drawn out of the plant by wounds, or naturally run out; though what is called *naturally running out* is generally the effect of a wound in the plant, from a sort of canker, or some other internal cause. Different parts of the same plant yield different juices. The same veins in their course through the different parts of the plant yield juices of a different appearance. Thus, the juice in the root of the cow-parsnep is of a briar stone colour; but in the stalk it is white.

Among these juices of vegetables which are clammy and readily coagulate, there are some which readily break with a whey. The great wild lettuce, with the smell of opium, yields the greatest plenty of milky juice of any known British plant. When the stalk is wounded with a knife, the juice flows readily out like a thick cream, and is white and rosy; but if these wounds are made at the top of the stalks, the juice that flows out of them is dashed with a purple tinge, as if cream had been sprinkled over it with a few drops of red wine. Some little time after letting this out, it becomes much more purple, and thickens; and finally, the thicker part of it separates, and the thin whey swims at top. The whey or thin part of this separated matter is easily pressed out from the curd by squeezing between the fingers, and the curd will then remain white; and on washing with water, it becomes like rags. The purple whey (for in this is contained all the colour) soon dries into a purple cake, and may be crumbled between the fingers into a powder of the same colour. The white curd being dried and kept for some time, becomes hard and brittle. It breaks with a shining surface like resin, and is inflammable; taking fire at a candle, and burning all away with a strong flame. The same thick part being held over a gentle heat, will draw out into tough long threads, melting like wax. The purple cake made from the whey is quite different from this; and when held to a candle scarce flames at all, but burns to a black coal. The whole virtue of the plant seems also to consist in this thin part of its juice: for the coagulum or curd, though looking like wax or resin, has no taste at all; whereas the purple cake made from the serum is extremely bitter, and of a taste somewhat resembling that of opium.

Of the same kind with the wild lettuce are the throatwort, spurge, and many other plants. These are all replete with a milky juice, which separates into curds and whey like that already described. But this, though a common law of nature, is not universal; for there are many plants which yield the like milky juices without any separation ensuing upon their extravasation. The white juice of the fenchus never separates, but dries into a uniform cake; the common red wild poppy bleeds freely with a milky juice; and the heads or capsules of seed bleed not less freely than the rest of the plant, even after the flower is fallen. This juice, on being received into a shell or other small vessel, soon changes its white to a deep yellow colour, and dries into a cake which seems resinous and oily, but no whey separates from it. The tragopogon, or goat's beard, when wounded, bleeds freely a milky juice; it is at first white, but becomes immediately yellow, and then more and more red, till at length it is wholly of a dusky red. It never separates, but dries together into one cake; and is oily and resinous, but of an insipid taste. The great bindweed also bleeds freely a white juice; the flowers, as well as the stalks and leaves,

affording this liquor. It is of a sharp taste; and as many of the purging plants are of this class, it would be worth trying whether this milk is not purgative.

These juices, as well as the generality of others which bleed from plants, are white like milk; but there are some of other colours. The juice of the greatcelandine is of a fine yellow colour; it flows from the plant of the thickness of cream, and soon dries into a hard cake, without any whey separating from it. Another yellow juice is yielded by the seed-vessels of the yellow centaury in the month of July, when the seeds are full-grown. This is very clammy; it soon hardens altogether into a cake, without any whey separating from it. It sticks to the fingers like birdlime, is of the colour of pale amber, and will never become harder than soft wax if dried in the shade; but if laid in the sun, it immediately becomes hard like resin.—These cakes burn like wax, and emit a very pleasant smell. The great angelica also yields a yellowish juice on being wounded; and this will not harden at all, but if kept several years will still be soft and clammy, drawing out into threads like half-melted resin.

Another kind of juices very different from all these, are those of a gummy nature. Some of these remain liquid a long time, and are not to be dried without the assistance of heat; the others very quickly harden of themselves, and are not inflammable. The gum of the juice of rhubarb-leaves soon hardens; and is afterwards soluble in common water, and sparkles when put into the flame of a candle. The clusters of the common honeysuckle are full of a liquid gum. This they frequently throw out, and it falls upon the leaves, where it retains its own form. The red hairs of the ros solis are all terminated by large bladders of a thin watery fluid. This is also a liquid gum; it sticks to the fingers, draws out into long threads, and stands the force of the sun all day. In the centre of each of these dew-drops there is a small red bladder, which stands immediately on the summit of the red hair, and contains a purple juice which may be squeezed out of it. The pinguicula, or butter-wort, has also a gummy matter on its leaves in much greater quantity than the ros solis.

Some plants yield juices which are manifestly of an oily nature. These, when rubbed, are not at all of a clammy nature, but make the fingers glib and slippery, and do not at all harden on being exposed to the air. If the stalk of elecampane be wounded, there flows out an oily juice swimming upon a watery one. The stalks of the hemlock also afford a similar oily liquor swimming upon the other; and in like manner the white mullein, the berries of ivy, the bay, juniper, dog-berry tree, and the fruit of the olive, when wounded, show their oil floating on the watery juice. Some of these oily juices, however, harden into a kind of resin. Our ivy yields such a juice very abundantly; and the juice of the small purple-berried juniper is of the same kind, being hard and fat, and not very gummy. If the bark of the common ivy is wounded in March, there will ooze out a tough and greasy matter of a yellowish colour, which, taken up between the fingers, feels not at all gummy or sticking, but melts in handling into a sort of oil, which in process of time hardens and crusts upon the wounds, and looks like brown sugar. It burns with a lasting flame, and smells very strong. The tops of the wild lettuce, and the leaves growing near the tops, if examined with a magnifying glass, show a great number of small bladders or drops of an oily juice of a brownish colour, hardening into a kind of resin; they are easily wiped off when of any size, and are truly an oily juice a little hardened. It is probable also, that the fine blue flour or powder, called the *lapis*, upon the surface of our common plums, is no other than such an oily juice exuding from their pores in small particles, and hardening into a sort of resin.

JUJUBES, in the materia medica, the name of a fruit of

the pulpy kind, produced on a tree which Linnæus makes a species of rhamnus. See RHAMNUS. The jujubes have been made a general ingredient in pectoral decoctions; but they are now seldom used on these occasions, and are scarce at all heard of in prescription, or to be met with in our shops.

JUL, or JOL, a Gothic word signifying a "sumptuous treat;" and particularly applied to a religious festival, first among the heathens and afterwards among Christians. By the latter it was given to CHRISTMAS; which is still known under the name of *Jul*, or *Yool*, in Denmark, Norway, Iceland, and Sweden; nay, even in the north of Britain; and whence the month of Januarius by the Saxons was styled *Giuli*, i. e. "the Festival." As this feast had originally been dedicated by our heathen ancestors to the Sun, their supreme deity; so the Christians, for the purpose of engaging the minds of their Ethnic (gentile) brethren, ordered it should be celebrated in memory of the birth of Christ: and thus it has been through ages a feast of joy and entertainment. We are indebted to Procopius for the first account of this feast.

JULEP, in pharmacy, a medicine composed of some proper liquor and a syrup or sugar, of extemporaneous preparation without decoction. See PHARMACY.

JULIAN, the famous Roman emperor, styled *the Apostate*, because he professed the Christian religion before he ascended the throne, but afterwards openly embraced Paganism, and endeavoured to abolish Christianity. He made no use of violence, however, for this purpose; for he knew that violent measures had always rendered it more flourishing: he therefore behaved with a politic mildness to the Christians; recalled all who had been banished on account of religion under the reign of Constantius; and undertook to pervert them by his caresses, and by temporal advantages, and mortifications covered over by artful pretences: but he forbade Christians to plead before courts of justice, or to enjoy any public employments. He even prohibited their teaching polite literature; well knowing the great advantages they drew from profane authors in their attacks upon paganism and irreligion. Though he on all occasions showed an outward contempt for the Christians, whom he always called *Galileans*, yet he was sensible of the advantage they obtained by their virtue and the purity of their manners; and therefore incessantly proposed their example to the pagan Priests. At last, however, when he found that all other methods failed, he gave public employments to the most cruel enemies of the Christians, when the cities in most of the provinces were filled with tumults and seditions, and many of them were put to death. Though it has been pleaded by Julian's apologists that the behaviour of the Christians furnished sufficient pretence for most of his proceedings against them, and the animosities among themselves furnished him with the means: that they were continually prone to sedition, and made a merit of insulting the public worship; and, finally, that they made no scruple of declaring, that want of numbers alone prevented them from engaging in an open rebellion. Historians mention, that Julian attempted to prove the falsehood of our Lord's prediction with respect to the temple of Jerusalem; and resolved to have that edifice rebuilt by the Jews, about 300 years after its destruction by Titus: but all their endeavours served only the more perfectly to verify what had been foretold by Jesus Christ; for the Jews, who had assembled from all parts to Jerusalem, digging the foundations, flames of fire burst forth and consumed the workmen. However, the Jews, who were obstinately bent on accomplishing that work, made several attempts; but it is said, that all who endeavoured to lay the foundation perished by these flames, which at last obliged them entirely to abandon the work. Julian being mortally wounded in a battle with the Persians, it is said, that he then caught in his hand some of the blood which flowed from his wound; and throwing it towards heaven,

cried, "Thou, Galilean, hast conquered." But notwithstanding this popular report, Theodoret relates, that Julian discovered a different disposition; and employed his last moments in conversing with Maximus the philosopher, on the dignity of the soul. He died on the following night, aged 32. A particular account of his reign and exploits is recorded in the different *Histories of Constantinople*.

No prince was ever more oppositely represented by different authors; on which account it is difficult to form a true judgment of his real character. It must, however, be acknowledged, that he was learned, liberal, temperate, brave, vigilant, and a lover of justice: but, on the other hand, he had apostatized to paganism; was an enemy to the Christian religion; and was, in fact, a persecutor, though not of the most sanguinary class. We have several of his discourses or orations; some of his letters; a treatise entitled *Misopogon*, which is a satire on the inhabitants of Antioch; and some other pieces, all written in an elegant style. They were published in Greek and Latin by father Petau in 1630 in quarto; and of which Spanheimius gave a fine edition in folio in 1696. His most famous work was that composed against the Christians, of which there are some fragments in Cyril's refutation of it.

JULIAN Period, in chronology, a period so called, as being adapted to the Julian year. See CHRONOLOGY. It is made to commence before the creation of the world. Its principal advantage lies here, that the same years of the cycles of the sun, moon, and indiction, of which three cycles it was made to consist by Joseph Scaliger in 1580, belonging to any year of this period, will never fall together again till after the expiration of 7980 years. There is taken for the first year of this period that which hath the first of the cycle of the sun, the first of the cycle of the moon, and the first of the indiction cycle, and so reckoning on.

The first year of the Christian era is always, in our systems of chronology, the 4714th of the Julian period.—To find what year of the Julian period any given year of Christ answers to: To the given year of Christ add 4713, because so many years of the Julian period were expired A. D. 1; and the sum gives the year of the Julian period sought. On the contrary, having the year of the Julian period given, to find what year of Christ answers thereto: From the year of the Julian period given subtract 4713, and the remainder will be the year sought.

JULIAN (St.), a harbour on the south of Patagonia, in South America, where ships usually touch that are bound to the south seas. S. lat. 48. 15.

JULIEN DU SAULT (St.), a town of France, in the department of Yonne, and late province of Burgundy, seated between two mountains covered with vines, near the river Yonne, five miles from Joigny.

JULIEN (St.), a town of France, in the department of Upper Vienne, and late province of Limosin, 13 miles W. of Limoges.

JULIERS, a duchy in the circle of Westphalia, in Germany, seated between the rivers Mæse and Rhine, and bounded by Prussian Guelderland on the north, by the electorate of Trier on the south, by the electorate of Cologne on the east, and by the Netherlands on the west. It is about 60 miles long, and 30 broad; and is a very plentiful country, abounding in cattle, corn, and fine meadows, and is well supplied with wood; but it is most remarkable for a fine breed of horses, and woad for dyeing, which is gathered here in abundance. The chief towns are Juliers, Aix-la-Chapelle, Duren, Munster-Eifel, Bedbur, Wesinburg, and Lasteren. It is subject to the Elector Palatine, with the consent of the king of Prussia and heretofore of Poland.

JULIERS, a city, capital of the duchy of Juliers in Westphalia. Some think this city was founded by Julius Cæsar or Julia

Agrippina; but this is much questioned by others, because it is not mentioned before Antoninus's Itinerary and Theodosius's Tables. The town is small, but well fortified, and neatly built; the houses are of brick, and the streets broad and regular. The citadel is large and very strong, containing a palace of the ancient dukes, and a spacious piazza. In the suburbs there is a monastery of Carthusians, nobly endowed by several dukes of Juliers. The town is but poorly inhabited, though they have a fine woollen manufactory in this country, and likewise another of linen. It was taken by prince Maurice of Nassau in 1610, and by the Spaniards in 1622. It is seated on the river Roer, in E. lon. 6. 35. N. lat. 50. 55.

JULIO ROMANO. See ROMANO.

JULIUS CÆSAR. See CÆSAR.

JULIUS II. (Julian de la Rovere), pope, remarkable for his warlike disposition, and his political negotiations: by the latter, he engaged the principal powers of Europe to league with him against the republic of Venice, called *the league of Cambray*, ratified in 1508. The Venetians having purchased peace by the cession of part of Romania, Julius turned his arms against Louis XII. king of France, and appeared in person armed cap-a-pee, at the siege of Mirandola; which place he took by assault in 1511. But proceeding to excommunicate Louis, the king wisely turned his own weapons against him, by calling a general council at Pisa: at which the pope refusing to appear, he was declared to be suspended from the holy see; and Louis, in his turn, excommunicated the pope, who died soon after in 1512. He built the famous church of St. Peter at Rome, and was a patron of the polite arts.

JULIUS VICUS, in ancient geography, a town of the Nemetes in Gallia Belgica: situated between the Tres Tabernæ and Noviomagus. Now *Germerheim*, a town of the Lower Palatinate, on the west side of the Rhine. E. lon. 8. 15. N. lat. 49. 12.

JULIUS POLLUX. See POLLUX.

JULPHA, OLD, once the capital of Armenia, in Asia, now in ruins, the inhabitants having been transplanted to a suburb of Ispahan, called New Julpha, where they have several churches. They were brought thither for the sake of trade.

IULUS, a son of Ascanius, born in Lavinium. In the succession to the kingdom of Alba, Æneas Sylvius, the son of Æneas and Lavinia, was preferred to him. He was, however, made chief priest.

IULUS, in zoology; a genus of insects of the order aptera. See pl. 25. The feet are very numerous, being on each side twice as many as the segments of the body; the antennæ are moniliform; there are two articulated palpi; and the body is of a semicylindrical form. 1. The terrestris is a small species, having on each side 100 very short closely-set feet. The body is cylindrically round, consisting of 50 segments, each of which gives rise to two pair of feet; by which means the feet stand two and two by the side of each other, so that between every two there is a little more space. Its colour is blackish, and the animal is very smooth. It is met with under stones, and in the earth. 2. The sabulosus is of an ashen-colour, smooth, and sometimes has two longitudinal bands of a dun-colour upon the back. The body is composed of about sixty segments, which appear double; one part of the segment being quite smooth, the other charged with longitudinal striæ very closely set together, which causes the cylindric body of the insect to appear intersected alternately with smooth and striated segments. Each segment gives rise to two pair of feet, which makes 240, or 120 feet on each side. These feet are slender, short, and white. The antennæ are very short, and consist of five rings. The insect, when touched, rolls itself up into a spiral; so that its feet are inwards, but yet turned towards the ground. It is found together with the preceding one, to which it bears a resemblance, though it is much larger. There are other species.

VOL. IV.

JULY, the seventh month of the year; during which the sun enters the sign Leo. The word is derived from the Latin *Julius*, the surname of C. Cæsar the dictator, who was born in it. Mark Antony first gave this month the name *July*, which before was called *Quintilius*, as being the fifth month of the year in the old Roman calendar established by Romulus, which began in the month of March. For the same reason, August was called *Sextilis*; and September, October, November, and December, still retain the name of their first rank. "*Quæ sequitur, numero turba notata suo.*" OVID. Fast. On the 19th day of this month the dog-days are commonly supposed to begin; when, according to Hippocrates and Pliny, the sea boils, wine turns sour, dogs go mad, the bile is increased and irritated, and all animals decline and languish.

JULY-Flowers. See DIANTHUS.

JUMIEGE, a town of France, in the department of Lower Seine and late province of Normandy, with a late celebrated Benedictine abbey. It is seated on the river Seine, 12 miles S. W. of Rouen, and 77 N. W. of Paris. E. lon. 0. 55. N. lat. 49. 24.

JUMNA, a large river of Hindoostan Proper, which rises to the N. W. of Delhi, waters that capital, as well as the city of Agra, and joins the Ganges about 100 miles below Benares.

JUNCI LAPIDEI, in natural history, the name given by authors to a species of fossile coral, of the tubular kind, and composed of a congeries of small tubules, which are usually round, and striated within. See Plate 31. Vol. III.

JUNCTURE, any joint or closing of two bodies. See JOINT. In oratory, *junction* denotes a part of composition, particularly recommended by Quintilian, and denotes such an attention to the nature of the vowels, consonants, and syllables, in the connection of words, with regard to their sound, as will render the pronunciation most easy and pleasant, and best promote the harmony of the sentence. Thus the coalition of two vowels, occasioning an hollow and obscure sound, and likewise of some consonants, rendering it harsh and rough, should be avoided: nor should the same syllable be repeated at the beginning and end of words, because the sound becomes thereby harsh and unpleasant. The following verse in Virgil's *Æneid* is an example of junction. "*Arma virumque cano, Trojæ qui primus ab oris.*"

JUNCUS, the RUSH, in botany; a genus of the monogynia order, belonging to the hexandria class of plants; and in the natural method ranking under the 5th order, *Tripetaloidææ*. The calyx is hexaphyllous; there is no corolla; the capsule is unilocular. There are many species, which are universally known, being very troublesome weeds, and difficult to be eradicated. The pith of two kinds, called the *conglomeratus* and *effusus*, or round-headed and soft rushes, is used for wicks to lamps and rush-lights. The *conglomeratus*, and *aculus* or marine rush, are planted with great care on the banks of the sea in Holland in order to prevent the water from washing away the earth; which would otherwise be removed every tide, if it were not for the roots of those rushes, which fasten very deep in the ground, and mat themselves near the surface in such a manner as to hold the earth closely together. Therefore, whenever the inhabitants perceive that the roots of these rushes are destroyed, they are very assiduous in repairing them. In the summer-time when the rushes are fully grown, they are cut and tied up in bundles, which are dried, and afterwards carried into the larger towns and cities, where they are wrought into baskets, and several other useful things, which are frequently sent into England. These sorts do not grow so strong in this country as on the Maese, where they sometimes arrive at the height of four feet and upwards.

A species of rush termed *juncus odoratus*, "sweet rush, or

camel's hay," is sometimes brought to us from Turkey and Arabia, tied up in bundles about a foot long. The stalk, in shape and colour, somewhat resembles a barley-straw; it is full of fungous pith like that of our common rushes: the leaves are like those of wheat, and surround the stalk with several coats, as in the reed. The flowers are of a carnation colour, striped with a lighter purple. The whole plant, when in perfection, has a hot, bitterish, not unpleasent, aromatic taste, and a very fragrant smell: by long keeping it loses greatly its aromatic flavour. Distilled with water, it yields a considerable quantity of an essential oil. It was formerly often used in medicine as an aromatic, and in obstructions of the viscera, &c. but is very little employed at present.

JUNE, the sixth month of the year, during which the sun enters the sign of Cancer. The word comes from the Latin *Junius*, which some derive à *Junno*. Ovid, in the 6th of his *Fasts*, makes the goddess say, "*Junius à nostro nomine nomen habet.*" Others rather derive it à *junioribus*, this being for young people, as the month of May was for old ones. "*Junius est juvenum; qui fuit ante senum.*" In this month is the summer solstice.

JUNGERMANNIA, in botany; a genus of the natural order of algæ, belonging to the cryptogamia class of plants. The male flower is pedunculated, and naked; the anthera quadrivalved: the female flower is sessile, naked, with roundish seeds. There are 29 species, all natives of Britain, growing in woods, shady places, by the sides of ditches, &c. Many of them are beautiful objects for the microscope.

JUNGIA, in botany; a genus of the polygamia segregata order, belonging to the syngenesia class of plants: the common receptacle is chaffy; the perianthium three-flowered; the florets tubular, two-lipped; the exterior lip ligulate; the interior one bipartite.

JUNIPERUS, the **JUNIPER-TREE**; a genus of the monadelphia order, belonging to the monœcia class of plants; and in the natural method ranking under the 51st order, *Conifera*. The male amentum is a calyx of scales; there is no corolla; three stamina: the female calyx tripartite; there are three petals; and as many styles; the berry is trispermous, and equal, by means of three tubercles of the indurated calyx adhering to it.

The *Species* are, 1. The *communis*, or common juniper, grows naturally in many parts of Britain upon dry barren commons, where it seldom rises above the height of a low shrub. Mr. Evelyn assures us, that "the juniper, though naturally of the growth of England, is very little known in many parts of the country: for it grows naturally only in dry, chalky, or sandy land; and, where the soil is opposite to this, the plant is rarely found. Those who have been used to see it in its wild state, on sandy barren commons, &c. will have little inducement to plant it; as there they will see it procumbent, seldom shewing a tendency to aspire: but when planted in a good soil, it will rise to the height of 15 or 16 feet, and produce numerous branches from the bottom to the top, forming a well-looking bushy plant. These branches are exceeding tough, and covered with a smooth bark of a reddish colour, having a tinge of purple. The leaves are narrow and sharp-pointed, growing by threes on the branches; their upper surface has a greyish streak down the middle; but their under surface is of a fine green colour, and they garnish the shrub in great plenty. The flowers are small, and of a yellowish colour. They are succeeded by the berries, which are of a blueish colour when ripe." Of this species there is a variety called *Swedish juniper*, which grows 10 or 12 feet high, very branchy the whole length, with the branches growing more erect, and leaves, flowers, and fruit, like the former. But Mr. Miller affirms the Swedish juniper to be a distinct species. A prostrate and very

dwarfish variety is mentioned by Mr. Lightfoot, under the name of *dwarf Alpine juniper*. It is frequently found in the mountains in the Highlands of Scotland, and has broader and thicker leaves than the former: the berries are also larger, or more oval than spherical. 2. The *oxycedrus*, or Spanish juniper, rises from 10 to 15 feet high, closely branched from bottom to top; having short, awl-shaped spreading leaves by threes, and small diœcious flowers, succeeded by large reddish-brown berries. 3. The *thurifera*, or blue-berried Spanish juniper, grows 20 feet high or more, branching in a conic form, with acute imbricated leaves growing by fours, and small diœcious flowers, succeeded by large blue flowers. 4. The *Virginiana*, or Virginia cedar, grows 30 or 40 feet high, branching from bottom to top in a conic manner, small leaves by threes adhering at their base; the younger ones imbricated, and the old ones spreading; with diœcious flowers, succeeded by small blue berries. 5. The *Lycia*, Lycian cedar, or olibanum tree, grows 20 feet high, branching erect; garnished with small obtuse oval leaves, every where imbricated; having diœcious flowers, succeeded by large oval brown berries. It is a native of Spain and Italy. 6. The *Phœnicia*, or Phœnician cedar, grows about 20 feet high, branching pyramidally; adorned with ternate and imbricated obtuse leaves; and diœcious flowers succeeded by small yellowish berries. It is a native of Portugal. 7. The *Bermudiana*, or Bermudian cedar, grows 20 or 30 feet high, has small acute leaves by threes below, the upper ones awl-shaped, acute, and decurrent, by pairs or fours, spreading outward, and diœcious flowers succeeded by purplish berries. It is a native of Bermudas. 8. The *Sabina*, or favin tree; of which there are the following varieties, viz. spreading, upright, and variegated favin. The first grows three or four feet high, with horizontal and very spreading branches; with short, pointed, decurrent, erect, opposite leaves; and diœcious flowers, succeeded by blueish berries, but very rarely producing either flowers or fruit. The second grows eight or ten feet high, with upright branches, dark-green leaves like the former, and diœcious flowers, succeeded by plenty of berries. The third has the ends of many of the shoots and young branches variegated with white, and the leaves finely striped; so that it makes a beautiful appearance. There are two other species; the *Barbadensis*, with leaves all imbricated four ways, the younger ones ovate, the elder acute; and the *Chinensis*, with leaves decurrent imbricate-expanding crowded, the stem-leaves threefold, the branch-leaves fourfold.

The propagation of all the junipers is by seed, and of the favins by layers and cuttings; but these last may also be raised from the berries, if they can be procured. They may all be sowed in beds of common light earth; except the cedar of Bermudas, which must be sowed in pots, to have shelter in winter. When the hardy kinds have had two or three years growth in the seed-bed, they may be planted out in autumn or in spring, in nursery rows two feet asunder, there to remain till of due size for final transplantation into the shrubbery. The Bermudas cedar must be sheltered under a frame for the first year or two; when they must be separated into small pots, to be sheltered also in winter for three or four years, till they have acquired some size and strength; then turned out into pots in the full ground, where they are to remain in a warm situation; though a shelter of mats for the first winter or two during hard frosts will be of great service. The season for transplanting all the sorts is either in autumn, October, or November, or in March, and early in April.

Juniper-berries have a strong not disagreeable smell; and a warm, pungent, sweet taste; which, if they are long chewed, or previously well bruised, is followed by a bitterish one. The pungency seems to reside in the bark; the sweet in the juice; the aromatic flavour in oily vesicles spread through the sub-

stance of the pulp, and distinguishable even by the eye; and the bitter in the seeds. The fresh berries yield, on expression, a rich, sweet, honey-like aromatic juice; if previously pounded so as to break the seeds, the juice proves tart and bitter. From these berries a spirituous water and essential oil are prepared; and they are also ingredients in various medicines. The liquor remaining after the distillation of the oil, passed through a strainer, and gently exhaled to the consistence of a rob, was once reckoned a medicine of great utility, and in many cases preferable to the oil or the berry itself. Hoffman is expressly of this opinion, and recommends the rob of juniper in debility of the stomach and intestines; and says it is particularly serviceable to old people who are subject to these disorders, or labour under a difficulty with regard to the urinary secretion. This rob is of a dark brownish-yellow colour, a balsamic sweet taste, with a little of the bitter, more or less according as the seeds in the berry have been more or less bruised. But perhaps one of the best forms under which they can be used is that of a simple watery infusion. This, either by itself or with the addition of a small quantity of gin, is a very useful drink for hydropic patients. An infusion of the tops has also been advantageously employed in the same manner. The Swedes prepare an extract from the berries, probably of the nature of the rob above mentioned, which some eat for breakfast. In Germany the berries are bruised and put into the sauce made use of for a wild boar; and are frequently also eaten with other pork, to give it a wild-boar flavour. In Carniola and some other districts, the inhabitants make a kind of wine of them steeped in water; but it is difficult to prevent this liquor from growing sour. The Laplanders, as we are told by Linnæus, drink infusions of the juniper-berries as we do tea and coffee. Thrushes and grouse feed on the berries, and disseminate the seed in their dung. It is remarkable that the berries of the juniper are two years in ripening. They sometimes appear in an uncommon form; the leaves of the cup grow double the usual size, approaching, but not closing; and the three petals fit exactly close, so as to keep the air from the *tipula juniperi* which inhabit them. The whole plant has a strong aromatic smell. The wood when burnt emits a fragrant odour like incense. It is of a reddish-colour, very hard and durable; and, when large enough, is used in marquetry and veneering, and in making cups, cabinets, &c. Grass will not grow beneath juniper, but this tree itself is said to be destroyed by the meadow-oat. The oil of juniper resembles that of turpentine, and when mixed with nut-oil makes an excellent varnish for pictures or wood-work, and for preserving iron from rust. The resin powdered and rubbed into paper prevents the ink from sinking through it, for which it is frequently used under the name of Pounce.—The charcoal made from this wood is said to endure longer than any other. For the properties of some other species, see the articles SANDARACH (*Gum*), and OLIBANUM.

JUNIUS (ADRIAN), one of the most learned men of the age in which he lived, was born at Horn in Holland in 1511. He travelled into all parts of Europe, and practised physic with reputation in England; where, among other works, he composed a Greek and Latin Lexicon, to which he added above 6500 words; an *Epithalamium* on the marriage of queen Mary with king Philip of Spain; and *Ani aduersa Et de Coma Commentarius*, which is the most applauded of all his works. He died in 1575.

JUNIUS (Francis), professor of divinity at Leyden, was born at Bourges in 1545, of a noble family, and studied some time at Lyons. Bartholomew Aneau, who was principal of the college in that city, gave him excellent instructions with regard to the right method of studying. He was remarkable for being proof against all temptations to lewdness;

but a libertine so far overpowered him by his sophistry, that he made him an atheist: however, he soon returned to his first faith; and, averse as he was to unlawful love, he had no aversion to matrimony, but was married no less than four times. He was employed in public affairs by Henry IV.; and at last was invited to Leyden to be professor of divinity, which employment he discharged with honour, till he was snatched away by the plague in 1602. Du Pin says, he was a learned and judicious critic. He wrote, in conjunction with Emmanuel Tremellius, a Latin version of the Hebrew text of the Bible. He also published Commentaries on a great part of the Holy Scriptures; and many other works, all in Latin.

JUNIUS (Francis), or *Francis du Jon*, the son of the preceding, was born at Heidelberg in 1589. He at first designed to devote himself to a military life; but after the truce concluded in 1609, he applied himself entirely to study. He came to England in 1620, and lived 30 years in the earl of Arundel's family. He was greatly esteemed not only for his profound erudition, but also for the purity of his manners; and was so passionately fond of the study of the northern languages, that, being informed there were some villages in Friesland where the ancient language of the Saxons was preserved, he went and lived two years in that country. He returned to England in 1675; and, after spending a year at Oxford, retired to Windsor, in order to visit Vossius, at whose house he died in 1677. The university of Oxford, to which he bequeathed his manuscripts, erected a very handsome monument to his memory. He wrote, 1. *De Pictura Veterum*, which is admired by all the learned; the best edition of it is that of Rotterdam in 1694. He published the same work at London in English. 2. An explication of the old Gothic manuscript, called the *Silver* one, because the four Gospels are there written in silver Gothic letters: this was published with notes by Thomas Mareschal, or Marshal. 3. A large Commentary on the Harmony of the four Gospels by Tatian, which is still in manuscript. 4. A Glossary in five languages, in which he explains the origin of the Northern languages; published at Oxford in 1745, in folio, by Mr. Edward Lee.

JUNIUS, the fictitious name of an unknown but highly eminent writer on political topics in England. His celebrated letters, which appeared in 1769, form a single volume, and have been universally read. They are not less distinguished for able remark, keen invective, and polished satire, than for their extraordinary beauties of composition. He was opposed by our noted Lexicographer Dr. Samuel Johnson, who, nevertheless, quotes Junius repeatedly in his Dictionary of the English Language, and considered him a strictly classical writer.

JUNK, in sea-language, a name given to any remnants or pieces of old cable, which is usually cut into small portions, for the purpose of making points, mats, gaskets, fennit, &c.

JUNO, in pagan worship, was the sister and wife of Jupiter, and the goddess of kingdoms and riches; also styled the *queen of Heaven*: she presided over marriage and child-birth, and was represented as the daughter of Saturn and Rhea. She married Jupiter; but was not the most complaisant wife: for, according to Homer, that god was sometimes obliged to make use of all his authority to keep her in due subjection; and the same author observes, that on her entering into a conspiracy against him, he punished her by suspending her in the air with two anvils fastened to her feet, and golden manacles on her hands, whilst all the other deities looked on without a possibility of helping her. However, her jealousy made her frequently find opportunities of interrupting her husband in the course of his amours; and prompted her to punish with unrelenting fury Europa, Semele, Io, Latona, and the rest of his mistresses. Jupiter himself having conceived without any commerce with a female; Juno, in revenge, conceived Vul-

can by the wind, Mars by touching a flower pointed out to her by the goddesses Flora, and Hebe by eating greedily of lettuce.

Juno, as the queen of Heaven, preserved great state: her usual attendants were Terror and Boldness, Castor, Pollux, and 14 nymphs; but her most faithful attendant was the beautiful Iris, or the rainbow. Homer describes her in a chariot adorned with precious stones, the wheels of which were of ebony, and which was drawn by horses with reins of gold. But she is more commonly painted drawn by peacocks. She was represented, in her temple at Corinth, seated on a throne, with a crown on her head, a pomegranate in one hand, and in the other a sceptre with a cuckoo on its top. This statue was of gold and ivory.

Some mythologists suppose that Juno signifies the air: others, that she was the Egyptian Isis; who being represented under various figures, was by the Greeks and Romans described as so many distinct deities.

JUNONALIA, a festival observed by the Romans in honour of Juno. It was instituted on account of certain prodigies that happened in Italy, and was celebrated by matrons. In the solemnity two white cows were led from the temple of Apollo into the city through the gate called *Carmentalis*, and two images of Juno, made of cypress, were borne in procession. Then marched 27 girls, habited in long robes, singing an hymn to the goddess; then came the Decemviri, crowned with laurel, in vestments edged with purple. This pompous company, going through the *Vicus Jugarius*, had a dance in the great field of Rome; from thence they proceeded through the *Forum Boarium* to the temple of Juno, where the victims were sacrificed by the Decemviri, and the cypress images were left standing. This festival is not mentioned in the *Fasts* of Ovid, but is fully described by Livy, lib. 7. dec. 3. The hymn used upon the occasion was composed by Livius the poet.

JUNSALAM, a seaport of Asia, in the kingdom of Siam. It is a shelter for all the ships that are bound to the coast of Coromandel, when they are surpris'd by a storm. It is seated to the N. of a large island of the same name. E. lon. 98. 30. N. lat. 8. 56.

JUNTO, in matters of government, denotes a select council for taking cognizance of affairs of great consequence, which require secrecy. In Spain and Portugal it signifies much the same with convention, assembly, or board among us: thus we meet with the junto of the three estates, of commerce, of tobacco, &c. See **BOARD**, &c.

IVORY, in natural history, &c. a hard, solid, and firm substance, of a white colour, and capable of a very good polish. It is the tusk of the elephant (See **ELEPHAS**), and is hollow from the base to a certain height, the cavity being filled up with a compact medullary substance, seeming to have a great number of glands in it. It is observed, that the Ceylon ivory, and that of the island of Achem, do not become yellow in the wearing, as all other ivory does: for this reason the teeth of these places bear a larger price than those of the coast of Guinea.

Hardening, Softening, and Staining of IVORY. See **BONES** and **HORNS**.

JUPITER, the supreme god of the ancient pagans. The theologians, according to Cicero, reckoned up three Jupiters; the first and second of whom were born in Arcadia; of these two, the one sprang from Æther, the other from Cœlus. The third Jupiter was the son of Saturn, and born in Crete, where they pretended to shew his sepulchre. Cicero in other places speaks of several Jupiters who reigned in different countries. The Jupiter, by whom the poets and divines understand the supreme God, was the son of Saturn king of Crete. He

would have been devoured by his father as soon as born, had not his mother Rhea substituted a stone instead of the child, which Saturn immediately swallowed. Saturn took this method to destroy all his male children, because it had been foretold by Cœlus and Terra, that one of his sons should deprive him of his kingdom. Jupiter, being thus saved from his father's jaws, was brought up by the Curetes in a den on mount Ida. Virgil tells us, that he was fed by the bees; out of gratitude for which he changed them from an iron to a golden colour. Some say, that his nurses were Amalthæa and Melissa, who gave him goats-milk and honey; and others, that Amalthæa was the name of the goat which nourished him; and which, as a reward for her great services, was changed into a constellation. According to others, he was fed by wild pigeons, who brought him ambrosia from Oceanus; and by an eagle, who carried nectar in his beak from a steep rock: for which he rewarded the former, by making them the foretellers of winter and summer; and the last by giving him immortality, and making him his thunder-bearer. When grown up, he drove his father out of heaven, and divided the empire of the world with his brothers. For himself, he had heaven and earth. Neptune had the sea and waters; and Pluto hell. The Titans undertook to destroy Jupiter, as he had done his father. These Titans were giants, the sons of Titan and the Earth. They declared war against Jupiter, and heaped mountains upon mountains, in order to scale heaven: but their efforts were unsuccessful. Jupiter overthrew them with his thunder, and shut them up under the waters and mountains, from which they were not able to get out.

Jupiter had several wives: the first of whom, named *Metis*, he is said to have devoured when big with child, by which he himself became pregnant: and Minerva issued out of his head, completely armed and fully grown. His second was Themis; the name of his third is not known; his fourth was the celebrated Juno, whom he deceived under the form of a cuckoo, which to shun the violence of a storm fled for shelter to her lap. He was the father of the Muses and Graces; and had a prodigious number of children by his mistresses. He metamorphosed himself into a satyr to enjoy Antiope; into a bull, to carry off Europa; into a swan, to abuse Leda; into a shower of gold, to corrupt Danaë; and into several other forms to gratify his passions. He had Bacchus by Semele, Diana and Apollo by Latona, and was the father of Mercury and the other gods.

The heathens in general believed that there was but one supreme God: but when they considered this one great being as influencing the affairs of the world, they gave him as many different names; and hence proceeded their variety of nominal gods. When he thundered or lightened, they called him *Jupiter*; when he calmed the sea, *Neptune*; when he guided their councils, *Minerva*; and when he gave them strength in battle, *Mars*. In process of time they used different representations of this Jupiter, &c. and considered them, vulgarly at least, as so many different persons. They afterward regarded each of them in different views: *e. g.* The Jupiter that showered down blessings was called the *Kind Jupiter*; and when punishing, the *Terrible Jupiter*. There was also one Jupiter for Europe, and another for Africa; and in Europe, there was one great Jupiter who was the particular friend of the Athenians, and another who was the special protector of the Romans: nay, there was scarce a town or hamlet perhaps in Italy, that had not a Jupiter of its own; and the Jupiter of Terracina, or Jupiter Auxur, represented in medals as young and beardless, with rays round his head, more resembled Apollo than the great Jupiter at the Capitol. In this way Jupiter at length had temples and different characters almost every where: at Carthage, he was called *Ammon*; in Egypt, *Serapis*; at Athens,

the great Jupiter was the Olympian Jupiter; and at Rome the greatest Jupiter was the Capitoline Jupiter, who was the guardian and benefactor of the Romans, and whom they called the best and greatest Jupiter; *Jupiter optimus maximus*. The figure of this Jupiter was represented in his chief temple on the Capitoline hill, as sitting on a curule chair, with the fulmen or thunder, or rather lightning, in one hand, and a sceptre in the other. This fulmen in the figures of the old artists was always adapted to the character under which they were to represent Jupiter. If his appearance was to be mild and calm, they gave him the conic fulmen, or bundle of flames wreathed close together, held down in his hand. When punishing, he holds up the same figure, with two transverse darts of lightning, sometimes with wings added to each side of it, to denote its swiftness; this was called by the poets the three-forked bolt of Jove: and when he was going to do some exemplary execution, they put in his hand a handful of flames, all let loose in their utmost fury; and sometimes filled both his hands with flames. The superiority of Jupiter was principally manifested in that air of majesty which the ancient artists endeavoured to express in his countenance: particular attention was paid to the head of hair, the eye-brows, and the beard. There are several heads of the mild Jupiter on ancient seals; where his face has a mixture of dignity and ease in it, admirably described by Virgil, *Æn.* i. v. 256. The statues of the terrible Jupiter were generally of black marble, as those of the former were of white: the one sitting with an air of tranquillity; the other standing, more or less disturbed. The face of the one is pacific and serene; of the other angry or clouded. On the heads of the one the hair is regular and composed; in the other it is so discomposed, that it falls half-way down the forehead. The face of the Jupiter Tonans resembles that of the Terrible Jupiter; he is represented on gems and medals as holding up the triple bolt in his right hand, and standing in a chariot, which seems to be whirled on impetuously by four horses. Thus he is also described by the poets. Ovid. *Deian. Herc.* v. 28. Horace, lib. i. od. 4. v. 8. Jupiter, as the intelligence presiding over a single planet, is represented only in a chariot and pair: on all other occasions, if represented in a chariot, he is always drawn by four horses. Jupiter is well known as the chief ruler of the air, whose particular province was to direct the rains, the thunders and the lightnings. As the dispenser of rain, he was called *Jupiter Pluvius*: under which character he is exhibited seated in the clouds, holding up his right hand, or extending his arms almost in a straight line each way, and pouring a stream of hail and rain from his right hand upon the earth; whilst the fulmen is held down in his left. The wings that are given him relate to his character of presiding over the air: his hair and beard in the Antonine pillar are all spread down by the rain, which descends in a sheet from him, and falls for the refreshment of the Romans; whilst their enemies are represented as struck with the lightnings, and lying dead at their feet.

Some consider a great part of the fable of Jupiter to include the history of Noah and his three sons; and that Saturn is Noah, who saw all mankind perish in the waters of the deluge; and who, in some sort, swallowed them up, by not receiving them into the ark. Jupiter is Ham; Neptune, Japheth; and Shem, Pluto.

The Titans, it is thought, represent the old giants, who built the tower of Babel, and whose pride and presumption God had confounded, by changing their language, and pouring out the spirit of discord and division among them. The name of *Jupiter*, or *Jovis Pater*, is thought to be derived from Jehovah, pronounced with the Latin termination *Jovis* instead of *Jova*; and in medals we meet with *Jovis* in the nominative as well as oblique cases: for example *Jovis Custis*, *Jo is Propugnator*, *Jovis Sator*. To the name *Jovis* was added *pater*; and after-

wards instead of "*Jovis pater*," *Jupiter* was used by abbreviation.

The name *Jupiter* was not known to the Hebrews till the reign of Alexander the Great, and the kings his successors. Antiochus Epiphanes commanded the idol of Jupiter Olympius to be placed in the temple at Jerusalem; and that of Jupiter the Defender of Strangers in the temple on mount Gerizim. 2 Macc. vi. 2. While St. Paul and St. Barnabas were at Jystra, they were taken for gods, because they cured one who had been lame from his birth, and that by an expression only: St. Paul was taken for Mercury, by reason of his eloquence: and St. Barnabas for Jupiter (Acts xiv. 11, 12.), on account probably of his good mien.

JUPITER, Υ , in astronomy, one of the superior planets, remarkable for its brightness; and which by its proper motion seems to revolve round the earth in about twelve years. See ASTRONOMY.

JURA, one of the Western Isles of Scotland, to the N. E. of the island of May, on the coast of Argyleshire. It is 10 miles long, and seven broad. Some parts of the southern and western sides are fertile. There are only three mountains on the whole island. These are of a conic form, of a stupendous height, and are called the Paps of Jura. The rest of the island is flat, and generally covered with heath. A few wild roes are still seen here.

JURA, a department of France, including part of the late province of Franche Comté. It contains mines of iron of a superior quality, mines of copper and lead, and many quarries of black marble, of jasper of different colours, and of alabaster. It takes its name from Mount Jura.

JURA is also the name of a chain of mountains in Switzerland, beginning in the canton of Zurich, extending from thence along the Rhine into the canton and bishopric of Basle, stretching into the canton of Soleure and the principality of Neuchâtel, and branching out towards the Pays de Vaud; separating that county from Franche Comté and Burgundy, and continued beyond the Genevan territories as far as the Rhone. Many elevated valleys are formed by different parts of this chain in the country of the Pays de Vaud; among which one of the most remarkable is the valley of the lake of Joux, on the top of that part of the chain named Mount Joux. It contains several populous villages, and is beautifully diversified with wood, arable land, and pasture. It is watered by two lakes; the largest of which is that of Joux already mentioned. This has one shore of a high rock covered with wood; the opposite banks forming a gentle ascent, fertile and well cultivated; behind which is a ridge covered with pines, beech and oak wood. The smaller lake, named *Brenet*, is bordered with fine corn-fields and villages; and the stream which issues from it is lost in a gulf named *Entonnoir*, or *thé Funnel*, where the people have placed several mills, which are turned by the force of the falling current. The river Orbe issues from the other side of the mountain, about two miles from this place; and probably owes its origin to the subterraneous stream just mentioned. The largest lake is supplied by a rivulet which issues from the bottom of a rock, and loses itself in it. The valley contains about 3000 inhabitants, remarkable for their industry. Some are watch-makers; but the greatest number employ themselves in polishing crystals, granites, and marcasites. The country is much infested with bears and wolves. In ascending to this place there is a very extensive prospect of great part of the Pays de Vaud, the lake of Geneva, and that of Neuchâtel, which from that high point of view appear to be nearly on a level; though M. de Luc found the latter to be 159 feet above the level of the lake of Geneva.

JURATS, JURATI, magistrates in the nature of ALDERMEN, for the government of several corporations. Thus we meet with

the mayor and jurats of Maidstone, Ryc, Winchelsea, &c.— So also Jersey has a bailiff and twelve jurats, or sworn assistants, to govern the island.

IVREA, an ancient and strong town of Italy, in Piedmont, and capital of Canavez, with a strong fort, a bishop's see, and an ancient castle. It is seated on the river Doria, between two hills, 20 miles N. of Turin, and 32 E. by N. of Susa. E. lon. 7. 48. N. lat. 45. 22.

JURIFU (PETER), an eminent French Protestant divine, called ironically by the papists the *Goliath* of the Protestants, was born in 1637. He was educated in England under his maternal uncle Peter du Moulin, and took orders in the English church; but returning to succeed his father as pastor of a reformed congregation at Mer in the diocese of Blois, he was made professor of divinity and Hebrew at Sedan, where he acquired great reputation. This university being taken from the Protestants, a professorship of divinity was founded for him at Rotterdam; and he was also appointed minister of the Walloon church in the same town. Being now in a place of liberty, he gave full scope to an imagination naturally warm, and applied himself to study the book of Revelation, of which he fancied he had by a kind of inspiration discovered the true meaning; a notion that led him to many enthusiastical conjectures. He was moreover so unfortunate as to quarrel with his best friends for opposing his visionary opinions, which produced violent disputes between him and Messrs. Bayle and de Beauval. He died in 1713; and left a great number of esteemed works behind him.

JURIN (Dr. JAMES), a distinguished person, who cultivated medicine and mathematics with equal success. He was secretary of the Royal Society in London, as well as president of the College of Physicians there. He had great disputes with Michelloti upon the momentum of running waters, with Robins upon distinct vision, and with the partisans of Leibnitz upon moving bodies. A treatise of his "upon Vision" is printed in Smith's "Optics." He died in 1750.

JURISCONSULTUS, *Jus*, among the Romans, was a person learned in the law; a master of the Roman jurisprudence, who was consulted on the interpretation of the laws and customs, and on the difficult points in law-suits. The fifteen books of the Digests were compiled wholly from the answers or reports of the ancient juriconsulti. Trebonianus, in destroying the 2000 volumes from whence the Code and Digest were taken, has deprived the public of a world of things which would have given them light into the ancient office of the juriconsulti. We should scarce have known any thing beyond their bare names, had not Pomponius, who lived in the second century, taken care to preserve some circumstances of their office.

The Roman juriconsulti seem to have been the same with our chamber counsellors, who arrived at the honour of being consulted through age and experience, but never pleaded at the bar. Their pleading advocates or lawyers never became juriconsulti. See ADVOCATE. In the times of the commonwealth, the advocati had by much the more honourable employment, as being in the ready way to attain the highest preferments. They then despised the juriconsulti, calling them in derision *formularii* and *leguleii*, as having invented certain forms and monosyllables, in order to give their answers the greater appearance of gravity and mystery. But in process of time they became so much esteemed that they were called *prudentes* and *sapientes*, and the emperors appointed the judges to follow their advice. Augustus advanced them to be public officers of the empire; so that they were no longer confined to the petty counsels of private persons.—Bern. Rutilius has written the lives of the most famous juriconsulti who have lived within these 2000 years.

JURISDICTION, a power or authority which a man has to do justice in cases of complaint made before him. There are

two kinds of jurisdiction; the one *ecclesiastical*, the other *secular*.

Secular JURISDICTION belongs to the king and his justices or delegates. The courts and judges at Westminster have jurisdiction all over England, and are not restrained to any county or place; but all other courts are confined to their particular jurisdictions, which if they exceed, whatever they do is erroneous. There are three sorts of inferior jurisdictions: the first is *tenere placita*, to hold pleas, and the plaintiff may sue either there or in the king's courts. Another is the conveyance of pleas, where a right is invested in the lord of the franchise to hold pleas: and he is the only person that can take advantage of it, by claiming his franchise. The third sort is an exempt jurisdiction, as where the king grants to some city, that the inhabitants shall be sued within their city and not elsewhere; though there is no jurisdiction that can withstand a *certiorari* to the superior courts.

Ecclesiastical JURISDICTION belongs to bishops and their deputies. Bishops, &c. have two kinds of jurisdiction; the one *internal*, which is exercised over the conscience in things purely spiritual; and this they are supposed to hold immediately of God. The other is *contentious*, which is a privilege some princes have given them in terminating disputes between ecclesiastics and laymen.

JURISPRUDENCE, the science of what is just or unjust; or the knowledge of laws, rights, customs, statutes, &c. necessary for the administration of justice. See LAW.

JUROR, JURATOR, in a legal sense, is one of those twenty-four or twelve men who are sworn to deliver truth upon such evidence as shall be given them touching any matter in question. The punishment of petty jurors attainted of giving a verdict contrary to evidence, willingly, is very severe.

IVRY, a town of France, in the department of Eure and late province of Normandy, with a late Benedictine abbey. It is seated on the river Eure, 10 miles N. by W. of Dreux. E. lon. 1. 28. N. lat. 48. 54.

JURY, a certain number of men sworn to inquire into and try a matter of fact, and to declare the truth upon such evidence as shall appear before them. Juries are, in these kingdoms, the supreme judges in all courts and in all causes in which either the life, property, or reputation, of any man is concerned: this is the distinguishing privilege of every Briton, and one of the most glorious advantages of our constitution; for, as every one is tried by his peers, the meanest subject is as safe and as free as the greatest. See the article TRIAL.

JURY-Mast, whatever is set up in room of a mast that has been lost in a storm or an engagement, and to which a lesser yard, ropes, and sails, are affixed.

JUS CORONÆ. See HEREDITARY Right, and SUCCESSION.

Jus Civile, among the Romans, signified no more than the interpretation given by the learned, of the laws of the twelve tables, though the phrase now extends to the whole system of the Roman laws.

Jus Civitatis signifies freedom of the city of Rome, which entitled those persons who had obtained it to most of the privileges of Roman citizens—yet it differs from *Jus Quiritium*, which extended to all the advantages which a free native of Rome was entitled to—the difference is much the same as betwixt *denization* and *naturalization* with us.

Jus Honorarium was a name given to those Roman laws which were made up of edicts of the supreme magistrates, particularly the *prætors*.

Jus Imaginis, was the right of using pictures and statues amongst the Romans, and had some resemblance to the right of bearing a coat of arms amongst us. This honour was allowed to none but those whose ancestors or themselves had

borne some *curule office*, that is, had been *Curule Aedile, Censor, Prætor, or Consul*. The use of statues, &c. which the *Jus Imaginis* gave, was the exhibiting them in funeral processions, &c. See *IMAGE*.

Jus Papirianum, was the laws of Romulus, Numa, and other kings of Rome, collected into a body by Sextus Papirius, who lived in the time of Tarquin the Proud; which accounts for the name.

Jus Trium Liberorum was a privilege granted to such persons in the city of Rome as had three children, by which they were exempted from all troublesome offices. The same exemption was granted to any persons who lived in other parts of Italy, having four children; and those that lived in the provinces, provided they had five (or as some say seven) children, were entitled to the same immunities. This was good policy, and tended to the population of the empire. See *CHILDREN*.

JUSSICA, in botany; a genus of the monogynia order, belonging to the decandria class of plants; and in the natural method ranking under the 17th order, *Calycanthemæ*. The calyx is quadripartite or quinquepartite superior; there are four or five petals; the capsule quadrilocular or quinquelocular, oblong, opening at the angles: the seeds are numerous and small.

JUST, a sportive kind of combat on horseback, man against man, armed with lances. The word is by some derived from the French *jouste*, of the Latin *juxta*, because the combatants fought near one another. Salmasius derives it from the modern Greek *zoustra*, or rather *ζουστρα*, which is used in this sense by Nicephorus Gregorius. Others derive it from *justa*, which in the corrupt age of the Latin tongue was used for this exercise, by reason it was supposed a more just and equal combat than the tournament.

The difference between justs and tournaments consists in this, that the latter is the genus, of which the former is only a species. Tournaments included all kinds of military sports and engagements made out of gallantry and diversion: justs were those particular combats where the parties were near each other, and engaged with lance and sword. Add, that the tournament was frequently performed by a number of cavaliers, who fought in a body: the just was a single combat of one man against another. Though the justs were usually made in tournaments after a general rencounter of all the cavaliers, yet they were sometimes singly, and independent of any tournament. See *TOURNAMENT*. He who appeared for the first time at a just, forfeited his helm or casque unless he had forfeited before at a tournament.

JUSTEL (CHRISTOPHER), a learned counsellor, and secretary to the French king, was born at Paris in 1580, and applied himself to the study of ecclesiastical history. He maintained a correspondence with the most learned men of his time, as Archbishop Uther, Sir Henry Spelman, Blondel, &c. till his death, which happened in 1649. He wrote, 1. The code of the canons of the church universal, and the councils of Africa, with notes. 2. A genealogical history of the house of Auvergne. And, 3. Collections of Greek and Latin canons, from several manuscripts, which formed the *Bibliotheca juris canonici veteris*, published in 2 vols. folio, by William Voet and our author's son.

JUSTEL (Henry), son of the foregoing, was born at Paris in 1620. He became secretary and counsellor to the king; and was as distinguished for his own learning as remarkable for encouraging it in others. He came to London in 1681, on the persecution of the Protestants; and was made keeper of the royal library at St. James's; which office he held till his death in 1693, when he was succeeded by the famous Dr. Bentley.

He wrote several books, the titles of which may be seen in the catalogue of the Bodleian library.

JUSTICE, in a moral sense, is one of the four cardinal virtues, which gives every person his due. Civilians distinguish justice into two kinds; *communicative* and *distributive*. The former establishes fair dealing in the mutual commerce between man and man; and includes sincerity in our discourse, and integrity in our dealings. The effect of sincerity is mutual confidence, so necessary among the members of the same community; and this mutual confidence is sustained and preserved by the integrity of our conduct.

Distributive justice is that by which the differences of mankind are decided, according to the rules of equity. The former is the justice of private individuals; the latter of princes and magistrates.

Fidelity and truth are the foundation of justice. As to be perfectly just is an attribute of the Divine Nature, to be so to the utmost of our ability is the glory of man. History abounds with various examples, of which we shall mention only the following. Among the several virtues of Aristides, that for which he was most renowned was justice; because this virtue is of most general use, its benefits extending to a greater number of persons, as it is the foundation, and in a manner the soul, of every public office and employment. Hence it was that Aristides, though in low circumstances, and of mean extraction, obtained the glorious surname of the *Just*; a title, says Plutarch, truly royal, or rather truly divine: but of which princes are seldom ambitious, because generally ignorant of its beauty and excellence. They choose rather to be called the conquerors of cities and the thunderbolts of war, preferring the vain honour of pompous titles, which convey no other idea than violence and slaughter, to the solid glory of those expressive of goodness and virtue. How much Aristides deserved the title given him, will appear in the following instance; though it ought to be observed, that he acquired it not by one or two particular actions, but by the whole tenor of his conduct.

Themistocles having conceived the design of supplanting the Lacedæmonians, and of taking the government of Greece out of their hands, in order to put it into those of the Athenians, kept his eye and his thoughts continually fixed upon that great project; and as he was not very nice or scrupulous in the choice of his measures, whatever tended towards the accomplishing of the end he had in view he looked upon as just and lawful.

On a certain day then he declared in a full assembly of the people, that he had a very important design to propose; but that he could not communicate it to the people, because its success required it should be carried on with the greatest secrecy: he therefore desired they would appoint a person to whom he might explain himself upon the matter in question. Aristides was unanimously fixed upon by the whole assembly, who referred themselves entirely to his opinion of the affair; so great a confidence had they both in his probity and prudence. Themistocles, therefore, having taken him aside, told him that the design he had conceived was to burn the fleet belonging to the rest of the Grecian states, which then lay in a neighbouring port; and by this means Athens would certainly become mistress of all Greece. Aristides hereupon returned to the assembly, and only declared to them, that indeed nothing could be more advantageous to the commonwealth than Themistocles's project, but that at the same time nothing in the world could be more unjust. All the people unanimously ordained that Themistocles should entirely desist from his project.

There is not perhaps in all history a fact more worthy of

admiration than this. It is not a company of philosophers (to whom it costs nothing to establish fine maxims and sublime notions of morality in the school) who determine on this occasion that the consideration of profit and advantage ought never to prevail in preference to what is honest and just; but the whole people, who are highly interested in the proposal made to them, that are convinced it is of the greatest importance to the welfare of the state, and who, however, reject it with unanimous consent, and without a moment's hesitation; and for this only reason, that it is contrary to justice. How black and perfidious, on the other hand, was the design which Themistocles proposed to them, of burning the fleet of their Grecian confederates at a time of entire peace, solely to aggrandize the power of the Athenians! Had he an hundred times the merit ascribed to him, this single action would be sufficient to fully all his glory; for it is the heart, that is to say, integrity and probity, which constitutes and distinguishes true merit.

JUSTICE is also an appellation given to a person deputed by the king to administer justice to his subjects, whose authority arises from his deputation, and not by right of magistracy. Of these justices there are various kinds in England; viz.

Chief Justice of the King's Bench is the capital justice of Great Britain, and is a lord by his office. His business is chiefly to hear and determine all pleas of the crown; that is, such as concern offences against the crown, dignity, and peace of the king; as treasons, felonies, &c. This officer was formerly not only chief justice, but also chief baron for the exchequer, and master of the court of wards. He usually sat in the king's palace, and there executed that office formerly performed *per comitem palatii*; he determined in that place all the differences happening between the barons and other great men. He had the prerogative of being the vicegerent of the kingdom whenever the king went beyond sea, and was usually chosen to that office out of the prime nobility; but his power was reduced by king Richard I. and king Edward I. His office is now divided, and his title changed from *capitalis Angliæ justitarius*, to *capitalis justitarius ad placita coram rege tenenda*, or *capitalis justitarius banci regii*.

Chief Justice of the Common Pleas, he who with his assistants hears and determines all causes at the common law; that is to say, all civil causes between common persons, as well personal as real; and he is also a lord by his office.

Justice of the Forest, is a lord by his office, who has power and authority to determine offences committed in the king's forests, &c. which are not to be determined by any other court of justice. Of these there are two; whereof one has jurisdiction over all the forests on this side Trent, and the other beyond it.

By many ancient records, it appears to be a place of great honour and authority, and is never bestowed but on some person of great distinction. The court where this justice sits is called the *justice-seat of the forest*, held once every three years, for hearing and determining all trespasses within the forest, and all claims of franchises, liberties and privileges, and all pleas and causes whatsoever therein arising. This court may fine and imprison for offences within the forest, it being a court of record; and therefore a writ of error lies from hence to the court of king's bench. The last court of justice-seat of any note was that held in the reign of Charles I. before the earl of Holland. After the restoration another was held for form sake before the earl of Oxford; but since the revolution in 1688, the forest laws have fallen into total disuse, to the great advantage of the subject. This is the only justice who may appoint a deputy: he is also called *justice in eyre of the forest*.

JUSTICES of Assize were such as were wont by special commission to be sent into this or that county to take assizes, for the ease of the subjects. For, whereas these actions pass always by jury, so many men might not without great damage and charge be brought up to London; and therefore justices, for this purpose, by commissions particularly authorized, were sent down to them. These continue to pass the circuit by two and two twice every year through all England, except the four northern counties, where they go only once, dispatching their several businesses by several commissions; for they have one commission to take assizes, another to deliver gaols, and another of oyer and terminer. In London and Middlesex a court of general gaol-delivery is held eight times in the year. All the justices of peace of any county wherein the assizes are held, are bound by law to attend them, or else are liable to a fine; in order to return recognizances, &c. and to assist the judges in such matters as lie within their knowledge and jurisdiction, and in which some of them have been probably concerned by way of previous examination. See ASSIZES and JURY.

JUSTICES in Eyre (*justitiarum itinerantes*, or *errantes*), were those who were anciently sent with commission into divers counties to hear such causes especially as were termed *pleas of the crown*; and that for the ease of the subject, who must else have been hurried to the courts of Westminster, if the cause were too high for the county-courts. According to some, these justices were sent once in seven years; but others will have them to have been sent oftener. Camden says, they were instituted in the reign of king Henry II. A. D. 1184; but they appear to be of an older date. They were somewhat like our justices of assize at this day; though for authority and manner of proceeding very different.

JUSTICES of Gaol Delivery, those commissioned to hear and determine causes appertaining to such as for any offence are cast into prison. Justices of gaol-delivery are empowered by the common law to proceed upon indictments of felony, trespass, &c. and to order execution or reprieve; and they have power to discharge such prisoners as upon their trials shall be acquitted; also all such against whom, on proclamation made, no evidence appears to indict; which justices of oyer and terminer, &c. may not do. 2 Hawk. 24, 25. But these justices have nothing to do with any person not in the custody of the prison, except in some special cases: as, if some of the accomplices to a felony may be in such prison and some of them out of it, the justices may receive an appeal against those who are out of the prison as well as those who are in it; which appeal, after the trial of such prisoners, shall be removed into B. R. and process issue from them against the rest. But if those out of prison be omitted in the appeal, they can never be put into any other; because there can be but one appeal for one felony. In this way the gaols are cleared, and all offenders tried, punished, or delivered, in every year. Their commission is now turned over to the justices of assize.

JUSTICES of Nisi Prius are now the same with justices of assize. It is a common adjournment of a cause in the Common Pleas to put it off to such a day, *Nisi prius justitiarum venerint ad eas partes ad capiendas assisas*: from which clause of adjournment they are called justices of nisi prius, as well as justices of assize; on account of the writ and actions they have to deal in.

JUSTICES of Oyer and Terminer, were justices deputed on some special occasions to hear and determine particular causes. The commission of oyer and terminer is directed to certain persons, upon any insurrection, heinous demeanour, or trespass committed, who must first inquire, by means of the grand jury or inquest, before they are empowered to hear and determine by the help of the petit jury. It was formerly held, that no judge

or other lawyer could act in the commission of oyer and terminer, or in that of gaol-delivery, within the county where he was born or inhabited: but it was thought proper by 12 Geo. II. cap. 27. to allow any man to be a justice of oyer and terminer and general gaol-delivery within any county of England.

JUSTICES of the Peace are persons of property and credit, appointed by the king's commission to keep the peace of the county where they live. Of these some for special respect are made of the quorum, so as no business of importance may be dispatched without the presence or assent of them or one of them. However, every justice of peace hath a separate power, and his office is to call before him, examine, issue warrants for apprehending, and commit to prison, all thieves, murderers, wandering rogues; those that hold conspiracies, riots, and almost all delinquents which may occasion the breach of the peace and quiet of the subject; to commit to prison such as cannot find bail, and to see them brought forth in due time to trial; and bind over the prosecutors to the assizes. And if they neglect to certify examinations and informations to the next gaol-delivery, or do not bind over prosecutors, they shall be fined. A justice may commit a person that doth a felony in his own view, without warrant; but if on the information of another, he must make a warrant under hand and seal for that purpose. If complaint and oath be made before a justice of goods stolen, and the informer, suspecting that they are in a particular house, shows the cause of his suspicion, the justice may grant a warrant to the constable, &c. to search in the place suspected, to seize the goods, and person in whose custody they are found, and bring them before him or some other justice. The search on these warrants ought to be in the day-time, and doors may be broke open by constables to take the goods. The justices of peace may make and persuade an agreement in petty quarrels and breaches of the peace, where the king is not entitled to a fine, though they may not compound offences, or take money for making agreements. A justice hath a discretionary power of binding to good behaviour; and may require a recognizance, with a great penalty, of one, for his keeping of the peace, where the party bound is a dangerous person, and likely to break the peace, and do much mischief; and for default of sureties he may commit him to gaol. But a man giving security for keeping the peace in the king's bench or chancery, may have a *superse-deas* to the justices in the county not to take security; and also by giving surety of the peace to any other justice. If one make an assault upon a justice of peace, he may apprehend the offender, and commit him to gaol till he finds sureties for the peace, and a justice may record a forcible entry on his own possession: in other cases he cannot judge in his own cause. Contempts against justices are punishable by indictment and fine at the sessions. Justices shall not be regularly punished for any thing done by them in the sessions as judges; and if a justice be tried for any thing done in his office, he may plead the general issue, and give the special matter in evidence; and if a verdict is given for him, or the plaintiff be nonsuited, he shall have double costs; and such action shall only be laid in the county where the offence was committed. 7 Jac. cap. 5. 21 Jac. cap. 12. But if they are guilty of any misdemeanour in office, information lies against them in the king's bench, where they shall be punished by fine and imprisonment; and all persons who recover a verdict against a justice for any wilful or malicious injury, are entitled to double costs. By 24 Geo. II. cap. 44. no writ shall be sued out against any justice of peace, for any thing done by him in the execution of his office, until notice in writing shall be delivered to him one month before the suing out of the same, containing the cause of action, &c. within which month he may tender amends; and if the tender

be found sufficient, he shall have a verdict, &c. Nor shall any action be brought against a justice for any thing done in the execution of his office, unless commenced within six months after the act committed.

A justice is to exercise his authority only within the county where he is appointed by his commission, not in any city which is a county of itself or town corporate; having their proper justices, &c. but in other towns and liberties he may. The power and office of justices terminate in six months after the demise of the crown, by an express writ of discharge under the great seal, by writ of *superse-deas*, by a new commission, and by accession to the office of sheriff or coroner.

The origin of justices of the peace is referred to the fourth year of Edward III. They were first called *conservators* or *wardens of the peace*, elected by the county, upon a writ directed to the sheriff; but the power of appointing them was transferred by statutes from the people to the king; and under this appellation appointed by 1 Edw. III. cap. 16. Afterwards the statute 34 Edward III. cap. 1. gave them the power of trying felonies; and then they acquired the appellation of *justices*. They are appointed by the king's special commission under the great seal, the form of which was settled by all the judges A. D. 1590; and the king may appoint as many as he shall think fit in every county in England and Wales, though they are generally made at the discretion of the lord chancellor, by the king's leave. At first the number of justices was not above two or three in a county. 18 Edw. III. cap. 2. Then it was provided by 34 Edw. III. cap. 1. that one lord, and three or four of the most worthy men in the county, with some learned in the law, should be made justices in every county. The number was afterwards restrained first to six, and then to eight, in every county, by 12 Ric. II. cap. 10. and 14 Ric. II. cap. 11. But their number has greatly increased since their first institution. As to their qualifications, the statutes just cited direct them to be of the best reputation and most worthy men in the county; and the statute 13 Ric. II. cap. 7. orders them to be of the most sufficient knights, esquires, and gentlemen of the law; and by 2 Hen. V. stat. 1. cap. 4. and stat. 2. cap. 1. they must be resident in their several counties. And by 18 Hen. VI. cap. 11. no justice was to be put in commission, if he had not lands to the value of 20l. *per annum*. It is now enacted by 5 Geo. II. cap. 11. that every justice shall have 100l. *per annum*, clear of all deductions; of which he must make oath, by 18 Geo. II. cap. 20. And if he acts without such qualification, he shall forfeit 100l. It is also provided by 5 Geo. II. that no practising attorney, solicitor, or proctor, shall be capable of acting as a justice of the peace.

JUSTICES of Peace within Liberties are justices of the peace who have the same authority in cities or other corporate towns as the others have in counties; and their power is the same; only that these have the assize of ale and beer, wood and vic-tuals, &c. Justices of cities and corporations are not within the qualification act, 5 Geo. II. cap. 18.

Fountain of JUSTICE, one of the characters or attributes of the king. *SEC PREROGATIVE*. By the fountain of justice the law does not mean the *author* or *original*, but only the *distributor*. Justice is not derived from the king, as from his *free gift*; but he is the steward of the public, to dispense it to whom it is *due*. He is not the spring, but the reservoir; from whence right and equity are conducted, by a thousand channels, to every individual. The original power of judicature, by the fundamental principles of society, is lodged in the society at large; but as it would be impracticable to render complete justice to every individual, by the people in their collective capacity; therefore every nation has committed that power to certain select magistrates,

who with more ease and expedition can hear and determine complaints; and in England this authority has immemorially been exercised by the king or his substitutes. He therefore has alone the right of erecting courts of judicature: for though the constitution of the kingdom hath entrusted him with the whole executive power of the laws, it is impossible, as well as improper, that he should personally carry into execution this great and extensive trust: it is consequently necessary that courts should be erected, to assist him in executing this power; and equally necessary, that, if erected, they should be erected by his authority. And hence it is, that all jurisdictions of courts are either mediately or immediately derived from the crown, their proceedings run generally in the king's name, they pass under his seal, and are executed by his officers.

It is probable, and almost certain, that in very early times, before our constitution arrived at its full perfection, our kings in person often heard and determined causes between party and party. But at present, by the long and uniform usage of many ages, our kings have delegated their whole judicial power to the judges of their several courts; which are the grand depository of the fundamental laws of the kingdom, and have gained a known and stated jurisdiction, regulated by certain and established rules, which the crown itself cannot now alter but by act of parliament. And in order to maintain both the dignity and independence of the judges in the superior courts, it is enacted by the statute 13 W. III. c. 2. that their commissions shall be made (not, as formerly, *durante bene placito*, but) *quamdiu bene se gesserint*, and their salaries ascertained and established; but that it may be lawful to remove them on the address of both houses of parliament. And now, by the noble improvements of that law in the statute of 1 Geo. III. c. 23. enacted at the earnest recommendation of the king himself from the throne, the judges are continued in their offices during their good behaviour, notwithstanding any demise of the crown (which was formerly held immediately to vacate their seats), and their full salaries are absolutely secured to them during the continuance of their commissions: his majesty having been pleased to declare, that "he looked upon the independence and uprightness of the judges, as essential to the impartial administration of justice; as one of the best securities of the rights and liberties of his subjects; and as most conducive to the honour of the crown."

In criminal proceedings or prosecutions for offences, it would still be a higher absurdity, if the king personally sat in judgment; because in regard to these he appears in another capacity, that of *prosecutor*. All offences are either against the king's peace, or his crown and dignity; and are so laid in every indictment. For though in their consequences they generally seem (except in the case of treason and a very few others) to be rather offences against the kingdom than the king; yet, as the public, which is an invisible body, has delegated all its power and rights, with regard to the execution of the laws, to one visible magistrate, all affronts to that power, and breaches of those rights, are immediately offences against him, to whom they are so delegated by the public. He is therefore the proper person to prosecute for all public offences and breaches of the peace, being the person injured in the eye of the law. And this notion was carried so far in the old Gothic constitution (wherein the king was bound by his coronation oath to conserve the peace), that in case of any forcible injury offered to the person of a fellow-subject, the offender was accused of a kind of perjury, in having violated the king's coronation oath; *dicebatur frogisse juramentum regis juratum*. And hence also arises another branch of the prerogative, that of *pardonning offences*; for it is reasonable, that he only who is injured should have the power of forgiving. See PARDON.

In this distinct and separate existence of the judicial power in a peculiar body of men, nominated indeed, but not removeable at pleasure, by the crown, consists one main preservative of the public liberty; which cannot subsist long in any state, unless the administration of common justice be in some degree separated both from the legislative and also from the executive power. Were it joined with the legislative, the life, liberty, and property of the subject would be in the hands of arbitrary judges, whose decisions would be then regulated only by their own opinions, and not by any fundamental principles of law; which though legislators may depart from, yet judges are bound to observe. Were it joined with the executive, this union might soon be an over-balance for the legislative. For which reason, by the statute of 16 Car. I. c. 10. which abolished the court of star-chamber, effectual care is taken to remove all judicial power out of the hands of the king's privy-council; who, as then was evident from recent instances, might soon be inclined to pronounce that for law which was most agreeable to the prince or his officers. Nothing therefore is more to be avoided in a free constitution, than uniting the provinces of a judge and a minister of state. And indeed, that the absolute power, claimed and exercised in some European nations, is more tolerable than that of the eastern empires, is in a great measure owing to their having vested the judicial power in a parliament, or other body separate and distinct from both the legislative and executive: and if ever those nations recover their liberty, they will owe it to the efforts of those assemblies. In Turkey, where every thing is centred in the sultan or his ministers, despotic power is in its meridian, and wears a more dreadful aspect.

A consequence of this prerogative is the legal ubiquity of the king. His majesty, in the eye of the law, is always present in all his courts, though he cannot personally distribute justice. His judges are the mirror by which the king's image is reflected. It is the regal office, and not the royal person, that is always present in court, always ready to undertake prosecutions or pronounce judgment, for the benefit and protection of the subject. And from this ubiquity it follows, that the king can never be non-suit; for a non-suit is the desertion of the suit or action by the non-appearance of the plaintiff in court. For the same reason, also, in the forms of legal proceedings, the king is not said to appear by his attorney, as other men do; for he always appears, in contemplation of law, in his own proper person. From the same original, of the king's being the fountain of justice, we may also deduce the prerogative of issuing proclamations, which is vested in the king alone. See PROCLAMATION.

JUSTICE-Seat. See FOREST-Courts.

JUSTICIA, MALABAR-NUT; a genus of the monogynia order, belonging to the diandria class of plants; and in the natural method ranking under the 40th order, *Perfonate*. The corolla is ringent; the capsule bilocular, parting with an elastic spring at the heel; the stamina have only one anthera. There are 19 species, all of them natives of the East Indies, growing many feet high; some adorned with fine large leaves, others with small narrow ones, and all of them with monopetalous ringent flowers. Only two species are cultivated in our gardens, viz. the adhatoda or common Malabar-nut, and the hysopifolia or snap-tree. The first grows ten or twelve feet high, with a strong woody stem, branching out widely all around; having large, lanceolate, oval leaves, placed opposite; and from the ends of the branches short spikes of white flowers, with dark spots, having the helmet of the corolla concave. The second hath a shrubby stem branching from the bottom pyramidally three or four feet high; spear-shaped, narrow, entire leaves, growing opposite; and white flowers, commonly by threes, from the sides of the branches; succeeded by capsules.

which burst open with elastic force for the discharge of the seeds; whence the name of *snap-tree*. Both species flower here in summer, but never produce any fruit. They are propagated by layers and cuttings, and require the same treatment with other tender exotics.

JUSTICIAR, in the old English laws, an officer instituted by William the Conqueror, as the chief officer of state, who principally determined in all cases civil and criminal. He was called in Latin *Capitaneus Justiciarus totius Angliæ*. The office of *Justiciar*, and a *Court of Justiciary*, exist at this time in Scotland.

JUSTIFICATION, in law, signifies a maintaining or showing a sufficient reason in court why the defendant did what he is called to answer. Pleas in justification must set forth some special matter: thus, on being sued for a trespass, a person may justify it by proving that the land is his own freehold; that he entered a house in order to apprehend a felon; or by virtue of a warrant, to levy a forfeiture, or in order to take a distress; and in an assault, that he did it out of necessity.

JUSTIFICATION, in theology, that act of grace which renders a man just in the sight of God, and worthy of eternal happiness. See **THEOLOGY**. The Romanists and Reformed are extremely divided about the doctrine of justification; the latter contending for justification by faith alone, and the former by good works.

JUSTIN, a celebrated historian, lived, according to the most probable opinion, in the second century, under the reign of Antoninus Pius. He wrote, in elegant Latin, an abridgment of the history of Trogus Pompeius; comprehending the actions of almost all nations, from Ninus the founder of the Assyrian empire to the emperor Augustus. The original work, to the regret of the learned, is unfortunately lost: this abridgment, being written in a polite and elegant style, was probably the reason why that age neglected the original. The best editions of Justin are, *ad usum Delphini*, in 4to; and *cum notis variorum et Gronovii*, in 8vo.

JUSTIN (St.) commonly called *Justin Martyr*, one of the earliest and most learned writers of the eastern church, was born at Neapolis, the ancient Sechem of Palestine. His father Priscus, a Gentile Greek, brought him up in his own religion, and had him educated in all the Grecian learning. To complete his studies he travelled to Egypt; and followed the sect of Plato, with whose intellectual notions he was much pleased. But one day walking by the sea side, wrapt in contemplation, he was met by a grave ancient person of a venerable aspect; who falling into discourse with him, turned the conversation by degrees from the excellence of Platonism to the superior perfection of Christianity; and reasoned so well, as to raise in him an ardent curiosity to inquire into the merits of that religion; in consequence of which inquiry, he was converted about the year 132. On his embracing that religion, he quitted neither the profession nor the habit of a philosopher: but a persecution breaking out under Antoninus, he composed *An Apology for the Christians*; and afterwards presented another to the emperor Marcus Aurelius, in which he vindicated the innocence and holiness of the Christian religion against Crescens a Cynic philosopher, and other calumniators. He did honour to Christianity by his learning and the purity of his manners; and suffered martyrdom in 167. Besides his two Apologies, there are still extant his *Dialogue with Trypho*, a Jew; two treatises addressed to the Gentiles, and another on the unity of God. Other works are also ascribed to him. The best editions of St. Justin are those of Robert Stephens, in 1551 and 1571, in Greek and Latin; that of Morel, in Greek and Latin, in 1656; and that of Dom Prudentius Marandus, a learned Benedictine, in 1742, in folio. His style is plain, and void of all ornament.

JUSTINIAN I. son of Justin the elder, was made Cæsar

and Augustus in 527, and soon after emperor. He conquered the Persians by Belisarius his general, and exterminated the Vandals; regained Africa; subdued the Goths in Italy; defeated the Moors; and restored the Roman empire to its primitive glory. When the empire was in the full enjoyment of a profound peace and tranquillity, Justinian made the best use of it, by collecting the immense variety and number of the Roman laws into one body. To this end, he selected ten of the most able lawyers in the empire; who, revising the Gregorian, Theodosian and Hermogenian codes, compiled one body, called *Codex Justinianus*. This may be called the *statute law*, as consisting of the rescripts of the emperors. But the reduction of the other part was a much more difficult task: it was made up of the decisions of the judges and other magistrates, together with the authoritative opinions of the most eminent lawyers; all which lay scattered, without any order, in no less than 2000 volumes and upwards. These were reduced to the number of 50; but ten years were spent in the reduction. However, the design was completed in the year 529, and the name of *Digest* or *Pandects* given to it. Besides these, for the use chiefly of young students in the law, to facilitate that study, Justinian ordered four books of institutes to be formed, containing an abstract or abridgment of the text of all the laws: and lastly, the laws of modern date, posterior to that of the former, were thrown into one volume in the year 529, called the *Novellæ*, or New Code. This emperor died in the year 565, aged 83, in the 39th of his reign, after having built a great number of churches; particularly the famous Sancta Sophia at Constantinople, which is esteemed a masterpiece of architecture.

JUSTINIANI (St. LAURENCE), the first patriarch of Venice, was born there of a noble family in 1381. He was a very pious prelate, and died in 1485; he left several pieces of piety, which were printed together at Lyons in 1568, in one volume folio, with his life prefixed by his nephew. Clement VII. beatified him in 1524; and he was canonized by Alexander VIII. in 1690.

JUSTINIANI (Bernard), was born at Venice in 1408. He obtained the senator's robe at the age of 19, served the republic in several embassies, and was elected procurator of St. Mark in 1474. He was a learned man, and wrote *the History of Venice*, with some other works of considerable merit; and died in 1498.

JUSTINIANI (Augustin), bishop of Nebo, one of the most learned men of his time, was descended from a branch of the same noble family with the two foregoing; and was born at Genoa in 1480. He assisted at the fifth council of the Lateran, where he opposed some of the articles of the concordat between France and the court of Rome. Francis I. of France made him his almoner; and he was five years regius professor of Hebrew at Paris. He returned to Genoa in 1522, where he discharged all the duties of a good prelate; and learning and piety flourished in his diocese. He perished at sea in his passage from Genoa to Nebo, in 1536. He composed several pieces; the most considerable of which is, *Psalterium Hebræum, Græcum, Arabicum, et Chaldeum, cum tribus Latinis interpretationibus et glossis*. This was the first psalter of the kind printed; and there is also ascribed to the same prelate a translation of Maimonides's *Mora Nevochim*.

JUSTNESS, the exactness or regularity of any thing. Justness is chiefly used in speaking of thought, language, and sentiments. The justness of a thought consists in a certain precision or accuracy, by which every part of it is perfectly true, and pertinent to the subject. Justness of language consists in using proper and well chosen terms; in not saying either too much or too little. M. de Mere, who has written on justness of mind, distinguishes two kinds of justness; the one arising from taste and genius, the other from good sense or right reason. There

are no certain rules to be laid down for the former, *viz.* to show the beauty and exactness in the turn or choice of a thought; the latter consists in the just relation which things have to one another.

JUTES, the ancient inhabitants of Jutland in Denmark.

JUTLAND, a large peninsula, which makes the principal part of the kingdom of Denmark. It is bounded on the south-east by the duchy of Holstein, and is surrounded on the other sides by the German ocean and the Baltic sea. It is about 180 miles in length from north to south, and 50 in breadth from east to west. The air is very cold, but wholesome; and the soil is fertile in corn and pastures, which feed a great number of bees, that are sent to Germany, Holland, and elsewhere. This was anciently called the *Cimbrian Chersonesus*, and is supposed to be the country from whence the Saxons came into England. It is divided into two parts, called *North* and *South Jutland*: the latter is the duchy of Sleswick, and lies between North Jutland and the duchy of Holstein; and the duke of that name is in possession of that part of it whose capital town is Gottorp, for which reason the sovereign is called the *Duke of Holstein Gottorp*.

JUVENAL (DECIUS JUNIUS), the celebrated Roman satirist, was born about the beginning of the emperor Claudian's reign, at Aquinum in Campania. His father was probably a freed man, who, being rich, gave him a liberal education, and, agreeably to the taste of the times, bred him up to eloquence; in which he made a great progress, first under Fronto the grammarian, and afterwards, as is generally conjectured, under Quintilian; after which he attended the bar, and made a distinguished figure there for many years by his eloquence. In the practice of this profession he had improved his fortune and interest at Rome before he turned his thoughts to poetry, the very style of which, in his satires, speaks a long habit of declamation; *subactum redolent declamatorem*, say the critics. It is said he was above 40 years of age when he recited his first essay to a small audience of his friends; but being encouraged by their applause, he ventured a greater publication; which reaching the ears of Paris, Domitian's favourite at that time, though but a pantomime player, whom our satirist had severely insulted, that minion made his complaint to the emperor; who sent him thereupon into banishment, under pretence of giving him the command of a cohort in the army, which was quartered at Pentapolis, a city upon the frontiers of Egypt and Libya.

After Domitian's death, Juvenal returned to Rome, sufficiently cautioned not only against attacking the characters of those in power, under arbitrary princes, but against all personal reflections upon the great men then living; and therefore he thus wisely concludes the debate he is supposed to have maintained for a while with a friend on this head, in the first satire, which seems to be the first that he wrote after his banishment:

——— *Experiar quid concedatur in illos*
Quorum Flaminia tegitur cinis atque Latina.

“I will try what liberties I may be allowed with those whose ashes lie under the Flaminian and Latin ways,” along each side of which the Romans of the first quality used to be buried.—It is believed that he lived till the reign of Adrian in 128. There are still extant 16 of his satires, in which he discovers great wit, strength, and keenness, in his language: but his style is not perfectly natural; and the obscenities with which these satires are filled render the reading of them dangerous to youth.

JUVENCUS (CAIUS VECTICUS AQUILINUS), one of the first of the Christian poets, was born of an illustrious family in Spain. About the year 320 he put the Life of Jesus Christ into Latin verse, of which he composed four books. In this

work he followed almost word for word the text of the four evangelists; but his verses are written in a bad taste, and his Latin is not pure.

JUVENTAS, in mythology, the goddess who presided over youth among the Romans. This goddess was long honoured in the Capitol, where Servius Tullius erected her statue. Near the chapel of Minerva there was the altar of Juventas, and upon this altar a picture of Proserpine. The Greeks called this goddess of youth *Hebe*; but it has been generally supposed that this was not the same with the Roman *Juventas*.

JUXON (Dr. WILLIAM), born at Chichester in 1682, was bred at Merchant-Tailors' school, and from thence elected into St. John's college Oxford, of which he became president. King Charles I. made him bishop of London; and in 1635 promoted him to the post of lord high treasurer of England. The whole nation, and especially the nobility, were greatly offended at this high office being given to a clergyman; but he behaved so well in the administration, as soon put a stop to all the clamour raised against him. This place he held no longer than the 17th of May 1641, when he prudently resigned the staff, to avoid the storm which then threatened the court and the clergy. In the following February, an act passed depriving the bishops of their votes in parliament, and incapacitating them from any temporal jurisdiction. In these leading steps, as well as the total abolition of the episcopal order which followed, he was involved with his brethren; but neither as bishop nor as treasurer was a single accusation brought against him in the long parliament. During the civil wars, he resided at his palace at Fulham, where his meek, inoffensive, and gentle behaviour, notwithstanding his remaining steady in his loyalty to the king, procured him the visits of the principal persons of the opposite party, and respect from all. In 1648 he attended on his majesty at the treaty in the isle of Wight; and, by his particular desire, waited upon him at Cotton-house, Westminster, the day after the commencement of his trial; during which he frequently visited him in the office of a spiritual father; and his majesty declared he was the greatest comfort to him in that afflictive situation. He likewise attended his majesty on the scaffold, where the king, taking off his cloak and George, gave him the latter: after the execution, this pious bishop took care of the body, which he accompanied to the royal chapel at Windsor, and stood ready with the common prayer book in his hands to perform the last ceremony for the king; but was prevented by Colonel Whichcot, governor of the castle.—He continued in the quiet possession of Fulham-palace till the ensuing year 1649, when he was deprived, having been spared longer than any of his brethren. He then retired to his own estate in Gloucestershire, where he lived in privacy till the restoration, when he was presented to the see of Canterbury; and, in the little time he enjoyed it, expended in buildings and reparations at Lambeth-palace and Croydon-house near 15,000l. He died in 1663; having bequeathed 7000l. to St. John's college, and to other charitable uses near 5000l. He published a sermon on Luke xviii. 31. and *Some Considerations upon the Act of Uniformity*.

JUXTAPOSITION, is used by philosophers to denote that species of growth which is performed by the apposition of new matter to the surface or outside of old. In which sense it stands opposed to *intusufception*; where the growth of a body is performed by the reception of a juice within it diffused through its canals.

IVY, in botany. See **HEDERA**.

IVY-BRIDGE, a village of Devonshire, remarkable for its rural and picturesque scenery; having on the N. the rude barren mountains of Dartmoor, and on the S. one of the most fertile and best cultivated countries in the kingdom; while the

river Arne, which here crosses the road from London to Plymouth, and which runs with great rapidity through the village, having its course interrupted by many huge masses of granite, which lie in a confused manner on its bed, forces its way among them with great noise and impetuosity, and, when swelled with heavy rains, exhibits a very romantic appearance. A little above the bridge (from which probably the village derives its name, is a considerable paper-manufactory. Ivy Bridge is 11 miles N. E. of Plymouth, and 20; S. W. of London.

IXER, or HIGAR, a town of Spain, in Arragon, seated on the river Martin. W. lon. 0. 19. N. lat. 41. 12.

IXIA, in botany; a genus of the monogynia order, belonging to the triandria class of plants; and in the natural method ranking under the 6th order, *Enfalæ*. The corolla is hexapetalous, patent, and equal; there are three stigmata a little upright and petalous. There are several species, consisting of herbaceous, tuberous, and bulbous-rooted showery perennials, from one to two feet high, terminated by hexapetalous flowers of different colours. They are propagated by off-sets, which should be taken off in summer at the decay of the leaves: but as all the plants of this genus are natives of warm climates, few of them can bear the open air of this country in winter.

IXION, in fabulous history, king of the Lapithæ, married Dia the daughter of Deionius, to whom he refused to give the customary nuptial presents. Deionius in revenge took from him his horses; when Ixion, dissembling his resentment, invited his father-in-law to a feast, and made him fall through a trap-door into a burning furnace, in which he was immediately consumed. Ixion, being afterwards slung with remorse for his cruelty, ran mad; on which Jupiter, in compassion, not only forgave him, but took him up into heaven; where he had the impiety to endeavour to corrupt Juno. Jupiter, to be the better assured of his guilt, formed a cloud in the resemblance of the goddess, upon which Ixion begat the centaurs: but boasting of his happiness, Jove hurled him down to Tartarus, where he lies fixed on a wheel encompassed with serpents, which turn without ceasing.

IXORA, in botany; a genus of the monogynia order, belonging to the tetrandria class of plants; and in the natural method ranking under the 47th order, *Stylatæ*. The corolla is monopetalous, funnel-shaped, and long, superior; the stamina above the throat; the berry tetraspermous.

IXWORTH, a town in Suffolk, with a market on Friday. It is 79 miles N. E. by N. of London. Several Roman coins have been dug up here.

JYEPOUR, a city of Hindoostan Proper, capital of a territory of the same name (otherwise called Jaypour, Jaynagur, Joinagur, or Jyenagur) in the eastern quarter of Agimere, and subject to one of the Rajpoot Princes. It was built by

the celebrated Rajah Jessing, who also erected an observatory here, and invited Claude Bondier to it, in 1734. Wendel represents Jyepour as a place of great wealth and consequence in 1779, being the staple of the principal part of the goods that are brought from every quarter of India. It is 136 miles W. by S. of Agra. E. lon. 76. 9. N. lat. 26. 56.

JYNY, in ornithology, a genus of birds belonging to the order of picæ; the characters of which are, that the bill is slender, round, and pointed; the nostrils are concave and naked; the tongue is very long, very slender, cylindric, and terminated by a hard point; and the feet are formed for climbing. There is only one species, *viz.* the *torquilla*. (See pl. 23.) The colours of this bird are elegantly pencilled, though its plumage is marked with the plainest kinds: a list of black and ferruginous strokes divides the top of the head and back; the sides of the head and neck are ash-coloured, beautifully traversed with fine lines of black and reddish-brown; the quill feathers are dusky, but each web is marked with rust-coloured spots; the chin and breast are of a light yellowish brown, adorned with sharp-pointed bars of black; the tail consists of ten feathers, broad at their ends and weak, of a pale ash-colour, powdered with black and red, and marked with four equidistant bars of black: the irides are of a yellowish colour.—The wry-neck, Mr. Pennant apprehends, is a bird of passage, appearing with us in the spring before the cuckoo. Its note is like that of the kestrel, a quick-repeated squeak; its eggs are white, with a very thin shell; it builds in the hollows of trees, making its nest of dry grass. It has a very whimsical way of turning and twisting its neck about, and bringing its head over its shoulders, whence it had its Latin name *torquilla*, and its English one of *wry-neck*: it has also the faculty of erecting the feathers of the head like those of the jay. It feeds on ants, which it very dexterously transfixes with the bony and sharp end of its tongue, and then draws them into its mouth; and while the female is sitting, the male has been observed to carry these insects to her.—We find this bird mentioned as an inhabitant throughout Europe, and of many parts of the old Continent. It is in Russia, Sweden, Lapland, Greece, Italy, Babylon, and Bengal; authorities for which Buffon mentions, and says, that at the end of summer this bird grows very fat, when it becomes excellent eating; for which reason some have named it the *Ortolan*. The young ones, while in the nest, will hiss like so many snakes; inasmuch that many have been prevented plundering the old ones of their offspring, on a supposition that they were advancing their hands on the brood of this loathsome reptile.

IZQUINTENANGO, a rich and handsome town of N. America, in New Spain, and in the province of Chiapa. The country about it produces cotton and a great number of ananas or pine-apples.

K.

K

K, the tenth letter, and seventh consonant, of our alphabet; being formed by the voice, by a guttural expression of the breath through the mouth, together with a depression of the lower jaw and opening of the teeth. Its sound is much the same with that of the hard *c* or *qu*; and it is used, for the most part, only before *e*, *i*, and *n*, in the beginning of words; as *ken*, *kill*, *known*, &c. It used formerly to be always joined with *c* at the end of words, but is at present very properly omitted, at least in words derived from the Latin: thus, for *publick*, *musick*, &c. we say *public*, *music*, &c. However, in monosyllables it is still retained, as *jack*, *block*, *mock*, &c.

Vol. IV.

K

K is borrowed from the Greek *κappa*, and was but little used among the Latins: Priscian looked on it as a superfluous letter; and says, it was never to be used except in words borrowed from the Greek. Dausquius, after Sallust, observes, that it was unknown to the ancient Romans.—Indeed we seldom find it in any Latin authors, excepting in the word *kalendæ*, where it sometimes stands in lieu of a *c*.—Carthage, however, is frequently spelt on medals with a *K*: SALVI AUG. ET CAES. FEL. KARE. and sometimes the letter *K* alone stood for *Carthage*.—M. Berger has observed, that a capital *K*, on the reverse of the medals of the Emperors of Constantinople,

signified *Konstantinus*; and on the Greek medals he will have it to signify ΚΟΙΛΗ ΣΥΡΙΑ, "Coelesyria."

Quintilian tells us, that in his time some people had a mistaken notion, that wherever the letter *c* and *a* occurred at the beginning of a word, *k* ought to be used instead of the *c*. See C. Lipsius observes, that *K* was a stigma anciently marked on the foreheads of criminals with a red-hot iron.

The letter *K* has various significations in old charters and diplomas; for instance, KR. stood for *chorus*, KR. C. for *cara civitas*, K R M. for *carmen*, KR. AM. N. *carus amicus noster*, K S. *chaos*, K T. *capite tonsus*, &c.

The French never use the letter *k* excepting in a few terms of art and proper names borrowed from other countries. A-blancourt, in his dialogue of the letters, brings in *k* complaining, that he has often been in a fair way to be banished out of the French alphabet, and confined to the countries of the north.

K is also a numeral letter, signifying 250, according to the verse; "K quoque ducentos & quinquaginta tenet." When it had a stroke at top, *K̄*, it stood for 250,000.

K on the French coinage denotes money coined at Bourdeaux.

KADESH, KADFSH-BARNFA, or EN-MISHPAT, in ancient geography, a city celebrated for several events. At Kadesh, Miriam the sister of Moses died (Numb. xx. 1.). Here it was that Moses and Aaron, showing a distrust in God's power when they smote the rock at the waters of strife, were condemned to die without the consolation of entering the promised land (Numb. xxvii. 14.). The king of Kadesh was one of the princes killed by Joshua (xii. 22.). This city was given to the tribe of Judah, and was situated about eight leagues from Hebron to the south. Mr. Wells is of opinion, that this Kadesh, which was situated in the wilderness of Zin, was a different place from Kadesh-barnea in the wilderness of Paran.

KADMONÆI, or CADMONÆI, in ancient geography, a people of Palestine, said to dwell at the foot of mount Hermon; which lies east, and is the reason of the appellation, with respect to Libanus, Phœnicia, and the north parts of Palestine. Called also *Hevæi* (Moses).

KÆMPFERIA, ZEDOARY, in botany; a genus of the monogynia order, belonging to the monandria class of plants; and in the natural method ranking under the 8th order, *Scitamineæ*. The corolla is sexpartite, with three of the segments larger than the rest, patulous; and one only bipartite.

The *speis* are, 1. The galanga, common galangal, or long zedoary, has tuberous, thick, oblong, fleshy roots; crowned with oval, close-fitting leaves, by pairs, four or five inches long, without footstalks; and between them close-fitting white flowers, with purple bottoms, growing singly. 2. The rotunda, or round zedoary, has thick, fleshy, swelling, roundish, clustering roots, sending up spear-shaped leaves, six or eight inches long, near half as broad, on upright footstalks; and between them, immediately from the roots, rise whitish flowers, tinged with green, red, yellow, and purple centres. Both these are perennial in root; but the leaves rise annually in spring, and decay in winter. They flower in summer: each flower is of one petal, tubulous below, but plain above, and divided into six parts; they continue three or four weeks in beauty, but are never succeeded by seeds in this country. Both these plants must be potted in light rich mould, and always kept in the hot-house, giving plenty of water in summer, but more sparingly in winter. They are propagated by parting the roots in the spring, just before they begin to push forth new leaves.

This plant is cultivated with great care by many of the inhabitants of Siam for the sake of its root; the use of which is to strengthen the bowels and nervous system. The root was

was formerly used in this country in bitter infusions; but is now laid aside.

KALENDAR, a distribution of time, accommodated to the uses of life; or a table or almanac, containing the order of days, weeks, months, feasts, &c. happening throughout the year. See TIME, MONTH, YEAR, &c. It is called *kalendar*, from the word *kalendæ*, anciently written in large characters at the head of each month. See KALENDS. The days in calendars were originally divided into *octoades*, or eights; but afterwards, in imitation of the Jews, into *hebdomades*, or sevens; which custom, Scaliger observes, was not introduced among the Romans till after the time of Theodosius.

There are various calendars, according to the different forms of the year and distributions of time established in different countries. Hence the Roman, the Jewish, the Persian, the Julian, the Gregorian, &c. calendars. The ancient *Roman* calendar is given by Ricciolus, Struvius, Danet, and others; by which we see the order and number of the Roman holidays and work-days. The three *Christian* calendars are given by Wolfius in his Elements of Chronology. The *Jewish* calendar was fixed by rabbi Hillel about the year 360, from which time the days of their year may be reduced to those of the Julian calendar.

The *Roman* KALENDAR owed its origin to Romulus; but it has undergone various reformations since his time. That legislator distributed time into several periods, for the use of the people under his command: but as he was much better versed in matters of war than of astronomy, he only divided the year into ten months, making it begin in the spring, on the first of March; imagining the sun made his course through all the seasons in 304 days.

Romulus's calendar was reformed by Numa, who added two months more, January and February; placing them before March: so that his year consisted of 355 days, and began on the first of January. He chose, however, in imitation of the Greeks, to make an intercalation of 45 days, which he divided into two parts; intercalating a month of 22 days at the end of each two years; and at the end of each two years more another of 23 days; which month, thus interposed, he called *Marcedonius*, or the intercalary February. But these intercalations being ill observed by the pontiffs, to whom Numa committed the care of them, occasioned great disorders in the constitution of the year; which Cæsar, as sovereign pontiff, endeavoured to remedy. To this end, he made choice of Sosigenes, a celebrated astronomer of those times; who found, that the dispensation of time in the calendar could never be settled on any sure footing without having regard to the annual course of the sun. Accordingly, as the sun's yearly course is performed in 365 days six hours, he reduced the year to the same number of days. The year of this correction of the calendar was a year of confusion; they being obliged, in order to swallow up the 65 days that had been imprudently added, and which occasioned the confusion, to add two months besides the *Marcedonius*, which chanced to fall out that year; so that this year consisted of 15 months, or 445 days. This reformation was made in the year of Rome 708, 42 or 43 years before Christ.

The *Roman* calendar, called also *Julian* calendar, from its reformer Julius, is disposed into quadriennial periods; whereof the first three years, which he called *communis*, consist of 365 days; and the fourth, *bissextile*, of 366; by reason of the six hours, which in four years make a day or somewhat less, for in 134 years an intercalary day is to be retrenched. On this account it was, that Pope Gregory III. with the advice of Clavius and Ciaconius, appointed, that the hundredth year of each century should have no bissextile, excepting in each fourth century: that is, a subtraction is made of three bissextile days in the space of four centuries; by reason of the 11 minutes

wanting in the six hours whereof the bissextile consists. The reformation of the kalendar, or the *new style*, as we call it, commenced on the 4th of October 1582, when ten days were thrown out at once, so many having been introduced into the computation since the time of the council of Nice in 325, by the defect of 13 minutes.

Julian Christian KALENDAR is that wherein the days of the week are determined by the letters A, B, C, D, E, F, G, by means of the solar cycle; and the new and full moons, especially the paschal full moon, with the feast of Easter, and the other moveable feasts depending thereon, by means of golden numbers, rightly disposed through the Julian year. See CYCLE, and CHRONOLOGY, p. 525. In this kalendar, the vernal equinox is supposed to be fixed to the 21st day of March; and the cycle of 19 years, or the golden numbers, constantly to indicate the places of the new and full moons; yet both are erroneous. And hence arose a very great irregularity in the time of Easter. To show this error the more apparently, let us apply it to the year 1715. In this year, then, the vernal equinox falls on the 10th of March; and therefore comes too early by 11 days. The paschal full moon falls on the 7th of April; and therefore, too late, with regard to the cycle, by three days. Easter, therefore, which should have been on the 10th of April, was that year on the 17th. The error here lies only in the metempepsis, or postponition of the moon, through the defect of the lunar cycle. If the full moon had fallen on the 11th of March, Easter would have fallen on the 13th of March; and therefore the error arising from the anticipation of the equinox would have exceedingly augmented that arising from the postponition. These errors, in course of time, were so multiplied, that the kalendar no longer exhibited any regular Easter. Pope Gregory XIII. therefore, by the advice of Aloysius Lilius, in 1582, threw 10 days out of the month of October, to restore the equinox to its place, viz. the 21st of March; and thus introduced the form of the Gregorian year, with such a provision, as that the equinox should be constantly kept to the 21st of March. The new moons and full moons, by advice of the same Lilius, were not to be indicated by golden numbers, but by epacts. The kalendar, however, was still retained in Britain without this correction: whence there was a difference of 11 days between our time and that of our neighbours. But by 24 Geo. II. c. 23. the Gregorian computation is established here, and accordingly took place in 1752.

Gregorian KALENDAR is that which, by means of epacts rightly disposed through the several months, determines the new and full moons, and the time of Easter, with the moveable feasts depending thereon, in the Gregorian year. The Gregorian kalendar, therefore, differs from the Julian, both in the form of the year, and in that epacts are substituted in lieu of golden numbers: for the use and disposition whereof, see EPACT.

Though the Gregorian kalendar be preferable to the Julian, yet it is not without its defects (perhaps, as Tycho Brahe and Cassini imagine, it is impossible ever to bring the thing to a perfect justness). For, first, the Gregorian intercalation does not hinder but that the equinox sometimes succeeds the 21st of March as far as the 23d; and sometimes anticipates it, falling on the 19th; and the full moon, which falls on the 20th of March, is sometimes the paschal; yet not so accounted by the Gregorians. On the other hand, the Gregorians account the full moon of the 22d of March the paschal; which yet, falling before the equinox, is not paschal. In the first case, therefore, Easter is celebrated in an irregular month; in the latter, there are two Easters in the same ecclesiastical year. In like manner, the cyclical computation being founded on mean full moons, which yet may precede or follow the true ones by some hours, the paschal full-moon may fall on Saturday, which is

yet referred by the cycle to Sunday: whence, in the first case, Easter is celebrated eight days later than it should be; in the other, it is celebrated on the very day of the full-moon, with the Jews and Quartodeciman heretics; contrary to the decree of the council of Nice. Scaliger and Calvisius show other faults in the Gregorian kalendar, arising from the negligence and inadvertency of the authors; yet is this kalendar adhered to by the Romanists throughout Europe, and used wherever the Roman breviary is used.

Reformed or Corrected KALENDAR is that which, setting aside all apparatus of golden numbers, epacts, and dominical letters, determines the equinox, with the paschal full-moon, and the moveable feasts depending thereon, by astronomical computation, according to the Rudolphine Tables. This kalendar was introduced among the Protestant states of Germany in the year 1700, when 11 days were at once thrown out of the month of February; so that in 1700 February had but 18 days: by this means, the corrected style agrees with the Gregorian. This alteration in the form of the year they admitted for a time; in expectation that, the real quantity of the tropical year being at length more accurately determined by observation, the Romanists would agree with them on some more convenient intercalation.

French KALENDAR. Among the most extraordinary of the innovations of the French republicans, is the alteration of their kalendar: agreeably to their favourite project of rooting both royalty and religion from the minds of the people, they have introduced a new system, of the excellence of which the reader will judge from the following correct account taken from authentic documents.

By a decree of the *French National Convention*, passed Oct. 15th, 1793, for the reform of the kalendar, the following regulations were adopted:

1. The French æra commences from the foundation of the republic, which took place on the 22d of Sept. 1792, of the vulgar æra, the day on which the sun arrived at the true autumnal equinox, entering the sign of the balance 9 hours 18 minutes 30 seconds A. M. for the observatory of Paris.
2. The vulgar æra is abolished for civil purposes.
3. The commencement of each year is fixed at midnight, the beginning of that day in which falls the true autumnal equinox for the observatory of Paris.
4. The year is divided into twelve equal months, of thirty days each, after which five supplementary days are added to complete the 365 days of the ordinary year. These five days do not belong to any month.
5. Each month is divided into three decades, of ten days each; distinguished by first, second, and third.
6. The twelve months, the five supplementary days, and the ten days of the decade, shall be named *ordinally*—the first, second, third month, &c. the first, second, third supplementary day; the first, second, third day of the first, second, third decade. Nevertheless, when speaking of a very late period, we may say the fifteenth or twenty-fifth day of the first, second, or third month, of the year, &c.
7. The years which shall receive an intercalary day as the position of the equinox shall require, now called Bissextile, or Embolismic, are named Olympic. The period of four years, ending with an Olympic year, is called an Olympiade.
8. The intercalary day of the Olympic year shall always be placed after the five supplementary days; it shall be called the day of the Revolution.
9. The day from midnight to midnight is divided into ten parts, each part into ten others, and so on to the least measurable portion of time.
10. The second year of the republic commenced, according to the old calendar, on the 22d of September, 1793, at mid-

night, the true autumnal equinox falling, for the observatory of Paris, 9 hours 7 minutes 19 seconds A. M.

The 6th and 8th articles underwent some alteration in consequence of a report made by *Fabre d'Églantine*, one of the Deputies of Paris to the Convention.

“ The commission you have named (says he) to render the new kalendar more sensible to the thought, and more accessible to the memory, have accordingly conceived they should attain this end, if they could succeed in striking the imagination by denominations, and in instructing by nature and a series of images.

“ The first idea which has served us as a basis, is to consecrate, by this kalendar, the agricultural system, and to lead the nation towards it by marking the epochs and fractions of the year by signs either intelligible or visible, drawn from agriculture and rural economy.

“ The more stations and points of support are presented to the memory, the greater is the facility with which it acts. We have accordingly contrived to give to each of the months of the year a characteristic name, which may express the temperature that is proper to it, and the kind of productions of the earth then existing, and which may indicate at the same time the nature of the season in which it is stationed, among the four that compose the year.

“ This last effect is produced by four appropriate terminations, each for three succeeding months, and producing four sounds, each of them pointing out to the ear the season to which it is applied.

“ We have even endeavoured to profit by the imitative harmony of the language, in the composition and prosody of these words, and in the mechanism of their terminations, insomuch that the names of the months which compose the autumn have a grave sound and a medium measure, those of winter a heavy sound and a long measure, those of spring a sprightly sound and a short measure, and those of summer a sonorous expression and a large measure.

“ Thus the first three months of the year of which the autumn is composed, take their etymology, the first from the vintage, which takes place from September to October: this month is named *Vendémiaire*. The second, from the mists and low fogs, which are the transudation (if I may so express myself) of nature from October to November: this month is named *Brumaire*. The third, from the cold, sometimes dry and sometimes moist, which is felt from November to December: this month is named *Frimaire*.

“ The three winter months take their etymology, the first from the snow, which whitens the earth from December to January: this month is named *Nivose*. The second from the rains, which usually fall in greater abundance from January to February: this month is called *Pluviose*. The third from the transient showers which descend, and the wind which dries the earth, from February to March: this month is named *Ventose*.

“ The three spring months take their etymology, the first from the fermentation and development of the sap from March to April: this month is called *Germinal*. The second from the blowing of the flowers, from April to May, is named *Floreale*. And the third from the smiling fecundity of the meadow crops from May to June: this month is called *Prairial*.

“ Lastly, the three summer months take their etymology, the first from the appearance of the waving ears of corn and the golden harvests which cover the fields from June to July: this month is named *Messidor*. The second from the heat, at once solar and terrestrial, which inflames the air from July to August: this month is called *Thermidor*. The third from the fruits gilt and ripened by the sun from August to September: this month is named *Fructidor*.

AUTUMN.	WINTER.	SPRING.	SUMMER.
<i>Vendémiaire.</i>	<i>Nivose.</i>	<i>Germinal.</i>	<i>Messidor.</i>
<i>Brumaire.</i>	<i>Pluviose.</i>	<i>Floreale.</i>	<i>Thermidor.</i>
<i>Frimaire.</i>	<i>Ventose.</i>	<i>Prairial.</i>	<i>Fructidor.</i>

“ From these denominations, as I have already observed, it follows, that by the mere pronunciation of the names of the month every one will readily perceive three things and all their relations, namely, the kind of season, the temperature, and state of vegetation. 'Tis thus that, with relation to *Germinal*, his imagination will conceive, without any effort, by the termination of the word, that the spring commences; by the construction of the word, that the elementary agents are busied; and by the signification of the word, that the buds unfold themselves.

“ After the denominations of the months, we engaged in their divisions. We perceived that the divisions of the months being periodical, and recurring three times in each month, and thirty-six times in the year, were already very well entitled decades, or revolutions of ten days; and that this generical word agreed with a thing which, being thirty-six times repeated, could not, without leading to confusion, be represented to the ear by local images. Besides, decades being merely numerical fractions, should have, through the whole course of the year, but one common and numerical denomination: the name of the month is sufficient to give to each period of the three decades the colour of the images and accidents of the months in which they are comprehended.

“ As to the days, we observed that they have four complex movements, which should be impressed very distinctly on our memory, and should be present to the thought in four different ways. These four movements consist—of the diurnal movement, or the passage from one day to another—of the *decadatory* movement, or the passage from one decade to another—the monthly movement, or the passage from one month to another—and the annual movement, or the solar period.

“ The defect of the kalendar, such as you have decreed it, consists in its expressing the days, decades, months, and years, by the same denomination, by common numbers, insomuch that the figure 1, which presents merely an abstract quantity, and no image, applies equally to the year, the month, the decade and the day; insomuch that it is necessary to say—the first day of the first decade of the first month of the first year—a mode of expression abstract, dry, destitute of ideas, painful through its prolixity, and confused in civil use, more especially after the habit of the Gregorian kalendar.

“ It was our opinion, that, in imitation of the Gregorian kalendar, of which the seven days of the week bear the stamp of judicial astrology (a ridiculous prejudice it is necessary to reject), we ought to create names for each of the ten days of the decade. It also struck us that, since these names were to be repeated, each thirty-six times in the course of the year, it was expedient to deprive them of images, which, being local in their very essence, could have no relation to the thirty-six stations of each of these names. We perceived, finally, that it would be a great prop to the memory, if we were to succeed in distinguishing the names of the day of the decade from common numbers, preserving, nevertheless, the signification of these numbers in a compound word, so that we might, in the same word, profit at once by the numbers, and by a name differing from the numbers. Thus, to express the ten days of the decade, we say, *Primidi—Duodi—Tridi—Quartidi—Quintidi—Sextidi—Septidi—Octidi—Nonidi—Decadi*.

“ In this way, the difference between *Primidi* and *Duodi* expresses the passage from the first to the second day of the decade. This is the first movement of the days. The common numbers, from one to thirty, express the third, the monthly movement. The combination of these common numbers with the

names *Primidi, Duodi, &c.* expresses the second or decadatory movement. Thus the eleventh day of the month, and *Primidi*, will furnish the idea of the first day of the second decade, and so on of the rest.

“The very sensible advantage which will be drawn from the preservation of the common numbers in the compounded words *Primidi, Duodi, Tridi, &c.* is, that the day of the month will be constantly present to the recollection, without the necessity of recurring to the material calendar. For example, it is sufficient to know that the present day is *Tridi*, to be certain that it is also either the third, the thirteenth, or twenty-third day of the month; that it is *Quartidi*, to be satisfied that it is either the fourth, fourteenth, or twenty-fourth; and so on.

“We always know pretty nearly whether the month is at its commencement, its middle, or its end. Thus will it be said, *Tridi* is the third day at the commencement of the month, the thirteenth at its middle, the twenty-third at its close. Now this very simple calculation could not be effected, if the common numbers, which are here the denominators of the day, did not enter into the composition of the names of the days of the decade.”

In expressing the fourth or *annual* movement, the reporter recurs to his fundamental idea, and endeavours to draw from agriculture something on which the memory may repose, and which, in the reckoning and progress of the year, may convey useful instruction. The new French calendar, in consequence, arranges in the column of each month, the names of seeds, pasturages, trees, roots, flowers, fruits, and plants, which are so disposed that the place and the proportion occupied by each production, are precisely the time and the day when nature presents them to mankind.

At each *Quintidi*, that is to say, at each half decade, the fifth, fifteenth, and twenty-fifth days of each month, is inscribed a domestic animal: and betwixt the date of this inscription and the true utility of the animal inscribed there is a precise agreement.

Each termination of the decade, each *Decadi*, is marked with the name of an agricultural instrument, the same the labourer employs at the precise time at which it is placed; inasmuch that he will find, by opposition, on the day consecrated in the calendar, the instruments he is to take up on the morrow.

There is one month in which the earth is sealed up, and usually covered with snow: this is the month *Nivose*, the time of the earth's repose. Not being able to find on its surface, during this period, any vegetable or agricultural production that can be expressed, the productions, the substances of the animal and mineral kingdoms absolutely and immediately useful to agriculture are substituted.

It remains to speak of the days which were at first named *epagomines*, afterwards *complementary*, and since *sansculotides*. The word *complementary*, according to our conception, being merely didactic, and consequently dull and mute to the imagination, would present to the people nothing but a cold idea which they themselves commonly render by the paraphrase of *balance* of account, or by the barbarism of *definition*. “It has struck us,” says the reporter, “that these five days would need a collective denomination bearing the stamp of rationality, and capable of expressing at once the cheerfulness and the genius of the nation, during the five days of the festival to be celebrated at the termination of each year.

“Our ancestors, the Gauls, from the remotest antiquity, conceived themselves honoured by their national appellation. History informs us that a part of Gaul, afterwards called *Lyonnoise*, the country of the Lyonnois, was entitled *Gallia braccata, breeched Gaul*. Consequently the rest of Gaul, as far as the banks of the Rhine, was *Gallia non braccata, unbreeched Gaul*:

our forefathers were therefore *sans-culottes*. Whether the origin of the denomination be ancient or modern, as liberty has rendered it illustrious, so should it be dear to us: this is sufficient to give it a solemn consecration. We shall accordingly call the five days, collectively taken, the *Sansculotides*.

“The five *Sansculotide* days, composing a half decade, are to be denominated *Primidi, Duodi, Tridi, Quartidi, and Quintidi*: and, in the bissextile year, the sixth day *Sextidi*. On the following day the new year commences by *Primidi* the first of *Vendémiaire*.”

Five public festivals are to be held on the *Sansculotides*; and every fourth year, at the end of the bissextile year, on the sextide, or sixth day of the *Sansculotides*, national sports are to be celebrated. This epoch of one day is by way of distinction styled *The Sansculotide*; a title reckoned the most analogous to the assemblages of different portions of the French people from every part of the Republic, to celebrate liberty and equality at this epoch.

The following specimen will convey a more perfect idea of the new calendar, and of the contrast it forms with the old one:

	JANVIER.	NIVOSE; IV mois.
Nouv. Lune le 1 à 11 h 57 m. du soir.	1 merc. <i>La Circoncision</i>	duodi . 12 Thérébentine
	2 jeudi; f. Macaire	tridi . 13 Argile

		duodi . 12 Brocoli.

Construction of a KALENDAR, or Almanac. 1. Compute the sun's and moon's place for each day of the year; or take them from ephemerides. 2. Find the dominical letter, and by means thereof distribute the kalendar into weeks. 3. Compute the time of Easter, and thence fix the other moveable feasts. 4. Add the immoveable feasts, with the names of the martyrs. 5. To every day add the sun's and moon's place, with the rising and setting of each luminary; the length of day and night; the crepuscula, and the aspects of the planets. 6. Add in the proper places the chief phases of the moon, and the sun's entrance into the cardinal-points; i. e. the solstices and equinoxes; together with the rising and the setting, especially heliacal, of the planets and chief fixed stars. See ASTRONOMY.

The duration of the crepuscula, or the end of the evening and beginning of the morning twilight, together with the sun's rising and setting; and the length of days, may be transferred from the kalendars of one year into those of another; the differences in the several years being too small to be of any consideration in civil life. Hence it appears, that the construction of a kalendar has nothing in it of mystery or difficulty, if tables of the heavenly motions be at hand.

Some divide kalendars or almanacs into *public* and *private*, *perfect* and *imperfect*; others into *Heathen* and *Christian*.

Public ones are those of a larger size; more commonly called *street-almanacs*, usually hung up for common or family use; private are those of a smaller kind, bound up to be carried about in the pocket. Perfect, are those which have the dominical letters as well as primes and feasts inscribed on them; imperfect, those which have only the primes and immoveable feasts. Till about the fourth century, they all carry the marks of heathenism; from that age to the seventh, they are generally divided between heathenism and christianity.

Almanacs are of somewhat different composition, some containing more points, others fewer. The essential part is the kalendar of months and days, with the rising and setting of the sun, age of the moon, &c. To these are added various parerga, astronomical, astrological, meteorological, chronological, and even political, rural, medical, &c. as calculations, and accounts of eclipses, solar ingresses, aspects, and configurations of the heavenly bodies, lunations, heliocentric and geocentric motions of the planets, prognostics of the weather, and predictions of other events, tables of the planetary motions, the tides, terms, interest, twilight, equation, kings, &c.

Gelalcan or *Jellalcan* KALENDAR is a correction of the Persian kalendar, made by order of sultan Gelaledan, in the 467th year of the Hegira; of Christ 1089.

KALENDAR is also applied to various other compositions respecting the 12 months of the year. In this sense, Spencer has given the shepherd's kalendar; Evelyn and Miller the gardener's kalendar, &c.

KALENDAR is used for the catalogue or fasti anciently kept in each church of the saints both universal and those particularly honoured in each church; with their bishops, martyrs, &c. Kalendars are not to be confounded with martyrologies, for each church had its peculiar kalendar; whereas the martyrologies regarded the whole church in general, containing the martyrs and confessors of all the churches. From all the several kalendars were formed one martyrology: so that martyrologies are posterior to kalendars.

KALENDAR is also extended to an orderly table or enumeration of persons or things. Lord Bacon wishes for a kalendar of doubts. A late writer has given a kalendar of the persons who may inherit estates in fee-simple.

KALENDAR, *Kalendariun*, originally denoted, among the Romans, a book containing an account of moneys at interest, which became due on the kalends of January, the usual time when the Roman usurers lent out their money.

KALENDAR *Months*, the solar months, as they stand in the kalendar, viz. January 31 days, &c.

Astronomical KALENDAR, an instrument engraved upon copper-plates, printed on paper, and passed on-board, with a brass slider which carries a hair, and shows by inspection the sun's meridian altitude, right ascension, declination; rising, setting, amplitude, &c. to a greater exactness than our common globes will show.

KALENDAR *of Prisoners*. See CALENDAR.

KALENDAR *Brothers*, a sort of devout fraternities, composed of ecclesiastics as well as laymen; whose chief business was to procure masses to be said, and alms distributed, for the souls of such members as were deceased. They were also denominated

kalend-brothers, because they usually met on the kalends of each month, though in some places only once a quarter.

KALENDARILUM-FESTUM. The Christians retained much of the ceremony and wantonness of the kalends of January, which for many ages was held a feast, and celebrated by the clergy with great indecencies, under the names *festum kalendarum*; or *hypodidaxonarum*; or *stultorum*, that is, "the feast of fools," sometimes also *libertas decembria*. The people met masked in the church; and in a ludicrous way proceeded to the election of a mock pope, or bishop, who exercised a jurisdiction over them; suitable to the festivity of the occasion. Fathers, councils; and popes, long laboured to restrain this licence, to little purpose. We find the feast of the kalends in use as low as the close of the 15th century.

KALENDERS. See CALENDERS.

KALENDUS; or CALENDUS, in the Roman chronology, the first day of every month. The word is formed from *καλεω*, *I call*, or *proclaim*; because, before the publication of the Roman fasti, it was one of the offices of the pontifices to watch the appearance of the new moon, and give notice thereof to the *rex sacrficulus*; upon which a sacrifice being offered, the pontiff summoned the people together in the Capitol, and there with a loud voice proclaimed the number of kalends, or the day whereon the nones would be; which he did by repeating this formula as often as there were days of kalends, *Celo Juno Novella*. Whence the name *calendæ* was given thereto, from *calo*, *calare*. This is the account given by Varro. Others derive the appellation hence, that the people being convened on this day, the pontifex called or proclaimed the several feasts or holidays in the month; a custom which continued no longer than the year of Rome 450, when C. Flavius, the curule ædile, ordered the fasti or kalendar to be set up in public places, that every body might know the difference of times, and the return of the festivals.

The kalends were reckoned backwards, or in a retrograde order. Thus, v. g. the first of May being the kalends of May; the last or the 30th of April was the *pridie kalendarum*, or second of the kalends of May; the 29th of April, the third of the kalends; or before the kalends: and so back to the 13th, where the ides commence; which are likewise numbered invertedly to the fifth, where the nones begin; which are numbered after the same manner to the first day of the month, which is the kalends of April. See IDES, and NONES. The rules of computation by kalends are included in the following verses:

Prima dies mensis cuiusque est dicta kalendæ:

Sæx Maius nonas, October, Julius, & Mars;

Quatuor at reliquis habet idus quilibet octo.

Inde dies reliquos omnes dic esse kalendas;

Quas retro numerans dicis a mense sequente.

To find the day of the kalends answering to any day of the month we are in, see how many days there are yet remaining of the month, and to that number add two: for example, suppose it the 22d day of April; it is then the 10th of the kalends of May. For April contains 30 days: and 22 taken from 30, there remain 8; to which two being added, the sum is 10. The reason of adding two is, because the last day of the month is called *secundo kalendas*, the last but one *tertio kalendas*; &c. The Roman writers themselves are at a loss for the reason of this absurd and whimsical manner of computing the days of the month: yet it is still kept up in the Roman chancery: and by some authors, out of a vain affectation of learning, preferred to the common, more natural, and easy manner.

KALENDUS are also used in church-history to denote conferences anciently held by the clergy of each deanry, on the first day of every month, concerning their duty and conduct, especially in what related to the imposition of penance.

KALENDS of January, in Roman antiquity, was a solemn festival consecrated to Juno and Janus; wherein the Romans offered vows and sacrifices to those deities; and exchanged presents among themselves as a token of friendship. It was only a melancholy day to debtors, who were then obliged to pay their interests, &c. Hence Horace calls it *triples kalendæ*; lib. i. Serm. sat. 3.

KALI, in botany. See **SALSOLA**.

KALISCH, a palatinate of Poland, bounded on the W. by the palatinate of Polesia, on the E. by that of Syrad, on the N. by Western Prussia, and on the S. by Silesia. This province was forcibly seized by the king of Prussia in 1793.

KALISCH, a town of Poland, capital of a palatinate of the same name, where the Jesuits had a magnificent college. It is seated on the river Prozna, in a morass, which renders it difficult of access, 110 miles W. of Warsaw. E. lon. 18. 5. N. lat. 52. 0.

KALMIA, in botany; a genus of the monogynia order, belonging to the decandria class of plants; and in the natural method ranking under the 18th order, *Bicornes*. The calyx is quinquepartite; the corolla salver shaped, formed with five nectariferous horns on the under or outer side; the capsule quinquelocular. Of this genus there are two species, viz.

1. The *latifolia*, a most beautiful shrub, which rises usually to the height of five or six feet, and sometimes twice that height in its native places. The stems of some are as big as the small of a man's leg, though generally they are smaller, and covered with a brown rough bark. The wood is very close-grained, heavy, and hard like box. The limbs in general are crooked, and grow irregular; but are thick-clothed with stiff smooth leaves of a shining bright green. The flowers grow in bunches on the tops of the branches to foot-stalks three inches long: they are white stained with purplish red, consisting of one leaf in form of a cup divided at the verge into five sections: in the middle is a stylus and 12 stamina; which, when the flower first opens, appear lying close to the sides of the cup at equal distances, their apices being lodged in ten little hollow cells, which, being prominent on the outside, appear as so many little tubercles. The flowers are succeeded by small round capsules; which, when ripe, open in five parts, and discharge their small dust-like seeds. This plant is a native of Carolina, Virginia, and other parts of the northern continent of America; yet are not common, but found only in particular places; they grow on rocks hanging over rivulets and running streams, and on the sides of barren hills. They blossom in May, and continue in flower the greatest part of the summer. The noxious qualities of this elegant plant lessen that esteem which its beauty claims; for, although deer feed on its green leaves with impunity, yet when cattle and sheep, by severe winters deprived of better food, feed on the leaves of these plants, a great many of them die annually.

2. The *angustifolia*, rises to the height of about 16 feet, producing ever green leaves in shape like the lauro-cerasus, but small, and of a shining dark green. The flowers grow in clusters, the buds of which appear in autumn wrapped up in a conic scaly perianthium, on which is lodged a viscous matter, which protects them from the severe cold in winter. These buds dilating in the following spring, break forth into twenty or more monopetalous flowers divided into five segments, and set singly on pedicles half an inch long. These flowers, when blown, appear white; but, on a near view, are of a faint blueish colour, which as the flower decays grows paler. One of the five petals is longer and more concave than the rest, and is blended with purple, green, and yellow specks, being a viscous matter on the extremities of very fine hairs. The convex side of the same petal is also speckled with yellowish green. The pointal rises from the centre of the flower, and has its head adorned with

scarlet, and surrounded by 10 stamina, whereof three are long and seven short, whose farina issues out at a small round hole at its top. This elegant tree adorns the western and remote parts of Pennsylvania, always growing in the most sterile soil, or on the rocky declivities of hills and river-banks, in shady moist places.

KALMUCS, a tribe of Tartars called also *Eutbs*, inhabiting the larger half of what the Europeans call *Western Tartary*. Their territory extends from the Caspian sea, and the river Yaik or Ural, in 72 degrees of longitude from Ferro, to mount Altay, in 110 degrees, and from the 40th to the 52d degree of north latitude: whence it may be computed about 19,50 miles in length from west to east, and in breadth from north to south about 650 miles where broadest. It is bounded on the north by Russia and Siberia, from which it is separated by a chain of mountains; on the east by mount Altay; on the south by the countries of Karazm and the two Bukharias, from which it is also separated partly by a chain of mountains and partly by some rivers. See **TARTARY**.

Of the Kalmuc Tartars the following curious account is given by professor Pallas: They are in general, says he, of a middle size, and it is even rare to see among them a person that is tall; the women especially are of low stature, and have very agreeable features. Their limbs are neatly turned, and very few have any defects contrasted in infancy. Their education, being left solely to nature, procures for them a well-formed body and sound constitution. The only defect which is common among them is their having the thighs and legs somewhat bent. A fat person is hardly ever to be met with; the richest and most distinguished, though they lead a life sufficiently indolent, and enjoy abundance of every thing they desire, are never excessively corpulent. Their skin is pretty fair, especially when young; but it is the custom of the lower sort to allow their male children to go quite naked both in the heat of the sun and in the smoky atmosphere of their felt huts: the men too sleep naked, covered only with their drawers; and from these circumstances they acquire that yellowish-brown colour which characterises them. The women, on the contrary, have a very delicate complexion; among those of a certain rank are found some with the most beautiful faces, the whiteness of which is set off by the fine black of their hair; and in this as well as in their features they perfectly resemble the figures in Chinese paintings.

The physiognomy which distinguishes the Kalmucs is pretty generally known. Strangers are made to believe that it is frightfully deformed; and though indeed there are very ugly men to be found, yet in general their countenance has an openness in it that bespeaks a mild, a frank, and social disposition. In many it is of a roundish shape, and exceedingly agreeable; among the women some would be thought beauties even in those European cities where the taste is most scrupulous. The characteristic features of a Kalmuc or Mongol countenance are the following; The interior angle of the eye is placed obliquely downwards towards the nose, and is acute and fleshy; the eye-brows are black, narrow, and much arched; the nose is of a structure quite singular, being generally flat and broken towards the forehead; the cheek-bone is high, the head and face very round; the eye is dark, the lips thick and fleshy, the chin short, and the teeth exceedingly white, continuing so to old age; the ears are of an enormous size, standing out from the head. These characters are more or less visible in each individual; but the person that possesses them all in the highest degree is considered as the most beautifully formed.

Amongst all the Mongul nations, the men have much less beard than in our European countries, and among the Tartars it appears much later. The Kalmucs have most of it; and yet even with them the beard is very scanty and thin, and few have much hair on any other part of the body.

People that lead a pastoral life enjoy the bodily senses in

the greatest perfection. The Kalmucs find the subtilty of their sense of smell very useful in their military expeditions, for by it they perceive at a distance the smoke of a fire or the smell of a camp. There are many of them who can tell by applying the nose to the hole of a fox, or any other quadruped, if the animal be within or not. They hear at a great distance the trampling of horses, the noise of an enemy, of a flock of sheep, or even of strayed cattle; they have only to stretch themselves on the ground, and to apply their ear close to the turf. But nothing is more astonishing than the acuteness of sight in most of the Kalmucs, and the extraordinary distance at which they often perceive very minute objects, such as the dust raised by cattle or horses, and this from places very little elevated in immense level deserts; though the particular inequalities of the surface, and the vapours which in fine weather are seen to undulate over the soil in great heats, considerably increase the difficulty. They are also accustomed to trace the print of a foot in these deserts by the sight alone.

These people possess many good qualities, which give them a great superiority over the wandering Tartars. A certain natural sagacity, a social disposition, hospitality, eagerness to oblige, fidelity to their chiefs, much curiosity, and a certain vivacity accompanied with good humour, which hardly ever forsakes even the most wretched among them, form the fair side of their character. On the other hand, they are careless, superficial, and want true courage; besides, they are remarkable for credulity, distrust, and a natural inclination, authorized by custom, for drunkenness and debauchery, but especially for a great degree of cunning, which they too often practise. The disposition to indolence is common and natural, especially among the men, to all Asiatic nations, who lead a kind of life exempt from subjection and devoid of activity; but this is less to be perceived among the Kalmucs, on account of their natural vivacity, and does not prevent their endeavours to oblige. Those among them who exercise any little trade, or who are reduced by poverty to hire themselves to the Russians either for labour or for fishing, are very assiduous and indefatigable. They sleep but little, going to rest late and rising with the sun. To sleep through the day, unless a person is drunk, is considered by them as dishonourable. But their extreme dirtiness can neither be disguised nor justified, and proceeds much more from their education, from the slovenliness attached to the profession of a herdsman, and from levity, than from laziness; for the Kalmuc women are indefatigable in whatever concerns domestic matters: and it is for this reason, as well as on the score of sensuality, that the Kirgisiens are eager to seize and carry them off whenever an opportunity presents itself.

With regard to the intellectual faculties of the Kalmucs, notwithstanding their want of instruction and information, they possess good natural parts, an excellent memory, and a strong desire to learn. They acquire the Russian language with great facility, and pronounce it well; in which last article they very much surpass the Chinese. It would be very easy to civilize them, if their petulance and manner of life did not render it impracticable.

Although the Kalmucs are generally of a sanguine and choleric temperament, they live more amicably together than one could expect in a people that lead so independent a life. They seldom come to blows even over their cups, and their quarrels are hardly ever bloody. A murder very rarely happens, though their anger has something in it exceedingly fierce. It would seem that the morality of their religion, though extremely idolatrous, has been able to moderate their natural disposition in this respect; for, in consequence of their dogmas with regard to the transmigration of souls, every wanton murder either of men or beasts is thought a deadly sin.

The Kalmucs are exceedingly affable; and of so social a

disposition, that it is rare for a traveller to perceive another even at the distance of several miles without going to salute him, and to enquire into the object of his journey. When a troop of Kalmucs perceive any person at a distance, it is customary for them to detach one of their number to the next eminence, from whence he makes a signal with his cap for the person to draw near. If this signal is not obeyed, the person is considered as an enemy or a robber, and is often pursued as such. They enter willingly into friendships: but these connections are not quite disinterested; for to give and to receive presents are with them essential articles. A mere trifle, however, is sufficient to induce them to do you all manner of service; and they are never ungrateful as far as they are able. Adversity cannot deprive them of courage, nor alter their good humour. A Kalmuc will never beg if he were in the extremest misery, but rather endeavour to acquire a subsistence by cheating; and when no other way remains, he will hire himself to some rich individual of his nation, or to some Russian, either as a herdsman, a fisherman, or for any other sort of labour. Very few of the rich value themselves much upon their wealth; but those who do, show no contempt for the poor of their own nation; though the meaner sort pay their court very obsequiously to the rich, who are always surrounded with a swarm of idle dependants.

Nothing can be more prudent than that exercise of hospitality practised by wandering nations: it is of the greatest advantage to those among them who travel across their deserts; and each individual who practises it, may rely on reaping the benefit of it wherever he goes. A Kalmuc provided with a horse, with arms and equipage, may ramble from one place to another for three months together, without taking with him either money or provisions. Wherever he comes he finds either distant relations or friends to whom he is attached by the ties of hospitality, from whom he meets with the kindest reception, and is entertained in the best manner their circumstances afford. Perhaps he lodges in the first unknown cottage he finds upon his road; and scarcely has he entered it, but his wants are supplied with the most affectionate cordiality. Every stranger, of whatsoever nation, never fails to be well received by a Kalmuc; and he may depend upon having his effects in the greatest security the moment he has put himself under the protection of his host: for, to rob a guest, is considered by the Kalmucs as the most abominable of all crimes.

When the master of the house sits down to meat in company with others of inferior rank, he begins indeed by serving himself and his family, but whatever remains is distributed among the assistants. When they smoke tobacco, the pipe circulates incessantly from one to another. When any one receives a present either of meat or drink, he divides it faithfully with his companions, even though of inferior rank. But they are much more niggardly of their other effects, and especially of their cattle, and do not willingly give these away except when they hope to receive a suitable return: or if any relation has accidentally suffered the loss of his flocks, he is sure to be most willingly assisted: Perhaps too it may be related as an evidence of their hospitality, that they abandon their wives to their friends with the greatest facility, and in general they are very little inclined to jealousy.

Their robberies are never committed upon their equals, and even the greater part of the rapine exercised on other tribes is founded on hatred or national quarrels; neither do they willingly attempt this by open force, but prefer the machinations of cunning, which are so natural to them. It must also be confessed, that it is only those that live with princes, and in camps where these hold their courts, or their priests, that are most addicted to these practices: while the common people, satisfied with the pleasures of the pastoral life, spend their days

in innocent simplicity, and never attack the property of another till forced by necessity, or led by their superiors, who show them the example.

The Kalmucs are very faithful to their lawful prince; they endure every sort of oppression, and yet are with difficulty induced to revolt: but if they belong to a prince who has not become so by right of succession, they very easily rebel. They honour old age. When young men travel with such as are older than themselves, they take upon them the whole care of the cattle as well as of the feast. They are exceedingly prudent in matters that relate to their sovereign or their nation, or which are recommended to their direction by the priests, to whom they yield an unreserved obedience.

The moveable habitations of the Kalmucs are those felt huts with a conical roof in use among all the roaming Asiatics. The truly ingenious invention of these tents was undoubtedly conceived in the eastern parts of Asia, and most probably by the Mongul nations. As they can be entirely taken to pieces and folded in a small compass, they are very useful, and perfectly agree with the migratory life of these people, who are still ignorant of the use of carriages. The frame of these huts, and the felt they are covered with, though made as light as possible, yet are a sufficient load for a camel or two oxen. But the capacity of these huts, their warmth in winter, their strength in resisting tempests and excluding rain, abundantly compensate for this inconvenience. The wood endures many years; and though the felt begins to break into holes in the second year, the common people, who do not consider it as disgraceful to have them mended and patched, make them serve a good deal longer. The huts are in general use from the prince down to the meanest Kalmuc, differing only in size and in the embellishments within. In winter, they are warm even when heated with the dried excrements of their cattle, to which they are often obliged to have recourse for want of other combustibles in many places of the deserts which are destitute of wood. In summer they remove the felt to enjoy the fresh air.

The master of the tent has his bed placed opposite the door behind the fire-place. The bedsteads are low, and made of wood. The rich adorn their beds with curtains, and spread carpets of felt upon the ground. When a Kalmuc possesses an idol, he places it near the head of his bed, and sets before it several small consecrated cups full of water, milk, or other food. Before this sort of altar he fixes in the ground the trunk of a tree, on which he places a large iron basin destined to receive the libations of all the drink he makes use of in a day. On festivals the idol is decorated, the lamps are lighted, and perfumes burnt before it.

The riches of the Kalmucs, and their whole means of subsistence, depend on their flocks, which many of them reckon by hundreds and even by thousands. A man is thought capable of living on his possessions when he is master of ten cows with a bull, eight mares with a stallion. The animals they have in greatest abundance are horses, horned cattle, and sheep. Camels, which it requires time and pains to rear, cannot multiply much with them: they are besides too delicate; and it is only the rich or the priests who possess any of them. Their horses are but small, too weak for the draught, and too wild: but they do not yield to any in swiftness, and support with ease the weight of a man. They may be made to gallop for several hours successively without injury; and when necessity requires it, they can pass twice 24 hours without drinking. They have a little loof, but very hard; and they may be used at all times without being shod. In this country the horses live and perpetuate themselves without any assistance from man. The Kalmucs castrate the greater part of their male foals, and at the same time slit their nostrils, that they may breathe

more freely when they run. The stallions are never separated from the mares, that there may always be plenty of milk. The stallions are leaders of the herd, and often wander at a distance into the deserts at the head of their females, defending them from the wolves with the greatest intrepidity. The Kalmucs have the art of breaking a young horse without using a bridle. They seize him before he is two years old, by means of a noose fixed to the end of a long pole; an instrument they use in taking their riding-horses, which feed in the midst of the herd. They put no saddle at first on the colt they mean to break, but tie a strait girth round his body; by the help of which the horseman can keep himself firm. When he is mounted, the horse is abandoned to his fury; they allow him to run and agitate himself as much as he pleases in the open plain till he is fatigued. The horseman is solicitous only to keep himself fast; and when the horse begins to abate of his impetuosity, he urges him again with the whip till his strength is almost gone: he is then saddled and bridled, and made to go for some time at a moderate pace; after which he is entirely tamed.

The horned cattle of the Kalmucs are of a beautiful shape. They keep more bulls than are necessary for the cows, and employ a great number of them as beasts of burden for carrying their houses and their other furniture from place to place. They think a bull equal to 50 cows. These and the mares give milk only while they suckle their calves or their foals, which are accordingly kept close to the tents during the day, and only suffered to suck freely during the night; a practice which the Kalmucs pretend makes their cattle stronger and more durable. They generally milk their mares three or four times a day, and sometimes every two hours when the herbage is abundant. The cows are milked but twice a day.

The Kalmuc sheep are of the same species with those found in all Great Tartary, having large tails like a bag, exceedingly fat, and which furnish a suet as soft as butter. They have also large pendent ears, and their head is much arched. Their wool is coarse, and the ewes seldom have horns. One ram is sufficient for an hundred ewes. Little use is made of the milk. The wool is fit for nothing but to make felt for the tents. A great many sheep die during winter, and a greater number still of the early lambs; the skins of which are wrought into those fine furs so much esteemed in Russia and foreign parts.

Camels belong only to the rich; for they are very dear, multiply very slowly, and are subject to many diseases. The deserts of the Wolga, and almost all those of the southern parts of Great Tartary, furnish excellent pasture for these animals; but they require not only much attention in winter, but they must be continually under the eye of the herdsmen; for, notwithstanding the advantage of their stature, they are of all animals least able to defend themselves against the wolf. They are guarded with much care against the violence of the cold and the winds of winter; nevertheless many of them die of a consumption accompanied with a diarrhoea, occasioned most probably by the moisture of their pasture and of the season. This disease, for which no remedy has been found, makes them languish for six months or more. They are in general so delicate, that a slight wound or blow often proves fatal to them. Besides, no animal is so much tormented with insects; and they often die in summer of those they swallow in eating the leaves of the oak and of the birch. The *maloe profcarabzus*, which covers all the plants in many of those places where they feed, is generally fatal to them. In spring, when they cast their hair, and which falls at once from every part of their body, they are exposed to the bite of the spider-scorpion, an animal very common in southern countries. The wound inflicted by this insect on the skin thus naked is so venomous, that the camel dies of it in less than eight days, sometimes in three. In winter, and especially after rutting-time, which happens at

the end of March, the camels become lean and weak; the bunch upon their back grows flabby, and hangs down upon the side, nor does it recover its plumpness till summer.

Camels-milk is thick, unctuous, and of a saltish taste, especially when the animals frequent pastures abounding with saline plants; and this last property makes the Kalmucs fond of it to tea. They make use of the hair for stuffing cushions, and for making ropes, packthread, and felt. It may be wrought into the most beautiful camlets, or into the finest and softest cloths. The camels with two bunches are a very uneasy seat to the person who mounts them; their trot is so heavy, and even their walk so rude, that he receives the most violent shocks at every step.

When a Kalmuc horde intends to remove in search of fresh pasture, which in summer necessarily happens every four, six, or eight days, people are in the first place dispatched to reconnoitre the best place for the khan or prince, for the lama, and for the huts containing the idols. These begin the march, and are followed by the whole troop, each choosing for himself the place he thinks most convenient. The camel that is loaded with the most precious furniture is decorated with little bells; the rest march in a string one behind another, and the bulls with burdens are driven on before. On these days the women and girls dress themselves in their best clothes, and lay on abundance of paint. They have the charge, together with the boys, of leading the flocks and the beasts of burden; and on the road they beguile the tediousness of the journey with their songs.

The Kalmucs are supplied by their flocks with milk, cheese, butter, and flesh, which are the principal articles of their food. With regard to the last, they are so little squeamish, that they not only eat the flesh of their own diseased cattle, but that of almost every sort of wild beast; and the poor will even feed upon carrion. They eat, however, the roots and stalks of many plants; such as the bulbous-rooted chervil and dandelion, &c. which they use both boiled and raw.

Their ordinary drink is the milk of mares or cows; but the former is for several reasons preferred. This, when fresh, has indeed a very disagreeable taste of garlic: but beside that it is much thinner than cow-milk, it takes as it grows four a very agreeable vinous flavour; it yields neither cream nor curd, but furnishes a very wholesome refreshing beverage, which sensibly inebriates when taken to excess. They never make use of new milk, and still less of milk or of water that has not been boiled. Their milk is boiled as soon as it is taken from the animal; when it is cold, it is poured into a large leathern bag, in which there remains as much of the old milk as is sufficient to turn the new quantity sour, for they never think of cleansing those bags; and as the inside is lined with a crust deposited by the caseous part of the milk and other impurities, it is easy to imagine that a nauseous smell must exhale from them. But this is precisely the circumstance in which the secret consists of communicating to the milk a vinous fermentation.

In summer, and as often as the Kalmucs procure much milk from their flocks, they never fail to intoxicate themselves continually with the spirituous liquor which they know how to distil from it. Mares-milk is the most spirituous; and the quantity meant to be distilled remains twenty-four hours in summer, and three or four days in winter, in those corrupted bags we mentioned, to prepare it for the operation. The cream is left, but the butter which forms at top is taken off and reserved for other purposes. Cows-milk yields one-thirtieth part, and mares-milk one fiftieth part of spirit. This liquor is limpid and very watery, and consequently does not take fire, but is capable of being long kept in glass-bottles. The rich Kalmucs increase its strength by a second distillation.

These people are exceedingly fond of tea and tobacco. The

former is so dear, as it comes to them from China by the way of Russia, that the poor people supply its place with various wild plants; such as a species of liquorice, the seed of the sharp-leaved dock, the roots of wild angelica, and the seed of the Tartarian maple.

The Kalmucs are excellent horsemen. Their arms are lances, bows and arrows, poniards, and crooked sabres, though the rich have fire-arms. They wear, when at war, coats of mail, which cost 50 horses, and their helmets are gilded at top. They are fond of falconry, and hunting of all sorts is their principal amusement. Their passion for play, especially with those who play cards, is carried to as great excess among them as in any other nation.

The greater part of their time is spent in diversions; and however miserable their manner of life may seem to us, they are perfectly happy with it. They cannot endure for any time the air of a close room; and think our custom of living in houses insupportable. The greatest part of them, notwithstanding the apparent unhealthiness of their way of life, arrive at a vigorous old age; their diseases are neither frequent nor dangerous. Men of 80 or 100 years old are not uncommon; and at that age they can still very well endure the exercise of riding. Simple food, the free air which they constantly breathe, a hardy vigorous constitution, continual exercise without severe labour, and a mind free from care, are the natural causes of their health and longevity.

It is very remarkable, that a migratory people, whose manner of life seems so congruous to the natural liberty of mankind, should have been subjected from time immemorial to the unlimited authority of an absolute sovereign. The Monguls of Asia afford the only instance of it; for neither written records nor ancient tradition have preserved the smallest trace of their ever having enjoyed a state of independence. On the contrary, they acknowledge that they have at all times been subject to khans and princes, whose authority has been transmitted to them by succession, and is considered as a right perfectly established, sacred, and divine.

KALNICK, a strong town of Poland, in the palatinate of Bracklaw. E. lon. 29. 18. N. lat. 48. 57.

KALO, or **KALOO**, a town of Upper Hungary, seated in a lake, 22 miles S. E. of Tockay. E. lon. 21. 54. N. lat. 47. 56.

KALUGA, a government of the Russian empire, formerly a province in the government of Moscow. It contains 12 districts, and its principal town, of the same name, is seated on the river Occa.

KAMAKURA, a famous island of Japan, about three miles in circumference, lying on the south coast of Nippon. It is here they confine their great men when they have committed any fault. The coast of this island is so steep, that they are forced to be lifted up by cranes.

KAMBALA MOUNT, a ridge of mountains in Thibet, between the lake Palte and the river Sanpoo, or Burranpooter. From the top of this ridge may be seen, to the N. a range of still higher mountains, covered with snow. The foot of Mount Kambala is 31 miles S. of Lassa.

KAMEEL, **KAMEL**, or *Camel*, a machine for lifting ships. See **CAMEL**.

KAMINIECK, a very strong town of Poland, capital of Podolia, with a castle and a bishop's see. It was taken by the Turks in 1672, who restored it, in 1690, after the treaty of Carlowitz. When the Russians forcibly seized part of the Polish territories in the beginning of 1793, this fortress held out a long time, but at last surrendered to their arms. The castle is seated on a craggy rock, 85 miles W. of Bracklaw, and 100 S. E. of Lemburg. E. lon. 26. 30. N. lat. 48. 58.

KAMSIN, the name of a hot southerly wind common in

Egypt, of which we find the following description in M. Volncy's Travels.—These winds, says he, are known in Egypt by the general name of *winds of 50 days*; not that they last 50 days without intermission, but because they prevail more frequently in the 50 days preceding and following the equinox. Travellers have mentioned them under the denomination of *poisonous winds*, or, more correctly, *hot winds of the desert*. Such in fact is their quality; and their heat is sometimes so excessive, that it is difficult to form any idea of its violence without having experienced it; but it may be compared to the heat of a large oven at the moment of drawing out the bread. When these winds begin to blow, the atmosphere assumes an alarming aspect. The sky, at other times so clear in this climate, becomes dark and heavy; the sun loses his splendour, and appears of a violet colour; the air is not cloudy, but grey and thick, and is in fact filled with an extremely subtle dust, which penetrates every where. This wind, always light and rapid, is not at first remarkably hot, but it increases in heat in proportion as it continues. All animated bodies soon discover it by the change it produces in them. The lungs, which a too rarefied air no longer expands, are contracted, and become painful. Respiration is short and difficult; the skin parched and dry, and the body consumed by an internal heat. In vain is recourse had to large draughts of water; nothing can restore perspiration. In vain is coolness sought for; all bodies in which it is usual to find it deceive the hand that touches them. Marble, iron, water, notwithstanding the sun no longer appears, are hot. The streets are deserted, and the dead silence of night reigns every where. The inhabitants of towns and villages shut themselves up in their houses, and those of the desert in their tents or in wells dug in the earth, where they wait the termination of this destructive heat. It usually lasts three days, but if it exceeds that time it becomes insupportable. Woe to the traveller whom this wind surprises remote from shelter! He must suffer all its horrible effects, which sometimes are mortal. The danger is most imminent when it blows in squalls; for then the rapidity of the wind increases the heat to such a degree as to cause sudden death. This death is a real suffocation; the lungs being empty are convulsed, the circulation is disordered, and the whole mass of blood driven by the heart towards the head and breast; whence the hæmorrhage at the nose and mouth which happens after death. This wind is especially destructive to persons of a plethoric habit, and those in whom fatigue has destroyed the tone of the muscles and the vessels. The corpse remains a long time warm, swells, turns blue, and soon becomes putrid. These accidents are to be avoided by stopping the nose and mouth with handkerchiefs; an efficacious method likewise is that practised by the camels. On this occasion these animals bury their noses in the sand, and keep them there till the squall is over. Another quality of this wind is its extreme aridity; which is such, that water sprinkled on the floor evaporates in a few minutes. By this extreme dryness it withers and strips all the plants; and by exhaling too suddenly the emanations from animal bodies, crisps the skin, closes the pores, and causes that feverish heat which is the constant effect of suppressed perspiration.

KAMTCHATKA, KAMSCHATKA, or *Kamchatka*; a large peninsula on the north-eastern part of Asia, lying between 51 and 62° of north latitude, and between 173 and 182° of east longitude from the isle of Ferro. It is bounded on the east and south by the sea of Kamtchatka, on the west by the seas of Ochotsk and Penschinsk, and on the north by the country of the Koriaes.

This peninsula was not discovered by the Russians before the end of the last century. It is probable, however, that some of that nation had visited Kamtchatka before the time above mentioned. For when Volodimir Atlassoff entered upon the conquest of this peninsula in 1697, he found that the inhabi-

tants had already some knowledge of the Russians. A common tradition as yet prevails among them, that, long before the expedition of Atlassoff, one Feodotoff and his companions had resided among them, and had intermarried with the natives; and they still show the place where the Russian habitations stood. None of the Russians remained when Atlassoff first visited Kamtchatka. They are said to have been held in great veneration and almost deified by the natives; who at first imagined that no human power could hurt them, until they quarrelled among themselves, and the blood was seen to flow from the wounds which they gave each other; and soon after, upon a separation taking place, they were all killed by the natives.—These Russians were thought to be the remains of a ship's crew who had sailed quite round the north-eastern promontory of Asia called *Tschukutskoi-Nos*. The account we have of this voyage is as follows.—In 1648, seven kotchcs or vessels sailed from the mouth of the river Kovyma or Kolyma, lying in the frozen ocean in about 72° north latitude, and 173° or 174° east longitude from Ferro, in order to penetrate into the eastern ocean. Four of these were never more heard of; the remaining three were commanded by Simon Deshneff, Gerasim Ankudinoff, two chiefs of the Cossacs, and Feodotoff Alexeeff, head of the Promythlenics or wandering Russians, who occasionally visited Siberia. Each vessel was probably manned with about 30 persons. They met with no obstructions from the ice; but Ankudinoff's vessel was wrecked on the promontory above mentioned, and the crew were distributed on board the two remaining vessels. These two soon after lost sight of each other, and never afterwards rejoined. Deshneff was driven about by tempestuous winds till October, when he was shipwrecked on the northern part of Kamtchatka. Here he was informed by a woman of Yakutsk, that Feodotoff and Gerasim had died of the scurvy; that part of the crew had been slain; and that a few had escaped in small vessels, who had never afterwards been heard of; and these were probably the people who, as we have already mentioned, settled among the Kamtchatkans.

As the inhabitants of this country were neither numerous nor warlike, it required no great force to subdue them; and in 1711 the whole peninsula was finally reduced under the dominion of the Russians.—For some years this acquisition was of very little consequence to the crown, excepting the small tribute of furs exacted from the inhabitants. The Russians indeed occasionally hunted in this peninsula foxes, wolves, ermines, sables and other animals, whose skins form an extensive article of commerce among the eastern nations. But the fur-trade carried on from thence was very inconsiderable, until the series of islands mentioned in the next article were discovered; since which time the quantities of furs brought from these islands have greatly increased the trade of Kamtchatka, and rendered it an important part of the Russian commerce.

The face of the country throughout the peninsula is chiefly mountainous. It produces in some parts birch, poplars, alders, willows, underwood, and berries of different sorts. Greens and other vegetables are raised with great facility; such as white cabbage, turnips, radishes, beet-root, carrots, and some cucumbers. Agriculture is in a very low state, owing chiefly to the nature of the soil and the severe hoar frosts: for though some trials have been made with respect to the cultivation of grain, and oats, barley and rye have been sown; yet no crop has ever been procured sufficient in quantity or quality to answer the trouble of raising it. Hemp, however, has of late years been cultivated with great success.—Every year a vessel belonging to the crown sails from Ochotsk to Kamtchatka laden with salt, provisions, corn, and Russian manufactures; and returns in June or July of the following year with skins and furs.

Many traces of volcanoes have been observed in this peninsula; and there are some mountains which are in a burning state at

present. The most considerable of these is situated near the middle of the peninsula. In 1762, a great noise was heard issuing from the inside of that mountain, and flames of fire were seen to burst from different parts. These flames were immediately succeeded by a large stream of melted snow-water, which flowed into the neighbouring valley, and drowned two natives who were there on a hunting party. The ashes and burning matters thrown from the mountain were spread over a surface of 300 versts. In 1767 was another discharge, but less considerable. Every night flames of fire were observed streaming from the mountain; and considerable damage was done by the eruption which attended them. Since that year no flames have been seen; but the mountain emits a constant smoke.

Kamtschatka is divided by the Russians into four districts; and the government of the whole is dependent upon, and subject to, the inspection of the chancery of Ochotsk. The whole Russian force stationed in this peninsula amounts to no more than 300 men. The present population of Kamtschatka is very small, amounting to scarce 4000 souls. Formerly the inhabitants were more numerous; but in 1768 the small-pox carried off 5368 persons. There are now only about 700 males in the whole peninsula who are tributary, and few more than 100 in the neighbouring islands, called the *Kuril Isles*, who are subject to Russia. The fixed annual tribute consists in 279 sables, 464 red foxes, 50 sea-otters with a dam, and 38 cub otters. All furs exported from Kamtschatka pay a duty of 10 *per cent.* to the crown; the tenth part of the cargoes brought from the neighbouring islands is also delivered into the customs.

The natives of Kamtschatka are as wild as the country itself. Some of them have no fixed habitations, but wander from place to place with their herds of rein-deer; others have settled habitations, and reside upon the banks of the rivers and the shore of the Penschinska sea, living upon fish and sea-animals, and such herbs as grow upon the shore: the former dwell in huts covered with deer-skins; the latter in places dug out of the earth; both in a very barbarous manner. Their dispositions and tempers are rough; and they are entirely ignorant of letters or religion. The natives are divided into three different peoples, namely, the Kamtschatkans, Koreki, and Kuriles. The Kamtschatkans live upon the south side of the promontory of Kamtschatka: the Koreki inhabit the northern parts on the coast of the Penschinska sea, and round the eastern ocean almost to the river Anadir, whose mouth lies in that ocean almost in 68° N. lat.: the Kuriles inhabit the islands in that sea, reaching as far as those of Japan. The Kamtschatkans have this particular custom, that they endeavour to give every thing a name in their language which may express the property of it; but if they do not understand the thing quite well themselves, then they take a name from some foreign language, which perhaps has no relation to the thing itself; as, for example, they call a priest *bogbog*, because probably they hear him use the word *bozboz*, "God;" bread they call *brightatin augsh*, that is, Russian root; and thus of several other words to which their language is a stranger.

It appears probable, that the Kamtschatkans lived formerly in Mungalia beyond the river Amur, and made one people with the Mungals; which is farther confirmed by the following observations, such as the Kamtschatkan having several words common to the Mungal-Chinese language, as their terminations in ong, ing, oang, chin, cha, ching, ksh, kfung; it would be still a greater proof, if we could show several words and sentences the same in both languages. The Kamtschatkans and Mungals also are both of a middling stature, are swarthy, have black hair, a broad face, a sharp nose, with the eyes falling in, eyebrows small and thin, a hanging belly, slender legs and arms; they are both remarkable for cowardice, boasting, and slavish-

ness to people who use them hard, and for their obstinacy and contempt of those who treat them with gentleness.

Although in outward appearance they resemble the other inhabitants of Siberia, yet the Kamtschatkans differ in this, that their faces are not so long as the other Siberians'; their cheeks stand more out, their teeth are thick, their mouth large, their stature middling, and their shoulders broad, particularly of those people who inhabit the sea-coast.

Before the Russian conquest, they lived in perfect freedom, having no chief, being subject to no law, not paying any taxes; the old men, or those who were remarkable for their bravery, bearing the principal authority in their villages, though none had any right to command or inflict punishment.

Their manner of living is slovenly to the last degree: they never wash their hands or face, nor cut their nails; they eat out of the same dish with the dogs, which they never wash; they never comb their heads, but both men and women plait their hair in two locks, binding the ends with small ropes. When any hair starts out they sew it with threads to make it lie close; by this means they have such a quantity of lice, that they can scrape them off by handfuls, and they are nasty enough even to eat them. Those that have not natural hair sufficient, wear false locks, sometimes as much as weigh 10 pounds, which makes their heads look like a haycock.

They place their chief happiness in idleness, and satisfying their natural lust and appetites; which incline them to singing, dancing, and relating of love-stories; and they think it more eligible to die than to lead a disagreeable life; which opinion often leads them to self-murder. This was so common after the conquest, that the Russians had great difficulty to put a stop to it. They have no notion of riches, fame, or honour; therefore covetousness, ambition, and pride, are unknown among them. On the other hand, they are careless, lustful, and cruel: these vices occasion frequent quarrels and wars among them, sometimes with their neighbours, not from a desire of increasing their power, but from some other causes; such as the carrying off their provisions, or rather their girls, which is frequently practised as the most summary method of procuring a wife. Their trade is almost entirely confined to procuring the immediate necessaries and conveniences of life. They sell the Koreki sables, fox and white dog-skins, dried mushrooms, and the like, in exchange for clothes made of deer-skins and other hides. Their domestic trade consists in dogs, boats, dishes, troughs, nets, hemp, yarn, and provisions: and this kind of barter is carried on under a great show of friendship; for, when one wants any thing that another has, he goes freely to visit him, and without any ceremony makes known his wants, although perhaps he never had any acquaintance with him before: the host is obliged to behave according to the custom of the country, and give his guest what he has occasion for; but he may afterwards return the visit, and must be received in the same manner. They fill almost every place in heaven and earth with different spirits, and offer them sacrifices upon every occasion. Some carry little idols about them, or have them placed in their dwellings; but with regard to God, they not only neglect to worship him, but in case of troubles and misfortunes they curse and blaspheme him.

It is very diverting to see them attempt to reckon above ten: for, having reckoned the fingers of both hands, they clasp them together, which signifies ten; then they begin with their toes, and count to twenty; after which they are quite confounded, and cry, *Metcha?* that is, *Where shall I take more?* They reckon ten months in the year, some of which are longer and some shorter; for they do not divide them by the changes of the moon, but by the order of particular occurrences that happen in those regions. They commonly divide our year into two, so that winter is one year and summer another: the sum-

mer year begins in May, and the winter in November. They do not distinguish the days by any particular appellation, nor form them into weeks or months, nor yet know how many days are in the month or year. They mark their epochs by some remarkable thing or other; such as the arrival of the Russians, or the first expedition to Kamtchatka.

If any one kills another, he is to be killed by the relations of the person slain. They burn the hands of people who have been frequently caught in theft; but for the first offence the thief must restore what he hath stolen, and live alone in solitude, without expecting the assistance of others. They never have any disputes about their land or their huts, every one having land and water more than sufficient for his wants. They think themselves the happiest people in the world, and look upon the Russians who are settled among them with contempt. However, this notion begins to change: for the old people, who are confirmed in their customs, drop off; and the young ones, being converted to the Christian religion, adopt the customs of the Russians, and despise the barbarity and superstition of their ancestors.

In every ostrog or large village, by order of her imperial majesty, is appointed a chief, who is sole judge in all causes except those of life and death; and not only those chiefs, but even the common people, have their chapels for worship. Schools are also erected in almost every village, to which the Kamtchatkans send their children with great pleasure: by this means it is to be hoped that barbarity will be in a short time rooted out from amongst them.

Under the name of *ostrog* is understood every habitation consisting of one or more huts, all surrounded by an earthen wall or palisado.—The huts are built in the following manner: They dig a hole in the earth about five feet deep, the breadth and length proportioned to the number of people designed to live in it. In the middle of this hole they plant four thick wooden pillars; over these they lay balks, upon which they form the roof or ceiling, leaving in the middle a square opening, which serves them for a window and chimney; this they cover with grass and earth, so that the outward appearance is like a round hillock; but within they are an oblong square, with the fire in one of the long sides of the square. Between the pillars round the walls of their huts they make benches, upon which each family lies separately; but on that side opposite to the fire there are no benches, it being designed for their kitchen furniture, in which they dress their victuals for themselves and dogs. In those huts where there are no benches, there are balks laid upon the floor, and covered with mats. They adorn the walls of their huts with mats made of grass. They enter their huts by ladders, commonly placed near the fire-hearth; so that, when they are heating their huts, the steps of the ladder become so hot, and the smoke so thick, that it is almost impossible for a stranger to go up or down without being burnt, and even stifled to death: but the natives find no difficulty in it; and though they can only fix their toes on the steps of the ladder, they mount like squirrels; nor do the women hesitate to go through this smoke with their children upon their shoulders, though there is another opening through which the women are allowed to pass; but if any man pretend to do the same, he would be laughed at. The Kamtchatkans live in these huts all the winter, after which they go into others called *balagans*: these serve them not only to live in during the summer, but also for magazines. They are made in the following manner: Nine pillars, about two fathoms long or more, are fixed in the ground, and bound together with balks laid over them, which they cover with rods, and over all lay grass, fastening spars, and a round sharp roof at top, which they cover with bramble, and thatch with grass. They fasten the lower ends of the spars to the balks with ropes and thongs, and have a door on each side, one directly

opposite to the other. They make use of the same kind of huts to keep their fish, &c. till winter comes on, when they can more easily remove it; and this without any guard, only taking away the ladders. If these buildings were not so high, the wild beasts would undoubtedly plunder them; for, notwithstanding all their precaution, the bears sometimes climb up and force their way into their magazines, especially in the time of harvest, when the fish and the berries begin to grow scarce.

The southern Kamtchatkans commonly build their villages in thick woods and other places which are naturally strong, not less than 20 versts from the sea; and their summer habitations are near the mouths of the rivers; but those who live upon the Penschinska sea and the eastern ocean build their villages very near the shore. They look upon that river near which their village is situated as the inheritance of their tribe.

In order to kindle fire, they use a board of dry wood with round holes in the sides of it, and a small round stick; this they rub in a hole till it takes fire; and instead of tinder they use dry grass beat soft. These instruments are held in such esteem by the Kamtchatkans, that they are never without them, and they value them more than our steels and flints; but they are excessively fond of iron instruments, such as hatchets, knives, or needles: nay, at the first arrival of the Russians, a piece of broken iron was looked upon as a great present; and even now they receive it with thankfulness, finding use for the least fragment, either to point their arrows or make darts, which they do by hammering it out cold between two stones. As some of them delight in war, the Russian merchants are forbidden to sell them any warlike instruments: but they are ingenious enough to make spears and arrows out of the iron pots and kettles which they buy; and they are so dexterous, when the eye of a needle breaks, as to make a new eye; which they will repeat until nothing remains but the point.

The Kamtchatkans make their boats of poplar-wood; but the Kuriles, not having any wood of their own, make use of what is thrown on shore by the sea, and is supposed to come from the coasts of Japan, China, or America. The northern inhabitants of Kamtchatka, the settled Koreki, and Tschukotskoi, for want of proper timber and plank, make their boats of the skins of sea-animals. They sew the pieces together with whales' beards, and caulk them with moss or nettles beat small. These boats hold two persons; one of whom sits in the prow, and the other in the stern. They push them against the stream with poles, which is attended with great trouble: when the current is strong, they can scarcely advance two feet in ten minutes; notwithstanding which, they will carry these boats, fully loaded, sometimes 20 versts, and, when the stream is not very strong, even 30 or 40 versts. The larger boats carry 30 or 40 pood; when the goods are not very heavy, they lay them upon a float or bridge resting upon two boats joined together. They use this method in transporting their provisions down the stream, and also to and from the islands.

Their clothes for the most part are made of the skins of deer, dogs, several sea and land animals, and even of the skins of birds; those of different animals being frequently joined in the same garment. They make the upper garment after two fashions; sometimes cutting the skirts all of an equal length, and sometimes leaving them long behind in form of a train, with wide sleeves of a length to come down below the knee, and a hood or caul behind, which in bad weather they put over their heads below their caps. The opening above is only large enough to let their heads pass: they sew the skins of dogs' feet round this opening, with which they cover their faces in cold stormy weather; and round their skirts and sleeves they put a border of white dog-skin; upon their backs they sew the small fureds of skins of different colours. They commonly wear two coats; the under coat with the hair side inwards,

the other side being dyed with alder; and the upper with the hair outwards. For the upper garment they choose black, white, or speckled skins, the hair of which is most esteemed for the beauty of its colour.

Men and women without distinction use the above-mentioned garments; their dress only differing in their under-clothing and in the covering of their feet and legs. The women have an under garment, which they commonly wear at home in the house, consisting of breeches and waistcoat sewed together. The breeches are wide like those of the Dutch skippers, and tie below the knée; the waistcoat is wide above, and drawn round with a string. The summer habits are made of dressed skins without hair: their winter-garment is made of deer or stone-ram skins with the hair on. The undress or household habit of the men is a girdle of leather with a bag before, and likewise a leathern apron to cover them behind; these girdles are sewed with hair of different colours. The Kamtchatkans used formerly to go a-hunting and fishing during the summer in this dress; but now this fashion is changed, and they wear linen shirts, which they buy from the Russians.

The covering of their feet and legs is made of skins of different sorts: in the summer time, during the rains, they wear the skins of seal with the hair outwards; but their most common covering is the skin of the legs of the rein-deer, and sometimes of the legs of other beasts, the shaggiest they can find, to preserve them against the cold. But the buskins which both the Collacs and Kamtchatkans use in their finest dress, are made in the following manner: The sole is of white seal skin, the upper part of white fine leather, the hind quarters of white dog-skin; what comes round the legs is of dressed leather or dyed seal-skin; the upper parts are embroidered. These buskins are so extraordinary, that if a bachelor is observed to wear them, he is immediately concluded to be upon a scheme of courtship.

They wear the same sort of caps as the people of Yakutski. In summer they have a sort of hats of birch bark tied about their head. The Kuriles use in the summer-time caps made of plaited grass. The women's head-dress is the perukes that we formerly mentioned; and these were so dear to them, that when they came to be Christians they were with difficulty prevailed upon to quit this dress for one more decent: however, at present, round the Russ settlements all is entirely changed, the women wearing shirts, ruffles, waistcoats, caps, and ribbands; which change nobody now complains of except the very old people. The women do all their work in mittens; they formerly never washed their faces, but now they use both white and red paint: for white paint they make use of a rotten wood; and for red a sea plant, which they boil in seal's fat, and, rubbing their cheeks with it, make them very red. They dress most in the winter time, especially when they either receive or pay visits.

The common clothes for a Kamtchatkan and his family will not cost him less than 100 rubles; for the coarsest worsted stockings, which cost in Russia 20 kopeeks, cannot be bought here for less than a ruble; and all other things are sold in the same proportion. The Kuriles are more able to buy good clothes than the Kamtchatkans; for they can purchase for one sea-beaver as much as the Kamtchatkans can for twenty foxes; and one beaver costs the Kuriles no more trouble than five foxes do the Kamtchatkans; for he must be a good hunter who catches more than ten foxes in the winter; and a Kurile thinks himself unlucky if he doth not catch three beavers in the season; besides which, great numbers are thrown upon the shore by storms.

The Kamtchatkans divide their fish into six parts: the sides and tail are hung up to dry; the back and thinner part of the belly are prepared apart, and generally dried over the fire; the head is laid to sour in pits, and then they eat it like salt fish,

and esteem it much, though the stink is such that a stranger cannot bear it; the ribs and the flesh which remain upon them they hang up and dry, and afterwards pound for use; the larger bones they likewise dry for food for their dogs: in this manner all these different people prepare the yokola, which is the principal food, or, one may say, household bread; and they eat it for the most part dry.

Their second favourite food is caviar, or the roes of fish, which they prepare three different ways. They dry the roe whole in the air; or take it out of the skin which envelops it, and, spreading it upon a bed of grass, dry it before the fire; or, lastly, make rolls of it with the leaves of grass, which they also dry. They never take a journey or go to hunting without dry caviar; and if a Kamtchatkan has a pound of this, he can subsist without any other provision a great while: for every birch and alder tree furnishes him with bark, which with his dried caviar makes him an agreeable meal; but they cannot eat either separately, for the caviar sticks like glue to the teeth; and it is almost impossible to swallow the bark chewed ever so long by itself. There is still a fourth method, which both Kamtchatkans and Koreki use in preparing their caviar: the first having covered the bottom of a pit with grass, they throw the fresh caviar into it, and leave it there to grow sour: the Koreki tie theirs in bags, and leave it to sour; this is esteemed their most delicate dish.

There is a third sort of diet, called by the Kamtchatkans *chupriki*, which is prepared in this manner: In their huts, over the fire-place, they make a bridge of stakes, upon which they lay a heap of fish, which remains there until the hut becomes as warm as a bagnio. If there is no great thickness of fish, one fire serves to dress it; but sometimes they are obliged to make two, three, or more fires. Fish dressed in this manner is half roasted, half smoked, but has a very agreeable taste, and may be reckoned the best of all the Kamtchatkan cookery: for the whole juice and fat is prepared with a gradual heat, and kept in by the skin, from which they may when done enough be easily separated; and as soon as it is thus dressed, they take out the guts, and spread the body upon a mat to dry: this they afterwards break small, and, putting it into bags, carry it along with them for provision, eating it like the yokola.

The Kamtchatkans have a dish which they esteem very much, called *buigul*: it is fish laid to grow sour in pits; and though the smell of it is intolerable, yet the Kamtchatkans esteem it a perfume. This fish sometimes rots so much in the pits, that they cannot take it out without ladles; in which case indeed they use it for feeding their dogs.

As for the flesh of land and the larger sea animals, they boil it in their troughs with several different herbs and roots; the broth they drink out of ladles and bowls, and the meat they take out upon boards, and eat in their hands. The whale and sea-horse fat they also boil with roots.

There is a principal dish at all their feasts and entertainments, called *selaga*, which they make by pounding all sorts of different roots and berries, with the addition of caviar and of whale and seal's fat.

Before the conquest, they seldom used any thing for drink but plain water, unless when they made merry; then they drank water which had stood some time upon mushrooms. At present they drink spirits as fast as the Russians. After dinner they drink water; and, when they go to bed at night, set a vessel of water by them, with the addition of snow or ice to keep it cold, and always drink it up before morning. In the winter-time, they amuse themselves frequently by throwing handfuls of snow into their mouths: and the bridegrooms, who work with the fathers of their future brides, find it their hardest task to provide snow for the family in summer-time; for they must bring it from the highest hills, be the weather what it will, otherwise they would never be forgiven.

The Kamtchatkans commonly travel in sledges drawn by dogs. The animals used for this purpose differ very little from the common house-dogs; they are of a middling size, of various colours, though there seem to be more white, black, and grey, than of any other. In travelling, they make use of those that are castrated, and generally yoke four to a sledge. They drive and direct their dogs with a crooked stick about four feet long, which they sometimes adorn with different-coloured thongs; this is looked upon as a great piece of finery. They drive the sledge sitting upon the right side, with their feet hanging down; for it would be looked upon as a disgrace for a man to sit down at the bottom of the sledge, or to make use of any person to drive him, nobody doing this but the women. It is very difficult to travel in these sledges; for, unless a man keeps the exactest balance, he is liable every moment from the height and narrowness of them to be overturned: in a rugged road this would be very dangerous, as the dogs never stop till they come to some house, or are entangled by something upon the road; especially in going down steep hills, when they run with all their force, and are scarcely to be kept in; for which reason, in descending any great declivity, they unyoke all the dogs except one, and lead them softly down. They likewise walk up hills; for it is as much as the dogs can do to drag up the sledge empty. After a deep snow, before it has been hardened by a frost, there is no travelling with dogs till a road be made, which is effected by a man going before upon snow-shoes, whom they call *brodovshika*. The snow-shoes are made of two thin boards, separated in the middle, bound together at the ends, and with the fore part bent a little upwards. The *brodovshika*, having one of these shoes upon each foot, leaves the dogs and sledge, and going on clears the road for some way; then returning, leads forward the dogs and sledge so far as the road is made; a method which he must continue till he comes to some dwelling-house. This is very laborious; and it happens so often, that no driver ever gets out without his snow-shoes. When a storm of driven snow surprises them, they are obliged with all haste to seek the shelter of some wood, and stay there as long as the tempest lasts, which sometimes is a whole week. If they are a large company, they dig a place for themselves under the snow, and cover the entry with wood or brambles. Sometimes they hide themselves in caves or holes of the earth, wrapping themselves up in their furs; and when thus covered, they move or turn themselves with the greatest caution lest they should throw off the snow, for under that they lie as warm as in their common huts: they only require a breathing-place; but their clothes must not be tight or hard-girt about them, for then the cold is insufferable. Another danger attending travellers is, that in the severest frost several rivers are not quite frozen over: and as the roads for the most part lie close upon the rivers, the banks being very steep, scarce a year passes without many being drowned. A disagreeable circumstance also, to those who travel in these parts, is their sometimes being obliged to pass through copses, where they run the risk of having their eyes scratched out or their limbs broken; for the dogs always run most violently in the worst roads, and, to free themselves, very often overturn their driver. The best travelling is in the month of March or April, when the snow is turned hard or frozen a little at top: however, there is still this inconvenience attending it, that sometimes travellers are obliged to lodge two or three nights in desert places; and it is difficult to prevail upon the Kamtchatkans to make a fire either for warming themselves or dressing victuals, as they and their dogs eat dried fish, and find themselves so warm wrapped in their furs, that they want no other heat; nay, all the people of this climate bear cold so well, that they sleep in the open air as sound as others in a warm bed, and awake next morning perfectly refreshed and alert. This seems to be so natural to all here, that some of them have been

seen to lie down with their backs uncovered against a fire; and notwithstanding the fire has been burnt out long before morning, they continued to sleep on very comfortably, and without any inconvenience.

Islands in the Sea of KAMTCHATKA. So many of these have been discovered by the Russians, that the existence of almost a continued chain of islands between the continents of Asia and America is now rendered extremely probable. Many further discoveries of great importance to science, however, remain yet to be made. The principal islands already known are the Kuril isles, which stretch south-west towards the coasts of China or Japan, and are almost uninhabited; those called *Beering's*, and *Copper islands*, the Aleutian isles, and Fox-islands, or *Izysie Ostrova*, lie almost directly east, stretching nearly to 230° of longitude east from Ferro. The first project of making discoveries in that tempestuous sea which lies between Kamtchatka and America was set on foot by Peter the Great of Russia. Captains Beering and Tichirikoff were employed in the undertaking; the former of whom was shipwrecked and died on the island which is still called by his name. As this lies at no great distance from Kamtchatka, the inhabitants of the latter soon ventured over to it, as the sea otters and other animals of that kind were accustomed to resort thither in great numbers.

Mednoi Ostroff, or *Copper-island*, which lies in full sight of Beering's island, was next visited. This island has its name from the great quantity of copper with which the north-east coast of it abounds, the only side which is known to the Russians. It is washed up by the sea, and covers the shores in such abundance that many ships might be loaded with it. Perhaps an India trader might make a profitable voyage from thence to China, where this metal is in high demand. This copper is mostly in a metallic or malleable state, and many pieces seem as if they had formerly been in fusion. The island is not high; but has many hillocks, each of which has the appearance of having formerly been a volcano. With this kind of hillocks all the islands in the sea of Kamtchatka abound, insomuch that not a single island, though ever so small, was found without one; and many of them consisted of nothing else. In short, all the chain of islands above mentioned may without any stretch of imagination be considered as thrown up by some late volcanoes. The apparent novelty of every thing seems to justify this conjecture: nor can any objection be derived from the vegetable productions with which these islands abound; for the summer after the lower district of Zutphen in Holland was gained from the sea, it was covered over with wild mustard.—All these islands are subject to frequent and violent earthquakes, and abound in sulphur. We are not informed whether any lava is found upon them; but a parti-coloured stone as heavy as iron, probably a lava, is mentioned as being found there. From this account, it is by no means improbable that the copper above mentioned has been melted in some eruption.

Beering's island is situated due east from Kamtchatka, in the 185th degree of longitude; and Copper-island about one degree more to the eastward, and in the latitude of 54° north. The former is from 70 to 80 versts long, and stretches from north-west to south-east in the same direction as Copper-island. The latter is about 50 versts in length. About 300 versts east-by-south of Copper-island lie the Aleutian isles; of which *Atak* is the nearest: it is rather larger than Beering's island, and stretches from west to south-east. From thence about 20 versts eastwards is situated *Semitshi*, extending from west to east; and near its extremity is another small island. To the south of the strait which separates the two latter islands, and at the distance of 40 versts from both of them, lies *Shimiya* in a similar position, and not above 25 versts in length. All these islands lie between 54 and 55 degrees of north latitude.

The *Fox-islands* are situated east-north-east from the Aleu-

tians: the nearest of these, Atchak, is about 800 versts distant; it lies in 56° north latitude, and extends from west-south-west towards east-north-east. It greatly resembles Copper-island, and is provided with a commodious harbour on the north. From thence all the other islands of this chain stretch in a direction towards N. E. by E. The next to Atchak is Amlak, and about 15 versts distant; it is nearly of the same size, and has an harbour on its south side. Next follows Saugaganak, at about the same distance, but somewhat smaller; from thence is 50 versts to Amuchta, a small rocky island; and the latter to Yunakfan, another small island. About 20 versts from Yunakfan there is a cluster of five small islands, or rather mountains, Kigalgist, Kagamila, Tfigulac, Ulaga, and Tana-Unok; and which are therefore called by the Russians *Pat Sopki*, or the Five Mountains. Of these Tana-Unok lies most to the north-east, towards which the western point of Umnak advances within the distance of 20 versts.

Umnak stretches from south-west to north-east; it is 150 versts in length, and has a very considerable bay on the west end of the northern coast, in which there is a small island, or rock, called *Adugak*; and on the south side *Shemalga*, another rock. The western point of *Aghunalashka*, or *Unalashka*, is separated from the east end of *Umnak* by a strait near 20 versts in breadth. The position of these two islands is similar; but *Aghunalashka* is much the largest, and is above 200 versts long. It is divided towards the north-east into three promontories, one of which runs out in a westerly direction, forming one side of a large bay on the north coast of the island: the second stretches out north-east, ends in three points, and is connected with the island by a small neck of land. The third, or most southerly one, is separated from the last-mentioned promontory by a deep bay. Near *Unalashka* towards the east lies another small island called *Shirkin*. About 20 versts from the north-east promontory of *Aghunalashka* lie four islands: the first, *Akutan*, is about half as big as *Umnak*; a verst further is the small island *Akun*: a little beyond is *Akunok*; and lastly *Kigalga*, which is the smallest of these four; and stretches with *Akun* and *Akunok* almost from north to south. *Kigalga* is situated about the 61st degree of latitude. About 100 versts from thence lies an island called *Unimak*, upon which a Russian navigator (Captain *Krenitzin*) wintered; and beyond it the inhabitants said there was a large tract of country called *Alashka*, of which they did not know the boundaries.

The Fox-islands are in general very rocky, without containing any remarkably high mountains: they are destitute of wood; but abound in rivulets and lakes, which are mostly without fish. The winter is much milder than in Siberia: the snow seldom falls before the beginning of January, and continues on the ground till the end of March. There is a volcano in *Amuchta*, and sulphur is produced on another island; in some others are springs hot enough to boil provisions. Sulphureous flames also are sometimes seen at night upon the mountains of *Unalashka* and *Akutan*.

The Fox-islands are tolerably populous in proportion to their size. The inhabitants are entirely free, and pay tribute to no one; they are of a middle stature, and live, both in summer and winter, in holes dug in the earth. No signs of religion were found among them. Several persons indeed pass for sorcerers, pretending to know things past and to come; and are accordingly held in high esteem, but without receiving any emolument. Filial duty and respect towards the aged are not held in estimation by these islanders. They are not, however, deficient in fidelity towards each other; they are of a lively and cheerful temper, though rather impetuous, and naturally prone to anger. In general, they do not observe any rules of decency; but follow all the calls of nature publicly and without the least reserve. Their principal food consists in fish, and other sea-ani-

mals, small shell-fish, and sea plants; their greatest delicacies are wild lilies and other roots, together with different kinds of berries. When they have laid in a store of provisions, they eat at any time of the day without distinction; but in case of necessity, they are capable of fasting several days together. They seldom heat their dwellings: but when they are desirous of warming themselves, they light a bundle of hay, and stand over it; or else they set fire to train-oil, which they pour into a hollow stone. They feed their children when very young with the coarsest flesh, and for the most part raw. If an infant cries, the mother immediately carries it to the sea-side, and, be it summer or winter, holds it naked in the water until it is quiet. This custom, it is said, is so far from doing the children any harm, that it hardens them against the cold; and accordingly they go barefooted through the winter without the least inconvenience. They are also trained to bathe frequently in the sea; and it is an opinion generally received among the islanders, that by these means they are rendered bold and fortunate in fishing.

The men wear shirts made of the skins of cormorants, sea-divers, and gulls; and, in order to keep out the rain, they have upper garments of the bladders and other intestines of sea-lions, sea-calves, and whales, blown up and dried. They cut their hair in a circular form quite close to their ears; and have also a round place on the top. The women, on the contrary, let the hair descend over the forehead as low as the eye-brows, and tie the remaining part in a knot upon the top of the head. They pierce the ears, and hang in them bits of coral, which they get from the Russians. Both sexes make holes in the gristle of the nose, and in the under lip, in which they thrust pieces of bone, and are very fond of such kind of ornaments. They mark also and colour their faces with different figures. They barter among one another sea-otters, sea-bears, clothes made of birds skins and of dried intestines, skins of sea-lions and sea-calves for the coverings of their canoes, wooden masks, darts, thread made of sinews and hair of rein-deer.

Their household utensils are square pitchers or large troughs, which they make out of the wood driven ashore by the sea. Their weapons are bows and arrows pointed with flint, and javelins of two yards in length, which they throw from a small board. Instead of hatchets, they use crooked knives of flint or bone. Some iron knives, hatchets, and lances, were observed among them, which they had probably got by plundering the Russians.

According to the reports of the oldest inhabitants of *Umnak* and *Unalashka*, they have never been engaged in any war, either amongst themselves or with their neighbours; except with the people of *Alashka*, the occasion of which was as follows: The son of the toigon or chief of *Umnak* had a maimed hand; and some inhabitants of *Alashka*, who came to visit upon that island, fastened to his arm a drum, out of mockery, and invited him to dance. The parents and relations of the boy were offended at this insult: hence a quarrel ensued; and from that time the people have lived in continual enmity, attacking and plundering each other by turns. According to the reports of the islanders, there are mountains upon *Alashka*, and woods of great extent at some distance from the coast. The natives wear clothes made of the skins of rein-deer, wolves, and foxes; and are not tributary to any of their neighbours. The inhabitants of the Fox-islands seem to have no knowledge of any country beyond *Alashka*, which is one of the most easterly islands yet discovered in these seas, and is probably not far distant from the continent of America.

Faests are very common among these islanders; and more particularly when the inhabitants of one island are visited by those of the others. The men of the village meet their guests, beating drums, and preceded by the women, who sing and

dance. At the conclusion of the dance, the hosts invite them to partake of the feasts; after which ceremony the former return first to their dwellings, place mats in order, and serve up their best provision. The guests next enter, take their places, and, after they are satisfied, the diversions begin. First, the children dance and caper, at the same time making a noise with their small drums, while the owners of the huts of both sexes sing. Next, the men dance almost naked, tripping after one another, and beating drums of a larger size: when these are weary, they are relieved by the women, who dance in their clothes, the men continuing in the mean time to sing and beat their drums. At last the fire is put out which had been kindled for the ceremony. The manner of obtaining fire is by rubbing two pieces of dry wood against each other, or most commonly by striking two flints together, and letting the sparks fall upon some sea-otter's hair mixed with sulphur. If any forcerer is present, it is then his turn to play his tricks in the dark; if not, the guests immediately retire to their huts, which are made, on that occasion, of their canoes and mats. The natives who have several wives do not withhold them from their guests; but where the owner of a hut has himself but one wife, he then makes the offer of a female servant.

Their hunting season is principally from the end of October to the beginning of December; during which time they kill great numbers of young sea bears for their clothing. They pass all December in feasting and diversions similar to those above mentioned; with this difference, however, that the men dance in wooden masks representing various sea-animals, and painted red, green, or black, with coarse coloured earths found upon these islands.

During these festivals, they visit each other from village to village, and from island to island. The feasts concluded, masks and drums are broken to pieces, or deposited in caverns among the rocks, and never afterwards made use of. In spring, they go out to kill old sea-bears, sea-lions, and whales. During summer, and even in winter when it is calm, they row out to sea, and catch cod and other fish. Their hooks are of bone; and for lines they make use of a string made of a long tenacious sea-weed, which is sometimes found in those seas near 160 yards in length.

Whenever they are wounded in any encounter, or bruised by any accident, they apply a sort of yellow root to the wound, and fast for some time. When their head aches, they open a vein in that part with a stone-lancet. When they want to glue the points of their arrows to the shafts, they strike their nose till it bleeds, and use the blood to prepare glue.

Murder is not punished among them; for they have no judge. The following ceremonies are used in the burial of the dead. The bodies of poor people are wrapped up in their own clothes, or in mats; then laid in a grave, and covered over with earth. The bodies of the rich are put, together with their clothes and arms, in a small boat made of the wood driven ashore by the sea: this boat is hung upon poles placed cross-wise; and the body is thus left to rot in the open air.

The customs and manners of the inhabitants of the Aleutian isles are nearly similar to those of the inhabitants of the Fox-islands. The former indeed are rendered tributary and entirely subject to Russia; and most of them have a slight acquaintance with the Russian language, which they have learned from the crews of the different vessels who have landed there.

KAN, or KHAN, the name of an officer in Persia, answering to that of governor in Europe. There are kans of provinces, countries, and cities, who have different additions to distinguish them.

KANEM, a city of Africa, in the empire of Bornou, capital of an extensive and fertile province of the same name, in which the inhabitants, who are composed of Mussulmans and Pagans,

breed multitudes of cattle, and raise a number of horses for the service of the king. It is 150 miles N. W. by N. of Bornou.

KANGUROO. See DIDELPHIS.

KANIOW, a strong town of Poland, in the Ukraine, and in the palatinate of Kiow. It is near the river Dnieper, 62 miles S. by E. of Kiow, and 100 N. E. of Bracklaw.

KANISCA, a strong town of Lower Hungary, capital of the county of Salawar. It was taken by the Imperialists in 1690, and is seated on the river Drave, 54 miles S. W. of Alba Regalis, and 100 S. by E. of Vienna. E. lon. 17. 40. N. lat. 46. 43.

KAN-TCHEOU-FOU, a flourishing town of China, in the province of Kiang-si. Its rivers, port, riches, and population, all contribute to attract strangers. A day's journey from this city is a very rapid current, almost 20 leagues in length, which flows with great impetuosity over a number of scattered rocks that are level with the water. Travellers here are in great danger of being lost, unless they take care to be conducted by one of the pilots of the country: after this passage, the river becomes twice as large as the Seine at Rouen; it is continually covered with loaded barks and other vessels under sail. Near the walls of the city is a very long bridge, composed of 130 boats joined together by strong iron chains. The custom-house is upon this bridge, where a receiver constantly resides to visit all barks, and examine if they have paid the duties imposed on the commodities with which they are loaded. Two or three moveable boats are so placed, that by their means the bridge can be opened or shut, to give or refuse a passage; and no barks are ever permitted to pass until they have been examined. In the territory belonging to this city, grow a great number of those valuable trees from which varnish distils. Its district is extensive, and contains 12 cities of the third class.

KAOLIN, the name of an earth which is used as one of the two ingredients in oriental porcelain. Some of this earth was brought from China, and examined by Mr. Reaumur. He found that it was perfectly infusible by fire, and believed that it is a talky earth; but Mr. Macquer observes, that it is more probably of an argillaceous nature, from its forming a tenacious paste with the other ingredient called *petunse*, which has no tenacity. Mr. Bomare says, that by analysing some Chinese kaolin, he found it was a compound earth consisting of clay, to which it owed its tenacity; of calcareous earth, which gave it a mealy appearance; of sparkling crystals of mica; and of small gravel, or particles of quartz-crystals. He says, that he has found a similar earth upon a stratum of granite, and conjectures that it may be a decomposed granite. This conjecture is the more probable, as kaolins are frequently found in the neighbourhood of granites. See PORCELAIN.

KAOU'CHOUK. See CAOUTCHOUC.

KAPOSWAR, a fort of Lower Hungary, so called from the river Kapos, that washes its walls. It is 55 miles W. of Tolaa. E. lon. 18. 13. N. lat. 46. 31.

KARAITES. See CARAITES.

KARAT. See CARACT.

KARECK, an island in the Persian Gulph, subject to the Dutch. It was visited by Mr. Ives in 1758. He found the south part of the island well cultivated, with agreeable fields of corn, and producing plenty of esculent vegetables. In the middle are very high hills abounding with a variety of shells. Some fragments torn from their files afforded an opportunity of observing an immense quantity of oysters, scallop, cockle, and other shells. The common tree here is the hamian, but without those luxuriant shoots, which in some other places go downward and take root in the ground. The lavender-cotton is also found here; and the island abounds with fowl of various kinds. Pearl-oysters are also found here, but lie at considerable depths. Mr. Ives mentions one pearl of considerable size, which had upon it

a natural representation of the face of a human fœtus in the early months of pregnancy.

This settlement was founded by Baron Kniphausen, brother to one of that name some time ago ambassador at the court of London. Having left the Prussian service on some disgust, he entered into that of France. He afterwards went to the East Indies, and was appointed resident to the Dutch factory at Bassora. Here he became an object to the avarice and rapacity of the Turkish governor; who having got him accused of capital crimes, he was at last glad to compound with them for 50,000 rupees, the whole sum he was worth, besides giving directions how they might squeeze other 50,000 from his successor in office (who in truth wished him turned out) and the banian who did the business of the Dutch factory, and who had likewise been concerned in underhand practices against him.

The new resident was overjoyed at his accession, but lost all patience when he found himself obliged to pay 30,000 rupees to the governor as a compliment on his entering into a post of such consequence. Nor had the banian much better reason to be satisfied, being obliged to pay down 20,000 rupees to make up the sum which was to satisfy the rapacity of the governor.

Baron Kniphausen sailed from Bassora the very day after he was set at liberty; but having landed on this island, he, in conjunction with an Arabian sheick, formed the plan of the settlement. He then carried a letter from the sheick to the governor and council of Batavia, in which the former proposed to give up the sovereignty of the island. Before setting out for this place, however, the baron took care to dispatch a messenger across the desert to Constantinople, acquainting the Dutch ambassador with the treatment he had received, and requesting liberty of the grand vizir for the Dutch to settle at Kareck. The messenger returned with a favourable answer before the baron came back from Batavia. The governor of Bassora, then, having attempted in vain to persuade him to return to that place, wrote a letter of complaint to Batavia, accusing the baron in terms of the utmost exaggeration, but without any mention of the 100,000 rupees. The baron, however, having got intelligence of this proceeding, used such diligence that he got back to Batavia in the very ship which carried the letter. Being thus present on the spot to answer the charges brought against him, he acquitted himself so well that his scheme was instantly approved of, and he was sent back with two ships and 50 men to take possession of Kareck, whose inhabitants at that time amounted to no more than 100 poor fishermen.

Considerable difficulties now occurred in the establishment of the new colony; for he had but very few materials with him, and the government of Batavia was very slow in sending him the succours they had promised. He was therefore obliged to send for workmen from Persia and Arabia, with whose assistance he built a small compact fort, strong enough to defend itself against any of the country powers and any ships usually sailing to India, excepting those of our East India company. Nor was he content with putting himself in a posture of defence, but even commenced hostilities against the Turks; and by detaining two vessels very richly laden, which happened to touch at the island, he at last obliged the governor of Bassora to pay back the 100,000 rupees he had extorted, 30,000 of which he restored to his successor in office at Bassora, and 20,000 to the banian. When Mr. Ives visited him, he informs us, that surprising progress had been made during the little time the baron had held the sovereignty of the island, and that he intended to make it a strong and wealthy place; at the same time that he discovered his taste for literature by advancing a sum of money for books and instruments of various kinds, which were afterwards punctually sent. After that time, however, the baron quitted the service of the Dutch; and the island is again in possession of the sheick of Bundaric, to whom it formerly belonged. It is about

five miles long and two in breadth; lying nearly in the middle of the Persian Gulf, about seven leagues from each side, and about 30 leagues from the mouth of Bassora river, where all ships bound to that port must call for pilots.

KARLE, a Saxon word used in our law, sometimes simply for a man; and sometimes, with an addition, for a servant or clown. Thus the Saxons call a seaman *buscarle*, and a domestic servant *huscarle*. From hence comes the modern word *churl*.

KARLSRUH, a handsome town of Germany, in the circle of Suabia, and territory of the margrave of Baden Durlach, who has here a magnificent palace. The town is built on a regular plan, and the houses are all as uniform as the streets. It is 12 miles N. by E. of Eaden.

KARMATIANS, a sect of Mohammedans, who once occasioned great disorders in the empire of the Arabs.

KASAN, a large country of the Russian empire, lying on both sides of the river Volga. It was formerly an independent kingdom, subject to the Kalmuc Tartars, to whom the Great Dukes of Moscow, with the other petty principalities of Russia, were tributary. But Ivan Vassilievitch I. the founder of the Russian greatness, toward the end of the 15th century rescued his country from the Tartar yoke; and in 1552 the second duke of the same name conquered Kafan, which now forms the three Russian governments of Kafan, Simbirsk, and Penza.

KASAN, the capital of the Russian government of the same name, seated on the rivulet Casanka, where it falls into the Volga. It is 414 miles E. by N. of Moscow. E. lon. 49. 35. N. lat. 55. 23.

KASTRIL, or **KESTRIL**. See **FALCO**.

KATTEGATTE, a noted sea lying between part of Jutland and the coast of Sweden, and towards the latter covered with a great number of isles. It is almost closed at the extremity by the low Danish islands of Sealand and Funen, which had in old times been (with Sweden) the seat of the Suiones. Between the first and the coast of Sweden is the famous sound, the passage tributary to the Danes by thousands of ships. These islands were of old called *Codonania*, and gave to the Kattegatte the name of *Sinus Codanus*. Its greatest depth is 35 fathoms. It decreases as it approaches the sound; which begins with 16 fathoms, and near Copenhagen shallows even to four. The Roman fleet, under the command of Germanicus, failed, according to Pliny, round Germany, and even doubled the *Cimbricum Promontorium*, and arrived at the islands which fill the bottom of the Kattegatte: either by observation or information, the Romans were acquainted with 23. One they called *Glossaria*; from its amber, a fossil abundant to this day on part of the south side of the Baltic. A Roman knight was employed by Nero's master of the gladiators to collect in these parts that precious production, by which he became perfectly acquainted with this country.

KAUFFBEUREN, a free and imperial town of Germany, in the circle of Suabia and territory of Kempten. The inhabitants consist of Papists and Protestants. It is seated on the river Wardach, 18 miles N. E. of Kempten, and 30 S. by W. of Augsburg. E. lon. 10. 43. N. lat. 47. 58.

KAY, **QUAY**, or **Key**. See **KEY**.

KAYE'S-ISLAND, an island in the North Pacific Ocean, whose south-west point is a naked rock, considerably elevated above the land within it. Some parts of the shore are interrupted by small valleys filled with pine-trees. These also abound in other parts of the island, which indeed is covered, in a manner, with a broad girdle of wood. The trees, however, are far from being of an extraordinary growth; so that they would be of no great service for shipping, excepting as materials for small things. The pine-trees appear to be all of one species; and neither the Canadian pine, nor cypress, was to be

seen. This island, which was discovered by captain Cook in 1778, lies in W. lon. 131. 48. and N. lat. 59. 51.

KAYSERSBERG, a town of France, in the department of Upper Rhine and late province of Alsace, five miles N. W. of Colmar, and 25 N. W. of Basl. E. lon. 7. 25. N. lat. 48. 10.

KAYSERSLAUTERN, a town of Germany, in the Lower Palatinate, belonging to the Elector Palatine; seated on the river Lauter, 22 miles S. W. of Worms, and 38 S. by W. of Mentz. E. lon. 7. 51. N. lat. 49. 20.

KAYSARSTHUL, or KEISERSTOUL, a town of Switzer-land, in the county of Baden, with a bridge over the Rhine, and a castle. It belongs to the bishop of Constance, and is eight miles S. E. of Zurzach. E. lon. 8. 24. N. lat. 47. 8.

KAYSERVERD, or KEISERTWERT, a town of Germany, in the circle of Westphalia and duchy of Berg, subject to the Elector Palatine. The fortifications are demolished. It is seated on the Rhine, eight miles N. of Dusseldorp, and 22 N. W. of Cologne. E. lon. 6. 45. N. lat. 51. 14.

KAZY, in the East Indies, a Mahometan judge or magistrate; appointed originally by the court of Delhi to administer justice according to their written law; but particularly in matters relative to marriages, the sales of houses, and transgressions of the Koran. He attests or authenticates writings, which under his seal are admitted as the originals in proof.

KEBLA, an appellation given by the Mahometans to that part of the world where the temple of Mecca is situated, towards which they are obliged to turn themselves when they pray.

KECKERMAN (BARTHOLOMEW), a native of Dantzick, and professor of philosophy there about the beginning of the 17th century, composed systems of almost all the sciences, in which he shews more method than genius. He died in 1609, fairly worn out at the age of 38 with mere scholastic drudgery.

KEDAR, in ancient geography, a district in the desert of the Saracens (so called from *Cedar*, the son of Ishmael, according to Jerome, who in another place says that Kedar was uninhabitable), on the north of Arabia Felix. *Kedareni*, the people, who dwelt in tents like the other Seenites (Psalm cxx.), were rich in cattle (Isaiah lx.), of a swarthy complexion (Canticles i.), and excellent at the bow (Isaiah xxi.).

KEDES, in ancient geography, a city of refuge and Levitical in the tribe of Naphthali, on the confines of Tyre and Galilee (Josephus). Jerome calls it a sacerdotal city, situated on a mountain 20 miles from Tyre, near Paneas, and called *Cidiffus*, taken by the king of Assyria. Another *Kedes* in the tribe of Issachar (1 Chron. vii. 72.), which seems to be called *Kifion* (Joshua xix.).

KEEDGE, a small anchor, used to keep a ship steady whilst she rides in a harbour or river, particularly at the turn of the tide, when she might otherwise drive over her principal anchor, and entangle the stock or flukes with her slack cable, so as to loosen it from the ground. This is accordingly prevented by a kedge rope that hinders her from approaching it. The kedges are particularly useful in transporting a ship: i. e. removing her from one part of the harbour to another, by means of ropes which are fastened to these anchors. They are generally furnished with an iron stock, which is easily displaced for the convenience of stowing them.

KEDRON, or CEDRON, in ancient geography, a town which, from the defeat and pursuit of the Syrians (1 Mac. xvi.), appears to have stood on the road which led from the Higher India to Azotus: in that war it was burnt by the Jews.

KEDRON, or *Cedron*, in ancient geography. St. John calls it a brook, but Josephus a deep valley between Jerusalem and Mount Olivet to the east; called also *Kedron* from its blackness.

A brook only in winter, or in rainy weather, according to Maundrel.

KEEL, the principal piece of timber in a ship, which is usually first laid on the stocks in building. If we compare the carcase of a ship to the skeleton of the human body, the keel may be considered as the backbone, and the timbers as the ribs. It therefore supports and unites the whole fabric, since the stem and stern-post, which are elevated on its ends, are in some measure a continuation of the keel, and serve to connect and inclose the extremities of the sides by transoms; as the keel forms and unites the bottom by timbers. The keel is generally composed of several thick pieces placed lengthways, which, after being scarfed together, are bolted, and clenched upon the upper side. When these pieces cannot be procured large enough to afford a sufficient depth to the keel, there is a strong thick piece of timber bolted to the bottom thereof, called the *false keel*, which is also very useful in preserving the lower side of the main keel. In our largest ships of war, the false keel is generally composed of two pieces, which are called the *upper* and the *lower false keels*. See *MIDSHIP-Frame*. The lowest plank in a ship's bottom, called the *garboard-streak*, has its inner edge let into a groove or channel cut longitudinally on the side of the keel: the depth of this channel is therefore regulated by the thickness of the garboard-streak.

KEEL is also a name given to a low flat-bottomed vessel, used in the river Tyne to bring the coals down from Newcastle and the adjacent parts, in order to load the colliers for transportation.

KEEL-Hauling, a punishment inflicted for various offences in the Dutch navy. It is performed by plunging the delinquent repeatedly under the ship's bottom on one side, and hoisting him up on the other, after having passed under the keel. The blocks or pulleys by which he is suspended are fastened to the opposite extremities of the main yard, and a weight of lead or iron is hung upon his legs, to sink him to a competent depth. By this apparatus he is drawn close up to the yard-arm, and thence let fall suddenly into the sea, where, passing under the ship's bottom, he is hoisted up on the opposite side of the vessel. As this extraordinary sentence is executed with a serenity of temper peculiar to the Dutch, the culprit is allowed sufficient intervals to recover the sense of pain, of which indeed he is frequently deprived during the operation. In truth, a temporary insensibility to his sufferings ought by no means to be construed into a disrespect of his judges, when we consider that this judgment is supposed to have peculiar propriety in the depth of winter, whilst the flakes of ice are floating on the stream; and that it is continued till the culprit is almost suffocated for want of air, benumbed with the cold of the water, or stunned with the blows his head receives by striking the ship's bottom.

KEELSON, a piece of timber which may be properly defined the interior or counter-part of the keel; as it is laid upon the middle of the floor-timbers, immediately over the keel, and like it composed of several pieces scarfed together. In order to fit with more security upon the floor timbers and crotches, it is notched about an inch and a half deep, opposite to each of those pieces, and thereby firmly scored down upon them to that depth, where it is secured by spike nails. The pieces of which it is formed are only half the breadth and thickness of those of the keel. The keelson serves to bind and unite the floor timbers to the keel. It is confined to the keel by long bolts, which, being driven from without through several of the timbers, are fore-locked or clenched upon rings on the upper side of the keelson.

KEEPER OF THE GREAT SEAL, is a lord by his office, and styled *lord keeper of the great seal of Great Britain*; he is always one of the privy-council. All grants, charters, and commissions of the king under the great seal pass through the hands

of the lord-keeper; for without that seal many of those grants, &c. would be of no force. The king being, in the interpretation of the law, a corporation, he therefore passes nothing but by the great seal, which is also said to be the public faith of the kingdom, being in the highest esteem and reputation. Whenever there is a lord-keeper, he is invested with the same place, authority, pre-eminence, jurisdiction, or execution of laws, as the lord chancellor of Great Britain is vested with. The lord-keeper is constituted by the delivery of the great seal, &c.

KEEPER of the Privy seal, is also a lord by his office, through whose hands all grants, pardons, &c. pass before they come to the great seal; and even some things pass his hands which do not pass the great seal at all. This officer is also one of the privy-council, yet was anciently called *clerk of the privy seal*. His duty is to put the seal to no grant, &c. without a proper warrant; nor with warrant where it is against law, or inconvenient, but shall first acquaint the king therewith.

KEEPING, in painting, denotes the representation of objects in the same manner that they appear to the eye at different distances from it; for which the painter should have recourse to the rules of perspective. There are two instances in which the famous Raphael Urbin has transgressed these rules: in one of his cartoons, representing the miraculous draught of fishes, the men in each of the two boats appear of full size, the features of their faces being strongly marked; and the boats are represented so small, and the men so big, that any one of them appears sufficient to sink either of the boats by his own bare weight: and the fowls on the shore are also drawn so big, as to seem very near the eye of the observer, who could not possibly, in that case, distinguish the features of the men in the distant boats. Or, supposing the observer to be in either of the boats, he could not see the eyes or beaks of the fowls on the shore. The other instance occurs in his historical picture of our Saviour's transfiguration on the mount; where he is represented with those who were then with him, almost as large as the rest of his disciples at the foot of the mount, with the father and mother of the boy whom they brought to be cured; and the mother, though on her knees, is more than half as tall as the mount is high. So that the mount appears only of the size of a little hay-rick, with a few people on its top, and a greater number at its bottom on the ground; in which case, a spectator at a little distance could as well distinguish the features of those at the top as of those on the ground. But upon any large eminence, deserving the name of a mount, that would be quite impossible.

KEFTEEN, a large village of Asia, in Syria, 16 miles from Aleppo, on the road to Tripoly. It gives its name to a large, fertile, well-cultivated plain, where they feed a great number of pigeons.

KEGWORTH, a village in Leicestershire, 10 miles S. E. of Derby, and 12 S. W. of Nottingham. It is situated on a beautiful eminence, which commands an extensive prospect over the counties of Nottingham and Derby. Near it is a handsome stone bridge over the Trent, called Cavendish Bridge, it being built at the duke of Devonshire's expence.

KEHL, or **KEIL**, once an important fortress of Germany, in the circle of Suabia. It is seated on the Rhine, opposite Strasburg, to which when the latter was an imperial city it belonged. It was also strongly fortified by the French, who took possession of it in 1684. Being ceded to the empire at the peace of Ryswick, the emperor assigned it to the house of Baden, reserving to himself, however, the right of a garrison. But this garrison has been since greatly augmented, and the ruins of the ancient fortifications replaced, since the war with the French Republic, with the strongest that could be constructed. E. lon. 7. 53. N. lat. 50. 30.

KEILL (Dr. JOHN), a celebrated astronomer and mathema-

tician, was born at Edinburgh in 1671, and studied in the university of that city. In 1694 he went to Oxford, where, being admitted of Baliol college, he began to read lectures according to the Newtonian system in his private chamber in that college. He is said to have been the first who taught Sir Isaac Newton's principles by the experiments on which they are founded: and this, it seems, he did by an apparatus of instruments of his own providing; by which means he acquired a great reputation in the university. The first specimen he gave the public of his skill in mathematical and philosophical knowledge, was his *Examination of Dr. Burnet's theory of the earth*, with *Remarks on Mr. Whiston's theory*: and these theories being defended by their respective inventors, drew from Mr. Keill *An examination of the reflections on the theory of the earth*, together with *A defence of the remarks on Mr. Whiston's new theory*. In 1701 he published his celebrated treatise entitled *Introductio ad veram physiam*, which only contains 14 lectures; but in the following editions he added two more. This work has been translated into English, under the title of *An Introduction to Natural Philosophy*. Afterwards being made fellow of the Royal Society, he published, in the Philosophical Transactions, a paper on the laws of attraction; and being offended at a passage in the *Acta Eruditorum* of Leipzig, warmly vindicated against Mr. Leibnitz Sir Isaac Newton's right to the honour of the first invention of his method of fluxions. In 1709 he went to New-England as treasurer of the Palatines. About the year 1711, several objections being urged against Sir Isaac Newton's philosophy, in support of Des Cartes's notions of a plenum, Mr. Keill published a paper in the Philosophical Transactions on the rarity of matter, and the tenuity of its composition. But while he was engaged in this dispute, queen Anne was pleased to appoint him her decypherer; and he continued in that place under king George I. till the year 1716. He had also the degree of doctor of physic conferred on him by the university of Oxford in 1713. He died in 1721. He published, besides the works already mentioned, *Introductio ad veram astronomiam*, which was translated into English by Dr. Keill himself; and an edition of Commandinus's Euclid, with additions of his own.

KEILL (JAMES), M. D. an eminent physician, and brother of the former, was born in Scotland about the year 1673; and having travelled abroad, read lectures of anatomy with great applause in the universities of Oxford and Cambridge, by the latter of which he had the degree of doctor of physic conferred upon him. In 1700 he settled at Northampton, where he had considerable practice as a physician; and died there of a cancer in the mouth in 1719. He published, 1. An English translation of Lemery's Chemistry. 2. An account of animal secretion, the quantity of blood in the human body, and muscular motion. 3. A treatise on anatomy. 4. Several pieces in the Philosophical Transactions.

KEISERSBERG, a town of Alsace in France, and in the bailiwick of Haguenau, which has belonged to the French ever since the year 1548. It is seated in a pleasant country, in E. lon. 7. 25. N. lat. 48. 10.

KEISERSLAUTERN, a town of Germany, in the Lower Palatinate, belonging to the elector Palatine; seated on the river Lauter, in E. lon. 7. 51. N. lat. 49. 20.

KEISERSTOUL, a town of Switzerland, in the county of Baden, with a bridge over the Rhine, and a castle. It belongs to the bishop of Constance, and is situated in E. lon. 8. 40. N. lat. 47. 10.

KEISERSWERT, a town of Germany in the circle of Westphalia, the diocese of Cologne, and the duchy of Berg; subject to the elector Palatine. The fortifications are demolished. It is seated on the Rhine, in E. lon. 6. 49. N. lat. 51. 16.

KEITH (JAMES), field-marshal in the Prussian service, was the younger son of William Keith, earl-marshal of Scotland;

and was born in 1696. He was designed by his friends for the law; but his inclination led to arms, and the first occasion of drawing his sword was rather an unhappy one. When he was 18 years old, the rebellion broke out in Scotland; and through the instigation of his mother, he joined James's party: he was wounded at the battle of Sheriff-muir, and made his escape to France. Here he applied himself to military studies; and going to Madrid, he by the interest of the duke of Liria obtained a commission in the Irish brigades, then commanded by the duke of Ormond. He afterwards attended the duke of Liria, when he went ambassador to Muscovy; and being by him recommended to the czarina, was promoted to the rank of lieutenant general, and invested with the order of the black eagle. He distinguished himself by his valour and conduct in the Russian service, and had no inconsiderable share in the revolution that raised Elizabeth the daughter of Peter the Great to the throne: he also served in several embassies; but finding the honours of that country but a splendid kind of slavery, he left that court and entered the Prussian service. The king of Prussia made him field marshal of the Prussian armies, and governor of Berlin; and distinguished him so far by his confidence, as to travel in disguise with him over a great part of Germany, Poland, and Hungary. In business, he made him his chief counsellor; in his diversions, his chief companion. The king was much pleased with an amusement which the marshal invented in imitation of the game of chess. The marshal ordered several thousand small statues of men in armour to be cast by a founder; these he would set opposite to each other, and range them in battalia, in the same manner as if he had been drawing up an army; he would bring out a party from the wings or centre, and show the advantage or disadvantage resulting from the different draughts which he made. In this manner the king and the marshal often amused themselves, and at the same time improved their military knowledge. This brave and experienced general, after many important services in the late wars of that illustrious monarch, was killed in the unfortunate affair of Hochkirchen in the year 1758.

The family of Keith was among the most ancient in Europe. In 1010 the Scots gained a complete victory over the Danes at Camus-town in Angus; King Malcolm II. as a reward for the signal bravery of a certain young nobleman who pursued and killed Camus the Danish general, bestowed on him several lands, particularly the barony of Keith in East Lothian, from which his posterity assumed their surname. The king also appointed him hereditary great marshal of Scotland, which high office continued in his family till the year 1715, when the last earl engaged in the rebellion, and forfeited his estate and honours; and thus ended the family of Marshal, after serving their country in a distinguished capacity above 700 years.

KELLINGTON, or CALLINGTON, a borough in Cornwall, with a good market on Wednesday. It is 12 miles S. of Launceston, and 217 W. by S. of London. W. lon. 4. 35. N. lat. 50. 30.

KILLS, a fair and post-town of Ireland, in the county of Meath and province of Leinster, 31 miles from Dublin. It is a borough likewise, and returns two members to parliament; patron earl of Beftive. This place gives title of viscount to the family of Cholmondeley. Near it is Headfort, the magnificent seat of Lord Beftive. This town is pleasantly situated on the river Blackwater, and has four fairs. It was anciently called *Kenamus*, and afterwards *Kenlis*. In former ages it was one of the most famous cities in the kingdom; and on the arrival of the English was walled and fortified with towers. In 1178 a castle was erected where the market-place now is; and opposite to the castle was a cross of an entire stone, ornamented with bas-relief figures and many curious inscriptions in the ancient Irish character. Within a small distance was the church of St. Senau; and on the south of the church-yard is a round tower,

which measures 99 feet from the ground, the roof ending in a point; and near the top were four windows opposite to the cardinal points. There was a celebrated monastery founded here in 550 for regular canons, and dedicated to the Virgin Mary. It owed its origin to St. Columb, to whom the site of the abbey was granted by Dermond Mac Carval, or Dermond the son of Kervail, king of Ireland. An episcopal see was afterwards erected here, which in the 13th century was united to that of Meath. A priory or hospital was also erected by Walter de Lacie, lord of Meath, in the reign of Richard I. for cross-bearers or crouched friars following the order of St. Augustin. There was likewise a perpetual chantry of three priests or chaplains in the parish church of St. Columb in Kells to celebrate mass daily; one in the Rood chapel, another in St. Mary's chapel, and a third in the chapel of St. Catherine the virgin.

KELLS is also the name of a village, being a post and fair-town, in the county of Kilkenny, 64 miles from Dublin. It is an ancient place, situated on Kings-river; and was noted for a priory of Augustines, built and richly endowed by Geoffrey Fitz-Roberts, who came into this kingdom with Strongbow. The prior of this place had the title of *lord spiritual*, and as such sat in the house of peers before the Reformation; the ruins only of this abbey now remain: a synod was held in it anno 1151, when John Paparo, legate from Rome, made one of the number of bishops that were convened there at that time to settle the affairs of the church. The present church is built in the Gothic manner. A fair is held on the 13th of July.

There is a third place of the above name, situated in the county of Antrim and province of Ulster, 89 miles from Dublin, near which are the ruins of a church: this place is but a small village, seated on a river of the same name, over which it has a bridge.

KELLY (HUGH), an author of considerable repute, was born on the banks of Killarney lake in Ireland in 1739. His father, a gentleman of good family, being reduced in fortune by a series of unforeseen misfortunes, was obliged to repair to Dublin that he might endeavour to support himself by his personal industry. A tolerable school education was all he could afford to his son; who was bound an apprentice to a staymaker, and served the whole of his time with diligence and fidelity. At the expiration of his indentures, he set out for London to procure a livelihood by his business; where he encountered all the difficulties a person poor and without friends could be subject to on his first arrival in town. Happening, however, to become acquainted with an attorney, he was employed by him in copying and transcribing: an occupation which he prosecuted with so much assiduity, that he is said to have earned about three guineas a week; an income which, compared to his former gains, might be deemed affluent. Tired, however, of this drudgery, he soon after, about 1762, commenced author, and was intrusted with the management of the *Lady's Museum*, the *Court Magazine*, the *Public Ledger*, the *Royal Chronicle*, *Owen's Weekly Post*, and some other periodical publications, in which he wrote many original essays and pieces of poetry, which extended his reputation, and procured the means of subsistence for himself, his wife to whom he was then lately married, and a growing family. For several years after this period, he continued writing upon a variety of subjects, as the accidents of the times chanced to call for the assistance of his pen; and as during this period politics were the chief objects of public attention, he employed himself in composing many pamphlets on the important questions then agitated, the greater part of which are now buried in oblivion. Among these, however, was a *Vindication of Mr. Pitt's Administration*, which Lord Chesterfield makes honourable mention of in the second volume of his *Letters*. In 1767, *The Babler* appeared in two pocket volumes, which had at first been inserted in *Owen's Weekly Chronicle* in single papers; as did the *Memoirs of a*

Magdalene, under the title of *Louisa Mildmay*. About 1767 he was tempted by the success of Churchill's *Rosciad* to write some frictions on the performers of either theatre, in two pamphlets, entitled *Thyrsis*, both which gave great offence to some of the principal persons at each house. The talents for satire which he displayed in this work recommended him to the notice of Mr. Garrick, who in the next year caused his first play of *Falſe Delicacy* to be acted at Drury-lane. It was received with great applause; and from this time he continued to write for the stage with profit and success, until the last period of his life. As his reputation increased, he began to turn his thoughts to some mode of supporting his family less precarious than by writing, and for that purpose entered himself a member of the Middle Temple. After the regular steps had been taken, he was called to the bar in 1774, and his proficiency in the study of the law afforded promising hopes that he might make a distinguished figure in that profession. His sedentary course of life had, however, by this time injured his health, and subjected him to much affliction. Early in 1777 an abscess formed in his side, which after a few days illness put a period to his life. He was the author of six plays besides that above mentioned.

KELP, in the glass trade, a term used for a sort of potashes made use of in many of the glass works, particularly for the green glass. It is the calcined ashes of a plant called by the same name; and, in some places, of sea-thongs or laces, a sort of thick-leaved fucus or sea-wrack. See *FUCUS*. This plant is thrown on the rocks and shores in great abundance, and in the summer months is raked together and dried as hay in the sun and wind, and afterwards burned to the ashes called *kelp*. The process of making it is thus: The rocks, which are dry at low water, are the beds of great quantities of sea-weed; which is cut, carried to the beach, and dried: a hollow is dug in the ground three or four feet wide; round its margin are laid a row of stones, on which the sea-weed is placed, and set on fire within; and quantities of this fuel being continually heaped upon the circle, there is in the centre a perpetual flame, from which a liquid like melted metal drops into the hollow beneath: when it is full, as it commonly is ere the close of day, all heterogeneous matter being removed, the kelp is wrought with iron rakes, and brought to an uniform consistence in a state of fusion. When cool, it consolidates into a heavy dark-coloured alkaline substance, which undergoes in the glass-houses a second vitrification, and assumes a perfect transparency. The progress by which thus a parcel of sea-weed, formerly the stony bed of seals or dreary shelter of shell-fish, is converted into a crystal lustre for an assembly-room, or a set of glasses for his majesty's table, is a metamorphosis that might be a subject for an entertaining tale.

KELSO, a town of Roxburghshire in Scotland, pleasantly situated on the river Tweed, in W. lon. 1. 20. N. lat. 55. 38. Of this town Mr. Pennant gives the following description: It is built much after the manner of a Flemish town, with a square and town house. It contains about 2700 souls, has a very considerable market, and great quantities of corn are sold here weekly by sample. The abbey of Tyronensians was a vast pile, and, to judge by the remains, of venerable magnificence. The walls are ornamented with false round arches, intersecting each other. Such intersections form a true Gothic arch; and may as probably have given rise to that mode as the arched shades of avenues. The steeple of the church is a vast tower. This house was founded by David I. when earl of Cumberland. He first placed it at Selkirk, then removed it to Roxburgh, and finally, when he came to the crown, fixed it here in 1128. Its revenues were in money above 2000l. Scots a-year. The abbot was allowed to wear a mitre and pontifical robes, to be exempt from episcopal jurisdiction, and permitted to be present at all general councils. The environs of Kelso are very

fine: the lands consist of gentle risings, inclosed with hedges, and extremely fertile. They have much reason to boast of their prospects. From the Chalkheugh is a fine view of the forks of the rivers, Roxburgh-hill, Sir John Douglas's neat seat, and at a distance Fleurus; and from Pinnacle-hill is seen a vast extent of country, highly cultivated, watered with long reaches of the Tweed, well wooded on each margin. These borderers ventured on cultivation much earlier than those on the west and east, and have made great progress in every species of rural economy. Turnips and cabbages for the use of cattle cover many large tracts; and potatoes appear in vast fields. Much wheat is raised in the neighbourhood, part of which is sent up the frith of Forth, and part into England. The fleeces here are very fine. The wool is sent into Yorkshire, to Lincathgow, or into Aberdeenshire for the stocking-manufacture; and some is woven here into a cloth called *plains*, and sold into England to be dressed. Here is also a considerable manufacture of white leather, chiefly to supply the capital of Scotland. At Kelso there is a fine stone-bridge of six arches over the Tweed near its confluence with the Teviot.

KEMAC, a celebrated fort of Asia, 17 miles from Arzen-gain, on the confines of Natolia. It is seated on the river Euphrates.

KEMPEN, a town of Germany, in the electorate of Cologne; seated on the river Niers, 30 miles N. W. of Cologne. E. lon. 6. 30. N. lat. 51. 18.

KEMPIS (THOMAS A), a pious and learned regular canon, was born at the village of Kemp, in the diocese of Cologne, in 1380; and took his name from that village. He performed his studies at Deventer, in the community of poor scholars established by Gerard Groot; and there made a great progress in the sciences. In 1399 he entered the monastery of the regular canons of Mount St. Agnes, near Zwol, of which his brother was prior. Thomas à Kempis there distinguished himself by his eminent piety, his respect for his superiors, his charity to his brother canons, and his continual application to labour and prayer. He died in 1471, aged 70. The best editions of his works, which consist of sermons, spiritual treatises, and lives of holy men, are those of Paris in 1649, and of Antwerp in 1607. The famous and well-known book *De Imitatione Christi*, which has been translated into almost all the languages of the world, though it has almost always been numbered among the works of Thomas à Kempis, is also found printed under the name of *Gerson*; and on the credit of some MSS. has been since ascribed to the abbot Gerson of the order of St. Benedict. This has occasioned a violent dispute between the canons of St. Augustin and the Benedictines: but while devout Christians find spiritual comfort in the work, the name of the writer is of small importance.

KEMPTEN, a free imperial town of Germany, in the territory of the abbot of Kempten, who is a prince of the empire. The inhabitants are Protestants. It is seated on the river Iller, 45 miles S. by W. of Augsburg. E. lon. 10. 21. N. lat. 47. 49.

KEMPTEN, a territory in the circle of Suabia, in Germany, between the bishopric of Augsburg and the barony of Walburg. It is about 47 miles long and broad, and has no considerable place but the towns of Kempten and Kauffbeuren, which are imperial.

KEN (THOMAS), an eminent English bishop in the 17th century, was bred at Winchester-school, whence he went to Oxford; and in 1699 was made a prebend of Winchester. In 1675, the year of the Jubilee, he travelled to Rome; and used to say, He had reason to give God thanks for his travels, having returned more confirmed of the purity of the reformed religion than he was before. He was appointed by king Charles II. to attend the lord Dartmouth at the demolishing of Tangier; and at his return was made chaplain to his ma-

jefty, as he was some time after to the princefs of Orange, then refiding in Holland. In 1685 he was consecrated bilhop of Bath and Wells. The month following he attended king Charles II. at his death; and gave clofe attendance at the royal bed for three whole days and nights, watching proper intervals to fuggelt pious and proper thoughts on fo ferious an occafion. In the following reign he zealoufly oppofed the progrefs of popery; and in June 1688, he, with five other bilhops and the archbilhop of Canterbury, was committed prifoner to the Tower of London for fubfcribing a petition to his majefty againft the declaration of indulgence. Upon the Revolution, however, he refufed to take the oaths to king William and queen Mary, on which account he was deprived of his bilhopric. Her majefty queen Anne beftowed on him a yearly penfion of 200l. to his death in 1710. He publifhed feveral pious books. His charity was fo great, that when he was bilhop of Bath and Wells, having received a fine of 4000l. he gave a great part of it to the French Proteftants.

KEN, or **KAN**, a river of Weftmoreland, which flows by Kendal, and empties itfelf into the fandy wafh of Lancashire, called Morcambe Bay. It has a cataract near its mouth, which renders it incapable of navigation; fo that the village of Milthorpe, fituated on a little creek near the mouth of the Ken, is the only port of Weftmoreland; and this is capable of receiving very fmall veffels only. Hence the fine Weftmoreland flates are exported to Liverpool, London, Hull, &c.

KEN, a river of Scotland, which defcending from the mountains in the north of Kirkeudbrightfhire, flows in a fotherly direktion to the town of New Galloway, below which it expands into a fine lake, about four miles in length, and one in breadth. The river Dee, which defcends from the weft, joins the fream that iffues from this lake. Their united waters take the name of that river, and flow to the S. W. till they meet the Irish fea at Kirkeudbright.

KENDAL, a town of Weftmoreland, feated in a valley, among hills, on the weft fide of the river Ken or Can, over which there are two ftone bridges, and one of wood which leads to the cafile now in ruins. It is a large handsome place; and has two long ftreets, which crofs each other. The inhabitants have driven a trade with the cotton and woollen manufactory throughout England ever fince the reign of Edw. III. and particular laws were enacted for regulating Kendal cloths as early as Richard II. and Henry IV. It is of note alfo for the manufactory of cottons, druggets, ferges, hats, worfted and yarn ftockings, &c. Queen Elizabeth incorporated it with aldermen and burgefles; and king James I. with a mayor, recorder, town-clerk, 12 aldermen, 24 burgefles or common councilmen, and 2 attorneys. There are 7 companies here, who have each their hall, viz. mercers, fheermen, cordwainers, glovers, tanners, taylors, and pewterers. Here is an elegant town-hall lately repaired; and they enjoy a court of confcience granted by George III. for debts under 40s. It has a large beautiful church, which ftands on the other fide of the brook called Blindbeck, out of the liberty of the town: a large neat and handsome building 180 feet long and 99 broad, with 5 ailes, each parted by a row of 8 pillars, and a ftiong fquare fteeple. Near is Abbot's hall, the refidence of the abbot when this church belonged to an abbey diffolved by Henry VIII. In 1755 a new chapel was erected in the middle of the town, beftdes which there are 12 chapels of eafe belonging to it. The diffenters and quakers have meeting-houfes. Here is a fine grammar-fchool well endowed; and alfo a charity-fchool for 10 boys and 16 girls, who are all clothed as well as taught. Eaftward of the town, on the oppofite fide of the river on a hill, from whence is a fine profpect, ftand the ruins of a caftle, wherein was born Catharine Parr (the fixth wife of Henry VIII.). By the late inland navigation, it has communication with the rivers Merfey, Dee, Ribble, Oufe, Trent, Derwent, Severn, Humber, Thames,

Avon, &c. which navigation, including its windings, extends above 500 miles in the counties of Lincoln, Nottingham, York, Lancafter, Chefter, Stafford, Warwick, Leicefter, Oxford, Worcefter, &c. Here are kept the feffions of the peace for this part of the county, called the barony of Kendal; and there is a very great market on Saturday, with all kinds of provifions and woollen-yarn, which the girls bring hither in large bundles. It has fairs on May 6, and November 8; and between them a great beaft market every fortnight. The river here, which runs half through the town in a ftoney channel, abounds with trout and falmon; and on the banks of it live the dyers and tanners.

KENNEBEK, a river of N. America, which rifes in the northern part of the diftrict of Main, in New England; and flowing in a fotherly direktion, falls into the Atlantic Ocean between the bays of Cafco and Penobfcot.

KENNEL, a term ufed indifferently for a puddle, a water-course in the ftreets, a houfe for a pack of hounds, and the pack or cry of hounds themfelves. Mr. Beckford, in his Eflay on Hunting, is very particular in defcribing a kennel for hounds; and a kennel he thinks indifpenfably neceffary for keeping thofe animals in proper health and order. "It is true (fays he) hounds may be kept in barns and ftables; but thofe who keep them in fuch places can beft inform you whether their hounds are capable of anfwering the purpofes for which they are defigned. The fenfe of fmelling is fo exquisite in a hound, that I cannot but fuppofe that every ftench is hurtful to it. Cleanlinefs is not only abfolutely neceffary to the nofe of the hound, but alfo to the prefervation of his health. Dogs are naturally cleanly; and feldom, if they can help it, dung where they lie. Air and fresh ftraw are neceffary to keep them healthy. They are fubject to the mange; a diforder to which poverty and naftinefs will very much contribute. The kennel fhould be fituated on an eminence; its front ought to be to the eaft, and the courts round it ought to be wide and airy to admit the funbeams at any time of the day. It is proper that it fhould be neat without and clean within; and it is required to be near the mafter's houfe, for obvious reafons. It ought to be made large enough at firft, as any addition to it afterwards may fpoil it in appearance at leaft." Two kennels, however, in our author's opinion, are abfolutely neceffary to the well-being of hounds: "When there is but one (fays he), it is feldom fweet; and when cleaned out, the hounds, particularly in winter, fuffer both while it is cleaning and afterwards as long as it remains wet."

When the feeder firft comes to the kennel in a morning, he fhould let out the hounds into the outer court; and in bad weather, fhould fhut the door of the hunting kennel (that in which the hounds defigned to hunt next day are kept), left want of reft fhould incline them to go into it. The lodging-room fhould then be cleaned out, the doors and windows of it opened, the litter fhaken up, and the kennel made fweet and clean before the hounds return to it again. The floor of each lodging-room fhould be bricked, and floped on both fides to run to the centre, with a gutter left to carry off the water, that when they are wafhed they may foon be dry. If water fhould remain through any fault in the floor, it muft be carefully mopped up; for damp is always very prejudicial.

The kennel ought to have three doors; two in the front and one in the back; the laft to have a lattice window in it with a wooden fhutter, which is constantly to be kept clofed when the hounds are in, except in fummer, when it fhould be left open all the day.

At the back of Mr. Beckford's kennel is a houfe thatched and turzed up on the fides, big enough to contain at leaft a load of ftraw. Here fhould be a pit ready to receive the dung, and a gallows for the fleth. The gallows fhould have a thatched roof, and a circular board at the pofts to prevent vermin from

climbing up. He advises to enclose a piece of ground adjoining to the kennel for such dog-horses as may be brought alive; it being sometimes dangerous to turn them out where other horses go, on account of the disorders with which they may be infected. In some kennels a stove is made use of; but where the feeder is a good one, Mr Beckford thinks that a mop properly used will render the stove unnecessary. "I have a little hay-rick (says he) in the grass-yard, which I think is of use to keep the hounds clean and fine in their coats. You will frequently find them rubbing themselves against it. The shade of it is also useful to them in summer. If ticks at any time be troublesome in your kennel, let the walls of it be well washed; if that should not destroy them, the walls must then be white-washed."

Besides the directions already given concerning the situation of the kennel, our author recommends it to have a stream of water in its neighbourhood, or even running through it if possible. There should also be moveable stages on wheels for the hounds to lie on. The soil ought at all events to be dry.

To KENNEL, a term applied by fox-hunters to a fox when he lies in his hole.

KENNET (Dr. WHITE), a learned English writer, and bishop of Peterborough, in the 18th century, bred at St. Edmund-hall, Oxford; where he soon distinguished himself by his vigorous application to his studies, and by his translations of several books into English, and other pieces which he published. In 1695 our author published his Parochial Antiquities. A sermon preached by him on the 30th of January 1703 at Aldgate exposed him to great clamour. It was printed under the title of *A dispassionate inquiry into the causes of the civil war*. In 1706, he published his case of Improvements, and two other tracts on the same subject. In 1708, he published the third volume of *The Complete History of England* (the two former volumes compiled by Mr. Hughes). In 1709, he published *A Vindication of the Church and Clergy of England from some late reproaches rudely and unjustly cast upon them*; and a true Answer to Dr. Sacheverel's Sermon. When the great point in Dr. Sacheverel's trial, the change of the ministry, was gained, and very strange addresses were made upon it, there was to be an artful address from the bishop and clergy of London, and they who would not subscribe it were to be represented as enemies to the queen and the ministry. Dr. Kennet fell under this imputation. He was exposed to great odium as a low-church man, on account of his conduct and writings. When he was dean of Peterborough, a very uncommon method was taken to expose him by Dr. Walton, rector of the church of White-chapel; for in the altar-piece of that church, which was intended for a representation of Christ and his 12 apostles eating the passover and last supper, Judas the traitor was drawn sitting in an elbow-chair, dressed in a black garment, with a great deal of the air of Kennet's face. It was generally said that the original sketch was for a bishop under Dr. Walton's disguise; but the painter being apprehensive of an action of *Scandalum Magnatum*, leave was given to drop the bishop, and make the dean. This giving general offence, upon the complaint of others (for Dr. Kennet never saw it, or seemed to regard it), the bishop of London ordered the picture to be taken down. In 1713, he presented the Society for propagating the Gospel with a great number of books suitable to their design; published his *Bibliotheca Americana Primordia*, and founded an antiquarian and historical library at Peterborough. In 1715, he published a sermon, intitled *The Witchcraft of the present Rebellion*, and afterward several other pieces. In 1717, he was engaged in a dispute with Dr. William Nicholson, bishop of Carlisle, relating to some alterations in the bishop of Bangor's famous sermon; and disliked the proceeding of the Convocation against that bishop. Upon the death of Dr. Cumberland bishop of Peterborough,

he was promoted to that see, to which he was consecrated in 1718. He sat in it more than ten years, and died in 1728. He was an excellent philologist, a good preacher, whether in English or Latin, and well versed in the histories and antiquities of our nation.

KENNET (Basil), a learned English writer, and brother to the preceding, was educated in Corpus Christi college, in the university of Oxford, where he became fellow. In 1706 he went over chaplain to the English factory at Leghorn; where he met with great opposition from the Papists, and was in danger from the Inquisition. He died in the year 1714. He published *Lives of the Greek poets*; the *Roman Antiquities*; a volume of *Sermons preached at Leghorn*; A translation into English of Puffendorf's *Treatise of the Law of Nature and Nations*. He was a man of most exemplary integrity, generosity, piety, and modesty.

KENNET, a river, which rises among the chalky hills in the middle of Wilts, and flows to Newbury in Berks, where it becomes navigable, and below which it is augmented by the Lamborn. It then keeps along the southern edge of the county, till, turning up to Reading, it mingles with the Thames. Pope has celebrated this river, as "the Kennet swift, for silver eels renown'd."

KENNICOTT (Dr. BENJAMIN), well known in the learned world for his elaborate edition of the Hebrew Bible and other valuable publications, was born at Totness in Devonshire in the year 1718. With the rank and character of his parents we are entirely unacquainted; but it is certain they were unable to satisfy that thirst for knowledge which they could not but discover in their son. Some opportunities of early improvement must, however, have been afforded him, or (which we sometimes see) the natural vigour of his mind must have superseded the necessity of them. For in the year 1743, he wrote *A Poem on the Recovery of the Hon. Mrs. Eliz. Courtenay from her late dangerous Illness*; and this probably recommended him to the notice of those gentlemen who afterwards sent him to Oxford and supported him there. In judging of this performance, they may be supposed to have considered not so much its intrinsic merit, as the circumstances under which it was produced. For though it might claim just praise as the fruit of youthful industry struggling with obscurity and indigence, as a poem it never rises above mediocrity, and generally sinks below it. But in whatever light these verses were considered, the publication of them was soon followed by such contributions as procured for the author the advantages of an academical education. In the year 1744 he entered at Wadham college; nor was it long before he distinguished himself in that particular branch of study in which he afterwards became so eminent. His two dissertations, *On the Tree of Life*, and *the Oblations of Cain and Abel*, came to a second edition so early as the year 1747, and procured him the singular honour of a bachelor's degree conferred on him *gratis* by the University a year before the statutable time. The dissertations were gratefully dedicated to those benefactors whose liberality had opened his way to the University, or whose kindness had made it a scene not only of manly labour, but of honourable friendship. With such merit and such support, he was a successful candidate for a fellowship of Exeter college; and soon after his admission into that society, he distinguished himself by the publication of several occasional sermons. In the year 1753 he laid the foundation of that stupendous monument of learned industry, at which the wise and the good will gaze with admiration, when prejudice, and envy, and ingratitude, shall be dumb. This he did by publishing his first dissertation on the state of the Printed Hebrew Text, in which he proposed to overthrow the then prevailing notion of its absolute integrity. The first blow, indeed, had been struck long before, by Capellus, in his *Critica Sacra*, published after his

death by his son, in 1650—a blow which Buxtorf, with all his abilities and dialectical skill, was unable to ward off. But Capellus having no opportunity of consulting MSS. though his arguments were supported by the authority of the Samaritan Pentateuch, of parallel passages, and of the ancient versions, could never absolutely prove his point. Indeed the general opinion was, that the Hebrew MSS. contained none, or at least very few and trifling variations from the printed text; and with respect to the Samaritan Pentateuch very different opinions were entertained. Those who held the Hebrew verity, of course condemned the Samaritan as corrupt in every place where it deviated from the Hebrew; and those who believed the Hebrew to be incorrect, did not think the Samaritan of sufficient authority to correct it. Besides, the Samaritan itself appeared to a very great disadvantage; for no Samaritan MSS. were then known, and the Pentateuch itself was condemned for those errors which ought rather to have been ascribed to the incorrectness of the editions. In this dissertation, therefore, Dr. Kennicott proved that there were many Hebrew MSS. extant, which, though they had hitherto been generally supposed to agree with each other, and with the Hebrew text, yet contained many and important various readings; and that from those various readings considerable authority was derived in support of the ancient versions. He announced the existence of six Samaritan MSS. in Oxford only, by which many errors in the printed Samaritan might be removed; and he attempted to prove, that even from the Samaritan, as it was already printed, many passages in the Hebrew might undoubtedly be corrected. This work, as it was reasonable to expect, was examined with great severity both at home and abroad. In some foreign universities the belief of the Hebrew verity, on its being attacked by Capellus, had been insisted on as an article of faith—*Ista Capelli sententia adeo non approbata fuit Fidei sociis, ut potius Helvetii theologi, et speciatim Genevenses, anno 1678, peculiari canone caverint, ne quis in ditioe sua minister ecclesie recipiatur, nisi fateatur publice, textum Hebræum, ut bodie est in exemplaribus Masoreticis, quoad consonantes et vocales, divinum et authenticum esse* (Wolfii Biblioth. Heb. tom. ii. 27). And at home this doctrine of the corrupt state of the Hebrew text was opposed by Comings and Bate, two Hutchinsonians, with as much violence as if the whole truth of the revelation were at stake.

The next three or four years of Dr. Kennicott's life were principally spent in searching out and examining Hebrew MSS. though he found leisure not only to preach, but to publish several occasional sermons. About this time Dr. Kennicott became one of the king's preachers at Whitehall; and in the year 1759 we find him vicar of Culham in Oxfordshire. In January 1760 he published his second dissertation on the state of the Hebrew Text; in which, after vindicating the authority and antiquity of the Samaritan Pentateuch, he disarmed the advocates for the Hebrew verity of one of their most specious arguments. They had observed, that the Chaldee Paraphrase having been made from Hebrew MSS. near the time of Christ, its general coincidence with the present Hebrew Text must evince the agreement of this last with the MSS. from which the paraphrase was taken. Dr. Kennicott demonstrated the fallacy of this reasoning, by shewing that the Chaldee Paraphrase had been frequently corrupted, in order to reconcile it with the printed text; and thus the weapons of his antagonists were successfully turned upon themselves. He appealed also to the writings of the Jews themselves on the subject of the Hebrew Text, and gave a compendious history of it from the close of the Hebrew canon down to the invention of printing, together with a description of 103 Hebrew MSS. which he had discovered in England, and an account of many others preserved in various parts of Europe. A collation of the He-

brew MSS. was now loudly called for by the most learned and enlightened of the friends of biblical criticism; and in this same year (1760) Dr. Kennicott emitted his proposals for collating all the Hebrew MSS. prior to the invention of printing, that could be found in Great Britain and Ireland, and for procuring at the same time as many collations of foreign MSS. of note, as the time and money he should receive would permit. His first subscribers were the learned and pious Archbishop Secker, and the delegates of the Oxford press, who, with that liberality which has generally marked their character, gave him an annual subscription of 40l. In the first year the money received was about 500 guineas, in the next it rose to 900, at which sum it continued stationary till the tenth year, when it amounted to 1000. During the progress of the work the industry of our author was rewarded by a canonry of Christ Church. He was also presented, though we know not exactly when, to the valuable living of Mynhenyote, in Cornwall, on the nomination of the Chapter of Exeter. In 1776 the first volume was published, and in 1780 the whole was completed. If now we consider that above 600 MSS. were collated, and the whole work occupied 20 years of Dr. Kennicott's life, it must be owned that sacred criticism is more indebted to him than to any scholar of any age. Within two years of his death, he resigned his living in Cornwall, from conscientious motives, on account of his not having a prospect of ever again being able to visit his parish. Although many good and conscientious men may justly think, in this case, that his professional labours carried on elsewhere might properly have entitled him to retain this preferment, and may apply this reasoning in other cases; yet a conduct so signally disinterested deserves certainly to be admired and celebrated. Dr. Kennicott died at Oxford, after a lingering illness, September 18, 1783; and left a widow, who was sister to the late Edward Chamberlayne, Esq. of the treasury. At the time of his death he was employed in printing *Remarks on Select Passages in the Old Testament*; which were afterwards published, the volume having been completed from his papers.

KENNINGTON, a village of Surry, in the parish of Lambeth. Here is a barn, called the Long Barn, the remains of a royal palace, which was the residence, in particular, of Edward the Black Prince. Kennington Common is the place of execution for the county of Surry.

KENO. See KINO.

KENOQUE, a fort in Austrian Flanders, between Ypres and Furnes, six miles from Dixmude.

KENRICK (WILLIAM), an author of considerable abilities, was the son of a citizen of London, and brought up, it is said, to a mechanical employment. This, however, he seems early to have abandoned; and to have devoted his talents to the cultivation of letters, by which he supported himself during the rest of a life which might be said to have passed in a state of warfare, as he was seldom without an enemy to attack or to defend himself from. He was for some time student at Leyden, where he acquired the title of J. U. D. Not long after his return to England, he figured away as a poet in *Epistles Philosophical and Moral*, 1759, addressed to Lorenzo; an avowed defence of infidelity, written while under confinement for debt, and with a declaration that he was "much less ambitious of the character of a poet than of a philosopher." From this period he became a writer by profession; and the Proteus shapes under which he appeared, it would be a fruitless attempt to trace. He was for a considerable time a writer in *The Monthly Review*; but quarrelling with his principal, he began a *New Review* of his own. When our great Lexicographer's edition of Shakespeare first appeared in 1765, it was followed in a fortnight by a pamphlet, entitled, "A Review of Dr. Johnson's new Edition of Shakespeare, in which

the ignorance or inattention of that editor is exposed, and the poet defended from the persecution of his commentators, 1765." This pamphlet was followed by an Examination of it, and that by a Defence in 1766; in which year he produced his pleasant comedy of Falstaff's Wedding, at first intended to have been given to the public as an original play of Shakespeare retrieved from obscurity, and is, it must be acknowledged, a happy imitation of our great dramatic bard. With the celebrated English Rofcius Dr. Kenrick was at one time on terms of the strictest intimacy; but took occasion to quarrel with him in print, in a mode too unmanly to be mentioned. In politics also he made himself not a little conspicuous; particularly in the dispute between his friends Wilkes and Horne. He was the original editor of The Morning Chronicle; whence being ousted for neglect, he set up a new one in opposition. He translated in a very able manner the *Emilius* and the *Eloisa* of Rousseau; the *Elements of the History of England* by Millot (to injure, if possible, a translation of the same work by Mrs. Brooke); and produced several dramatic performances, together with an infinite variety of publications both original and translated. To him also the public are indebted for the collection (imperfect as it is) of The Poetical Works of Robert Lloyd, M. A. 1774, two vols. 8vo. Dr. Kenrick died June 9, 1777.

KENSINGTON, a village of Middlesex, on the western road from London, near 2 miles from Hyde Park Corner. It is extremely populous; and besides the palace, now neglected, contains many genteel houses, and several boarding-schools. The palace, which was the seat of the Lord Chancellor Finch afterwards Earl of Nottingham, was purchased by King William; who greatly improved it, and caused a royal road to be made to it, through St. James's and Hyde Parks, with lamp-posts erected at equal distances on each side. Queen Mary enlarged the gardens. Her sister Queen Ann improved what Mary had began; and was so pleased with the place, that she frequently supped during the summer in the green-house, which is a very beautiful one: but Queen Caroline completed the design by extending the gardens from the great road in Kensington towards Acton; by bringing what is called the Serpentine-River into them; and by taking in some acres out of Hyde-Park, on which she caused a mount to be erected, with a chair on it that could be easily turned round for shelter from the wind, since decayed. This mount is planted about with ever-greens, and commands a fine view over the noble gardens, and the country south and west. They were originally designed by *Kent*, and were afterwards much improved by *Brown*; and though they contain no striking beauties, which their flat situation will not admit, yet they have many pleasing parts, and afford much delight to the inhabitants of London, particularly to those whose professions will not allow of frequent excursions to more distant places. These gardens, which are three miles and a half in compass, are kept in great order. The palace indeed has none of that grandeur which ought to appear in the residence of a British monarch; but the royal apartments are noble, and some of the pictures good. It was at this place King William, Prince George of Denmark, Queen Ann, and King George II. died. The old church was pulled down in 1696, and a much better one built in its room. Part of this village, from the palace-gate to the Bell, is in the parish of St. Margaret's, Westminster.

KENT, one of the counties of England, situated at the south-east corner of the island, and from thence enjoying many advantages. The capacious æstuary of the Thames washes its northern parts, as the sea does the south-east; whence some with no great impropriety have styled it a *peninsula*. In point of extent, this is the fifth shire in South Britain, little less in its dimensions than the province of Holland; larger in size

than the duchy of Juliers in Germany; and almost exactly equal to that of Modena in Italy. Kent is, with great appearance of truth, supposed to be so styled from the ancient British word *kant*, signifying a *corner*, or, when applied to a country, an *head-land*. It is certain, that the Romans bestowed the name of *Cantium* on the province, and on its most conspicuous promontory the north Foreland; and from the district they inhabited, the people were called *Cantii*; which has prevailed even to our times, when *Kent*, and *the men of Kent*, are the common appellatives. It is however probable, that these Cantii were not the original inhabitants, but a later colony from the opposite continent, established here, like the Belgæ, not long before the Roman invasion. At the time of Cæsar's coming, this spacious and fertile region was divided into four principalities, or, as they are, according to the manners of those days, commonly called, *kingdoms*. It was his observation of these people, that they were particularly distinguished by their civility and politeness; a character which their descendants have preserved. When that wise people became masters of the southern parts of the island, this province received the most conspicuous marks of their attention, as appears from the stations which they so prudently established, while their government flourished in its full vigour. The care they took of the ports on the sea-coast as soon as it came to be in danger, and the several fortresses which they erected for the defence of their subjects against the sudden attempts of barbarous invaders, are evidences of the same kind. These forts, so prudently disposed, and so well secured, were under the direction of a particular great officer, called *Littoris Saxonici Comes*, i. e. the count of the Saxon shore; which office seems to have been preserved by the British monarchs who governed here, after the Romans quitted the isle. The Saxon kings of Kent discharged this trust in their legal capacity, from the middle of the fifth to the beginning of the ninth century. Under the Norman princes, this post was again revived, though with a change of title, in the *Lord Warden of the Cinque Ports*. Indeed, under all governments the people of Kent have been especially considered; as appears from their claim to the post of honour in our land-armies, and the privileges granted to their havens in consideration of their undertaking the defence of our channel.

As to the climate of this county, it varies according to the situation of places. In the low flat lands, and especially in the marshes, the air is heavy, moist, and unhealthy; and yet not to such a degree as it has been sometimes represented; for, with a little care and caution, strangers, as well as natives, quickly reconcile their constitutions to the temperature even of these parts, and live in them without much inconveniency or apparent danger. But, in reference to the rest of the county, the air is as thin, pure, and wholesome, as in any part of Britain. There is no region more happily or more beautifully diversified in regard to soil, so that every kind thereof is, somewhere or other, to be met with in its bounds; and in no shire are any of these soils more fertile than they are in this. The Weald yields variety of fine timber, particularly of che'nut; the middle part has very rich arable land, annually bearing every species of grain in very great plenty, and these excellent in their several sorts. There are also many beautiful orchards, which produce a variety of fine fruits, and more especially apples and cherries, which were introduced here from Flanders by one Richard Harris, who was the king's fruiterer, in the reign of Henry VIII. The flat country is renowned for its meadows; and Rumney-marsh has hardly its equal. We may from this concise description very easily collect, that the natural products of Kent are numerous and of great value. In the bowels of the earth they find, in several places, a rough hard serviceable stone for paying, which turns to some ad-

vantage; but not so much as their exquisite fullers-earth, rich marl, and fine chalk, which are there in abundance. If we except iron-ore, indeed, they have no mines; but there are prodigious heaps of copperas-stones thrown on the coast. The isle of Shepey, and all the adjacent shore as far as Reculver, is justly famous for its wheat. Thanet is in no less credit for its barley, or rather was so; for it now produces, through the painful industry and skilful husbandry of its inhabitants, copious crops of good wheat as well as barley. Horses, black cattle, and sheep, they have in great numbers, and remarkable in point of size; and hop-grounds in all parts of the county, which turn to very considerable account. To which we may add, weld, or as some call it *dyers-wood*, which is a very profitable commodity, and of which there grows much in the neighbourhood of Canterbury; also madder, which is, or has been, occasionally cultivated. The rivers and sea-coasts abound with fish of different kinds. The excellency of its oysters on the eastern shore is celebrated by the Roman poets. Those of Faversham and Milton are not only in great esteem at the London market, but are likewise sent in great quantities to Holland.

The many rich commodities produced in this county is the reason why most of our writers have represented it as in a manner void of manufactures; which, however, as appears upon a strict and impartial examination, is very far from being the case. Of iron-works there were anciently many; and there are still some, where kettles, bombs, bullets, cannon, and such like, are made. At Deptford Sir Nicholas Crispe had in his lifetime a very famous copperas work; and, indeed, there that ingenious gentleman, one of the greatest improvers and one of the most public-spirited persons this nation ever bred, introduced several other inventions. Copperas was also formerly made, together with brimstone, in the isle of Shepey. But the original and for many ages the principal manufacture of this county was broad cloth of different colours, established chiefly at Cranbrook by King Edward III. who brought over Flemings to improve and perfect (the trade being introduced long before) his subjects in that important art. At this and other places it flourished so much, that even at the close of Queen Elizabeth's reign, and according to some accounts much later, the best for home consumption, and the largest quantities for exportation, were wrought here; many fulling-mills being erected upon almost every river, and the greatest plenty of excellent fullers-earth affording them singular assistance; in-somuch that it is still a tradition, that the yeomanry of this county, for which it has been ever famous, were mostly the descendants of rich clothiers, who laid out the money acquired by their industry in the purchase of lands, which they transmitted, with their free and independent spirit, to their posterity. The duke of Alva's persecution of the Protestants in the Low Countries drove a multitude of Walloons over hither, who brought with them that ingenuity and application for which they had been always distinguished. These diligent and active people settled a manufactory of flannel or baize at Sandwich. By them the silk-looms were set up at Canterbury, where they still subsist; and they also introduced the making of thread at Maidstone, where it yet remains, and merits more notice and encouragement than hitherto it has met with.

Upon the river Dart, at the confluence of which with the Thames stands the town of Dartford, was set up, in the reign of Queen Elizabeth, the first mill for making white paper, by Mr. John Spilman, a German, upon whom, long after, King James conferred the honour of knighthood; but King Charles more sensibly bestowed upon this Sir John Spilman a patent, and a pension of 200l. a year, as a reward of his invention, and for the support of the manufacture. About the year

1590, Godfrey Box, a German, erected upon the same river the first flattening-mill which was ever used for making iron-wire; and also the first battery-mill for making copper-plates. Other new inventions, requiring the assistance of water, have been set up on other streams; and a great variety of machines of this sort still subsist in different parts of this county. But these things are now so common, that it would be both tedious and useless to insist upon them. Amongst these, we may reckon the making gunpowder in several places. That manufacture, however, which is now the glory of this county, and indeed of Britain, is ship-building; more especially at the royal yards; as at Woolwich, which was settled by Henry VIII. and some considerable ships built there. At present, there is not only a most complete establishment for the building and equipping men of war, a rope walk, foundery, and magazines; but also many private docks, in which prodigious business is carried on, and multitudes of people are employed.

KENTISH-TOWN, a village of Middlesex, three miles north of London, near Hampstead, much improved of late by several handsome houses belonging to the citizens of London, &c. A new chapel has lately been erected there.

KENTUCKY, a country in N. America, situated in its central part, near the latitude of 38° N. and 85° W. longitude. It is bounded on the north by Great Sandy Creek; by the Ohio on the N. W. by N. Carolina on the S. and by the Cumberland mountain on the E. It is upwards of 250 miles in length, and 200 in breadth; and at present divided into seven counties, Lincoln, Fayette, Bourbon, Mercer, Jefferson, Nelson, and Maddison. The principal rivers are the Ohio, Kentucky, Licking River, Red River, Elkhorn, Dick's River, Green River, Cumberland River, and Great Kenhaway or New River. These are all navigable for boats almost to their sources, without rapids, for the greatest part of the year. This country is generally level, and abounding with limestone, which usually lies about six feet deep, except in hollows, where streams run, where we find the rock in the bottom of the channel. The springs and streams lessen in June, and continue low, hindering navigation, until November, when the autumnal rains soon prepare the rivers for boats, and replenish the whole country with water. The soil is amazingly fertile. The inhabitants distinguish its quality by first, second, and third rate lands; and scarcely any such thing as a marsh or swamp is to be found. This country is more temperate and healthy than the other settled parts of America. The winter begins about Christmas, and ends about the first of March; at farthest does not exceed the middle of that month. Snow seldom falls deep, or lies long. The W. winds often bring storms, and the E. winds clear the sky; but there is no steady rule of weather in that respect, as in the Northern States. The W. winds are sometimes cold and nitrous. The Ohio running in that direction, and there being mountains on that quarter, the westerly winds, by sweeping along their tops, in the cold regions of the air, and over a long tract of frozen water, collect cold in their course, and convey it over the country; but the weather is not so intensely severe as that which these winds bring with them in Pennsylvania. The country, in general, may be considered as well timbered, producing large trees of many kinds, and to be exceeded by no country in variety. Those which are peculiar to Kentucky are the sugar-tree, which grows in all parts in great plenty, and furnishes every family with plenty of excellent sugar; and the honey-locust, which is curiously surrounded by large thorny spikes, bearing broad and long pods in form of peas: this has a sweet taste, and makes excellent beer. Here are also the coffee-tree, which greatly resembles the black oak, grows large, and also bears a pod, in which is enclosed coffee; the papaw-tree, which does not grow to a great size, is a soft wood, bears a fine fruit, much like a cucumber in shape and size, which tastes sweet; the cucum-

ber-tree, which is small and soft, with remarkable leaves, and bears a fruit much resembling that from which it is named; black mulberry-trees in abundance; the wild cherry-tree, which is of a large size, and supplies the inhabitants with boards for all their buildings; the buck-eye, a very soft wood, bearing a remarkable black fruit; and some other kinds of trees not common elsewhere. Here is great plenty of fine cane, on which the cattle feed, and grow fat. This plant, in general, grows from three to twelve feet high, of a hard substance, with joints at eight or ten inches distance along the stalk, from which proceed leaves resembling those of the willow. There are many cane-brakes so thick and tall, that it is difficult to pass through them. Where no cane grows, there is abundance of wild rye, clover, and buffalo-grass, covering vast tracts of country, and affording excellent food for cattle. The fields are covered with abundance of wild herbage not common to other countries; as the Shawanese fallad, wild lettuce, pepper grass, and many more, as yet unknown to the inhabitants, but which, no doubt, have excellent virtues. Here are seen the finest crown-imperials in the world, and the cardinal-flower, so much extolled for its scarlet colour; and all the year, excepting the winter months, the plains and valleys are adorned with variety of flowers of the most admirable beauty. Here is also found the tulip-bearing laurel-tree, or magnolia, which has an exquisite smell, and continues to blossom and seed for several months together. Iron ore and lead are found in abundance, but we do not hear of any silver or gold mines. The western waters produce plenty of fish and fowl. The fish common to the Ohio are, the buffalo-fish, of a large size, and the cat-fish, sometimes exceeding one hundred weight. Trout have been taken in Kentucky weighing about 30 pounds. The mullet, roach, perch, garfish, and eel, are here in plenty. Suckers, sunfish, and other hook-fish, are abundant. On these waters, and especially on the Ohio, the geese and ducks are amazingly numerous. The land fowls are, turkeys; a species of grouse, which the inhabitants call pheasants; and quails, to which they give the name of partridges. Here likewise is the parroquet, a bird every way resembling a parrot, but much smaller; and the ivory-bill woodcock, of a whitish colour, with a white plume. It flies screaming exceedingly sharp; and it is asserted, that its bill is pure ivory; a circumstance very singular in the plummy tribe. Here also is the great owl, resembling its kind in other parts, but remarkably different in its vociferation, sometimes making a strange, surprising noise, like a man in the most extreme danger and difficulty. Serpents are not numerous, and are such as are to be found in other parts of the continent, except the bull, the horned, and the mockason snakes. Among the native animals is the buffalo, much resembling a large bull, of a great size, with a large head, thick, short, crooked horns, and broader in his forepart than behind. Upon his shoulder is a large lump of flesh, covered with a thick bos of long wool and curly hair, of a dark-brown colour. They do not rise from the ground as our cattle, but spring up at once upon their feet; are of a broad make, and clumsy appearance, with short legs; but run fast, and turn not aside for any thing when chafed, except a standing tree. They weigh from five to ten hundred weight, are excellent meat, supplying the inhabitants in many parts with beef; and their hides make good leather. They are innocent harmless creatures. There are still to be found many deer, elks, and bears. There are also panthers, wild cats, and wolves. The waters have plenty of beavers, otters, minks, and musk rats; nor are the animals common to other parts wanting, such as foxes, rabbits, squirrels, racoons, ground-hogs, polecats, and opossums. Most of the species of the domestic quadrupeds have been introduced since the settlement, such as horses, cows, sheep, and hogs, which are prodigiously multiplied, suffered to run in the woods without a keeper, and brought home only when wanted. Many

caves are found in this country amazingly large; in some of which we may travel several miles under a fine limestone rock, supported by curious arches and pillars: in most of them runs a stream of water. Kentucky, which in the year 1784 was computed to contain 30,000 souls, has been since rapidly increasing in population, and now forms one of the fifteen United States of America. Lexington is the capital.

KENTUCKY, a river of N. America, which rises with three heads from a mountainous part of the country of the same name. Its N. branch, which interlocks with Cumberland River, runs half way in a W. direction, and N. W. the other half, and falls into the Ohio in N. latitude 38. 27. It is amazingly crooked for upwards of 200 miles in length. Among the natural curiosities of the country are the winding banks of this river, and of that called Dick's River. They are rather precipices than banks; for, almost every where, the astonished eye beholds three or four hundred feet of a solid perpendicular limestone rock; in some parts a fine white marble, either curiously arched, pillared, or shaped up into fine building stones. These precipices are like the sides of a deep trench, or canal; the land above being level, except where creeks set in, and crowned with fine groves of red cedar. It is only at particular places that this river can be crossed, one of which is worthy of admiration; a great road, large enough for waggons to pass through, sloping with an easy descent from the top to the bottom of a very large steep hill, at or near the river above Leestown.

KEPLER (JOHN), a very eminent astronomer and mathematician, was born at Weil, in the county of Wirtemberg, in 1571. He was the disciple of Mæstlinus, a learned mathematician and astronomer, of whom he learned those sciences, and became afterwards professor of them to three successive Emperors, viz. Matthias, Rudolphus, and Ferdinand II.

To this sagacious philosopher we owe the first discovery of the great laws of the planetary motions, viz. that the planets describe areas that are always proportional to the times; that they move in elliptical orbits, having the sun in one focus; and that the squares of their periodic times are proportional to the cubes of their mean distances; which are now generally known by the name of Kepler's Laws. But as this great man stands as it were at the head of the modern reformed astronomy, he is highly deserving of an accurate account, which we shall extract chiefly from the words of that great mathematician Mr. Maclaurin.

Kepler had a particular passion for finding analogies and harmonies in nature, after the manner of the Pythagoreans and Platonists; and to this disposition we owe such valuable discoveries as are more than sufficient to excuse his conceits. Three things, he tells us, he anxiously sought to find out the reason of, from his early youth; viz. Why the planets were 6 in number? Why the dimensions of their orbits were such as Copernicus had described from observations? And what was the analogy or law of their revolutions? He sought for the reasons of the two first of these, in the properties of numbers and plane figures, without success. But at length reflecting, that while the plane regular figures may be infinite in number, the regular solids are only five, as Euclid had long ago demonstrated; he imagined, that certain mysteries in nature might correspond with this remarkable limitation inherent in the essences of things; and he rather, as he found that the Pythagoreans had made great use of those five regular solids in their philosophy. He therefore endeavoured to find some relation between the dimensions of these solids and the intervals of the planetary spheres: thus, imagining that a cube inscribed in the sphere of Saturn would touch by its six planes the sphere of Jupiter; and that the other four regular solids in like manner fitted the intervals that are between the spheres of the other planets; he became persuaded that this was the true reason why the primary planets

were precisely six in number, and that the author of the world had determined their distances from the sun, the centre of the system, from a regard to this analogy. Being thus possessed, as he thought, of the grand secret of the Pythagoreans, and greatly pleased with his discovery, he published it in 1596, under the title of *Mysterium Cosmographicum*; and was for some time so charmed with it, that he said he would not give up the honour of having invented what was contained in that book, for the electorate of Saxony.

Kepler sent a copy of this book to Tycho Brahe, who did not approve of those abstract speculations concerning the system of the world, but wrote to Kepler, first to lay a solid foundation in observations, and then, by ascending from them, to endeavour to come at the causes of things. Tycho however, pleased with his genius, was very desirous of having Kepler with him to assist him in his labours: and having settled, under the protection of the Emperor, in Bohemia, where he passed the last years of his life, after having left his native country on some ill usage, he prevailed upon Kepler to leave the university of Gratz, and remove into Bohemia with his family and library, in the year 1600. But Tycho dying the next year, the arranging the observations devolved upon Kepler, and from that time he had the title of Mathematician to the Emperor all his life, and gained continually more and more reputation by his works. The Emperor Rudolph ordered him to finish the tables of Tycho Brahe, which were to be called the *Rudolphine Tables*. Kepler applied diligently to the work: but unhappy are those learned men who depend upon the good humour of the intendants of the finances; the treasurers were so ill affected towards our author, that he could not publish these tables till 1627. He died at Ratibon in 1630, where he was soliciting the payment of the arrears of his pension.

Kepler made many important discoveries from Tycho's observations, as well as his own. He found, that astronomers had erred, from the first rise of the science, in ascribing always circular orbits and uniform motions to the planets; that, on the contrary, each of them moves in an ellipsis which has one of its foci in the sun: that the motion of each is really unequal, and varies so, that a ray supposed to be always drawn from the planet to the sun describes equal areas in equal times.

It was some years later before he discovered the analogy there is between the distances of the several planets from the sun, and the periods in which they complete their revolutions. He easily saw, that the higher planets not only moved in greater circles, but also more slowly than the nearer ones; so that, on a double account, their periodic times were greater. Saturn, for example, revolves at the distance from the sun $9\frac{1}{2}$ times greater than the earth's distance from it; and the circle described by Saturn is in the same proportion: but as the earth revolves in one year, so, if their velocities were equal, Saturn ought to revolve in 9 years and a half; whereas the periodic time of Saturn is about 29 years. The periodic times of the planets increase, therefore, in a greater proportion than their distances from the sun: but yet not in so great a proportion as the squares of those distances; for, if that were the law of the motions (the square of $9\frac{1}{2}$ being $90\frac{1}{4}$), the periodic time of Saturn ought to be above 90 years. A mean proportion between that of the distances of the planets, and that of the squares of those distances, is the true proportion of the periodic times; as the mean distance between $9\frac{1}{2}$ and its square $90\frac{1}{4}$ gives the periodic time of Saturn in years. Kepler, after having committed several mistakes in determining this analogy, hit upon it at last, May the 15th, 1618; for he is so particular as to mention the precise day when he found that "the squares of the periodic times were always in the same proportion as the cubes of their mean distances from the sun."

When Kepler saw, according to better observations, that his disposition of the five regular solids among the planetary spheres was not agreeable to the intervals between their orbits, he endeavoured to discover other schemes of harmony. For this purpose, he compared the motions of the same planet at its greatest and least distances, and of the different planets in their several orbits, as they would appear viewed from the sun; and here he fancied that he found a similitude to the divisions of the octave in music. These were the dreams of this ingenious man, which he was so fond of that, hearing of the discovery of four new planets (the satellites of Jupiter) by Galileo, he owns that his first reflections were from a concern how he could save his favourite scheme, which was threatened by this addition to the number of the planets. The same attachment led him into a wrong judgment concerning the sphere of the fixed stars: for, being obliged, by his doctrine, to allow a vast superiority to the sun in the universe, he restrains the fixed stars within very narrow limits. Nor did he consider them as suns, placed in the centres of their several systems, having planets revolving round them, as the other followers of Copernicus have concluded them to be, from their having light in themselves, from their immense distances, and from the analogy of nature. Not contented with these harmonies, which he had learned from the observations of Tycho, he gave himself the liberty to imagine several other analogies, that have no foundation in nature, and are overthrown by the best observations. Thus, from the opinions of Kepler, though most justly admired, we are taught the danger of espousing principles, or hypotheses, borrowed from the abstract sciences, and of applying them with such freedom to natural inquiries.

A more recent instance of this fondness for discovering analogies between matters of abstract speculation and the constitution of nature, we find in Huygens, one of the greatest geometers and astronomers any age has produced: when he had discovered that satellite of Saturn which from him is still called the Huygenian satellite, this, with our moon, and the four satellites of Jupiter, completed the number of six secondary planets then discovered in the system; and because the number of primary planets was also six, (and this number is called by mathematicians a perfect number, being equal to the sum of its aliquot parts, 1, 2, 3,); Huygens was hence induced to believe that the number of the planets was complete, and that it was in vain to look for any more. This is not mentioned to lessen the credit of this great man, who never perhaps reasoned in such a manner on any other occasion; but only to shew, by another instance, how ill-grounded reasonings of this kind have always proved. For, not long after the celebrated Cassini discovered four more satellites about Saturn, not to mention the two more that have lately been discovered to that planet by Dr. Herschel, with another new primary planet and its two satellites, besides many others, of both sorts, as yet unknown, which possibly may belong to our system. The same Cassini having found that the analogy, discovered by Kepler, between the periodic times and the distances from the centre, takes place in the lesser systems of Jupiter and Saturn, as well as in the great solar system; his observations overturned that groundless analogy which had been imagined between the number of the planets, both primary and secondary, and the number six; but established, at the same time, that harmony in their motions, which will afterwards appear to flow from one real principle extended over the universe.

But to return to Kepler; his great sagacity, and continual meditations on the planetary motions, suggested to him some views of the true principles from which these motions flow. In his preface to the Commentaries concerning the planet Mars, he speaks of gravity as of a power that was mutual between bodies, and tells us, that the earth and moon tend

towards each other, and would meet in a point, so many times nearer to the earth than to the moon as the earth is greater than the moon, if their motions did not hinder it. He adds, that the tides arise from the gravity of the waters towards the moon. But not having notions sufficiently just of the laws of motion, it seems he was not able to make the best use of these thoughts; nor does it appear that he adhered to them steadily, since in his epitome of astronomy, published many years after, he proposes a physical account of the planetary motions, derived from different principles.

He supposes, in that treatise, that the motion of the sun on his axis is preserved by some inherent vital principle; that a certain virtue, or immaterial image of the sun, is diffused with his rays into the ambient spaces, and, revolving with the body of the sun on his axis, takes hold of the planets, and carries them along with it in the same direction; like as a load-stone turned round near a magnetic needle, makes it turn round at the same time. The planet, according to him, by its inertia, endeavours to continue in its place, and the action of the sun's image and this inertia are in a perpetual struggle. He adds, that this action of the sun, like his light, decreases as the distance increases; and therefore moves the same planet with greater celerity when nearer the sun, than at a greater distance. To account for the planet's approaching towards the sun, as it descends from the aphelion to the perihelion, and receding from the sun while it ascends to the aphelion again, he supposes that the sun attracts one part of each planet, and repels the opposite part; and that the part attracted is turned towards the sun in the descent, and the other towards the sun in the ascent. By suppositions of this kind he endeavoured to account for all the other varieties of the celestial motions.

But, now that the laws of motion are better known than in Kepler's time, it is easy to shew the fallacy of every part of this account of the planetary motions: The planet does not endeavour to stop in consequence of its inertia, but to persevere in its motion in a right line. An attractive force makes it descend from the aphelion to the perihelion in a curve concave towards the sun: but the repelling force, which he supposed to begin at the perihelion, would cause it to ascend in a figure convex towards the sun. There will be occasion to shew afterwards, from Sir Isaac Newton, how an attraction or gravitation towards the sun alone produces the effects, which, according to Kepler, required both an attractive and repelling force; and that the virtue which he ascribed to the sun's image, propagated into the planetary regions, is unnecessary, as it could be of no use for this effect, though it were admitted. For now his own prophecy, with which he concludes his book, is verified; where he tells us, that "the discovery of such things was reserved for the succeeding ages, when the author of nature would be pleased to reveal these mysteries."

The works of this celebrated author are many and valuable; as, 1. His *Cosmographical Mystery*, in 1596. 2. *Optical Astronomy*, in 1604. 3. *Account of a New Star in Sagittarius*, 1605. 4. *New Astronomy*; or, *Celestial Physics*, in Commentaries on the planet Mars. 5. *Dissertations*; with the *Nuncium Siderius* of Galileo, 1610. 6. *New Gauging of Wine Casks*, 1615. Said to be written on occasion of an erroneous measurement of the wine at his marriage by the revenue officer. 7. *New Ephemerides*, from 1617 to 1620. 8. *Copernican System*, three first books of the, 1618. 9. *Harmony of the World*; and three books of *Comets*, 1619. 10. *Cosmographical Mystery*, 2d edit. with Notes, 1621. 11. *Copernican Astronomy*; the three last books, 1622. 12. *Logarithms*, 1624; and the *Supplement*, in 1625. 13. His *Astronomical Tables*, called the *Rudolphine Tables*, in honour of the Emperor Rudolphus, his great and learned patron, in 1627. 14. *Epitome of the Copernican Astronomy*, 1635. Beside these, he wrote se-

veral pieces on various other branches, as *Chronology*, *Geometry of Solids*, *Trigonometry*, and an excellent treatise of *Dioptrics*, for that time.

KEPLER'S *Laws* are those laws of the planetary motions discovered by Kepler. These discoveries in the mundane system are commonly accounted two, viz. 1st, That the planets describe about the sun areas that are proportional to the times in which they are described, namely, by a line connecting the sun and planet; and 2d, That the squares of the times of revolution are as the cubes of the mean distances of the planets from the sun. Kepler discovered also that the orbits of the planets are elliptical.

These discoveries of Kepler, however, were only found out by many trials, in searching among a great number of astronomical observations and revolutions, what rules and laws were found to obtain. On the other hand, Newton has demonstrated, *a priori*, all these laws, shewing that they must obtain in the mundane system, from the laws of gravitation and centripetal force; viz. the first of these laws resulting from a centripetal force urging the planets towards the sun, and the 2d, from the centripetal force being in an inverse ratio of the square of the distance. And the elliptic form of the orbits, from a projectile force regulated by a centripetal one.

KEPLER'S *Problem* is the determining the true from the mean anomaly of a planet, or the determining its place, in its elliptic orbit, answering to any given time; and so named from the celebrated astronomer Kepler, who first proposed it. The general state of the problem is this: To find the position of a right line, which, passing through one of the foci of an ellipsis, shall cut off an area which shall be in any given proportion to the whole area of the ellipsis; which results from this property, that such a line sweeps areas that are proportional to the times. Many solutions have been given of this problem, some direct and geometrical, others not: viz. by Kepler, Bulliald, Ward, Newton, Keill, Machin, &c. See Newton's Princip. lib. 1, prop. 31, Keill's Astron. Lect. 23, Philos. Trans. abr. vol. 8. p. 73, &c.

In the last of these places, Mr. Machin observes, that many attempts have been made at different times, but with no great success, towards the solution of the problem proposed by Kepler: To divide the area of a semicircle into given parts, by a line drawn from a given point in the diameter, in order to find an universal rule for the motion of a body in an elliptic orbit. For, among the several methods offered, some are only true in speculation, but are really of no service; others are not different from his own, which he judged improper. And as to the rest, they are also limited and confined to particular conditions and circumstances, as still to leave the problem in general untouched. To be more particular; it is evident, that all constructions by mechanical curves are seeming solutions only, but in reality inapplicable; that the roots of infinite series are, on account of their known limitations in all respects, so far from being sufficient rules, that they serve for little more than exercises in a method of calculation. And then, as to the universal method, which proceeds by a continued correction of the errors of a false position, it is no method of solution at all in itself; because, unless there be some antecedent rule or hypothesis to begin the operation (as suppose that of an uniform motion about the upper focus, for the orbit of a planet; or that of a motion in a parabola for the perihelion part of the orbit of a comet, or some other such), it would be impossible to proceed one step in it. But as no general rule has ever yet been laid down, to assist this method, so as to make it always operate, it is the same in effect as if there were no method at all. And accordingly in experience it is found, that there is no rule now subsisting but what is absolutely useless in the elliptic orbits of comets; for in such cases there is no other way

to proceed but that which was used by Kepler: to compute a table for some part of the orbit, and in it examine if the time to which the place is required, will fall out any where in that part. So that, upon the whole, it appears evident, that this problem, contrary to the received opinion, has never yet been advanced one step towards its true solution.

Mr. Machin then proceeds to give his own solution of this problem, which is particularly necessary in orbits of a great eccentricity; and he illustrates his method by examples for the orbits of Venus, of Mercury, of the comet of the year 1682, and of the great comet of the year 1680, sufficiently shewing the universality of the method.

KERATOPHYTUM, in natural history, a species of *GORGONIA*. The keratophyta are called the *frutices coralloides*, or sea shrubs; and generally known among naturalists by the different appellations of *litophyta*, *litoxyla*, and *keratophyta*; epithets tending to convey an idea of their composition, which at first view seems to consist partly of a woody or horny, partly of a stony or calcareous substance, variously disposed with respect to each other. Their general form approaches to that of shrubs, having a root-like base, by which they adhere to some solid support in the ocean; and a stem or trunk, and branches differently disposed; some rising up in one or more different twigs, subdivided into smaller and separate ramifications; while others have their smaller branches connected in such a manner, as to form a curious net-like structure: from this diversity of figure they borrow the names of *sea-fans*, *sea-feathers*, &c. The seeming fibres of the base are, in reality, small tubes, of which the whole shrub consists: these tubes run up longitudinally into the trunk, and are also circularly disposed about the centre of the trunk: the woody part, as naturalists have called it, thus formed, affords when burnt a strong smell like burning horn; whence some have called it *the horny part*. Upon this part is superinduced a kind of stony or calcareous coat, which covers both trunk and branches to their extremities. In this coat may be discovered regular orders or pores of cells; and viewed by the microscope, it always appears to be an organical body consisting of a regular congeries, like the cells in which animals have been formed or existed. Some of this kind of bodies have lost their calcareous covering by the violence of the waves and other accidents. In some specimens of an advanced growth, the calcareous tubes just mentioned send out little cells of animals of the polype kind, with proper openings to them all: these cells are diffused along the branches in some regular order, much in the same manner as they are in the corallines. From the cells the animals have been discovered extending themselves, as well to procure food as materials for the increase of this surprising structure; and therefore there is no reason to doubt that they are animal productions.

A small sprig of the keratophyton flabelliforme, or warded sea-fan, is represented in Vol. II. pl. 8. fig. 7. The outside is covered with a crust full of little lumps like warts; which, when dissolved in vinegar, discover the contracted bodies of polypes, like claws. C and C₁ are two views of one of the warts magnified; C₂ is the appearance of the polype when the cretaceous matter is dissolved; C₃ represents the particles that compose the incrustation, magnified.—D represents a sea-willow, or keratophyton dichotomum. On both edges of the flat branches are regular rows of little rising cells in the calcareous part, with small holes for an entrance to each. See *CORALLINES*.

KERCRING (THEODORF), a famous physician of the 17th century, was born at Amsterdam, and acquired a great reputation by his discoveries and his works. He found out the secret of softening amber without depriving it of its transparency; and made use of it in covering the bodies of curious insects in order to preserve them. He was a member of the Royal Society of London, and died in 1693 at Hamburgh, where he

had spent the greatest part of his life, with the title of *Resident of the Grand duke of Tuscany*. His principal works are, 1. *Spicilegium anatomicum*. 2. *Anthropogenice iconographice*. There is also attributed to him an anatomical work, printed in 1671 in folio.

KERCOLANG, an island of Asia, in the Indian Ocean. It is between 80 and 100 miles in circumference, and, in general, of a very good height. The face of the country seems to be steep hills and extensive valleys, and every part to be covered with trees and verdure, with some pleasant cultivated grounds. The houses stand on posts, and appear to be well-built, and neatly thatched. Their fishing-hooks and lines are mostly European; and the inhabitants are Malays. Their clothing, in general, is made of a coarse kind of calico, though some wear silk, and most of them have a kind of turban round their head; and a few have been seen with a Chinese pointed hat. They are a mild and apparently quiet people: and the confidence they put in strangers proves that the latter are not unwelcome guests. E. lon. 126. 31. N. lat. 4. 28.

KERGUELEN'S LAND, an island in the Southern Ocean, visited by captain Cook in 1779. From its sterility, it might properly have been called the island of Desolation: but captain Cook was unwilling to rob M. Kerguelen of the honour of its bearing his name. Mr. Anderson, who accompanied captain Cook in this voyage, says, that no place hitherto discovered in either hemisphere affords so scanty a field for the naturalist as this spot. Some verdure indeed appeared, when at a small distance from the shore, which might raise the expectation of meeting with a little herbage; but all this lively appearance was occasioned by one small plant, resembling saxifrage, which grew upon the hills in large spreading tufts, on a kind of rotten turf, which, if dried, might serve for fuel, and was the only thing seen here that could possibly be applied to that purpose. E. lon. 69. 37. S. lat. 49. 3.

KERI-CETIB are various readings in the Hebrew Bible: *keri* signifies that which is read; and *cetib* that which is written. For where any such various readings occur, the wrong reading is written in the text, and that is called the *cetib*; and the true reading is written in the margin with \aleph under it, and called the *keri*. It is generally said by the Jewish writers, that these corrections were introduced by Ezra; but it is most probable, that they had their original from the mistakes of the transcribers after the time of Ezra, and the observations and corrections of the Masorites. Those Keri-cetibs which are in the sacred books written by Ezra himself, or which were taken into the canon after his time, could not have been noticed by Ezra himself; and this affords a presumption, that the others are of late date. These words amount to about 1000; and Dr. Kennicott, in his *Dissertatio Generalis*, remarks, that all of them, excepting 14, have been found in the text of manuscripts.

KERMAN, a province of Persia, lying on the gulph of Persia. Here are sheep, which, after grazing from January to May, have their fleeces fall off their backs, and become as naked as sucking pigs; and the inhabitants drive a great trade in their wool. Kerman is the capital.

KERMAN, a town of Persia, capital of a province of the same name. It is 120 miles N. of Gombroon. E. lon. 57. 55. N. lat. 29. 40.

KERMES, in zoology, the name of an insect produced in the excrescences of a species of the oak. See *COCCUS*.

KERMES Mineral, so called from its colour, which resembles that of vegetable kermes, is one of the most important antimonial preparations, both with regard to its chemical phenomena and to its medicinal uses. The use of kermes-mineral was not established in medicine before the beginning of this century. Some chemists, indeed, amongst others Glauber and Lemery,

had before that time mentioned in their works several preparations of antimony which approach more or less to kermes; but these preparations, being little known, were confounded with many others which are entirely neglected, although much praised by their authors. The fame of kermes was occasioned by friar Simon, apothecary to the Chartreux friars. He received this preparation from a surgeon called *La Ligerie*, who had procured it from a German apothecary who had been a scholar of the famous Glauber. Friar Simon, from the commendations given to this new remedy by *La Ligerie*, administered it to a Chartreux friar, who was dangerously ill of a violent peripneumony, by which the friar was suddenly, and as it had been miraculously, cured. From that time the friar-apothecary published the virtue of his remedy. Several other remarkable cures were performed by means of kermes. The public believed in its medicinal qualities, and called it *powder of Chartreux*; because it was prepared only in the apothecary's shop belonging to these monks. The reputation of kermes extended itself more and more; till at length the duke of Orleans, then regent of France, procured the publication of the process by *La Ligerie*.

This process consists in boiling, during two hours, pulverised crude antimony in the fourth part of its weight of the liquor of nitre fixed by coals, and twice its weight of pure water: at the end of this time the liquor is to be decanted, and filtrated, while boiling, through brown paper. It continues clear while it is boiling-hot; but when it cools, it becomes turbid, acquires a red brick colour, and again becomes clear by the deposition of a red sediment, which is the kermes. The boiling may be thrice repeated, and each time the same quantity of water is to be added to the antimony, and a fourth part less of the liquor of fixed nitre. The several sediments from these three boilings are to be added together, washed with clean water till the water acquires no taste; and the kermes is then to be dried. *La Ligerie* directs, that aquavitæ shall be once or twice poured upon it and burnt, and the kermes dried again.

We now proceed to explain the nature of kermes, and the phenomena of its preparation. Crude antimony is composed of regulus of antimony and common sulphur, united naturally with each other, as in almost all metallic minerals. The fixed alkali with which the crude antimony is boiled, although it is diluted with much water, acts upon the sulphur of the antimony, and forms with it liver of sulphur: and as this compound is a solvent of all metallic matters, it dissolves a certain quantity of the regulus of antimony. In this operation then a combination is formed of fixed alkali, of sulphur, and of regulus of antimony. Of these three substances the fixed alkali only is soluble in water, and is the intermediate substance by which the sulphur and regulus are suspended in the water. But we are to observe, that the alkali becomes impregnated by this operation, and by boiling, with a larger quantity of regulus, and especially of sulphur, than can be suspended in cold water: hence the decoction of kermes, which is clear, limpid and colourless while boiling-hot, becomes turbid and deposits a sediment while it cools. This compound, therefore, like certain salts, may be kept dissolved in larger quantity by hot than by cold water, and much of it is therefore deposited by cooling.

Further, while the kermes is precipitating, the whole antimoniated liver of sulphur, which is dissolved by the boiling liquor, may be divided into two parts; one of which, [that is the kermes, being overcharged with the regulus, and particularly with the sulphur, contains but a little alkali, which it draws along with it during its deposition. The other part, as it contains much more alkali, remains dissolved even in the cold liquor, by means of this larger quantity of alkali.

All these propositions are to be explained and demonstrated

by the following observations: *First*, when the decoction of kermes is cold, and has formed all its sediment, if, without adding any thing to it, it be heated till it boil, it again entirely redissolves the kermes; the sediment disappears; the liquor becomes clear, and by cold is again rendered turbid and deposits sediment as before. Thus the kermes may be made to precipitate and to redissolve as often as we please. *Secondly*, by digesting kermes in aqua regia, which dissolves its alkali and regulus, the sulphur is separated pure. The acids of aqua regia form a nitre and a febrifugal salt of Sylvius with the alkali of the kermes; and if a certain quantity of kermes be melted with black flux after having destroyed its sulphur by roasting, a true regulus of antimony may be obtained from it. These experiments, which were made by Mr. Geoffroy, and the detail of which is found in memoirs given to the Academy in the years 1734 and 1735, upon the analysis of kermes, show evidently the presence of sulphur, of fixed alkali, and of regulus of antimony, in this compound. From Mr. Geoffroy's experiments we find, that 72 grains of kermes contain about 16 or 17 grains of regulus, 13 or 14 grains of alkaline salt, and 40 or 41 grains of common sulphur. *Thirdly*, by repeating the boiling of the liquor upon the antimony, more and more kermes will be formed each time by cooling, as at first; and this experiment may be repeated a great many times. Mr. Geoffroy says, that he repeated it 78 times without any other addition than that of pure water to supply that which was lost by evaporation; and that each time a considerable quantity of kermes was formed by cooling. This experiment proves, that the alkali transforms the antimony into kermes by overcharging itself with regulus and sulphur, and at each precipitation the kermes does not retain and take with it but a very small quantity of alkali. *Fourthly*, if any acid be poured upon the liquor in which the kermes has been formed, and from which it has been entirely separated by cooling, Mr. Baumé has observed, that this liquor is again rendered turbid, and that a second sediment is formed of a yellow-reddish colour, which is nothing else than golden sulphur of antimony; that is, regulus of antimony and sulphur mixed together, but in very different proportions, and with very different strengths of union, from those in which they are found in the crude antimony.

After this precipitation, in the liquor a neutral salt is left, which is formed by the contained alkali and the precipitating acid. From this experiment we find, that in the liquor from which the kermes has been deposited, a considerable quantity of antimoniated liver of sulphur remains, which differs from kermes by containing a much larger proportion of alkali; so that it can keep dissolved the regulus and sulphur with which it is united, even when the liquor is cold.

In the process for several antimonial preparations, a kermes, or compounds like it, is formed. This always happens when crude antimony is treated by fusion with a quantity of alkaline salt, so that an antimoniated liver of sulphur results from it, overcharged with regulus and sulphur; that is, containing more of these two substances than it can keep dissolved in cold water. If any of these combinations be boiled in water, a matter analogous to kermes is always deposited by cooling. This happens, for instance, to the scoria of the regulus of antimony, and in an operation described by Mr. Geoffroy to abridge the process for making kermes by fusion.

To make kermes by fusion, Mr. Geoffroy fuses two parts of antimony with one part of alkaline salt; he powders this matter while yet hot, and keeps it during two hours in boiling water; he then filtrates it, and receives the liquor into more boiling water, from which, when it cools, about six gros of kermes is deposited, when an ounce of antimony has been used. This method of making kermes is much more expeditious, but less perfect; for, as the author himself confesses, the kermes pro-

duced is not so fine and soft as that made in the ordinary method.

Mr. Lemery the elder mentions also, in his Treatise concerning Antimony, an operation from which his son pretends that kermes may be obtained. This operation consists in digesting, and afterwards boiling, powdered crude antimony in a very pure liquor of fixed nitre. This liquor, if it be in sufficient quantity, is capable of dissolving quickly and entirely powdered crude antimony; and we cannot doubt but that, by cooling, a considerable quantity of a substance very analogous to kermes will be produced. Nevertheless, none of these short methods of making kermes is directed by dispensatories, or by the best books for describing the preparation of chemical remedies.

Kermes is used in medicine only; and from it singularly excellent effects may be produced, when administered by able physicians. In kermes are united the exciting and evacuant virtues of the emetic preparations of antimony, with the tonic, dividing, aperitive, and resolving properties of the liver of sulphur; that is to say, it is capable of answering two principal indications in the treatment of many acute and chronic diseases. Properly managed, it may become an emetic, a purgative, a diuretic, a sudorific, or an expectorant, as is required, and it is always attenuating and resolving. When seven or eight grains are taken at once, it chiefly acts upon the primæ viæ, generally as an emetic and as a purgative. A dose of three or four grains is seldom emetic, and more frequently purgative. When taken in these quantities as an evacuant, a little of it passes also into the viæ secundæ & tertiæ. When it is administered in smaller doses, it passes almost entirely into the lacteal, blood, and lymphatic vessel. In these it occasions such spasms and oscillations as it does in the primæ viæ; so that it increases all secretions and excretions, but particularly those of urine, sweat and expectoration, according to the dose, to the nature of the disease, and to the disposition of the patient. It produces very good effects in those diseases of the breast which proceed from fullness and obstruction.

Kermes may be administered in linctures, in oily or in cordial potions, in any vehicle; or incorporated in a bolus with other suitable remedies. One precaution, hitherto little observed, is very necessary; that is, not to join it with acids, if it is intended to act as kermes. Anti-acid and absorbent substances ought to be joined with it, if the patient has an acid in the primæ viæ, or an acceſcent disposition; for, as these acids saturate the alkali by which the kermes is rendered an antimoniated liver of sulphur, and by which alone it differs from golden sulphur of antimony, they accordingly render the kermes entirely similar to the golden sulphur of antimony, the properties of which are very different from those of kermes.

KERN, or KERNE, a term in the ancient Irish militia, signifying a *foot-soldier*. Camden tells us, the armies of Ireland consisted of cavalry, called *gall-glaſſes*; and infantry, lightly armed, called *kerns*. The kerns bore swords and darts; to the last were fitted cords, by which they could recover them after they had been launched out.

KERNES, in our laws, signify idle persons or vagabonds.

KERPEN, a town of Germany, in the circle of Westphalia and duchy of Juliers, 14 miles S. E. of Juliers. E. lon. 6. 56. N. lat. 50. 0.

KERRY, a county of Ireland, in the province of Munster, anciently called *Corrigiu*, or "the rocky country," from *Cerrig* or *Carric*, "a rock." It is bounded by the Shannon, which divides it from Clare on the north, by Limerick and Cork on the east, by another part of Cork on the south, and by the Atlantic Ocean on the west. The best town in it is Dingle, situated in a bay of the same name. It comprehends a great part of the territory formerly called *Dismond*, and consists of very different kinds of soil. The south parts are plain and fertile, but

the north full of high mountains, which, though remarkably wild, produce a great number of natural curiosities. It contains 636,905 Irish plantation acres, 84 parishes, 8 baronies, 3 boroughs, returns 8 members to parliament, and gives the title of earl to the family of Fitzmaurice. It is about 57 miles long, 45 broad, and lies within N. lat. 51. 30. and 52. 24; the longitude at the mouth of Kenmare river being 10° 35' west, or 42' 20" difference of time with London. It is the fourth county as to extent in Ireland, and the second in this province; but in respect to inhabitants and culture doth not equal many smaller counties. In it there are two episcopal sees, which have been annexed to the bishopric of Limerick since the year 1660, viz. Ardfert and Aghaloe. The see of Ardfert was anciently called the diocese of *Kerry*, and its bishops were named bishops of *Kerry*. Few mountains in Ireland can vie with those in this county for height; during the greater part of the year their sides are obscured by fogs, and it must be a very serene day when their tops appear. Iron ore is to be had in great plenty in most of the southern baronies. The principal rivers are the Blackwater, Feal, Gale, and Brick, Cashin, Mang, Lea, Fleſk, Laune, Carrin, Partin, Inry, and Roughty, and the principal lake is Killarney. There are some good medicinal waters discovered in this county; particularly Killarney-water, Iveragh Spa, Felloſwel, Dingle, Cattlemain, and Tralee Spas, as also a saline spring at Maherybeg. Some rare and useful plants grow in Kerry, of which Dr. Smith gives a particular account in his history of that county.

KERSEY, a kind of coarse woollen cloth, made chiefly in Kent and Devonshire.

KERTSCH, a fortress, situated on the E. coast of the Crimea, and near the N. entrance of the Straits of Caffa. This fortress and that of Yen'kale are of the greatest importance, as they command the passage which forms the communication between the sea of Aſoph and the Black Sea.

KESITAH. This word is to be met with in Genesis and in Job, and is translated in the Septuagint and Vulgate "sheep or lambs." But the Rabbins and modern interpreters are generally of opinion, that *keſitah* signifies rather a piece of money. Bochart and Eusebius are of opinion the Septuagint meant *mina*, and not lambs; in Greek *κεσισμνον*, *ἐκαστομνον*, instead of *ἐκαστον ομνον*. Now a mina was worth 60 Hebrew shekels, and consequently 6l. 6s. 10½d. sterling. M. de Pelletier of Rouen is of opinion, that *keſitah* was a Persian coin, stamped on one side with an archer (*Keſitah* or *Keſetib* in Hebrew signifying "a bow," and on the other with a lamb; that this was a gold coin known in the East by the name of a *daric*, and was in value about 12 livres and 10d. French money. Several learned men, without mentioning the value of the *keſitah*, say it was a silver coin, the impression whereof was a sheep, for which reason the Septuagint and Vulgate translate it by this name. Calmet is of opinion, that *keſitah* was a purse of gold or silver. In the East they reckon at present by purses. The word *keſit* in Chaldee signifies "a measure, a vessel." And Eusebius says, that *kista* is a Persian measure. Jonathan and the Targum of Jerusalem translate *keſitah* "a pearl." (Gen. xxxiii. 19; Job xli. 11.) Or 9l. English, supposing, as Dr. Prideaux does, that a shekel is worth 3s. A *daric* is a piece of gold, worth, as Dr. Prideaux says, 25s. English.

KESROAN, a chain of mountains in Asia, on the coast of Syria, which makes a part of Mount Libanus. It is one of the most pleasant countries in the East, as well on account of the goodness of the air, as the excellence of the corn, fruits, and all the necessaries of life.

KESSEL, a town of Upper Guelderland, in the Netherlands, with a handsome castle. It is the chief town in the territory of the same name, and seated on the river Meuse, between Ruremond and Venlo, it being about five miles from

each. It was ceded to the king of Prussia by the treaty of Utrecht. E. lon. 6. 13. N. lat. 41. 22.

KESSEL (John Van), an eminent painter, was born at Antwerp in 1626, and became exceedingly famous for painting those particular objects which he delighted to represent; and not only excelled in fruits and flowers, but was likewise eminent for painting portraits. In this manner he resembled Velvet Brueghel, and very nearly equalled him in his birds, plants and flowers. The prodigious high prices for which he sold his works, occasioned the rich alone to be the purchasers; and the king of Spain admired the performances of Van Kessel to such a degree, that he purchased as many of them as he could possibly procure, till at last he prevailed on that artist to visit his court, where he was appointed painter to the queen, and was retained in her service as long as she lived. He painted portraits admirably, with a light free touch, and a tone of colour that very much resembled Vandyck; nor are his works in that style considered in Spain as inferior to that great master. He died in 1708. aged 82.

KESSELDORF, a village of Germany, in the circle of Upper Saxony, three miles below Dresden, remarkable for the battle gained by the king of Prussia over the Saxons, on the 15th of December. 1745.

KESTEVEN, one of the three divisions of Lincolnshire, containing the western part of the county, from the middle to the southern extremity. It possesses variety of soil; but, on the whole, though intermixed with large heaths, is a fertile country. Part of the fens of Lincolnshire are in this district; the air of which, however, is more salubrious than that of the district of Holland; and the soil, moreover, is more fruitful.

KESTON, a village in Kent, $8\frac{1}{2}$ miles N. W. by N. of Westerham, and 14 S. E. by S. of London. On Holwood Hill, in this parish, is Holwood House, the seat of the right hon. William Pitt, in whose grounds are the remains of a large fortification (probably a Roman one) of an oblong form; the area of which is partly enclosed by rampires and double ditches of a great height and depth. It is two miles in circumference, inclosing near 100 acres of ground. A path descends from the camp to the springhead of the river Ravensbourn. Of this spring an excellent cold bath was formed, surrounded by pales and trees; but it has been long neglected. This river flows hence through Bromley, Hayes, Beckenham, and Lewisham, and, crossing the great road at Deptford bridge, falls into the Thames below.

KESTREL, the English name of a hawk, called also the *flannel* and the *windbover*, and by authors the *tinnunculus* and *obovis*. It builds with us in hollow oaks, and feeds on partridges and other birds. See **FALCO**.

KESWICK, a town of Cumberland, with a market on Saturday; seated in a vale surrounded by hills, near the rapid river Greeta. It was known formerly for its copper mines, which rendered it a considerable place; but it now consists only of one long street. It is 25 miles N. W. by N. of Kendal, and 287 N. N. W. of London. W. lon. 3. 16. N. lat. 58. 35.

KESWICK, Vale of, a delightful spot in the southern part of Cumberland, lately much visited by the admirers of nature. Here is the lake of Keswick, or, more properly, the lake of Derwent-water. To the N. of this romantic piece of water soars the lofty mountain Skiddaw, one of the most distinguished in England, and the haunt of eagles and other birds of prey. To the S. is the dreary region of Borrowdale. The water of the Derwent-water is subject to violent agitations, and often without any apparent cause. It has one peculiar characteristic; namely, that it retains its form, viewed from any point, and never assumes the appearance of a river. See **BORROWDALE**, **DERWENT-WATER**, and **SKIDDAW**.

KETCH, a vessel equipped with two masts, viz. the main-

mast and mizen-mast, and usually from 100 to 250 tons burden. Ketches are principally used as yachts or as bomb-vessels; the former of which are employed to convey princes of the blood, ambassadors, or other great personages, from one part to another; and the latter are used to bombard citadels, towns, or other fortresses. The bomb-ketches are therefore furnished with all the apparatus necessary for a vigorous bombardment; they are built remarkably strong, as being fitted with a greater number of *riders* than any other vessel of war; and indeed this reinforcement is absolutely necessary to sustain the violent shock produced by the discharge of their mortars, which would otherwise in a very short time shatter them to pieces.

KETTERING, a town of Northamptonshire, with a market on Friday. It is pleasantly seated on an ascent, and is a pretty good place, with a session-house for the justices, where they sometimes meet. It is 12 miles N. E. of Northampton, and 75 N. W. of London. E. lon. 0. 59. N. lat. 52. 20.

KETTLE, in the art of war, a term the Dutch give to a battery of mortars, because it is sunk under ground.

KITTLE-Drums, are formed of two large basins of copper or brass, rounded at the bottom, and covered over with vellum or goat-skin, which is kept fast by a circle of iron, and by several holes fastened to the body of the drum, and a like number of screws to screw up and down, and a key for that purpose. The two basins are kept fast together by two straps of leather, which go through two rings, and are fastened the one before and the other behind the pommel of the kettle-drum's saddle. They have each a banner of silk or damask, richly embroidered with the sovereign's arms or with those of the colonel, and are fringed with silver or gold; and, to preserve them in bad weather, they have each a cover of leather. The drum-sticks are of crab tree or of any other hard wood, eight or nine inches long, with two knobs on the ends, which beat the drum-head and cause the sound. The kettle-drum with trumpets is the most martial sound of any. Each regiment of horse has a pair.

KETTLE-Drummer, a man on horseback appointed to beat the kettle-drums, from which he takes his name. He marches always at the head of the Squadron, and his post is on the right when the Squadron is drawn up.

KETTLEWELL (JOHN), a learned divine, born in 1653, was descended from an ancient family in the North-riding of Yorkshire, bred in Edmund Hall Oxford, and elected fellow of Lincoln-College. In 1675 he went into orders; but after the Revolution was deprived of his living, on account of his refusal to take the oaths to King William and Queen Mary. He died of a consumption in 1695. He published several works, which were collected and reprinted together in 1718, in 2 vols. folio. He was a man of great candour, meekness, piety, and charity.

KEVELS, in ship-building, a frame composed of two pieces of timber, whose lower ends rest in a sort of step or foot, nailed to the ship's side, from whence the upper ends branch outward into arms or horns, serving to belay the great ropes by which the bottoms of the main sail and fore sail are extended.

KEW, a village of Surry, on the banks of the Thames, about seven miles W. by S. of London. It was formerly a hamlet to Kingston; but in 1763 an act of parliament was obtained, forming Kew and Petersham into one vicarage. Here is Kew House, a royal palace, celebrated for its fine gardens, and his majesty's exotic garden. The last has been brought to great perfection by the introduction of many new plants from Africa and New South Wales; and is known throughout all Europe by the late Mr. Aiton's Hortus Kewensis. From Kew to Brentford is a handsome stone bridge of seven arches over the Thames, built, in 1787, from a design of the late Mr. Paine. Kew gardens are open to the public, every Monday, from midsummer to the end of autumn.

KEXHOLM, that part of Finland which borders upon Russia. The lake Ladoga crosses it, and divides it into two parts. By the treaty between Russia and Sweden in 1721, the Swedes were obliged to abandon the best part to the Russians. The country in general is full of lakes and marshes, thinly inhabited, and badly cultivated. The lake above mentioned is 120 miles in length, and full of fish.

KEXHOLM, or *Carelgorod*, a town of Russia, in a territory of the same name, not very large, but well fortified, and has a strong castle. The houses are built with wood. It formerly belonged to the Russians, after which the Swedes had possession of it for a whole century; but it was retaken by the Russians in 1710. Near it is a considerable salmon-fishery. It is seated on two islands on the north-west side of the lake Ladoga, in E. lon. 30. 25. N. lat. 61. 12. Near it is another town called *New Keabotm*.

KEY, an instrument for the opening of locks. See **LOCK**. L. Molinus has a treatise on keys, *De clavibus veterum*, printed at Upsal: he derives the Latin name *clavis* from the Greek *κλειω κλειδο*, "I shut;" or from the adverb *κλειω* "privately;" and adds, that the use of keys is yet unknown in some parts of Sweden. The invention of keys is owing to one Theodore of Samos, according to Pliny and Polydore Vergil: but this must be a mistake, the use of keys having been known before the siege of Troy; mention even seems made of them in the 19th chapter of Genesis.

Molinus is of opinion, that keys at first only served for the untying certain knots, wherewith they anciently secured their doors: but the Laconic keys, he maintains, were nearly akin in use to our own; they consisted of three single teeth, and made the figure of an E; of which form there are still some to be seen in the cabinets of the curious. There was another key called *βαλαντινα*, made in the manner of a male screw; which had its corresponding female in a bolt affixed to the door. *Key* is hence become a general name for several things serving to shut up or close others.

KEY, or *Key-stone*, of an *Arch* or *Vault*, is the last stone placed a-top thereof; which being wider and fuller at the top than bottom, wedges, as it were, and binds all the rest. The key is different in the different orders: in the Tuscan and Doric it is a plain stone, only projecting; in the Ionic it is cut and waved somewhat after the manner of consoles; in the Corinthian and Composite it is a console enriched with sculpture, foliage, &c.

KEY is also used for ecclesiastical jurisdiction; particularly for the power of excommunicating and absolving. The Romanists say, the pope has the power of the keys, and can open and shut Paradise as he pleases; grounding their opinion on that explication of Jesus Christ to Peter, "I will give thee the keys of the kingdom of heaven." In St. Gregory we read, that it was the custom heretofore for the popes to send a golden key to princes, wherein they inclosed a little of the filings of St. Peter's chains kept with a world of devotion at Rome; and that these keys were worn in the bosom, as being supposed to contain some wonderful virtues.

KEY is also used for an index or explanation of a cipher. See **CIPHER**.

KEYS of an *Organ*, *Harp*, *Sickord*, &c. little pieces of ivory in the fore part of these instruments, by means whereof the jacks play, so as to strike the strings. These are in number 28 or 29. In large organs there are several sets of these keys, some to play the secondary organ, some for the main body, some for the trumpet, and some for the echoing trumpet, &c.: in some there are but a part that play, and the rest are only for ornament. There are 20 intervening black keys, which make half-notes. See the article **ORGAN**, &c.

KEY, in music, a certain fundamental note or tone, to which

the whole piece, be it in cantata, sonata, concerto, &c. is accommodated, and with which it usually begins, but always ends.

KEY, or *Quay*, a long wharf, usually built of stone, by the side of a harbour or river, and having several storehouses for the convenience of lading and discharging merchant ships. It is accordingly furnished with posts and rings, whereby they are secured; together with cranes, capsterns, and other engines, to lift the goods into or out of the vessels which lie along side. The verb *cajare*, in old writers, according to Scaliger, signifies, to *keep in* or *restrain*; and hence came our term *key* or *quay*, the ground where they are made being bound in with planks and posts.

KEYS are also certain sunken rocks lying near the surface of the water, particularly in the West-Indies.

KEYNSHAM, a town of Somersetshire, 116 miles from London. It is a great thoroughfare in the lower road between Bath and Bristol. They call it proverbially *smoky* Keynsham, and with equal reason they might call it *foggy*. It has a fine large church, a stone bridge of 15 arches over the Avon to Gloucestershire, and another over the river Chew. Its chief trade is malting. It has a charity school, a weekly market, and three fairs.

KEYSER'S PILLS, a celebrated mercurial medicine, the method of preparing which was purchased by the French government, and has since been published by M. Richard.

The first, and what, according to Mr. Keyser, is the most essential operation, consists in separating the mercury very exactly from all heterogeneous matter, by reducing it to an æthiops. This is effected by means of an hydraulic machine, a plan of which Mr. Keyser intended to have given to government before his death; but although he did not live to accomplish his resolution, his family still offer to do it when desired. According to the description given by M. Richard, this machine consists of a number of buckets, in which mercury is triturated with water, till the water acquires a black colour. This water, upon standing, deposits a sediment, which, being dried by a proper heat, is the æthiops required.

The second process consists in revivifying the mercury by distillation, in freeing it from all oily matters by means of quicklime, in detaching this quicklime by repeated washings, and afterwards in drying it by means of a sand heat.

The third operation consists in the reduction of the mercury purified by this process to a red calx, by means of heat. In conducting this operation, Mr. Keyser advises that the mercury be put into glass matrasses, a small quantity only in each. For the proper degree of heat, he directs those who would practise the operation to consult Lemery and other chemists.

The fourth operation is, the dissolution of the calcined mercury, obtained by the former process, in distilled vinegar, by means of triture. A pound of this mercury may be dissolved in eight pints of vinegar, by rubbing it for an hour or two in a mortar, which should be kept solely for that purpose. Care must also be taken that the vinegar be not distilled in a metallic but in a glass vessel.

The fifth process consists in the intimate mixture of this vinegar, impregnated with mercury, with manna. Each pound of the vinegar, containing about two ounces of mercury, will require two pounds of manna. They must be rubbed together upon marble stones till they acquire a uniform consistence, which will be liquid to such a degree as to pass through a hair-cloth, for separating the impurities of the manna. After being managed in this manner, it must be spread upon a marble slab, and left to dry there, without the assistance of fire, till it acquires such a consistence as not to run off upon the table being turned to its side. It must then be placed before the fire, and at the same time moved from one part of the stone to another,

by means of a knife, furnished with a large pliant blade. By this means, it is perfectly prepared for forming the pills.

The sixth and last process consists in the formation of the mass thus prepared into pills. These Mr. Keyser made to weigh either three grains or a grain and a half; the first for robust, the last for delicate constitutions.

To this account given for the preparation of these pills, Mr. Keyser has added some reflections by way of supplement. He observes, that, by the purification of the mercury from distillation, a great quantity of heterogeneous matter is separated from it. This, however, by no means frees it completely from all foreign matter. And, as mercury purified, upon being calcined and dissolved in vegetable acid, is a much more powerful medicine than mercury calcined without purification, he concludes, that repeated purifications would render it still more active.

Another remark which he gives, respects the dissolution of the mercurius calcinatus in the distilled vinegar. He observes, that the mercury thus dissolved may be made to unite with running mercury, and to form a very singular product. He formerly mentioned, that a pound of this mercurius calcinatus was to be dissolved in eight pints of vinegar. If to this be added two pounds of running mercury, and the agitation continued, a substance will arise to the surface in the form of cream. This being removed by the assistance of a wooden spoon, more will continue to rise as long as the agitation is continued. The cream being dried and incorporated with manna, in the proportion of one part of the cream to eight of manna, forms a very useful purgative, and is said to be an effectual remedy against recent venereal complaints, particularly against chancres.

M. Richard concludes his account of Keyser's pills with observing, that he considers it to be, without exception, the most effectual remedy for the venereal disease hitherto discovered. But before entering upon the detail, he remarks, that it is his opinion the process may be much abridged without diminishing the efficacy of the medicine. He judged it proper, however, to deliver to the public the method of preparing the pills in Mr. Keyser's own words; and he has not afterwards pointed out the improvements he proposes.

KEYSLER (JOHN GEORGE), a learned German antiquarian, was born at Thourneau in 1689. After studying at the university of Halle, he was appointed preceptor to Charles Maximilian and Christian Charles, the young counts of Giech Buchau; with whom he travelled through the chief cities of Germany, France, and the Netherlands, gaining great reputation among the learned as he went along, by illustrating several monuments of antiquity, particularly some fragments of Celtic idols lately discovered in the cathedral of Paris. Having acquitted himself of this charge with great honour, he procured, in 1716, the education of two grandsons of Baron Bernstorff, first minister of state to his Britannic majesty as elector of Brunswick-Lunenbourg. However, obtaining leave in 1718 to visit England, he was elected a fellow of the Royal Society for a learned essay *De Dea Nebeleunia numine veterum Walachorum topico*: he gave also an explanation of the ancient monument on Salisbury plain called *Stone henge*, with a Dissertation on the Consecrated Mistletoe of the Druids. Which detached essays, with others of the same kind, he published on his return to Hanover, under the title of *Antiquitates scilicet Septentrionales et Celtae*, &c. He afterwards made the grand tour with the young barons, and to this tour we owe the publication of his travels; which were translated into English, and published in 1756, in 4 vols. 4to. Mr. Keyser on his return spent the remainder of his life under the patronage of his noble pupils, who committed their fine library and museum to his care, with a handsome income. He died in 1743.

KHARKOF, a government of the Russian empire, formerly

comprised in the government of Ukraina-Slovodskaia. Its capital, of the same name, is seated on the river Uda, which falls into the Donetz.

KHERSON, or CHERSON, the capital of the Russian government of Catharinenslaf. See CHERSON.

KIAM, a great river of China, which takes its rise near the western frontier, crosses the whole kingdom eastward, and falls into the bay or gulph of Nanking a little below that city.

KIANG-si, a province of China, bounded on the north by that of Kiang-nan, on the west by Hou-quang, on the south by Quang-tong, and on the east by Po-kien and Tche-kiang. The country is extremely fertile; but it is so populous, that it can scarcely supply the wants of its inhabitants: on this account they are very economical; which exposes them to the sarcasms and raillery of the Chinese of the other provinces: however, they are people of great solidity and acuteness, and have the talent of rising rapidly to the dignities of the state. The mountains are covered with simples; and contain in their bowels mines of gold, silver, lead, iron, and tin: the rice it produces is very delicate, and several barks are loaded with it every year for the court. The porcelain made here is the finest and most valuable of the empire. This province contains 13 cities of the first class, and 78 of the second and third.

KIANG-Nan, a province of China, and one of the most fertile, commercial, and consequently one of the richest in the empire. It is bounded on the west by the provinces of Ho-nan and Hou-quang; on the south by Tche-kiang and Kiang-si; and on the east by the gulph of Nanking; the rest borders on the province of Chan-tong. The emperors long kept their court in this province; but reasons of state having obliged them to move nearer to Tartary, they made choice of Pe-king for the place of their residence. This province is of vast extent; it contains fourteen cities of the first class, and ninety-three of the second and third. These cities are very populous, and there is scarcely one of them which may not be called a place of trade. Large barks can go to them from all parts; because the whole country is intersected by lakes, rivers, and canals, which have a communication with the great river Yang-tse-kiang, which runs through the middle of the province. Silk-stuffs, lacquer-ware, ink, paper, and in general every thing that comes from Nanking, as well as from the other cities of the province, are much more esteemed, and fetch a higher price, than those brought from the neighbouring provinces. In the town of Chang-hai alone, and the villages dependent on it, there are reckoned to be more than 200,000 weavers of common cotton cloths. The manufacturing of these cloths gives employment to the greater part of the women.—In several places on the sea coast there are found many salt-pits, the salt of which is distributed all over the empire. In short, this province is so abundant and opulent, that it brings every year into the emperor's treasury about 32,000,000 taels (or ounces of silver), exclusive of the duties upon every thing exported or imported. The people of this country are civil and ingenious, and acquire the sciences with great facility: hence many of them become eminent in literature, and rise to offices of importance by their abilities alone. This province is divided into two parts, each of which has a distinct governor. The governor of the eastern part resides at Sou-tcheon-fou, that of the western at Nanking-fou. Each of these governors has under his jurisdiction seven fou or cities of the first class.

KIBURG, a town of Switzerland, in the canton of Zurich, with a castle. It is seated on the river Theoff, 14 miles N. E. of the town of Zurich. E. lon. 8. 46. N. lat. 47. 28.

KID, in zoology, the name by which young goats are called. See GOAT.

KIDDER (Dr. RICHARD), a learned English bishop, was born in Sussex, and bred at Cambridge. In 1689 he was in-

stalled dean of Peterborough; and in 1691 was nominated to the bishopric of Bath and Wells, in the room of Dr. Thomas Ken, who had been deprived for not taking the oaths to king William and queen Mary. He published, 1. The young man's duty. 2. A demonstration of the Messiah, 3 vols. 8vo. 3. A commentary on the five books of Moses, 2 vols. 8vo; and several other pious and valuable tracts. He was killed with his lady in his bed by the fall of a stack of chimneys, at his house in Wells, during the great storm in 1703. The bishop, in the dissertation prefixed to his commentary on the five books of Moses, having reflected upon Monsieur Le Clerc, some letters passed between them in Latin, which are published by Le Clerc in his *Bibliothèque Choisie*.

KIDDERMINSTER, or **KEDDERMINSTER**, a town of Worcestershire, seated under a hill on the river Stour, not far from the Severn, 128 miles from London. It is a large town of 1180 houses, with about 6000 inhabitants, who carry on an extensive trade in weaving in various branches. In 1735 a carpet manufactory was established with success, so as to employ in 1772 above 250 looms; and there are upwards of 700 looms employed in the silk and worsted. Above 1600 hands are employed as spinners, &c. in the carpet looms only in the town and neighbourhood; upwards of 1400 are employed in preparing yarn, which is used in different parts of England in carpeting; and it is supposed not less than 2000 are employed in the silk and worsted looms in the town and neighbourhood. The silk manufacture was established in 1755. The town is remarkably healthy, and has also an extensive manufacture of quilting in the loom in imitation of Marseilles quilting. Here is a Presbyterian meeting-house; and they have a handsome church, and two good free-schools, a charity-school, and two almshouses, &c. The town is governed by a bailiff, 12 capital burghesses, 25 common-councilmen, &c. who have a town-hall. It formerly sent members to parliament. By the late inland navigation, it has communication by the junction of the Severn canal with the rivers Mersey, Dee, Ribble, Ouse, Trent, Derwent, Severn, Humber, Thames, Avon, &c. which navigation, including its windings, extends above 500 miles, in the counties of Lincoln, Nottingham, York, Lancaster, Westmoreland, Chester, Stafford, Warwick, Leicester, Oxford, Worcester, &c. This parish extends to Bewdley-bridge, has a weekly market, and three fairs. W. lon. 2. 15. N. lat. 52. 28.

KIDDERS, those that badge or carry corn, dead victuals, or other merchandize, up and down to sell: every person being a common badger, kidder, lader, or carrier, &c. says the stat. 5 Eliz. cap. 12. And they are called *kiddiers*, 13 Eliz. cap. 25.

KIDDLE, or **KIDEL**, (*Kidellus*), a dam or weir in a river with a narrow cut in it, for the laying of pots or other engines to catch fish. The word is ancient; for in Magna Charta, cap. 24. we read, *Omnes kidelli deponantur per Thamesiam & Medweyam, & per totam Angliam, nisi per cosleram maris*. And by king John's charter, power was granted to the city of London, *de kidellis amovendis per Thamesiam & Medweyam*. A survey was ordered to be made of the weirs, mills, stanks, and kidells, in the great rivers of England, 1 Hen. IV. Fishermen of late corruptly call these dams *kittles*; and they are much used in Wales and on the sea-coasts of Kent.

KIDDINGTON, a town of Oxfordshire, four miles from Woodstock, and 12 from Oxford. It is situated on the Glym river, which divides the parish in two parts, viz. Over and Neith Kiddington, in the latter of which stands the church. This parish was given by King Offa in 780 to Worcester priory. Here King Ethelred had a palace; in the garden of the manor-house is an antique font brought from Edward the Confessor's chapel at Ilip, wherein he received baptism. In Hill-wood near this place is a Roman encampment in extraordinary preservation, but little noticed.

VOL. IV.

KIDNAPPING, the forcible abduction or stealing away of man, woman, or child, from their own country, and sending them into another. This crime was capital by the Jewish law: "He that stealeth a man, and selleth him, or if he be found in his hands, shall surely be put to death." Exod. xxi. 16. So likewise in the civil law, the offence of spiriting away and stealing men and children, which was called *plagium*, and the offenders *plagiarii*, was punished with death. This is unquestionably a very heinous crime, as it robs the king of his subjects, banishes a man from his country, and may in its consequences be productive of the most cruel and disagreeable hardships; and therefore the common law of England has punished it with fine, imprisonment, and pillory. And also the statute 11 and 12 W. III. c. 7. though principally intended against pirates, has a clause that extends to prevent the leaving of such persons abroad as are thus kidnapped or spirited away; by enacting, that if any captain of a merchant vessel shall (during his being abroad) force any person on shore, or wilfully leave him behind, or refuse to bring home all such men as he carried out, if able and desirous to return, he shall suffer three months imprisonment.

KIDNEYS, in anatomy. See **ANATOMY**.

KIDNEY-BAN. See **PHASEOLUS**.

KIDWELLY, a town of Carmarthenshire, in S. Wales, with a market on Tuesday. It is seated on a creek of the Bristol Channel, near the mouth of the Towy. From this town a canal has been cut to some collieries, whence coal is brought down and exported. It is eight miles S. of Carmarthen, and 224 W. by N. of London. W. lon. 4. 20. N. lat. 56. 44.

KIEL, a strong, rich, and considerable town of Germany, capital of the duchy of Holstein, with a castle, and a university. It stands upon a small peninsula in a bay of the Baltic, and has a very commodious harbour for ships of the largest size. It is already one of the most commercial places in Holstein; and its trade will be still farther augmented when the inland navigation across the peninsula is finished. By this navigation it is proposed to unite the Northern Sea with the Baltic; and it is to be formed across the duchy of Holstein, by the canal of Kiel, and the river Eyder, which passes by Rendsburg, and falls into the German Ocean at Tonningen. This canal was begun in 1777, has been since finished, and is now opened for the navigation of vessels. Kiel is 37 miles N. W. of Lubec, and 46 N. of Hamburg. E. lon. 10. 0. N. lat. 54. 20.

KIGGELARIA, in botany; a genus of the decandria order, belonging to the diœcia class of plants; and in the natural method ranking under the 37th order, *C. lumnifera*. The male calyx is quinquepartite; the corolla pentapetalous; there are five trilobous glandules; the antheræ are perforated at top; the female calyx and corolla as in the male; there are five styles; the capsule unilocular, quinquevalved, and polyspermous. There is but one species, viz. the *Africana*. It hath an upright woody stem, and purplish branches, growing 15 or 18 feet high; oblong, sawed, alternate leaves; and dioecious, greenish-white flowers, in clusters from the sides of the branches; succeeded by globular, rough fruit, the size of cherries, containing the seeds, which seldom ripen here. As this is a native of warm climates, it must be constantly kept in a stove in this country. It is propagated by seeds, layers, or cuttings, though most readily by seeds.

KIGHLEY, a town in the west riding of Yorkshire, six miles to the south-east of Skipton in Craven. It stands in a valley surrounded with hills, at the meeting of two Brooks, which fall into the river Aire one mile below it. Every family is supplied with water brought to or near their doors in stone troughs from a never-failing spring on the west side of it.

The parish is six miles long and two broad, and is 60 miles from the east and west seas; yet at the west end of it near Camel-Cross is a rising ground, from which the springs on the east side of it run to the east sea, and those on the west to the west sea. By the late inland navigation, this town has a communication with the rivers Mersey, Dee, Ribble, Onse, Trent, Derwent, Severn, Humber, Thames, &c. which navigation, including its windings, extends above 500 miles, in the counties of Lincoln, Nottingham, Lancaster, Westmoreland, Chester, Stafford, Warwick, Leicestershire, Oxford, Worcester, &c.

KILBARCHAN, a village of Renfrewshire in Scotland, to the N. W. of the lake called Loch Winnoch. It is a manufacturing place, and has several extensive bleaching-grounds. It is about five miles S. W. of Renfrew.

KILBEGGAN, a post, fair, and borough-town of Ireland, in the county of Westmeath and province of Leinster, 44 miles from Dublin. It returns two members to parliament; patronage in the Lambert family. It is seated on the river Brosna, over which there is a bridge. There was here a monastery founded in 1200, and dedicated to the Virgin Mary, and inhabited by monks from the Cistercian abbey of Melefont. The fairs are two.

KILBURN, a village of Middlesex, two miles N. W. by N. of London; famous for a fine well of mineral water.

KILDA (St.), one of the Hebrides or western islands of Scotland. It lies in the Atlantic ocean, about 58. 30. N. lat. and is about three English miles in length from east to west, and its breadth from south to north not less than two. The ground of St. Kilda, like much the greatest part of that over all the Highlands, is much better calculated for pasture than tillage.—Restrained by idleness, a fault or vice much more pardonable here than in any other part of Great Britain, or discouraged by the form of government under which they live, the people of the island study to rear up sheep, and to kill wild-fowl, much more than to engage deeply in the more toilsome business of husbandry. All the ground hitherto cultivated in this island lies round the village. The soil is thin, full of gravel, and of consequence very sharp. This, though naturally poor, is, however, rendered extremely fertile, by the singular industry of very judicious husbandmen: these prepare and manure every inch of their ground, so as to convert it into a kind of garden. All the instruments of agriculture they use, or indeed require, according to their system, are a spade, a mall, and a rake or harrow. After turning up the ground with a spade, they rake or harrow it very carefully, removing every small stone, every noxious root or growing weed that falls in their way, and pound down every stiff clod into dust. It is certain that a small number of acres well prepared in St. Kilda, in this manner, will yield more profit to the husbandman than a much greater number when roughly handled in a hurry, as is the case in the other western isles. The people of St. Kilda sow and reap much earlier than any of their neighbours on the western coast of Scotland. The heat of the sun, reflected from the hills and rocks into a low valley facing the south-east, must in the summer time be quite intense; and, however rainy the climate is, the corn must for these reasons grow very fall, and ripen early.

The harvest is commonly over at this place before the beginning of September; and should it fall out otherwise, the whole crop would be almost destroyed by the equinoctial storms. All the islands on the western coast have great reason to dread the fury of autumnal tempests: these, together with the excessive quantities of rain they have generally throughout seven or eight months of the year, are undoubtedly the most disadvantageous and unhappy circumstances of their lives.

Barley and oats are the only sorts of grain known at St. Kilda; nor does it seem calculated for any other. Fifty bolls

of the former, old Highland measure, are every year brought from thence to Harris; and all the western islands hardly produce any thing so good of the kind. Potatoes have been introduced among that people only of late, and hitherto they have raised but small quantities of them. The only appearance of a garden in this whole land, so the natives call their principal island in their own language, is no more than a very inconsiderable piece of ground, which is enclosed and planted with some cabbages. On the east side of the island, at the distance of a quarter of a mile from the bay, lies the village, where the whole body of this little people (the number amounting in 1764 to no more than 88) live together like the inhabitants of a town or city. It is certain that the inhabitants were much more numerous formerly than at present; and the island, if under proper regulations, might easily support 300 souls. Martin, who visited it about the end of the last century, found 180 persons there; but about the year 1730, one of the people coming to the island of Harris, was seized with the small-pox and died. Unluckily his clothes were carried away by one of his relations next year; and thus was the infection communicated, which made such havoc, that only four grown persons were left alive. Their houses are built in two rows, regular, and facing one another; with a tolerable causeway in the middle, which they call the *street*. These habitations are made and contrived in a very uncommon manner. Every one of them is flat in the roof, or nearly so, much like the houses of some oriental nations. That from any one of these the St. Kildans have borrowed their manner of building, no man of sense will entertain a suspicion. They have been taught this lesson by their own reason, improved by experience. The place in which their lot has fallen is peculiarly subject to violent squalls and furious hurricanes: were their houses raised higher than at present, they believe the first winter-storm would bring them down about their ears. For this reason, the precaution they take in giving them roofs much flatter than ordinary seems to be not altogether unnecessary. The walls of these habitations are made of a rough gritty kind of stones, huddled up together in haste, without either lime or mortar, from eight to nine feet high. In the heart of the walls are the beds, which are overlaid with flags, and large enough to contain three persons. In the side of every bed is an opening, by way of door, which is much too narrow and low to answer that purpose. All their dwelling-houses are divided into two apartments by partition-walls. In the division next the door, which is much the largest, they have their cattle stalled during the whole winter season; the other serves for kitchen, hall, and bed-room.

It will be readily expected, that a race of men and women bred in St. Kilda must be a very slovenly generation, and every way inelegant. It is indeed impossible to defend them from this imputation. Their method of preparing a sort of manure, to them indeed of vast use, proves that they are very indelicate. After having burnt a considerable quantity of dried turf, they spread the ashes with the nicest care over the floor of that apartment in which they eat and sleep. These ashes, so exactly laid out, they cover with a rich friable sort of earth; over this bed of earth they scatter a proportionable heap of that dust into which peats are apt to crumble away: this done, they water, tread, and beat the whole compost into a hard floor, on which they immediately make new fires very large, and never extinguished till they have a sufficient stock of new ashes on hand. The same operations are repeated with a never-failing punctuality, till they are just ready to sow their barley; by that time the walls of their houses are sunk down, or, to speak more properly, the floors risen about four or five feet.

To have room enough for accumulating heaps of this compost one above another, the ancient St. Kildans had ingenuity

enough to contrive their beds within the linings of their walls ; and it was for the same reason they took care to raise these walls to an height far from being common in the other western islands. The manure produced in this way must undoubtedly be good ; though probably rather sharp than of long duration, as it is scattered in small quantities upon the surface of the ground. Be that as it will, those who practise this art are abundantly lavish in its praises. They call it a *commodity ineffimably precious* ; and one may venture to affirm, that a genuine St. Kildan would scruple to barter it away for all the diamonds in Brasil and Golconda.

It is certain that cleanliness must contribute greatly to health, and of course longevity ; but in spite of that instance of indelicacy now given, and many more which might have been added, the people of this island are not more short-lived than other men. Their total want of those articles of luxury which have so natural a tendency to destroy the constitution of the human body, and their moderate exercises, will, together with some other circumstances, keep the balance of life equal enough between them and those who are absolute strangers to slovenliness.

Besides the dwelling-houses already described, there are a prodigious number of little cells dispersed over all the island ; which consist entirely of stones, without any the smallest help of timber. These cells are from 12 to 18 feet in length, and a little more than seven in height. Every stone hangs above that immediately below, not perpendicularly, but inclines forward, so as to be nearer the opposite side of the grotto, and thus by imperceptible degrees till the two highest courses are near enough to be covered by a single flag at the top. To hinder the rain from falling down between the interstices above, the upper part of the building is overlaid with turf, which looks like a fine green sward while new. The inhabitants secure their peats, eggs, and wild fowl, within these small repositories ; every St. Kildan has his share of them in proportion to the extent of land he possesses, or the rent he pays to the steward. From the construction of these cells, and the toil they must have cost before they could have been finished, it seems plain, that those who put them together were, if not more ingenious than their neighbours in the adjacent islands, at least more industrious than their own successors.

The St. Kilda method of catching wild fowl is very entertaining. The men are divided into fowling-parties, each of which consists generally of four persons distinguished by their agility and skill. Each party must have at least one rope about 30 fathoms long ; this rope is made out of a strong raw cow-hide, salted for that very purpose, and cut circularly into three thongs all of equal length ; these thongs being closely twisted together, form a three-fold cord, able to sustain a great weight, and durable enough to last for about two generations : to prevent the injuries it would otherwise receive from the sharp edges of the rocks, against which they must frequently strike, the cord is cased with sheep-skins, dressed in much the same manner. This rope is a piece of furniture indispensibly necessary, and the most valuable implement a man of substance can be possessed of in St. Kilda. In the testament of a father, it makes the very first article in favour of his eldest son : should it happen to fall to a daughter's share, in default of male heirs, it is reckoned equal in value to the two best cows in the island. By the help of such ropes, the people of the greatest prowess and experience here traverse and examine rocks prodigiously high. Linked together in couples, each having either end of the cord fastened about his waist, they go frequently through the most dreadful precipices : when one of the two descends, his colleague plants himself on a strong shelf, and takes care to have such sure footing there, that if his fellow-adventurer makes a false step, and tumbles over, he may be able to save him. This

method of fowling resembles that of the Norwegians, as described by Pontoppidan.

KILDARE, a county of Ireland, in the province of Leinster, which is 37 miles in length, and 20 in breadth ; and is bounded on the east by Dublin and Wicklow, on the west by King and Queen's county, on the north by East-Meath, and on the south by Catherlough. It is a fine arable country, well watered by the Barrow, Liffey, and other rivers, and well inhabited and cultivated, containing 228,590 Irish plantation acres, 100 parishes, 10 baronies, 4 boroughs, and returns 10 members to parliament. The chief town is of the same name, and gave title of earl to the noble family of Fitzgerald. It was anciently called *Cbilledair*, i. e. "the wood of oaks," from a large forest which comprehended the middle part of this county ; in the centre of this wood was a large plain, sacred to heathen superstition, and at present called the *Curragh of Kildare* ; at the extremity of this plain, about the commencement of the 6th century, St. Brigid, one of the heathen vestals, on her conversion to the Christian faith, founded, with the assistance of St. Conlæth, a church and monastery, near which, after the manner of the Pagans, St. Brigid kept the sacred fire in a cell, the ruins of which are still visible.

KILDARE, a town of Ireland, and capital of a county of the same name, is situated 28 miles south-west of Dublin. It returns two members to parliament, patron the duke of Leinster ; and is governed by a sovereign, recorder, and two portreeves. The church of Kildare was very early erected into a cathedral with episcopal jurisdiction, which dignity it retains to this day ; the cathedral, however, has been for several years neglected, and at present is almost in ruins. St. Brigid founded a nunnery at Kildare, which afterwards came into the possession of the regular canons of St. Augustin : this saint died 1st February 523, and was interred here ; but her remains were afterwards removed to the cathedral of Down. In the year 638 *Aod Dubb* or *Black Hugh* king of Leinster abdicated his throne, and took on him the Augustinian habit in this abbey ; he was afterwards chosen abbot and bishop of Kildare, and died on the 10th of May. In 756, Eiglitigin the abbot, who was also bishop of Kildare, was killed by a priest as he was celebrating mass at the altar of St. Brigid ; since which time no priest whatsoever was allowed to celebrate mass in that church in the presence of a bishop. In 1220 Henry de Loundres archbishop of Dublin put out the fire called *inextinguishable*, which had been preserved from a very early time by the nuns of St. Brigid. This fire was however relighted, and continued to burn till the total suppression of monasteries. Here was also a monastery on the south side of the town erected for friars of the Franciscan order, or, as they were more generally called, *Grey friars*, in the year 1260, by Lord William de Vesey ; but the building was completed by Gerald Fitzmaurice, Lord Ossaley. A considerable part of this building yet remains, which appears not to have been of very great extent. A house for White friars was likewise founded in this town by William de Vesey in 1290 ; the round tower here is 130 feet high, built of white granite to about 12 feet above the ground, and the rest of common blue stone. The pedestal of an old cross is still to be seen here ; and the upper part of a cross lies near it on the ground. Four fairs are held here in the year, viz. on 12th February, Easter Tuesday, 1st May, and 9th September.

KILDERKIN, a liquid measure, containing two firkins, or eighteen gallons beer measure, and sixteen ale measure. Two kilderkins make a barrel, and four a hoghead.

KILIAN (LUCAS), an eminent engraver, was a native of Augiburg in Germany, and flourished at the beginning of the 17th century. In what school he learned the art is uncertain ; but his style of engraving bears no small resemblance in many particulars to that of Henry Goltzius, and of John Muller his

dilciple. It appears, however, that he went to Italy in order to complete his studies, where he engraved several plates from the pictures of the great Italian masters. According to Mr. Strutt, few artists have manifested a greater command of the graver than Kilian, whether we consider the facility with which the strokes are turned upon each other, or the firmness with which they are executed; and one cannot help admiring it, though it evidently strikes us, that by paying too close attention to this part of the art, he neglected the correctness of his outlines, and fatigued the lights with unnecessary work; by which means he broke the masses, and often totally destroyed the effect of his prints. The naked parts of the human figure are seldom well expressed; the extremities especially are in general very heavy, and sometimes incorrect. Upon the works of this master, however, it appears, that Balechou, so famous for his skill in handling the graver, formed his taste. His works are exceedingly numerous. The time of his death is not any where mentioned. There were several other engravers of the same name and family; but of too inferior merit to deserve particular notice.

KILIANUS (CORNELIUS), a native of Brabant, distinguished himself as an excellent corrector of the press at the printing house of Plantin for 50 years. He likewise wrote several books, which are esteemed. His *Apology for Correctors against Authors*, an epigram of 18 verses, is a proof of his abilities in Latin poetry.

KILKENNY, a county of Ireland, in the province of Leinster, bounded on the south by the county of Waterford, on the north by the Queen's county, on the west by the county of Tipperary, on the east by the counties of Wexford and Catherlough, and on the north-west by Upper Ossory. The greatest length of this county from north to south is 38 miles, the breadth from east to west 18; and it contains 10 baronies. It is one of the most healthful, pleasant, and populous counties of Ireland. It contains 287,650 Irish plantation acres, 96 parishes, 9 baronies, and 7 boroughs, and returns 16 members to parliament. Gilbert Clare, Earl of Gloucester and Hereford, marrying Isabella, one of the daughters and co-heiresses of William Earl Marshal, received as her dower the county of Kilkenny.

KILKENNY, the capital of a county of the same name in Ireland, situated in the province of Leinster, 5 miles south-west of Dublin. It takes its name from the cell or church of Canic, who was an eminent hermit in this country; and is one of the most elegant cities in the kingdom. It is the seat of the bishop of Ossory, which was translated from Agabo in Ossory, about the end of Henry II's reign, by bishop O'Dulany. The city is pleasantly situated on the Nore, a navigable river that discharges itself into the harbour of Waterford. It is said of Kilkenny, that its air is without fog, its water without mud, its fire without smoke, and its streets paved with marble. The two latter are indeed matter of fact; for they have in the neighbourhood a kind of coal that burns from first to last without smoke, and pretty much resembles the Welsh coal. Most of the streets also are actually paved with a very good sort of black marble, of which they have large quarries near the town, which takes a fine polish, and is beautifully intermixed with white granite. The air too is good and healthy, though not remarkably clearer than in many other parts of the kingdom. The city is governed by a mayor, recorder, alderman, and sheriffs. It comprises two towns, viz. Kilkenny so called, and Irish-town, each of which sends two members to parliament, and both together are computed to contain about 20,000 inhabitants. This city was once of great consequence, as may be seen by the venerable ruins yet remaining of churches, monasteries, and abbeys, which even now in their dilapidated state exhibit such specimens of exquisite taste in

architecture as may vie with any modern improvements; and the remains of its gates, towers, and walls, show it to have been a place of great strength. Here too at different times parliaments were held, in which some remarkable statutes were passed. It has two churches, and several catholic chapels; barracks for a troop of horse and four companies of foot: a market is held twice in the week, and there are seven fairs in the year. Irish-town is more properly called the borough of *St. Canice*, vulgarly *Kenny*; the patronage of which is in the bishop of Ossory. The cathedral, which stands in a sequestered situation, is a venerable Gothic pile, built above 500 years; and close to it is one of those remarkable round towers which have so much engaged the attention of travellers. The bishop's palace is a handsome building, and communicates by a covered passage with the church. The castle was first built in 1195, on the site of one destroyed by the Irish in 1173. The situation in a military view was most eligible: the ground was originally a conoid, the elliptical side abrupt and precipitous, with the river running rapidly at its base: here the natural rampart was faced with a wall of solid masonry 4 feet high; the other parts were defended by bastions, curtains, towers, and outworks; and on the summit the castle was erected. This place, as it now stands, was built by the ancestors of the dukes of Ormond: here the Ormond family resided; and it is now in the possession of Mr. Butler, a descendant of that illustrious race. The college originally founded by the Ormond family is rebuilt in a style of elegance and convenience. The tholsel and market-house are both good buildings; and over the latter is a suit of rooms in which, during the winter and at races and allise times, assemblies are held. There are two very fine bridges of cut marble over the Nore. John's Bridge particularly is light and elegant. The Ormond family built and endowed a free school in this city. Here are the ruins of three old monasteries, called *St. John's*, *St. Francis's*, and the *Black abbey*: belonging to the latter are the remains of several old monuments, almost buried in the ruins; and the courts of the other are converted into barracks. The manufactures chiefly carried on here are, coarse woollen cloths, blankets of extraordinary fine quality, and considerable quantities of starch. In the neighbourhood also are made very beautiful chimney-pieces of that species of stone already mentioned, called *Kilkenny marble*: they are cut and polished by water, a mill for that purpose (the only one of its kind perhaps in Europe) being invented by the late Mr. Colles. The Kilkenny coal-pits are within nine miles of the town. This city came by marriage into the ancient family of Le Despencer. It was incorporated by charter from King James I. in 1609. The market-cross of Kilkenny continued an ornament to the city until 1771, when it was taken down; the date on it was MCCC. Sir James Ware mentions Bishop Cantwell's rebuilding the great bridge of Kilkenny, thrown down by an inundation about the year 1447. It appears also that St. John's bridge fell down by a great flood in 1564; and on the 2d October 1763, by another like circumstance, Green's bridge near the cathedral fell.—The borough of St. Canice, or Irish-town, always enjoyed very ancient prescriptive rights. A close roll of 5 Edward III. A. D. 1376, forbids the magistrates of Kilkenny to obstruct the sale of victuals in the market of Irish-town, or within the cross, under the pretence of custom for murage: and lest the ample grants made to Kilkenny might be interpreted so as to include Irish-town, the corporation of the latter secured their ancient rights by letters-patent 15 Edward IV. A. D. 1474. These renew their former privileges, and appoint a portrieve to be chosen every 21st September, and sworn into office on the 11th October. The portrieve's prison was at Troy-gate. When the mayor of Kilkenny came within Water gate, he dropt down the point of the city-sword, to show he claimed no pre-eminence within the borough.

INDEX to the TREATISES

IN THE

FOURTH VOLUME.

The Figures refer to the Page, Letter *a* to the First Column of the Page, and *b* to the Second.

GRAMMAR.

- ACTIVE** and passive voices defined, 48 *a*
Adverbs, what, 48 *b*
Agent, the, what, 47 *b*
Adjectives, on, 48 *a*
Antecedent, the, often left out, 46 *a*
Articles or *Definitives* defined, 41 *a*
Comparative degree, what, 48 *b*
Conjunctions, *Prepositions*, and *Interjections*, on, 49 *a*. Whence derived, *ib.*
Consonant, what, 39 *b*
Definitives, or *articles*, on, 41 *b*
Degrees in *adjectives* defined, 48 *b*
Diphthong, what, 39 *b*
Feminine gender, what, 41 *a*
Genders defined, 41 *a*
Grammar, definition of, 39 *a*. Introduction to, *ib.*
Indicative mood, what, 47 *b*
Interjections, on, 50 *a*
Letter, what, 39 *a*
Masculine gender, what, 41 *a*
Moods, on the, 47 *b*
Neuter gender, what, 41 *a*
Neuter verbs, what, 48 *a*
Noun, the, or *substantive*, of, 40 *a*—41
Participles, what, 48 *a*
Passive voice defined, 48 *a*
Patient, the, what, 47 *b*
Possessive pronouns, what, 43 *a*
Pronouns, on, 42 *a*—46. Personal pronouns, what, 43 *a*
Pronominal adjectives, what, 43 *a*
Relative pronouns, what, 43 *b*. When omitted, 45 *a*
Superlative degree, what, 48 *b*
Substantive, the, or *noun*, of, 40 *a*—41
Time, future, how expressed in English, 47 *b*
Time, past, how expressed in English, 47 *b*
Tenses, on the, 47 *b*
Thorough, the meaning of, 49 *b*
Tooke, Mr. his etymology of the *articles*, 41 *b*. Of *conjunctions* and *prepositions*, 49
Up and *upon*, the meaning of, 49 *b*
Verbs, on, 46 *b*—48
Voices, on the, 47 *b*
Vowel, what, 39 *a*
With, the meaning of, 49 *a*
Without, the meaning of, 49 *a*

HERALDRY.

- ACHIEVEMENT**, genealogical, what, 212 *b*
Alliance, arms of, 211 *a*
Annulet, the, what, 215 *a*
Arms, coats of, their origin, 210 *b*. Of *dominion*, 211 *a*.
Of *concession*, *ib.* Of *community*, *ib.* Of *family*, *ib.*
Of *succession*, *ib.*
Artificial figures borne in coats of arms, 216 *a*
Assumptive arms, what, 211 *a*
Bend, the, what, 214 *a*
Billet, the, what, 215 *a*
Canton, the, what, 214 *b*
Chapeaux, wreaths, and crests, of, 217 *b*
Charges, common, borne in coats of arms, of, 215 *b*
Charges in heraldry, what, 213 *b*
Cheveron, the, what, 214 *a*
Chief, in an *escutcheon*, what, 211 *b*
Chief, the, what, 213 *b*
Chimerical figures used in coats of arms, 216 *a*
Coats of arms, their origin, 210 *b*
Colours in heraldry, of, 211 *b*
Colours in heraldry, how expressed by dots and lines in engravings, 212 *a*

- Community*, arms of, 211 *a*
Concession, arms of, 211 *a*
Coronets, of, 216 *b*. Of dukes, 217 *a*. Of marquises, *ib.*
 Of earls, *ib.* Of viscounts, *ib.*
Crest, what, 218 *a*

Cross, the, what, 214 *a*
Crowns, of, 216 *a*
Diapering, what, 215 *b*
Differences of coats of arms, of the, 213 *a*
Dominion, arms of, 211 *a*
Engravings, how colours in heraldry are represented by, 212 *a*
Escallop work, what, 215 *b*
Escutcheon or shield, of the, 211 *a*
Escutcheons, funeral, of, 219 *b*
Etoye, what, 214 *a*
Family arms, of, what, 211 *a*
Fest point, what, 211 *b*
Fess, the, what, 214 *a*
Fields, lines used in the parting of, 212 *b*
Figures, natural, used in coats of arms, 215 *b*
Flanches, the, what, 215 *a*
Flasques, the, what, 215 *a*
Franc-quarter, what, 214 *b*
Fret, the, what, 214 *b*
Funeral escutcheons, of, 219 *b*
Furs, of, 212 *a*
Fusil the, what, 215 *a*
Gentleman, married, his hatchment described, 219 *b*
Gentlewoman, married, her hatchment described, 220 *a*
Giron, the, what, 214 *b*
Gutte, what, 215 *a*
Hatchments, what, 219 *b*
Helmets, of, 217 *a*
Heraldry, definition of, 210 *a*
Heraldry, of the laws of, 218 *b*
Honour, point of, the, 211 *b*
Inescutcheon, what, 214 *b*
Knighthood, of the orders of, 219 *b*
Lines used in the parting of fields, 212 *b*
Lozenge, the, what, 215 *a*
Mackenzie, Sir George, his opinion of heraldry, 210 *a*
Mantlings, of, 217 *b*
Marshalling of coats of arms, of the, 218 *b*
Mascle, the, what, 215 *a*
Mitres, of, 217 *a*
Nisbet, Alexander, his system of heraldry, 210 *a*
Nombril point, the, 211 *b*
Ordinaries, honourable, what, 213 *b*
Orle, the, what, 214 *b*
Ornaments, external, of escutcheons, 216 *a*
Pairle, the, what, 214 *b*
Pal, the, what, 214 *a*
Papillone, what, 215 *a*
Patronage, arms of, 211 *a*
Pean, what, 212 *a*
Pile, the, what, 214 *b*
Precedency, laws and order of, 220 *a*
Precedency of women, 221 *a*
Pretension, arms of, 211 *a*
Quartered field, what, 212 *b*
Rustre, the, what, 215 *a*
Saltiere, the, 214 *b*
Saltier quartered per, what, 212 *a*
Scroll and supporters, of the, 218 *a*
Shield or escutcheon, of the, 211 *a*
Styles, of, 221 *b*
Succession, arms of, 211 *a*
Supporters, what, 218 *a*
Tenny, how represented, 212 *a*
Tinctures, of, 211 *b*
Tressure, the, what, 215 *a*
Vair, what, 212 *a*
Voiders, the, what, 215 *a*
Women, precedency of, 221 *a*
Wreath, what, 217 *b*.

HISTORY.

- ACHÆAN* league, the, 287 *a*
Alexander the Great, his conquests, 284 *b*
Alexander's empire divided among his followers, 286 *a*
Antichrist, superstitious alarms about, 302 *b*
Antiochus the Great, his death, 287 *a*
Ascetics, account of them, 297 *b*
Balance of Europe, origin of that phrase, 293 *b*
Barbarians of the north, their inroads, 290 *a*
Carthage, when founded, 282 *b*

Style of history, of the, 311 b
Timur, the death of, 293 a

HORSEMANSHIP.

AIRS in horsemanship, what, 378 b
Bitted, what, 372 b
Breaking of horses, rules for, 368 b
Croup to the wall, what, 372 a
Epaul en dedans, the use of, 371 a
Fire and noise, how to accustom horses to, 372 b
Horseback, how to place the rider on, 369 a—370
Horsemanship defined, 368 a
Horsemen, bad, rules for, 374 b
Horses, how to supple them with men upon them, 371 a
Horses, how to prepare them to be mounted, 368 a
Horses, how to make them stand fire, noises, alarms, &c. 372 b
Horses, rules for breaking of, 368 b

Longe, a, when useful, 371 b
Noises and fire, how to make horses stand, 372 b
Pembroke, earl of, his directions for breaking horses, 368 b
Piafing, pillars, &c. of, 373 a
Pister, what, 371 b
Restiveness, vice, &c. how to cure in horses, 373 b
Reining back and moving forward, method of, 373 a
Rider, the, how to place on horseback, 369 a
Riding, rules for, 374 b—377
Rules for bad horsemen, 374 b.
Settled, what, in horsemanship, 372 b
Thompson, Mr. his rules for bad horsemen, 374 b—377
Wall, head to the, what is meant by that phrase, 372 a.

HUSBANDRY.

ALKALIS in plants, 436 b
Analysis of a fertile soil, 437 a
Anderfon, Dr. his opinion on manures, 459 b
Anderfon, Dr. his method of managing a farm, 530—540
Apiary, situation for, 528 a
Apples, of the raising of, 501 a
Argillaceous matter, what, 429 a
Ashes used for the improvement of soil, 431 a
Baker, Mr. of different kinds of potatoes, 479
Barley, of, 470 a
Barren mixtures, 438 b
Barren soils, analysis of, 437 b
*Beans, of, 472 b. When to be sown, *ib.* Various kinds of, 473*
Beech-wood contains coal, 435 a
Bees, of the management of, 527 b. Of the food of, 528 b
Beevor, Sir Thomas, his method of feeding bullocks, 476 b
Boggy soil, what, 430 a
Bones pounded used as manure, 432 a
Brake harrow, what, 446 b
Breeding of cattle, 511 b
Buck wheat, of, 469 b
Buildings about a farm, proper construction of, 337 b
Burnet, of, 492 b
Butter, how best obtained, 516 a
Cabbages, of, 486 b
Cabbage husbandry, a table of distances for, 488
Calf lea, what, 458 a
Calcareous matter, what, 429 a
Carbonic acid gas, what effect it has upon plants, 436 a
Carrots, of, 484 b. When sown, 485
Cattle, of feeding them in the house, 532 a
Cattle, of the breeding of, 511 b
Chain plough, what, 445 a
Chain and screw harrow described, 447 a
Chalk, description of, 429 b
Chalky loam, what, 429 b
Chapple, Mr. his mode of managing potatoes, 483 b—484 a
Charcoal used as manure, 431 b
Cherry wine, how to make, 504 a

Cheese, of making of, 518 a
Cherries, of, 404 a
Cheshire, how potatoes are planted there, 482 b
Clay, what, 429 b
Clayey soils, proper manure for them, 439 b
Clayey loam, 429 b
*Clover, of, 490 b—491. Red, of, *ib.* White, of, 491 b*
Coal, of, as nourishment of plants, 434 b
Common plough, what, 445 a
Condiments, importance of, 536 a
Cooke's drill machine described, 451 a
Coppices, of making, 507 b
Cows, of feeding of, 514 b.
Creeping soft grass described, 490 b
Cropping, preparation of land for, 463 a
Crops, the most advantageous course of, for different soils, 464 b
Cyder, of making of, 503 b
Cyder wine, of, 504 a
Ducks, of the management of, 526 a
Dairy, management of the, 516 a
Dibbling of wheat, of, 468 b
Ditches, the sweepings of, used as manure, 432 a
Dougal's, Mr. improved hoe, 454 a
Draining of lands, on the, 432 a
Drill rake described, 450 b
Drill plough described, 450 b
Duhamel, Mr. his elements of agriculture, 443 a
Dundonald, earl of, his observations upon manure, 431 b
Earths, of, as nourishment for plants, 435 a
England, progress of husbandry in, 427 a—427 b
Farm yard dung, used as manure, 431 b
Farm, a, the most economical consumption of the produce of, 530—531
Fattening and feeding of cattle, of, 512 b—513
Fallowing, of, 440 b
Fallow cleaning machine described, 447 b
Fallowing of land, on, 432 b
Ferruginous loam, what, 430 a
Fertile mixtures, 438 a

- Filberds*, of, 504 *b*
Flax, of, 495 *b*. Cultivation of, *ib.*
Flux, the, in fowls, the cause of, 526 *a*
Folding of sheep, of the, 532 *a*
Food of plants, 432 *b*
Four-coultered plough described, 445 *b*
Fowls, of the management of, 525 *b*
Fruits, of, 501 *a*
Geese, of the management of, 526 *b*
Gioberit, Mr. his analysis of fertile soils, 437 *a*
Grain, of itacking of, 498 *a*
Grass, what it loses by being dried into hay, 434 *b*
Grasses, of, 489 *b*
Grass lands, of taking the produce off them, 534 *a*
Gravelly loam, what, 430 *a*
Gravel, what, 429 *b*
Grey oats, of, 472 *a*
Grey pease, of, *ib.*
Gregory, Rev. Dr. on the nourishment of vegetables, 433 *a*
Gypsum, of, 441 *b*
Gypsum, used to improve soil, 431 *a*
Hand-hoe described, 452 *a*
*Harrow*s of various kinds described, 446—447
Harper, Mr. Henry, his experiments on manures, 461 *b*
Harper, Mr. Henry, his method of feeding cows, 514 *b*—515
Hassenfranz, Mr. on husbandry, 428 *b*
Hay of a fine quality, how to obtain, 536 *b*
Hay-collecting machine described, 454 *b*
Hay, of making of, 499 *a*. Of itacking of, 500 *b*
Hemp, of, 494 *a*. Cultivation of, *ib.*
Heathy soil, what, 430 *a*
Hives, how to cover, 529 *a*
Hoe plough described, 450 *b*
Hoeing, how performed, 443 *b*
Hogs, of the breeding of, 522 *b*. Experiments on the feeding of, 523—524
Hops, how to cultivate, 496 *b*
Horse-hoe and drill machine described, 452 *a*. Manner of using the machine, 453 *a*
Horses, of the management of, 509 *a*
Horse-hoe described, 452 *b*. Manner of using it, 453 *b*
Husbandry, theory of, 428 *b*. Practice of, 442—540. Different kinds of, *ib.*
Husbandry, the new method of, 444 *a*
Husbandry, definition of, 427 *a*. Introduction to, *ib.* Writers on, 428 *a*
Instruments of husbandry, 444 *b*
Instruments used in the new husbandry, 450—451
Kent, management of sheep in, 521 *a*
Kent, East, course of crops there, 466 *a*. West, course of crops there, 466 *b*
Kent, Mr. his account of Norfolk marle, 460 *a*
Kent, how to prepare land for turnips there, 475 *a*
Kirwan, Mr. his table of the constituent parts of manures, 432 *a*
Kirkpatrick, his mode of cultivating potatoes, 480 *a*
Knighit's harrow described, 441 *b*
Lancashire, mode of cultivating potatoes there, 480 *a*
Land, preparing of for cropping, 463 *a*
Land, how managed for turnips, 474 *a*
Leicestershire sheep, of, 520 *b*
Lime, powdered, its effect upon vegetables, 439 *a*
Lime used for the improvement of soil, 430 *b*
Lime, of, used as a manure, 459 *a*
Loam, what, 429 *b*
Loam, clayey, proper manure for, 439 *b*
Lothian, Mid-, rotation of crops there, 467 *a*
Lucern, of, 492 *b*
Madder, of, 496 *a*
Magnesian earth, 429 *a*
Mangel-wurzel, cultivation of that plant, 488—489
Manures, of the uses of, and means of preparing them, 458—459
Manures for different soils, 439 *a*
Manures, different kinds of, for potatoes, 478
Manures, a table of the constituent parts of, 432
Marle used as manure, 460 *a*
Marle used for the improvement of soil, 430 *b*
Marshall, Mr. his directions for planting of fruit trees, 501 *b*
Marshall, Mr. his method of making cheese, 518 *a*—519
Mazagan bean described, 473 *b*
Middleton's hay-collecting machine described, 454 *b*
Milk-house, the, how it should be situated, 517 *a*
Miner, the, a kind of plough, described, 144 *b*
Nonpareil, a species of wheat, 468 *a*
Norfolk, how turnips are cultivated there, 474 *b*
Oats, various kinds of, 471 *a*
Operations for the improvement of soils, 430 *a*
Oxen and horses used in husbandry, comparative utility of them, 510 *a*—511
Parmesan cheese, how to make, 519 *b*
Paring and burning of land, 432 *b*—441 *a*
Paring plough described, 445 *a*
Parfneps, of, 485 *b*. How to cultivate them, 486 *a*
Peat and lime mixed and used as manure, 460 *b*
Pease, of, 472 *a*. Various kinds of, *ib.*
Perry, of, 504 *a*
Pilbeam, a species of wheat, 468 *a*
Pip, the, in fowls, cause of, 526 *a*
Phosphorated calx in vegetables, 436 *b*
Plants, of the food of, 432 *b*
Ploughs, different kinds of, described, 445 *a*
Plough and sowing machine used together, of the, 449 *a*
Poland oats where used, 471 *b*
Potatoes, of preserving them, 484 *a*
Potatoes, of, 477—484. Different manures for, 477—478. Different kinds of, 479
Poultry, of, 525 *b*
Preparing of land for cropping, 463 *a*
Processes and manures, of, 440 *b*
Rabbits, of the management of, 525 *a*
Radish feed, of, 493 *b*
Reaping of crops, of, 497 *a*
Ridges, of, 454 *b*—455, 456
Roan red, what, 471 *a*
Rocking tree, what, 445 *b*
Roller, of the; 449 *b*. Of the spike roller, 450 *a*
Romans, the, their application to husbandry, 427 *a*
Rotherham plough described, 445 *a*
Roup, the, described, 526 *a*
Ruta-baga, what, 476 *b*
Rye grass, of, 490 *a*
Rye, of, 469 *b*. Small, of, *ib.*
Sainfoin, of, 491 *b*
Saline substances, their effects upon plants, 430 *b*
Salt, value of, in feeding beasts, 536 *a*
Sandy loam, what, 430 *a*
Sand, what, 429 *b*
Sea-weed used as manure, 461 *a*
Seeds, of, 493 *a*. Various kinds of, *ib.*
Silicious matter, what, 479 *a*
Sheep, how to feed them with turnips, 476 *a*
Sheep's fescue grass, 490 *b*
Shepey, isle of, course of crops there, 456 *b*

Soap-boiler's waste, used as manure, 431 *b*
 Sodburning, 464 *a*
 Soils, of the constituent principles of, 429 *a*. Of the substances and operations for the improvement of, 430 *a*
 Soils, fertile, their constitution, 437 *a*
 Somerville, Mr. his method of planting potatoes, 481 *a*
 Sowing machine, universal, described, 448 *a*. Of regulating it in various cases, 449
 Spart barley, what, 470 *b*
 Spanish bean described, 473 *b*
 Spinach, seed of, 494 *a*
 Stable dung, used as manure, 431 *b*
 Staffordshire, manure used there, 462 *b*
 Steeping of barley, of, 471 *a*
 Stock, live, of the management of, 508—523
 Stocking of pasture ground, of the, 532 *b*
 Substances for the improvement of soils, 430 *a*
 Sward-cutter, the patent one described, 445 *b*
 Swedish turnip described, 476 *b*
 Sweetness of pasture, what, 535 *a*
 Ted lay, how to, 500 *b*
 Thanet, isle of, the course of crops there, 465 *a*
 Toker bean, described, 473 *b*
 Trefoil, of, 491 *b*
Trifolium pratense, 435 *b*

Turnips, of, 473 *b*. Various kinds of, *ib*.
 Turnips, how to preserve, 475 *b*
 Turnips, of the consumption of, by sheep, 529 *a*
 Turnip cabbage, of the, 487 *a*
 Underwood, of the management of, 506 *a*
 Underwood, of the proper age of cutting, 507 *b*
 Utensils of a dairy, of the, 517 *b*
 Wagstaff, Mr. of dibbling of wheat, 468 *b*
 Water, of, as nourishment for vegetables, 433—434
 Watson, Dr. his experiments on burnt oak, 435 *b*
 Weeding-harrow described, 450 *b*
 Weeding of wheat, best mode of, 469 *a*
 Weeds, methods of destroying of, 457 *a*—458
 Wheat, of, 467 *b*
 White or egg-shell wheat, *ib*.
 Wimpey, Mr. his opinion respecting turnips, 474 *a*
 Windsor bean described, 473 *b*
 Winter barley, what, 470 *b*
 Woad, of, 496 *a*
 Woods, of the time of cutting, 507 *b*. Manner of disposing of, 408 *a*
 Woods, of the cultivation and management of, 504, 505, 506
 Woods of various kinds, the salme matter they produce, 436 *b*
 Yellow ragweed, how destroyed, 458 *b*.

HYDROSTATICS.

ACTION of fluids against the vessels which contain them, of the, 550 *a*
 Action of fluids on immersed bodies, of the, 552 *a*
 Adams, Mr. Geo. his definition of a fluid, 548 *a*
 Aqua regia, of gold suspended in, 559 *b*
 Archimedes, on bodies immersed in fluids, 552 *a*
 Bodies immersed in fluids, of, 552 *a*—553, 554
 Capacity of irregular vessels, how to find the, 560 *a*
 Chain-pump, what, 565 *a*
 Clark's hydrometer, of, 559 *a*
 Clepsydra, of the, 570 *a*
 Density of a body, what, 552 *b*
 Expansion of bodies, of the, 560 *b*
 Ferguson, Mr. his table for finding the dimensions of a pump, 566 *a*
 Fire engines, of, 567 *b*
 Fluids gravitate independently of each other, 549 *a*
 Fluids, to find the specific gravity of, 557 *b*
 Fluids, of the resistance of, 571 *a*
 Fluidity, of, 548 *a*
 Fountain, of, 564 *a*
 Friction in the passage of water, of, 569 *a*
 Gravity of fluids, 548 *b*
 Gravity, specific, of bodies, to estimate the, 556 *a*
 Hamilton, Mr. C. his clepsydra described, 570 *a*
 Hydraulics defined, 548 *a*
 Hydraulics, of, 561
 Hydraulics, of a new principle in, 572 *b*
 Hydrostatics defined, 548 *a*
 Hydrostatic bellows, what, 551 *b*
 Hydrostatic paradox illustrated, 551 *a*
 Hydrostatic balance, of the use of the, 557
 Hydrometer, of measuring the specific gravity of fluids by the, 558 *b*
 Jets d'eau, of, 564 *a*
 Lateral pressure of fluids, what, 551 *b*
 Magnitude of a body, what, 552 *b*

Motion of fluids, of the, 561 *a*
 Orifices, small, of the spouting of fluids through, 561 *a*
 Paradox, hydrostatic, the, illustrated, 551 *a*
 Phenomenon not to be accounted for on the doctrine of gravity, of a, 559 *b*
 Pipes, conduit, of the motion of water in, 569 *a*
 Pressure of fluids, of the, 553 *a*
 Pump, common, the, described, 565 *b*. Improvements of the, 563 *b*
 Pump, Vera's, described, 567 *b*
 Pump, new hand, the, described, 567 *a*
 Pump, forcing, the, described, 566 *a*
 Pumps, of, 565 *a*. Of those which act by the pressure of the atmosphere, *ib*.
 Quantities of fluids proceeding through apertures, of the, 561 *b*
 Ramsden, Mr. on the hydrometer, 559 *a*
 Reservoir, table of the altitudes of, 564 *b*
 Resistance of fluids, of the, 571 *a*
 Solids, to find the specific gravity of, 557 *b*
 Specific gravity of fluids, different methods of finding the, 559 *b*
 Specific gravities, a table of, 560 *a*
 Specific gravity, what, 552 *b*
 Spouting of fluids through small orifices, of the, 561 *a*
 Surface, of fluids, of, 549 *a*
 Syphon, of the, 569 *b*. The distillers, 570 *a*. Gravesand's, *ib*.
 Taylor, Mr. Walter, his new-hand pump described, 567 *a*
 Tubes, of the discharge of fluids through additional ones, 563 *a*
 A table of, 563 *b*
 Velocity of a moving body, of the, 572 *a*
 Velocity of water, of the, 561 *b*
 Vibratory motion of water in a syphon, of the, 570 *a*
 Water, a table of the quantities of, discharged through tubes of different diameters, 569 *a*
 Water running through apertures—table of the quantities of, 562
 Wave, of the oscillatory motion of, 571 *a*
